Lymphangitis is distinguished as reticular or tubular according as the fine capillary network or the trunks of the vessels are involved. In the former case the skin and its capillaries are usually implicated. In the latter variety the vessels become dilated, and their walls are thickened, the endothelium often disappears, and the internal coat becomes opaque and uneven. The lymph coagulates in their interior, blocking up their channels, and the clot may become organised, obliterating the vessels permanently, or occasionally it softens and suppurates in the centre, and the pus may find its way into the circulation, leading to septicæmia or pyæmia. Exudation also takes place, while the surrounding cellular tissue undergoes hyperplasia and becomes thickened. Lymphangitis may lead to inflammation in joints, which may be of a purulent character. In adenitis the affected glands become congested and swollen, as well as the seat of exudation, while the passage of the lymph through them is impeded. Resolution may take place after a time, but not uncommonly the inflammation terminates in suppuration, this beginning in the centre, the cavities of the glands becoming filled with pus, and the surrounding cellular tissue being also involved. In other cases the glands remain more or less indurated, and they may form adhesions to the surrounding structures, especially if the irritation is repeated several times. Glands which are chronically enlarged, as the result of inflammation, are very liable to become the seat of acute inflammation from slight causes. They may subsequently suppurate, or undergo a caseous degenerative change, but often remain unaltered for a considerable time. This condition of the glands interferes with the passage of the lymph through them.

When the superficial lymphatic vessels or glands are inflamed, this condition is evinced by objective signs. Lymphangitis is indicated by wavy or straight lines, running towards the glands, or sometimes there are isolated red patches, the skin and the capillaries being involved along with the lymphatics. The large vessels may be felt as firm and knotted cords. If the glands are affected, these can be felt, and seem to be more or less enlarged and swollen, at first feeling firm.

At the same time pain is experienced, often very acute, with sensations of heat, stiffness, and tenderness. When the affected structures are deeply situated, there are no red lines, and redness is not always present. There is induration of the part, more like that of œdema than inflammation. The inflammation may, however, pass through the intervening tissues from the deep to the superficial lymphatics, and *vice versâ*. Owing to the interference with the passage of the lymph, more or less swelling from lymphatic œdema is often present of a firm character, and a limb may be much enlarged from this cause. If suppuration should take place in glands, this will be evidenced by the ordinary signs characteristic of an abscess. There is more or less pyrexia, in proportion to the extent and intensity of the inflammation. In septic forms of lymphangitis, signs of general septicæmia are likely to arise.[13]

Regarding the morbid conditions of the lymphatic glands, manifested by enlargement, if we have regard to the anatomical characters, there are at least three, which it is extremely difficult, and often impossible, to distinguish from one another. These are simple inflammatory hyperplasia—lymphoma, the so-called scrofulous form of enlargement, and that morbid condition now generally known as lymphadenoma.

Lymphoma is a comprehensive term, and includes formations which are not strictly tumours, but rather hyperplasias of the tissue proper to lymphatic glands, lymphadenoid, or briefly, adenoid tissue, as it is called. Lymphoma, as a neoplasm, would imply the development and deposit of new adenoid tissue in the form of a tumour within a lymphatic gland, a follicle, or some other structure of the connective tissue group. In what is usually called lymphoma, this does not happen. What does happen is, that the tissue of the lymphatic gland, or follicle, increases in size because the lymphoid cells it contains are multiplied, while the reticular tissue undergoes hyperplasia. The process is often inflammatory in character, in other cases the lymphoid hyperplasia seems to begin idiopathically, that is, without any cause hitherto discovered. It may often be doubtful whether the increased growth of a lymphatic gland should be regarded as neoplastic or as hyperplastic. Many cases of lymphoma, especially the leukæmic kinds, seem referable to hyperplasia. The lymphatic glands, adenoid structures of the intestine, and lymphoid follicles of the spleen, all maintain their structure as they grow in size, or alter but slightly. Moreover, the functions of the glands seem to be more actively performed. This does not seem to indicate that they are invaded by anything of the nature of a neoplasm.

In addition to the hyperplastic lymphomata, there is a true or heteroplastic tumour, whose structure agrees with that of lymphadenoid tissue. As the term lymphoma has been invented to describe the hyperplastic formations, we may do well to distinguish the genuine tumour as lymphadenoma or lymphosarcoma. It is a sarcoma whose structure somewhat resembles that of a lymphatic gland. It most commonly originates in lymphatic glands, and in the adenoid tissue of the mucous membranes. It may, however, arise elsewhere. When it attacks a lymphatic gland, it may be distinguished from mere hyperplastic lymphoma by its rapid growth, and by its tendency to overpass the limits of the gland, and to form metastases.[14]

The term scrofulous is commonly applied to the slow

[13] Quain's "Dictionary of Medicine," vol. i., p. 907.
[14] Ziegler, Macalister's Translation, vol. i., p. 216.

and painless enlargement of groups of lymphatic glands, which occurs for the most part in children, and almost invariably ends in the destruction of the glands, by an imperfect kind of suppuration. Scrofulous glands are generally met with in either the neck, thorax, or abdomen, and are commonly limited to one of these regions. Indeed, in the neck, where their progress can best be followed, we often see that the enlargement commences in one gland only, that the glands in the vicinity are successively affected, and often at long intervals, and that, after a while, the morbid process ceases with the destruction of all the implicated glands, those on the opposite side of the neck possibly remaining all the time perfectly healthy. In the earlier stages of the affection the glands differ little, either to the naked eye or under the microscope, from such as are simply hyperplastic from inflammation, but they tend soon to become opaque, yellow, and friable, to undergo caseous degeneration. This change commences in the central parts, and gradually involves the whole mass, which presently breaks down into a semi-fluid *detritus*. Occasionally, the caseous lump dries up, earthy salts are deposited in it, and it becomes an inert earthy concretion. There is a good deal of vagueness in the sense in which the term "scrofulous" is generally employed. It is taken for the most part to imply that the morbid process to which we attach it is dependent upon some peculiar condition of the constitution, and further, that there is some close affinity, if not actual identity between it and tubercle. But the so-called "scrofulous glands" are certainly not tubercular; and, although their appearance is sometimes followed by that of tubercle, in a very large number of cases no such sequence is observed. And as regards cachexia, it is certain that "scrofulous glands" often develop in persons who appear in all other respects in the best of health; and further, if we may judge by the limitation of the morbid process, that we admit their dependence on a pre-existing state of cachexia, that cachexia must in many cases be limited to a definite part or district of the organism. It is well known, moreover, that when a single gland has undergone scrofulous proliferation, there is a remarkable tendency for the morbid process to spread thence to other glands in its immediate neighbourhood, and thence again to others; it seems, in fact, to spread from gland to gland, through the agency of some infective materials which the diseased organs evolve. It is well known, also, that scrofulous enlargement of the glands of the neck not unfrequently follow upon certain diseases affecting the throat, such as parotitis, diphtheria, and scarlatina. Now, basing his arguments upon such facts as these, Virchow maintains, and we think with reason, that scrofulous proliferation of the lymphatic glands, like ordinary inflammatory hyperplasia of the same organs, is always secondary to the same peculiar process, going on at the mucous surface or other part, which is in direct relation with them by means of the lymphatic vessels; that scrofulous disease of the glands of the neck is traceable to some inflammatory condition of the throat, fauces, or contiguous parts; of the bronchial and mediastinal glands to pulmonary or bronchial inflammations, and of the mesenteric and retro-peritonæal glands, to similar conditions of the alimentary canal. He considers that there may be some specific quality or element in the primary inflammation, and a tendency in its products to undergo rapid decay similar to that which characterises the morbid products of the diseased lymphatic glands, but that generally they are not recognisable, from the fact that in this case the cells are mostly developed at a free mucous surface, and are speedily shed from it. But he considers, further, that there may be some special aptitude, or weakness, congenital or acquired, in the lymphatic glands of certain persons, or of certain parts of them, which makes their inflammations, induced by indifferent causes, assume the scrofulous character.[15]

In contradistinction to the scrofulous enlargement, tuberculous lymphadenitis may be mentioned. It attacks certain parts of the lymphatic system rather than others, especially those through which the lymph is, as it were, filtered, namely, the lymphatic glands. It is in the glands that the tuberculous eruption is most intense. Generally, the process makes a kind of halt at these gland stations, but it sooner or later finds opportunity to spread onwards, and at length reaches the main trunks and the thoracic duct itself. Wherever the tuberculous process has become established, it is distinguished by the development of tubercles, and this in the lymphatic vessels as well as the glands. A more or less tense inflammation of the surrounding tissue is always associated with the tubercular eruption, it is manifested by hyperæmia with infiltration and swelling. If the process lasts for a certain time it not unfrequently happens that young connective tissue is developed at the seat of the eruption. The usual fate of the tuberculous growth is caseous necrosis and disintegration. It rarely issues in the formation of fibrous tissue, and still more rarely in complete resorption of the tubercle. The virus which engenders tubercle may be carried out of the lymphatic system into the blood, either from a tuberculous focus in a gland, or a tuberculous ulcer in the thoracic duct. It may thus be conveyed to distant organs.

In the morbid condition known as lymphadenoma, the enlargement of the lymphatic glands consists at first of mere hyperplasia, and subsequently of fibroid induration. It varies much in its extent. A few glands only may suffer, or every gland in the body may be enlarged. The former cases have the character of a local growth, the latter is distinctly a general disease, for which the term lymphadenosis seems the most exact. The glands vary in consistence, when soft there may be a considerable excess of leucocytes in the blood, when hard there may be simple anæmia. Microscopic examination reveals that the enlargement is due to hypertrophy of the glandular tissue, the whole structure being converted gradually into lymph cells, with a fine network of cellular tissue. In addition to the hypertrophy of the glands, other organs, in course of time, present growths of a similar nature, especially the spleen, and less commonly the liver, lungs, kidneys, and alimentary canal. Even the canals of the bones may be filled with lymphoid cells. Very little is positively known as to the ætiology and pathology of the condition, but it is assumed that it is a primary affection of the lymphatic system, depending upon some special constitutional condition or diathesis, named lymphadenosis. By some pathologists it is regarded as malignant, and is placed by Wilks between cancer and tubercle. In many cases the disease seems to begin without any obvious cause, but in others it evidently starts from some local irritation, and such irritation has probably been present in other instances where it has been too slight to attract attention. As regards predisposing causes, the disease is most common in early and late adult life, in males, and amongst the poor; its development being aided by bad food, insufficient clothing, cold and damp, and unfavourable hygienic conditions. When the affected glands are superficial, their enlargement is evident on objective examination, and their extension and growth can be observed. In the large majority of cases there is neither pain nor tenderness, but if the enlargement is very acute and rapid, sharp shooting pains may be complained of. When situated in internal cavities, the existence of lymphadenomatous growths can generally be made out by physical examination.

[15] Bristowe's "Medicine," p. 62.

*

Some of the most important symptoms result from pressure and irritation by the enlarged glands, these necessarily varying according to their position and their relation to adjoining structures. Obstructive dyspnœa is often a marked symptom when the growth is situated within the chest. Along with the local signs of the disease, the constitution is obviously affected, as a rule. This may occur before any local symptoms appear, but usually the general symptoms are gradually developed as the glands progressively enlarge, including emaciation, anæmia, and its attendant phenomena, often combined with an appearance of serious illness, marked muscular weakness, the patient often tottering and trembling, and feeble circulation. More or less pyrexia is present in most cases especially in young patients. Free perspirations are common, and the skin is pale and usually moist. Œdema of the legs is a frequent symptom. The blood does not present any excess of white corpuscles, but is often very watery and wanting in its normal colour, the red corpuscles being markedly deficient. The patient is much depressed and low spirited, and attacks of syncope are not uncommon. Bronzing of the skin arises from enlarged retro-peritonæal glands surrounding and compressing the solar plexus. Unless death should occur from the local effects of the enlarged glands, the course of the disease is generally chronic and progressive. In most cases death occurs within two years, either from gradual asthenia and exhaustion, from the effects of pressure, rarely from hæmorrhage, owing to perforation of a blood-vessel, or from some intercurrent complication, such as pneumonia, pleurisy, erysipelas, or kidney degeneration.

Hard lymphadenoma or lymphosarcoma occurs as a primary growth, most frequently in the superficial lymphatic glands. Other groups may be attacked in the further course of the affection. For example, if the affection starts in some of the cervical glands, the rest of the cervical glands and the thoracic and abdominal glands lying near the large vessels are attacked in succession. The glands are transformed into firm, tough, elastic, or hardened knots, forming dense clusters in combination. Simple glands may reach the size of a walnut. On microscopic examination, the lymphadenoid structure is seen to be preserved, while the cells are increased in number, and the reticulum is thickened. Fatty degeneration, calcification, or softening rarely supervene. In later stages the follicles of the spleen may be affected, and be changed like the glands into hard nodules. The spleen is never primarily affected in this form of lymphadenoma.

Sarcoma of the lymphatic glands is a somewhat uncommon affection. It occurs in single glands, or several of the same group are simultaneously affected, and cohere into a nodular tumour. It often overpasses the limits of the gland, and invades the adjoining tissues. Secondary growths are usually developed. Small round-celled sarcoma, spindle celled sarcoma, fibro-sarcoma, and alveolar sarcoma or alveolar angio-sarcoma are all forms which occur.

All the forms of tumour, which give rise to metastases may affect the lymphatic glands. Cancers especially are apt to do so, and the glands become enlarged and altered as the disease advances. Sarcomatous metastases, like the carcinomatous, may originate in sarcoma cells which have entered the gland through the lymphatic vessels.

Indian Medical Service.—The following were successful at the Competitive Examination held on the 11th instant, and following days. Fifteen candidates competed for five appointments. All were reported qualified:—D. Prain, 2,625 marks; A. T. Bown, 2,610; J. T. W. Leslie, 2,560; U. N. Mukerji, 2,411; W. L. Price, 2,378.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Epidemiological Society of London.

(Continued from page 863.)

Erysipelas.

In 1854 Mackinnon remarked:[1]—"The idiopathic erysipelas as it appears on the face and lower extremities, unconnected with wounds, is a rare affection in India, and I know of no instance of its epidemic appearance. Erysipelas attacking wounds I have frequently seen prevail as an epidemic, exciting in the merest abrasion of the skin, as in the sores on the legs of prisoners from the chafing of their irons, high and diffuse inflammation, requiring free incisions to prevent sloughing. It has been during humid sultry weather, and especially at the breaking up of the rains, I have seen wounds take on this action in an epidemic form. In the Medical College Hospital and in the Native Hospital in the Durrumtollah, wounds made in operating are apt to take on this action, especially in the rains.

Morehead (p. 200) agrees with Mackinnon in considering that idiopathic erysipelas was, in his time, rare in India. He met with very few cases in Bombay, either in Europeans or in natives. He added that traumatic erysipelas is of more common occurrence, and at times evinces almost an epidemic tendency. It was common in the Jamsetjee Jejeebhoy Hospital in November and December, 1851, after wounds of the scalp and lower extremities, but was easily subdued. It did not in all cases originate in the hospital, but in some was present on the admission of the patient; thus showing that it was not, at least in all cases, due to the air of the hospital. On one or two occasions he also noticed the liability to erysipelas after application of blisters, so marked as to render it expedient to discontinue their use for the time.

In my considerable Indian experience, between 1848 and 1873, so little *idiopathic* erysipelas appeared among my own patients, that I used to speak of a solitary (facial) case which had occurred in my medical wards in the Calcutta Medical College Hospital, which has 300 beds. In the eight years 1865–72, however, sixteen *traumatic* cases proved fatal in the surgical wards. In 1873 a wave of erysipelas arose in Calcutta, and from February, 1874, this disease appeared to have taken up its abode in the surgical wards of the hospital, spreading from case to case, and attacking traumatic cases so frequently that the surgeons became apprehensive that it would occur whenever they were obliged to operate. I then foresaw the appearance in our obstetric wards of puerperal fever. In the first week of June that disease became so prevalent there that Dr. Charles was obliged to remove his lying-in women to a separate building.

There was no accession of idiopathic cases to my medical wards.[2]

In his annual report of the General Hospital, Madras, for 1882, Surgeon-Major R. W. Cockerill observes that "regarding erysipelas, the experience of the past year agrees with that of all former ones. This disease is a rare one in Madras, and never attacks the patients in hospital. All the cases (four in number, all Europeans) came from outside; and, although the patients are generally treated in the ordinary wards, such a thing as the disease being conveyed from one patient to another, by infection or contagion, is unknown."

The returns for 1881 show that 8 *European Soldiers*

[2] For a detailed report on the outbreak, which I made to the Head of the Medical Department, see *Indian Medical Gazette*, for 1875, p. 314.

died of erysipelas, the distribution of cases being :— Bengal, 2 ; S. Afghanistan, 1 ; Madras, 3 ; Bombay, 2. Of *European Women*, 8 were admitted in Bengal, of whom 1 died, and 2 were admitted in the Bombay Presidency. Total, 10 cases, and 1 death. Of *Soldiers' Children*, 5 were admitted and 1 died ; 3 admissions with 1 fatal case in Bengal ; 2 admissions in Madras. Of *Native Troops*, there were 51 admissions in Bengal and 4 deaths. In the Punjab Frontier Force, 38 admissions, and 3 deaths. Hyderabad Contingent, 1 admission ; Bombay, 7 admissions ; Madras, 9 admissions, 3 deaths. In the *Gaol Population*, there were 150 admissions in Bengal, 29 deaths ; 12 admissions, and 2 deaths in Bombay ; in Madras 6 admissions, 1 death ; in British Burmah, 2 admissions ; in the Andamans and Nicobars, 7 admissions and 1 death.

For *Puerperal Fever* and *Ephemeral Puerperal Fever* see Malarious Cachexia, Diseases of Pregnancy, and Erysipelas.

Rheumatismus Aeutus see Diseases of the Heart.

Writing in 1835[3] Mr. Malcolmson, of Madras, said that the common acute rheumatism of Europe is very little known in India. In reviewing this work Dr. Corbyn, whose Bengal experience was large, by no means opposed this view. Morehead, writing from experience in Bombay, says,—"It may be that *aeute* articular rheumatism is not so common in India as in colder climates, yet it is by no means rare" (p. 561). I saw it very distinctly, with its cardiac complications only too well marked, in Calcutta, but only in three or four cases. In a European, there was the characteristic sweating, which I think I could not mistake, but the attack passed off in two or three days.

Reporting in 1839, Dr. John Murray stated that the "Service in Madras were losing more in efficient strength by rheumatism than by any other class of disease.[4] He attributed this mainly to the unfitting state of the barracks and guard-rooms in that command. Although great improvement has been effected in military buildings, the prevalence of rheumatic disease is still great. In the year 1881 the admissions for rheumatism among the European Troops in India numbered 2,757, or 47·0 per 1,000 of strength. No distinction of acute and chronic is made in the tables ; but the fact that *there were no deaths* appears to show that true rheumatic fever was neither prevalent nor grave in type. The invalids under this heading amounted to 1·48 per 1,000 of strength. The admissions of European Women were 40 in 3,741, with no deaths ; of children 10 in 6,548, no deaths. Among 100,844 prisoners, there were 447 admissions for acute rheumatism and only one death. The admissions for chronic and muscular rheumatism were 832 and 564 respectively. The incidence of rheumatism upon the prisoners in the Andaman and Nicobar Islands, averaging 11,225 strong, was remarkably heavy. The admissions were, acute, 31 ; chronic, 424 ; muscular, 207 ; total, 662, or 65·5 per 1,000 ; but no deaths.

Synovial Rheumatism of the smaller joints, as those of the phalanges of the fingers and toes, as well as of the larger synovial sacs, as the shoulders and knees, is frequent among Europeans who have long resided in the damp, malarious, and inconstant climate of Bengal. Although these painful affections are often very chronic, laming people, and resisting all treatment for years, they, like muscular rheumatism, seldom, if ever, cause material lesions in affected joints, and at length disappear, generally suddenly, of their own accord. I know persons, long retired from India, who, having suffered in almost every joint, are now free from pain or stiffness in any articulation, but who are liable to be attacked at any time, especially in damp and cold weather, with pain and disability almost anywhere, but most particularly in those joints which have hitherto suffered least.

Muscular Rheumatism is of very frequent occurrence during the rainy season in Lower Bengal. Under the head of Tetanus, I have spoken of a singularly marked coincidence, indicative, as I believe, of ætiological affinity, which is observable in the appearance of these two diseases. I think that there are now few large muscles in my own body which have not been subject to this malady, which I have endured without any attempt at medication, in the certainty that nature would relieve me. In my last voyage from India, the heat was so great that I could not occupy my berth, and lay in an exposed position on the deck under an open hatchway. The result was a pain in my left popliteus muscle which troubled and considerably lamed me for many months after my return. As I was beginning to think that I was crippled for life, still refraining from treatment, the affection suddenly disappeared and has never returned in that locality.

I have noted a remark made by Mr. Morgan in a report on the state of health of troops at Cannanore,[5] which, although true and useful, must be accepted with some reserve.

"A hundred and forty cases of this class of disease have been treated, and two of them were invalided ; no deaths. That most convenient complaint, 'Pains all over me,' in the mouths of soldiers who think they have completed service long enough to entitle them to discharge, has and will cram the wards of an hospital in a station where the facilities of 'catching cold' are certainly great during the rainy season. Such cases are really quite puzzling. There is no violence of inflammatory action to control ; the secretions are all healthy in quantity and quality ; yet the 'pains' go flying about from head to foot in all directions. If we blister or leech the loins, the most common site, in ten days we have the shoulders implicated, and *vice versâ*." Mr. Morgan evidently regarded most of those who thus complained as malingerers, and probably a large proportion of them were ; but such is the natural course of the affection in genuine cases.

Writing in 1837, Dr. Corbyn remarked that *Gout* is a disease scarcely known among the inhabitants of warm climates. He added that East Indians are rarely affected with gout. A young Englishman, born of gouty parents, but still free from joint disease, may enter upon a career in Lower Bengal with a strong hope that, with prudence, he may escape the threatened evil. I believe that *Gout* scarcely exists among the natives of India (Dr. Irvine wrote, in his "Medical Topography of Ajmeer," "I have heard of gout occurring among some of the Rajpoots, who drink hard, but I never met with any such cases"), and, although I have seen one or two very moderate cases of this disease among Europeans, and have heard of a very few others, I think that, with all its sanitary faults, Calcutta is an earthly paradise for those cautiously-living people whom gout threatens, but has not crippled. Before I went to India, I saw very little of the diseases of the rich. In the East, I saw much of the ailments of ladies and gentlemen born and living in wealth, but it was not until ten years ago, in helping an old gentleman with unmistakably characteristic hands and feet into a Bayswater omnibus, that I said to myself, "I now see typical gout for the first time !"

I have from time to time watched the sufferings from *gouty synovitis* of an esteemed brother officer. About seventeen years ago, Dr. ——, a remarkably well built and agile man, was caught when walking on the

[3] "Observations on some Forms of Rheumatism prevailing in India."

[4] Reporting from Bellary (Madras Presidency), Dr. Allman said that Rheumatism was the most troublesome and tedious disease which the Army Medical Officer has to deal with in India. Although in very few instances fatal, it deprived the Army annually of many soldiers.

[5] *Indian Journal of Medical Science*, vol. v., p. 335, N.S.

Midaun (plain) in one of the most terrible cyclones that has visited Calcutta in modern times. He stood long, clinging to a lamp-post, exposed to the fury of wind and rain. The consequence was an attack of acute synovitis of a knee-joint. In subsequent years other joints have become affected; but he recovers well from attacks, and it is clear that no large amount of deposit has occurred. These attacks are undoubtedly gouty.

Syphilis.

Those whose experience has been principally obtained in large Indian stations, or who, like myself, have practised chiefly in much frequented Oriental ports, have not, I believe, observed any remarkable differences in the type of the primary and secondary forms of that disease as they occur in Europe and in the East. Still, as our acquaintance with the remote hill tribes of India is daily upon the increase, it would be well if, while a community is still in its primitive condition, enquiry could be made into the prevalence of syphilis among them and into the characters of the disease as it now exists.[6]

Formerly it became a matter of observation by surgeons, especially in the Madras Presidency, that syphilis has greatly increased in prevalence and become aggravated in type during famine seasons. Dr. John Clark, of H.M.'s 13th Light Dragoons,[7] showed that, while his regiment was stationed at Bangalore, during the dreadful famine of 1833, the poor and half-starved village women were known to cohabit with the soldiers for a handful of grain. He adds that prostitution prevails to a great extent at such periods, and the state of debility induced appears to be favourable to discharges from the sexual organs of the female. He gives a return of admissions for syphilis and gonorrhœa in the regiment, showing that, whilst during ten of the years between 1820 and 1834 the number of cases ranged from 63 to 110 annually, only in one year reaching 140, the admissions during the four exceptional years, *which were years of famine*, ranged from 226 up to 350.

In this report Dr. Clark mentions a fact which is still noteworthy. From observations made in the 7th and 81st Regiments, he found that "more cases (of syphilis) often occur in one regiment in the East Indies than in the whole of the West India command." Dr. Clark assigned this difference to the infrequency of prostitution among the negro slave population of the West, "there being little or no encouragement for prostitution amongst a people who are clothed, fed, and encouraged to marry." The number of cases for all regiments in the West Indies in 1823 was 36; the returns of the 13th Light Dragoons in India for the same year showed that there were 44 cases of primary syphilis *treated*. The average of syphilitic cases in that regiment during eighteen years, 1820 to 1837, was 61, the average strength of the regiment probably not being above 800.

A report by Mr. McGregor on syphilis in H.M.'s 39th Regiment from 1833 to 1838, during the greater portion of which term they were in cantonments at Bangalore,[8] gives the very high average of 191 per mille for the six years. These averages may be usefully compared with those of the army of India of the present day, viz., primary, 87·6, secondary, 23 per mille.

All observation combines to show that syphilis rises to its greatest prevalence and malignity in armies worn out in long campaigns, and whenever the men's constitutions are tainted with scurvy. I have cited elsewhere facts leading to this conclusion.[9]

In the year 1860, when the measure of re-establishing Military Lock Hospitals in India was under discussion, I collected with much care and published[10] materials for a history of these establishments. Now that the Lock Hospitals in the United Kingdom stand nearly useless, and those in India appear to be immediately threatened with abolition, I would earnestly solicit the attention of the authorities and of army surgeons to that very striking array of facts. In 1797 the Governor-General established *hospitals for diseased women* at the stations of Dinapore, Berhampore, Cawnpore, and Futtyghur. Some thirty years subsequent to their establishment, these institutions had fallen into disrepute, assuredly under mal-administration. Accordingly they were abolished in the Bengal Presidency in 1830, but were permitted to survive in the presidencies of Madras and Bombay until 1835. Many medical officers of great ability and experience—Dr. Murray, senior, Surgeon Sievwright, Dr. Clark, Dr. Mouat, senior, and Dr. Arnott—deeply regretted the abandonment of this system and showed that an increase of syphilis was the result. I have fully cited their statistics and arguments. I have also shown that, being virtually left under the control of a native doctor and a female assistant, both people of the lowest class and upon the very smallest allowances, these places became dens of iniquity, and their keepers agents of extortion and oppression. The only surprise appeared to be that they could possibly have been maintained for nearly forty years in every large military station throughout India. My late honoured chief, Sir John Forsyth, Director-General of the Medical Department, held that the whole history of Lock Hospitals in India distinctly proves that such establishments, if conducted upon the old system, must almost inevitably be failures, as, with the exception of the European medical officer in charge, the whole system was carried on by native agency. The system of placing the women of the Regimental Bazar under the supervision of the quartermaster, and under the inspection of one of the medical officers, and those of the Sudder Bazar under the surveillance of the cantonment magistrate, was found to keep the Bazars tolerably free from disease. This eminent authority held that the only prospect of making a Lock Hospital really useful is by conducting it with the vigilant and zealous co-operation of these two authorities; and even then little good can be expected unless a medical officer of standing and activity is placed at the head of the establishment, assisted by an European matron; and, to be perfectly successful, even this scheme must have the hearty support of the whole of the regimental and medical authorities on the spot. The Director-General was "fully impressed with the necessity of adopting some such decisive and comprehensive measure as that sketched above for the prevention of a disease which is known to undermine the health of so large a proportion of our European force"

In the middle of 1859 a Lock Hospital at Meean Meer was sanctioned as an experimental measure. The system has been general until now.

Judged by the evidence of statistics, this much debated experiment, pursued for nearly a quarter of a century, has not been successful. It is shown in the Eighteenth and Nineteenth Reports of the Sanitary Commissioner with the Government of India, 1881 and 1882, that in the whole army of India during the six years 1876–81 the annual admissions per mille for *primary syphilis* have been at the rates of 60, 65, 95, 79, 88, 92, and 87·6. It has long been argued that, even if this system failed to diminish the number of cases, it would

have the effect of rendering the type of the disease less virulent. As evidence that this improvement has not been effected, Dr. Cuningham shows that during the above years the ratios per mille of *secondary syphilis* have been 24, 22, 22, 24, 23, 23, 23. The admissions for gonorrhœa in 1880 were at the rate of 106·5, in 1881 of 107·3, and in 1882 of 119·8, per 1,000. The Sanitary Commissioner observes: "In noting these results, the facts only are dealt with, and they are most unfavourable. As pointed out in this office annual report for 1878, they may in some measure be accounted for by the increased youth of the army and by the smaller proportion of married men, but making every allowance for these factors, *the failure of the Lock Hospital system is still most decided.*" [The italics are mine. N. C.].

In the latest report which I have seen (for 1882), the Commissioner writes: "In the report for 1881, it was shown, from the statistics of venereal diseases in the European Army of India, during a series of years that the Lock Hospital system in the cantonments of this country has proved a failure. It was there noted that the admission-rate for these diseases in the Army of India had been 260 per mille during the year 1881, and that, with the single exception of 1878, this ratio exceeded that of any year since 1871. Another year's experience confirms the conclusion then arrived at. During 1882, cases of venereal disease were more common than they had been even in 1881, and equalled 265 per 1,000. This admission rate . . . exceeds the average ratio of the ten-year period, 1870–1879, by 62 per mille.

It can hardly be doubted that, armed with these texts, the sentimentalists of the present day will take active measures for denouncing and crushing the Lock Hospital system in India, as their predecessors wrote and clamoured the system down in the third decade of this century. As I am writing this, I find it announced[11] that "venereal of the most virulent type is still the prevailing disease among the troops at all the military stations." "The Lock Hospitals are almost empty. Attendance at these institutions being now optional, but few unfortunates present themselves for treatment, and these, as a rule, are only bad cases." The writer adds, "Fostered and encouraged as it is, this loathsome disease is spreading to such an extent as to cause grave anxiety." As I have been long out of India, and as I have no personal experience of the working of the system during the past 24 years, I am not qualified to offer an opinion upon the Indian data cited above, but I most earnestly trust that, in the highest interests of suffering humanity, the whole facts of the case, as it affects the character and working of Lock Hospitals in the East, may be dispassionately investigated and reported upon by military surgeons of great Indian experience. However the question may be finally decided, I shall never cease to believe that, whatever the unavoidable short-comings of this system may be, *the direct tendency of Lock Hospitals, whether at home or abroad, is to reduce the prevalence and virulence of venereal disease*, PROVIDED THAT THE INSTITUTIONS ARE JUDICIOUSLY AND LIBERALLY CONDUCTED.

What the Indian Lock Hospitals needed in 1830–34, was reform, not abolition. The action of those who put them down was somewhat less rational than that of him who should deliberately prescribe a poisonous dose of Prussic acid in a case of inveterate scabies. Can we hope that, despite the action which is being adopted in the United Kingdom, a wiser course will now be taken in India?

Miserable cases of destruction of the tissues of the mouth and jaws, resulting from the native practice of salivating by mercurial fumigation in syphilis, are frequently seen at our hospitals. Doubtless many victims, previously the subjects of malarial and scorbutic cachexia, perish in this manner outside. Either the patient inhales mercurial fumes from a *bhuttee*, made in the form of the cord of raw cotton enclosed in cloth used as a pipe-light, or he sits enveloped in a blanket, on a cane-bottomed chair, under which is placed a pan of ignited charcoal, upon which a native preparation of mercury, usually Rascapur, a mixture of calomel and corrosive sublimate, is sprinkled. See the chapter on Diseases of the Jaw in Fayrer's "Observations," p. 264, and my chapter on *Diseases of the Mouth*. Dr. R. H. Stevens[12] narrates the case of a Bengali lad of 13, with spleen, in whom salivation by a Hakeem caused sloughing of the lower eyelid and destruction of the eyeball which came away almost without the use of the knife. He died exhausted.

Of *Tumours* generally, as they occur in India, it is observable that where, as happened more frequently in old times when the skill of European surgeons was less believed in than it now is, growths, especially the non-malignant, often attained enormous bulk. This was very graphically shown in a series of pictures of Chinese tumours which used to hang from the gallery in Guy's museum. Apart from scrotal tumours, many of these vast growths are pictorially represented in the Indian medical publications of fifty years ago. A case described and pictured by Dr. A. Campbell[13] is especially remarkable. A Nepaulese lady of high rank had a massive growth originating above the right breast. Its size and weight were such that she could only move by the assistance of her slaves. It had descended so low as to rest on her couch when she sat upright. The continued pressure of its base on the ground or bed brought on fatal ulceration with fever. I removed larger fatty tumours in Bengal than I ever met with in England. I saw my friend, the late Dr. Allan Webb, remove an enormous tumour from the outer triangle of the neck of a native, the position and loose attachments of which suggested his remark that, when bulky tumours, originally deep-seated, are dependent and not malignant, long neglect of surgical aid often has the advantage that their weight causes them to enucleate themselves; and thus their excision becomes easy and safe.

A NEW METHOD OF REMOVING SEWAGE FROM HOSPITALS, BEING A MODIFICATION OF CAPTAIN LEIRNUR'S SYSTEM.

By JAMES W. BARRETT, M.B., M.R.C.S.
Demonstrator of Physiology in King's College, formerly Resident Medical Officer to the Melbourne Hospital.

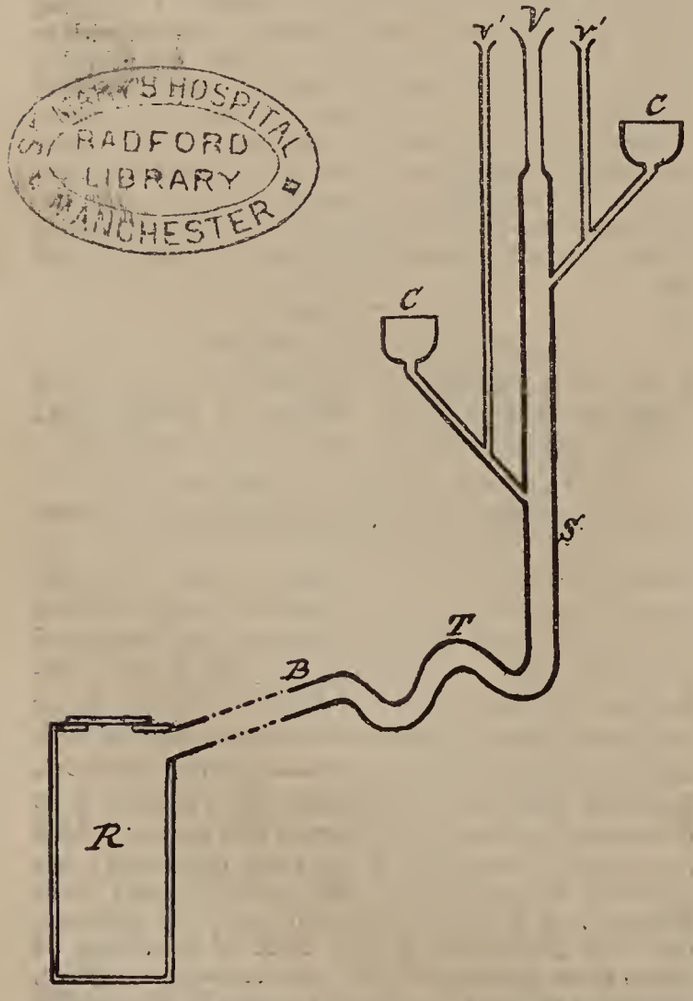
THE system of removing sewage (using the term strictly to mean excreta) from the Melbourne Hospital is a modification of Captain Leirnur's, and has proved so simple, cheap, and efficacious, that I have endeavoured in this article to briefly describe it. Being used in a hospital which was formerly ridden with septic and wound diseases (traumatic fever, erysipelas, spreading gangrene, septicæmia, and pyæmia), it is interesting to notice that whereas this system (which being unique was blamed for their production) has remained unchanged, yet the septic diseases have become very much less frequent since the introduction into Melbourne of that form of treatment to which in its widest sense the term antiseptic is given, and which all over Australia is known by the generic name of Listerism.

In the city of Melbourne the water carriage system

of removal was simply out of the question. Apart from the prevalent opinion that it was not equal to the dry earth system, the fall from the city to the sea is not sufficient to allow of its safe introduction, and when a system of removal of sewage had to be adopted the choice lay between the dry earth and the Leirnur system ; and as thirty years ago very little was known of Leirnur's method it was not adopted. But to the Melbourne Hospital (300 beds), which is built partly on the old or barrack plan, and partly on the new or pavilion method, the dry earth system was totally inapplicable for many reasons too lengthy to detail, and so Leirnur's method was experimentally tried, and being found to answer perfectly, was generally adopted.

The exact mechanism may be described as follows : —In the grounds of the hospital are placed four iron air-tight tanks, each of a capacity of from 200 to 300 cubic feet ; into these, receive pipes, which may be termed basal soil pipes, which convey the sewage from the base of the various segments of the building to the tanks. The soil pipes from the various commodes in the building, which are 36 or 38 in number, open at an acute angle into large vertical pipes which run to the bottom of the building, and there, after describing a horizontal S-shaped curve, and so forming a double trap, open into the basal soil pipes. The upper extremities of these vertical tubes are freely ventilated by air shafts opening on the highest points of the roof. The soil pipes leading from the commodes to the vertical pipes are also in many cases similarly treated.

The following diagram represents this air-tight scheme.

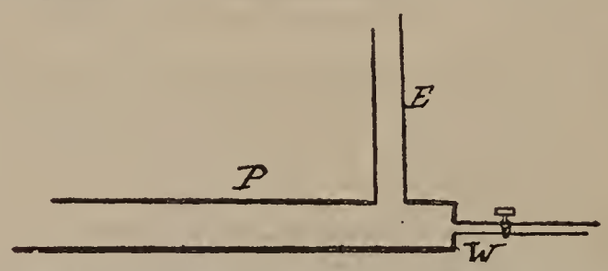


In this diagram, *R* represents one of the underground iron tanks which, as mentioned already, are situated in the hospital grounds ; and *B*, a basal soil pipe leading to it from one of the blocks of the building. This pipe *B* is double trapped at *T*. *S* represents a vertical soil pipe, into which the soil pipes of two commodes, *C*, *C*, open at an acute angle. These pipes and the vertical soil pipe are ventilated by tubes represented by *V'*, *V'*, and *V* respectively.

From this it will be seen that, in the first place, by virtue of the air-tight character of the system no reflux of gas to the commodes can occur ; if from imperfection any reflux did tend to occur it would have to overcome the double trap, and, finally, if any gases get as far as the vertical soil pipe, either the main (v) or the sub ordinate (v^1) ventilators would carry them off.

Any sewage thrown into the commodes falls through the vertical tubes to the traps, and there generally remains for some time. But once a day the tanks (R) are exhausted of air, and then everything in the system is driven with great violence into the tank and the system is thus thoroughly emptied and cleaned ; for the exhaustion of air is continued until it is empty throughout. Once a day also the tanks themselves have their contents transferred by the same pneumatic action to air-tight carts, and the sewage is taken into the country and buried. The mechanism by which the exhaustion is effected is equally simple and effective. In Melbourne the water pressure is very great, and this motive force is here utilized. Into a large metal tube is blown a small but powerful jet of water in the direction of the axis of the tube, whilst opening into the tube at right angles is the metal pipe leading to the chamber which it is required to exhaust, the actual connection being made by coarse india-rubber tubing.

The annexed diagram will serve to explain the arrangement.



In this diagram, *W* represents the waterpipe and tap, *P* the large metal tube, whilst *E* represents the tube which is connected with the chamber it is required to exhaust. With a very moderate expenditure of water, the exhaustive force obtained with this apparatus is enormous.

From these various considerations it will be seen that this system, carefully adapted with good material, is, in a city with a tolerably high pressure water supply, almost perfect, and is wonderfully cheap in application and use. Melbourne is, I believe, the only city in which this modification is used, and the results are there very good indeed. The only weak point in the system is the fact that the tanks must be opened once a day in order to be emptied, and are then apt to give rise to smells, &c. The objection is not insuperable and can be readily overcome by disinfectants. Of course any gases thus arising are at once in the open air and far from the hospital walls. The tanks, tubes, and carts are made of iron, and all doors and openings are closed by iron plates which screw on by a tolerably coarse but well fitting screw thread which proves sufficient to make them air-tight. The most ignorant men are found to be perfectly competent to successfully conduct the working part of the operations.

In-growing Nail.—In a note to the *Union Médicale*, June 22, M. Monod states that during the last twenty years he has treated in-growing nail by a very simple and effectual method, which does not involve the removal of the nail. He makes a free application of nitrate of silver at the commencement of the affection, without isolating the nail. If the cauterisation is carried deeply into the diseased furrow, the patient has usually, even by the next day, derived considerable relief, and is able, even thus early, to walk in moderation with an easy shoe. Extirpation of the nail should be reserved for quite exceptional cases.

REPORTS OF

HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

CASE OF MALIGNANT DISEASE OF CÆCUM —PERFORATION AND RAPID DEATH— AUTOPSY — SECONDARY GROWTH IN ABDOMINAL WALL AND BOTH KIDNEYS.

(Under the care of Dr. HARLEY.)

(For the notes of this case we are indebted to Mr. F. W. STONE, House Physician.)

HENRY B., aged 46, was admitted into the hospital on July 17th, 1884.

Family History.—The father died, aged 74, of bronchitis; the mother died, aged 60, cause unknown. The patient has lost two brothers of "consumption," one aged 24, the other aged 17. Two sisters died young, cause unknown. He has one brother living, aged 42—healthy. There is no family history of tumours, insanity, or epilepsy.

Previous History.—He had a bad attack of gonorrhœa 18 years ago, with abscess in right groin, and epididymitis. No history of syphilis can be obtained. He has never had rheumatic or scarlet fever.

Present Illness.—He has suffered from pains in abdomen and at the lower part of his back for one year. The pain was of an aching, continuous character; it occasionally extended along the front of the right thigh to the knee. There has been no trouble in defæcation or urination, but the patient has found his bowels have tended to be constipated for last five or six months, he having to take purgatives frequently. There has been no vomiting, but occasionally he has felt sick; no cough. No history of intestinal hæmorrhage. The motions are well formed and normal in appearance.

State on Admission.—His weight is 9st. 11lbs. He is a very anæmic, emaciated man, with an anxious expression. He is not in any pain. He states he is steadily losing flesh and strength. Skin clear, presents no eruption.

Thorax. — Chest barrel-shaped; movement impaired. Some slight dulness at posterior right apex, with prolonged expiration. No moist sounds. Apex-beat of heart in normal position. Sounds normal; no friction.

Abdomen.—Liver and spleen not enlarged. Abdomen not distended; tenderness in umbilical and right iliac regions. Three inches above umbilicus and one inch to left side is a nodule the size of a hazel nut, adherent to skin, but moving freely on the deeper tissues. There is a swelling in the right iliac fossa; hard, quite dull, and tender on pressure. In the skin covering this mass are several nodular growths about the size of walnuts, moving on the deeper seated swelling. The right superficial inguinal glands are slightly enlarged, and freely movable.

There is slight œdema about the ankles. The urine, sp. gr. 1015, is clear and pale yellow. There is no deposit, but a trace of albumen and rhomboid-shaped cystals of uric acid. No casts.

Reflexes are normal; pulsation in femoral arteries equal. Temperature 98·6° Fahr. He was ordered Tinct. Opii ℥ x. Mist. Pot. Cit. Efferv., ℥j. ter die sumendum.

July 18th.—Quite free from pain. Bowels regular. Sleeps well. The appetite is very bad.

July 21st. — Going on well. Complains of pain along front of right thigh. Was ordered simple enema as bowels had not acted for two days. Gets up each day. Temperature normal.

July 25th.—Simple enema again, as there had been constipation for two days. No change to note in shape or size of tumours.

July 29th.—Temperature last night rose to 100·2°. He has had diarrhœa since July 27th. Was ordered enema Amyli. c. Tr. Opii. ℥ xxx.

July 30th.—At 4 p.m. seized with sudden pain in abdomen, referred to umbilical region. The diarrhœa had stopped on the 29th. Vomited, *for first time since admission*, at 10 p.m. Vomit grumous and very offensive in smell, almost stercoraceous. Abdomen tense. Clammy sweat on face. Temperature 100·2°. Was ordered hot fomentations, c. Tr Opii. to abdomen, Tinct. Opii. ℥ xv. tertiis horis.

July 31st.—Temperature 100·2°. Vomiting incessantly. Vomit this morning is of bright yellow colour no blood; comes on five or ten minutes after taking nourishment. Enema Olei. Ricini ordered, but nothing came away. Knees drawn up to abdomen; quite conscious. Whole abdominal surface acutely tender. Opium continued. Ice and effervescent medicine.

August 1st.—Death.

Necropsy.—Fifty-one hours after death; rigor mortis present only in lower limbs; very little subcutaneous fat. Left pleura contains ℥ij of serum. Right pleura firmly adherent all over. No new growth in the lungs. Heart.—Hypertrophy and dilatation of right chambers; no new growth, valves healthy; slight atheroma of ascending aorta. Abdomen.—Liver very fatty; no new growth. Surface of large and small intestines covered with recent lymph. Great omentum firmly adherent to right abdominal wall. A quantity of pale liquid fæces well up through an opening in the cæcum; a fair amount of sero-purulent fluid is contained within the peritonæal cavity. Spleen, normal. Much new growth seen on parietal peritonæum near cæcum. The commencement of ascending colon is quite blocked by three nodular masses of new growth; the growth is white and tough. The opening previously noted, from which fæces welled out, is in anterior wall of cæcum, and is irregular in shape, one inch long; its edges are thickened with new growth. The walls of cæcum are throughout infiltrated with growth; its mucous membrane is soft and shreddy, and the disease had evidently commenced there and spread outwards. Left kidney.—The cortical portion is almost entirely replaced by confluent masses of new growth, similar in character to that already noted. Medullary portion free. Right kidney, smaller than the left, is similarly affected, but to a less degree. Three large cysts (serous) in cortex.

Remarks by Dr. Harley. — Two influences predisposing to morbid action may be recognised here. Firstly, an inherited weakly constitution resulting in some members of the family in the deposition of tubercle. Secondly, gonorrhœal inflammation of the right inguinal glands some seventeen years before the appearance of the present disease. That the latter may have an influence in the production of this low form of morbid action I have no doubt, for I have witnessed two or three cases of severe pain, and nodular swelling of the glands in the neighbourhood of the cæcum during gonorrhœal inflammation of the right inguinal glands. The kidneys may have received an impression of the same kind from the urethral or vesical surface.

SCROTAL HERNIA—RADICAL CURE.

By H. H. CLUTTON, M.B., F.R.C.S.,

Assistant Surgeon to St. Thomas's Hospital.

A BOY, aged 1 year 5 months, was admitted into St. Thomas's Hospital in August, 1882, for the radical cure of a large hernia which completely filled and distended the scrotum. A truss was only partially

successful in retaining the hernia within the abdomen. The outline of the testis could be felt resting on the hernial sac. It was therefore probable that the hernia had taken place into the funicular portion of the processus vaginalis. The swelling had been first noticed a few days after the child's birth, and had increased considerably in size during the last few months.

The operation was performed on August 30th, 1882, with full Listerian precautions. The sac was removed entire, and the pillars tied together with stout catgut. A catheter with elastic tubing attached was tied into the bladder, and was successful for five days in preserving the dressing from being fouled. At the end of this time it had to be removed on account of the irritation it had produced. The antiseptics were also discontinued a few days afterwards, as they were so frequently soiled with urine, but the wound was then quite superficial. On the twelfth day there was very little discharge, and no external swelling, but deeply in the position of the inguinal canal a hard mass of inflammatory material could be felt. In another week it was soundly healed. He left the hospital shortly after without a truss, and has never worn one since. For some time a lump could be felt in the inguinal canal, but at the end of six months this also had disappeared.

Examined on March 24th, 1884, there was no difference to be detected, when the child cried, between the two sides of the abdomen. There was not the slightest impulse beyond the abdominal wall, nor any aperture into which to put one's finger. He was not wearing a truss, and never had worn one since the operation.

Medical Times and Gazette.

SATURDAY, AUGUST 30, 1884.

The International Congress at Copenhagen having become a thing of the past, the reflection at once suggests itself—what has it achieved? A very large number of gentlemen of various nations have met together, and have devoted a vast amount of energy and attention to an almost equally vast range of subjects. To attempt to gauge with any approach to accuracy the absolute gain that has accrued to the common fund of medical knowledge would be altogether premature with only a brief *résumé* of the proceedings before us. Of the general addresses, however, which have already been presented to the reading public, there can be no doubt that M. Pasteur's communication on hydrophobia will attract the greater share of attention, as, indeed, it did when delivered before an overflowing audience in Copenhagen. A general consensus of opinion, whether of his own or other nationalities, seemed to hail M. Pasteur as the hero of the Congress. Not only in the outward evidences of respect with which he was everywhere greeted, but also in the close attention to his observations in debate was this feeling manifested. The same might be said with respect to the position of Professor Virchow, in whose case, however, it was not by any means difficult to trace a tinge of political feeling on the part of many whose admiration for the man of science evidently struggled for supremacy over certain other sentiments with respect to the politician. The absence of Professor Koch was in a measure to be regretted, more especially as some of the sectional meetings were largely occupied with the subject of tubercle, and the opportunity was not lost for a discussion upon the practical value of the discovery with which his name is universally associated. It cannot be denied that the general tone of the speakers on the subject was somewhat depreciatory. The feeling that the diagnosis and prognosis of pulmonary phthisis remains in much the same position as during the last twenty years, was clearly expressed by many speakers, and only combated by a few.

The proposal brought forward by Sir William Gull in his address at Copenhagen (which appeared in our columns a fortnight ago), to found an International Collective Committee, met with no opposition, and we are able to announce that the following have been selected to be members of that Committee. Denmark will be represented by Trier and C. Lange; Scandinavia by Ed. Bull, of Christiania; Russia by Rauchfuss, of St. Petersburg; whilst Despine of Geneva is to do battle for Switzerland, and Bouchard, of Paris, and Lepine, of Lyon, are the champions of France. Austria sends Schnitzler, of Vienna, Pribram, of Prage, and Korányi, of Buda-Pesth; and Germany, Ewald and Bernhardt, of Berlin. We are represented by Gull, Humphry, and Mahomed, whilst Fayrer is sponsor for India. For the United States Jacobi, of New York, and Davies, of Philadelphia, have been chosen; whilst the interests of South America are concentrated in Gutierrez Ponce, of Paris. Dr. Isambard Owen is the Secretary-General. A goodly list of names indeed, and if success could be obtained merely from the names of those connected with it, this movement might be written down as already successful in the highest degree. The Committee lost no time in getting to work; they immediately opened a bureau where the secretary sat every day from one to three to give such information as was in his power to those seeking it. A memorandum on the objects of the Committee is to be prepared by the Secretary, for publication in the European and American journals, and as a preliminary step, a sub-committee has been formed consisting of Professor Humphry, Dr. Mahomed, and Dr. Isambard Owen, who are not the men to let the grass grow under their feet.

So far as Toulon is concerned, the cholera seems to be nearly a thing of the past, the number of deaths per diem having been steadily decreasing for some time, and the same may be said of Marseilles, though it is not true to the same degree, but there is good reason to believe and hope that the disease has nearly worn itself out in both of these towns. At Arles too the latest reports do not seem to indicate that the disease is gaining ground. Perpignan, however, adds a notable contingent to the death-roll every day, and at Sisteron and Nimes the epidemic is reported to be on the increase. In Corsica also it seems to have got a pretty firm hold, though the authorities do not display much alacrity in affording facilities to those desirous of ascertaining the exact state of affairs there. But it is in Italy that the cholera is at present expending itself mainly, at least six provinces being infected.

Scattered groups of cholera cases in Italian towns and villages on the French frontier and throughout the north-western districts, each at present small and localised, but forming so many nuclei or centres, ready to coalesce into a widespread epidemic, and now a sudden outburst in the seaport town of Spezzia, 70 cases and 30 deaths in a single day, following immediately on a heavy rainfall, are precisely the consequences we should have expected from our knowledge of our neighbours' habits and practices in matters relating to the public health. We have all along maintained, contrary to the opinions expressed by some men of great experience, that cholera does not depend for its origin or spread on any meteorological conditions or influences beyond human control; that it is even more than doubtful whether it can originate in Europe, and that its importation may be always assumed. But the seed must be sown on good ground, not on the wayside or rock, if it is to yield its harvest of death, and this the nations of Southern Europe seem incapable of realising.

Granting, for argument's sake, that no amount of fæcal pollution of soil and water, combined with such high temperatures as have been experienced of late, can originate true cholera, whatever other diarrhœal diseases they may give rise to; they might enjoy immunity amid their filth if they would and could shut themselves out from all communication with other countries. But this is manifestly out of the question. Passengers by steamboat and railway may be arrested and confined, but who is to watch every country lane, and to board every fishing smack or coasting craft? And the very persons whose immigration is most to be feared, the poor and panic-stricken fugitives from cholera-smitten towns are just those who will find a way to evade such precautions. Sanitary cordons on land are a delusion and a snare, and quarantine in narrow seas is little better. The poison will be *smuggled* in; no word so well expresses the mode of its introduction and the practical impossibility of excluding it. But if, with the example of England and the teaching of the highest authorities in Germany before them, our Latin friends would take to heart the lessons of the past, the mortality from the present epidemic might lead to an incalculable saving of life from many other causes in the future. The only way to protect themselves from the inroads of cholera, and to reduce for ever the high death-rate from typhoid, diphtheria, diarrhœa, &c., which now disgraces so many of the fairest cities of the South is to be found in the rational disposal of excreta, and the provision of pure water supplies.

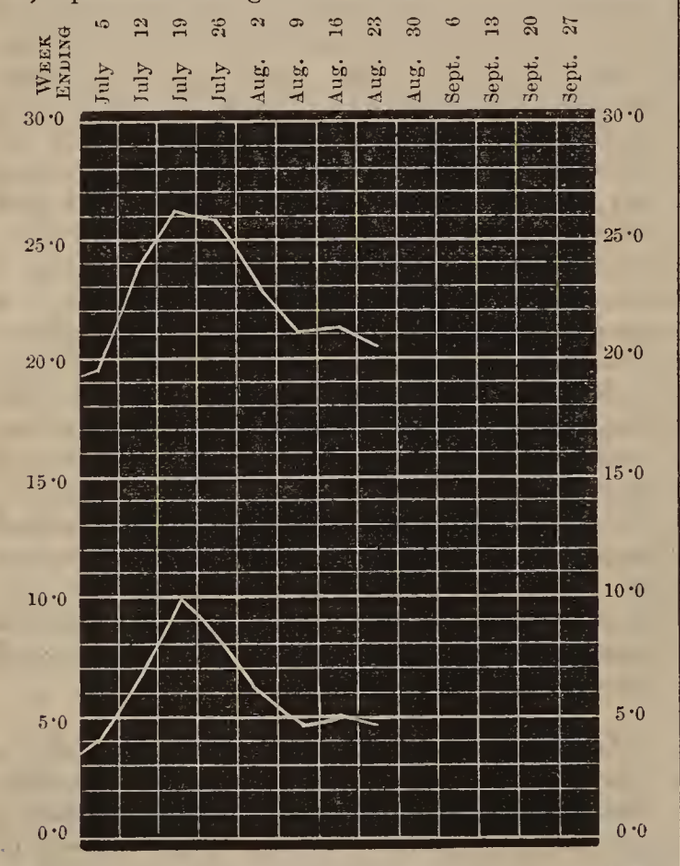
The occurrence of the outburst of cholera at Spezzia immediately after a heavy rainfall is most significant, and admits of but one explanation. In a well sewered town, deriving its supply of drinking water from sources beyond reach of contamination, such an event would have had precisely the opposite result. But where the infected excreta are habitually thrown on the open ground and trickle along the street gutters, or from pervious cesspools soak into the surrounding soil, the effect of a heavy rain is to cleanse the streets by carrying the filth into the nearest water course, on which the inhabitants probably depend for their supply of water for all purposes, and to raise the level of the wells to that of the excrement-sodden surface soil. The real and only defence against cholera will be found in measures for the speedy and complete removal of excreta from the proximity of the houses, either by well made sewers or some form of pail system, and the supply of water from irreproachable sources, which should not be difficult in a country traversed by mountain ranges; but neither exist, even in the capital itself, and we do not suppose that Spezzia is an exception to the rule.

The possibility of an invasion by cholera continues to occupy a leading place in the public mind, and the correspondents of the daily papers are evidently impressed with the necessity of being the first to announce the fact whenever a case does occur. As regards the stowaway who died in a union in the county of Waterford last week, it is understood that Dr. Brodie has reported to the Local Government Board that he could find no evidence that the disease was of an infectious or epidemic nature. There was nothing antecedently impossible in the history of the case, so far as we have been able to ascertain it, as regards the theory of Asiatic cholera, but on the other hand, it is not such a very unusual thing for a man, after exposure to a good deal of privation of all sorts, to succumb rather rapidly to an attack of diarrhœa. In any case, however, it cannot be denied that a case of cholera might find its way into the country, notwithstanding all the vigilance of our Port Officers of Health, and the recent report of the Local Government Board to Sir Charles Dilke should therefore be made known as widely as possible. It contains nothing new, but it once more emphasises the fact that "cholera derives all its epidemic destructiveness from filth, and especially from excremental uncleanliness," and urges the necessity for the prompt removal of all excremental products, and the most scrupulous care that the water supply shall be free from all pollution, and especially from excremental contamination.

Miss Emily Faithfull writes to us that she is about to open an institute for first class private nurses, through which, by abolishing all vexatious restrictions and excessive payments, they may reap the benefit of their own toil and be enabled to save a portion of their earnings for the time of need. Such a movement deserves, and we have no doubt will obtain, the hearty support of the profession. It must have occurred to everyone who has had much experience in the matter that the system of farming out private nurses, which is practically what the homes do, may, unless worked with exceptional liberality and sagacity, prove most unjust to the nurses themselves, and not most advantageous to the patient or the doctor. We believe that of late years the number of nurses engaged in private work on their own account has greatly increased, and we have always felt that they deserved every encouragement; and if Miss Faithfull's scheme should have the effect of inducing others to refrain from selling themselves to some institution, it will have done a good work.

The value of a good private nurse is every year becoming better appreciated by the public, and the proposal now made, by giving the nurse a more direct interest in her work, cannot fail to raise the standard even higher than it is at present.

Although there has been a further decline in the death-rate of London during the past week to 20·5 per 1,000, yet it has not sufficed to counterbalance the terrible mortality of the latter half of July, and the average death-rate for the first eight weeks of this quarter has reached the high figure of 22·7 per 1,000, being 2·5 per 1,000 higher than for the corresponding period last year, and no less than 4·0 per 1,000 higher than that of the year before. The zymotic death-rate has also exhibited a further decrease, but it has not yet got back to the level it steadily maintained during the first weeks of the present quarter. Whooping cough ranks highest of the zymotic diseases with 36 deaths, followed by scarlet fever with 32, and measles 28, diphtheria closing the list with 19. When we re-



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the first eight weeks of the current quarter.

member the number of deaths due to the sequelæ of these diseases, especially the two last, we cannot but feel that 105 deaths, high as the number seems, and is, do not by any means represent the whole mortality due to this cause. Of the 28 large towns, Preston claims the highest general death-rate, 39·3, whilst Norwich heads the list in the zymotic category, with an average of 19·6 per 1,000.

In the course of last year outbreaks of diphtheria and enteric fever at the borough of Calne, in Wiltshire, rendered a visit from a representative of the Local Government Board eminently desirable, and Dr. Blaxall was deputed to report on the sanitary condition of the town. In his report, which has recently been placed in our hands, Dr. Blaxall commences by pointing out the changes which have taken place since his visit in 1874, and shows that many of the existing evils are still present to which he then called attention, which would have been entirely obviated had all the recommendations which he then made been carried into effect. The outbreak of diphtheria commenced in May, 1883, and terminated in December, 84 persons having suffered in all, of whom ten died. The outbreak was clearly traced to two sources of personal infection, and in each instance the schools proved a most fertile soil for the propagation of the disease. Had the proper accommodation existed, it is tolerably evident that the disease might have been stamped out at once by the isolation at an infectious hospital of a servant girl who introduced it. There was not much evidence that insanitary conditions played any important part in connection with the diphtheria. As regards the outbreak of typhoid fever, however, it was quite otherwise. This was confined to a row of ten houses, of which one at one end and three at the other alone supplied any cases, the intervening houses all escaping. Out of fifteen persons occupying these houses, seven were attacked and one died. The row was in close proximity to a sewer which received the drainage from two slaughter houses, which Dr. Blaxall ascertained by personal examination to be exceedingly offensive, partly by reason of the animal matter in the shape of blood allowed to run into the drain, and partly owing to the use of hot water to clean out the slaughter-house, this naturally encouraging the decomposition of any animal matters. In addition, there was a ventilating hole from the sewer close to one of the houses, which had long been a nuisance and the source of constant complaint. Two of the houses had drains in direct communication with the sewer, the sewer air escaping into the dwellings, so that, after the occurrence of the first case, the cases in these two houses might clearly have been due to direct contamination with the specific poison. The chief faults Dr. Blaxall found were, that the construction of the sewers was defective, that they were insufficiently ventilated, and that a large quantity of offensive matter was allowed to pass into the sewer from the slaughter-houses instead of being burned.

Some months since a committee was appointed by the Suffolk District Medical Society to investigate the whole question of the milk supply of Boston, U.S. The committee is still prosecuting its useful work, and has recently presented a preliminary report, which deals mainly with the sources of supply and the manner in which the milk is collected, conveyed, and distributed. The report closes with a suggestion for the establishment of "milk stations" in accessible and well-known localities in the city, possibly in connection with the district dispensaries or with certain drug stores, to which the poorer people, and particularly the sick, might be referred by physicians and others. Provided with the necessary ticket or voucher, such persons would thus be able to obtain a supply of pure milk at a cost within their means. As a method of bringing pure and wholesome milk within the reach of the

inhabitants of the poorer parts of the city, such a plan is worth trying, and, if attempted, the experiment deserves to succeed. It is not a pauperising measure, and the poor are very generally shrewd enough to know that it is to their own interest to purchase good and genuine articles rather than "cheap" of fictitious value. It is by the fault of their circumstances, and to the shame of the small shopkeepers, rather than from an inherent love of false economy, that they are "compelled to buy, as is now too often the case, milk which has been diluted, sometimes to the extent of 60 per cent." In the same report we find corroboration of the views that, while the farmer and his milkers are answerable for much in the way of dirt and of carelessness in cooling the milk, it is the distributor—or his *proxime accessit*—who is responsible for the mixing, the staleness, and the watering. The contractor is sufficiently on the alert in detecting any sophistication of the milk sent to him from the farms, and appears to have devised an effectual method of dealing with such cases when they do occur. We are told that if a farmer waters the milk, it is immediately returned, and to every man who comes to the car, it is whispered very privately that Mr. X. has been caught, with a request "not to say anything about it." In a few days all the town knows it, "and if the man chances to be a Church member, his punishment seems to be adequate."

The fifth International Congress of Hygiene commenced its labours at the Hague, on Thursday week, in a business-like manner, and without much flourish of trumpets. Cholera would naturally at the present time claim a large share of the attention of such a gathering, and accordingly we find that the first section opened its proceedings with a discussion on this subject, introduced by Dr. Proust, who has, it will be remembered recently been investigating the outbreak at Toulon. Over-pressure in schools formed the subject of another debate, introduced by M. Huizinga, who denounced the modern system of education as conducive to the passing of examinations perhaps, but not as leading to the acquirement of real knowledge. On Tuesday last there was a debate on cremation, which aroused a very considerable amount of interest, and later on in the day the members of the Congress were entertained at a grand soiree given at the castle of Count Bylandt. The absence of Pasteur through ill-health has been the subject of general regret, as he was expected to have made a communication on preventable diseases. A committee of five has been appointed to consider the question of rags as an international danger; England will be represented on it by Professor Corfield. The Congress does not seem to have attracted that share of attention from the profession which the importance of the subjects with which it deals would fully entitle it to receive. This may be due to the fact of the Medical Congress having been held so recently, and at no great distance from it. Let us hope that this is the chief reason, for it is a perfectly intelligible one. He would indeed be more than an enthusiast who would, after a week's hard work at Copenhagen, care to rush off to the Hague for another, for after all the majority of men who go to these Congresses do work really very hard.

We are asked to state that the Winter Session at the Westminster Medical School will be opened on October 1st, at 3 p.m., with an introductory address by Dr. Hughes Bennett.

Last Monday the electors of the Belfast Royal Hospital met to appoint a surgeon to the institution in room of Dr. M. Moore, whose term of office had expired. There was considerable interest shown in the election as upwards of 100 life governors voted upon the occasion. Dr. Wheeler, who was already upon the hospital staff as an assistant-surgeon, was elected by 83 votes against Dr. Sinclair, who only polled 25. Dr. M. Moore's name was placed upon the list of Consulting Surgeons of the charity. The vacancy caused by Dr. Wheeler's election to the staff-surgeonship will be filled next month. There will probably be no opposition to Dr. Barron, who presents himself for the post. The term of office of Dr. J. W. T. Smith, who is senior physician to the hospital, had also expired, but as he was willing to accept office for a further term, he was unanimously re-elected.

Our contemporary, *Le Progrès Médical*, has once more found it necessary to call attention, in no unmeasured terms, to the spread of infectious diseases in the children's hospitals in Paris. For years it has not ceased to point out, in common with the other medical journals, though perhaps with more persistence, the great loss of life due to this cause, and these remonstrances have been so far successful that for the last few years diphtheria cases have not been treated in the general wards. But there its success ends up to the present, and its leading article of last week is written with a view to getting the rule enforced with regard to diphtheria put into practice in regard to measles, whooping cough, and scarlatina. Our own experience would have taught us to treat all these as more infectious than diphtheria, but this may partly be due perhaps to the fact that diphtheria is never so rife with us as it is in Paris. That there is urgent need for reform in the matter complained of is shown by the fact that in one year 52 children contracted measles and 30 died from it in the practice of one physician alone at one of the hospitals, and the writer of the article we are alluding to shows that assuming the other physicians to have a similar experience, and there is no reason to suppose that they had not, this would give an annual mortality, from measles alone, of 250 children admitted into the hospital for some other ailment; and making allowance for the deaths from scarlatina and whooping cough under similar circumstances, the total number of deaths caused in this way may be set down as 500 a year.

Such a state of affairs is simply scandalous, and has only to be made known to be condemned on all sides. All who undertake the charge of the sick, laymen as well as medical men, have one prime duty towards them, and that is to be quite sure that they do not do them any harm. Now to take a child into a hospital and to

put him into a bed alongside a case of measles, or to bring a case of measles into a hospital and put it into a bed adjoining that of a child in for some other ailment, is an act which under some circumstances might with perfect truth be said to differ only in degree from the putting of poison within reach of a child, and disclaiming afterwards any criminal intention. If hospital authorities wilfully expose a child to the contagion of measles, or other infectious disease, and if the child die from the disease so contracted, we must confess ourselves unable to distinguish between the crime of manslaughter and conduct of this kind. In London the general wards of our children's hospitals are closed most resolutely against any form of infectious disorder, and when such a case does by accident find its way in, and such occurrences will take place notwithstanding every precaution, the child is sent out without a moment's delay, either to a separate ward, or very often to a fever hospital. We doubt whether any of the physicians or surgeons attached to our children's hospitals would consent to serve in their present posts if the rules observed in the Paris hospitals were in force here.

Dr. Daunt, writing from Campenos, S. Paulo, Brazil, sends us some facts of interest to naturalists. The Municipal Chamber of the city of Porto Alegre, capital of the southernmost Brazilian Province of S. Pedro do Rio Grande do Sul, has ordered the uprooting and destruction of all the trees of the genus *Eucalyptus* planted and existing in the district, in virtue of the allegation that the *Eucalyptus globulus* and other species favour the production of the *Jequitirana Boia*, whose sting is irreparably mortal in a few minutes. This insect is a sort of large dragon fly, whose chief habitat has hitherto been the interior province of Goyaz. It seems to be the analogue of the Tsetsé fly of Africa. It attacks all living creatures. The Eucalyptus genus is therefore becoming "a suspect" in Brazil. The *Jornal do Commercio*, of Rio de Janeiro, of July 2nd, contains a notice of a curious parasitism which consists in the constant presence of a *crustaceum*, genus *Cymothea*, in the mouth of a fish, *Xiphoramphus hepsetus* (Cuvier), in the river Paranahyba, on the boundaries of the Provinces of Minas-Geraes and Goyaz. The description is very interesting, and proves the high degree of culture of the natural sciences in Brazil. It is a curious fact that in other rivers where this fish is found, the crustaceous parasite is absent, while in the river above named it is invariably present. The 55th Anniversary Session of the Imperial Academy of Medicine has recently been held; the Emperor and his son-in-law, the Count d'Eu, were present.

We were somewhat surprised at perusing in a journal of such well deserved reputation as the *Philadelphia Medical Times*, the editorial reply made to the question "Is embryotomy (craniotomy?) justifiable while the child is living?" This question was put in deprecation of an approval which had been expressed by Dr. Busey, the President of the Washington Obstetrical Society, of the position laid down by Dr. Barnes that "when the hard alternative is set before us, our first and paramount duty is to preserve the mother, even if it involve the sacrifice of the child." If ever a subject has been maturely and anxiously considered, this one has; and we were under the belief that Dr. Barnes was only stating a conclusion that has received such general assent as to have become axiomatic. Not so, it seems; for the editor of a journal, supposed to represent the most advanced thought of our day, declares that "it would be more correct to say that the destruction of a living child in order to save the mother has never been allowed by the best men in our profession from the earliest times until now, except by Arabian and German and English midwives." We do not understand whether the writer wishes it to be understood that America is free from the perpetration of so great a crime, but if so, he is rather inconsistent in adding that the pernicious doctrine "taught by Dr. Barnes has much to do with the fearfully prevalent crime of fœticide"—which as we all know predominates in some parts of the United States, not only among the destitute and ignorant, as elsewhere, but also among the wealthy and the indolent.

In conferring upon Dr. W. C. Hoffmeister the dignity of a knighthood, Her Majesty has shown her appreciation of a long and honourable career, many years of which, in part at least, have been spent more or less directly in her service.

THE NEW TEMPERANCE MOVEMENT.

The alternate and countervailing influence of action and of reaction is as much an ethical as a mechanical law. The pendulum of public opinion is always swinging in one direction or the other; although the mean of its excursions becomes less and less as knowledge grows wider and is more intelligently applied. In many respects the present is a period of reactions; that is to say, we may congratulate ourselves that in not a few instances our practice in carrying out the details of modern life is tending to the norm rather than diverging from it. And it is significant that, at a time which resounds with the cry for something more than moderation in drink, there is arising a demand for something like moderation in our methods of education. The parallel which might be traced between what may be called educationalism and alcoholism, does not, fortunately, run very far, but its extent is sufficient to be suggestive. Of alcohol as of the modern scheme of education, it may be said that each has been regarded by its partisans as the *elixir vitæ*; that both are capable of abuse and of adulteration; and that neither can be employed to advantage without the careful exercise of a discriminating judgment, and of continuous watchfulness. Alcohol is not necessary to those in robust health; over-indulgence, and especially precocious indulgence in it, induces a train of mischief from which the whole organism, and the nervous system in particular, inevitably suffers. On the other hand, while education is the natural—we should rather say, the necessary—complement of the physically healthy human being, its methods, if too zealously or carelessly applied, may blunt or overstrain the dawning powers of the young scholar, whose mental development needs often to be guided and guarded rather than to be driven and stimulated. It is not difficult to admit, on theoretical considerations, that each of two

such apparently dissimilar things as alcohol and education may have its use, and that each is liable to abuse; or that the heedless employment or application of either is likely to be followed by results which are sure to lead in time to a demand for moderation and reform. With respect to alcohol we have, unfortunately, only too good reasons for acknowledging the existence of excess, and for setting forth the virtues of moderation. In regard to the educational systems of the day, we stand on newer ground; the data at our command are derived from a shorter period and are, from the very nature of the enquiry, necessarily imperfect, but they are sufficient to enable us to form some definite conclusions which are not inconsistent with the teachings of physiology or opposed to the general consensus of experience. In this matter we believe that the opinions which have been expressed by those members of the profession who have paid special attention to the subject, have been, to a considerable extent, misunderstood, while their opponents do not always appear to understand themselves. Medical men do not undervalue education, but they regard schooling as only a part of it. Real education is to acquire the art of knowing, not merely to know. It implies all the difference between the poet and the parrot, between a Babbage and a calculating machine. It is the training of the powers of observation and of reasoning, with the coincident development of the physical agencies by which these powers are exercised. And its value is degraded, and its true relations woefully misunderstood if we regard the period for its acquisition as anything shorter than that of life itself. For the attainment of a result so vast and intricate, it follows that the foundations must be sound and thorough. But these foundations are laid in the training of young brains and bodies whose powers are just budding into activity, and at a time of life when the whole energy of the organism is often hardly taxed by the demands of mere existence and growth. Under these circumstances is there not need for care, is there no risk of harm, no unlikelihood of serious mischief being suffered and of the real value of the object in view being overlooked? Is it remarkable that those whose business implies familiarity with disease should be the first to detect a mischief which is greatly a question of degree, and should be the most earnest in warning against evils which others are unfortunately less able or less willing to appreciate? Surely it is unfair to blame the doctors for attempting to give advice in time—as though the signalman should show his danger lamp only when the collision has actually occurred; and it is, to say the least, unbusiness-like to treat such warnings and advice either in a purely partizan spirit or with a perfunctory heedlessness which would not be displayed in relation to any other business of life. The allegation of overpressure in connection with Board and Elementary schools has been established in comparatively few instances. Had it been otherwise, the conscience of the profession would have been less clear, for it would have been proof that there had been gross oversight or criminal silence respecting a great evil. Whether the charge has in all cases been investigated or dealt with fairly, is another question. Mr. Pridgin Teale's pungent criticism on the report of the Leeds' School Board Committee is within the recollection of our readers, and it is to the point. With reference to one of the smooth things lately prophesied in Parliament, Dr. Crichton Brown (who shares with Mr. Teale the honour of having his communication to the authorities relegated to a sort of *index expurgatorius*) states that it is quite true that the deaths from brain and nervous diseases amongst children have distinctly declined throughout the period during which the Education Act has been in operation; but he points out that a closer investigation of the statistics reveals a less satisfactory state of things; that the deaths from hydrocephalus (the disease to which the Registrar-General's returns mainly refer) of children under five years of age, have decreased very steadily in accordance with the spread of hygienic knowledge amongst the people, but that the deaths from the same cause amongst children at the school age (from five or seven to twelve) have undergone a very considerable and regular increase every year during the same period, and are continuing at the same progressive rate.

After a perusal of the Educational Blue Books for 1883–84, the existence of "overpressure" to some extent amongst the scholars in elementary schools must be admitted from the reports of the inspectors themselves; and we contend that whether this overpressure be due solely to the burden of an excessively exacting code; or to the mistaken zeal or, unwise methods, or reckless ambition of teachers; or to the struggle of a small school to make both ends meet by earning grants on the extra "class subjects;" or to the carelessness and ignorance of the managers, or, lastly, to the underfeeding and other physical disqualifications of the school children; wherever and whenever it exists, the medical observer is bound to notice it, and to protest against a system which allows it. The question of remedy is no doubt difficult enough, but his first business is to see that the evil does not go undetected.

It is not to be supposed that educational overstrain is confined to the scholars and pupil-teachers in elementary schools. Like every other organ of the body, the brain requires exercise, and is distinctly benefited by work proportioned to its capabilities. But give to the child who has such a brain—and a conscience—over much work of one sort to be done within a limited time, or work of different kinds under the same conditions, and you import into the problem the new and all-destructive factor *worry*. Worry of this kind appears on analysis to consist in the endeavour to do or to think of two or more things at once, so that one part of the brain is not at rest while another is working, and there is no chance of "turn-and-turn-about" in its labours. Hence, while worry is doubtless to some extent imported into the mental difficulties of the Board School children, it is much more common and more wearing amongst the more finely strung, the more conscientious and the more ambitious children of higher class schools. Mrs. Garrett Anderson has recently pointed out that in the middle-class schools—and especially those for girls—the temptations to and the existence of overpressure are considerable; and she rightly indicates that it is the mothers who should exercise the observation and supervision required for detecting, as they

possess the power of checking, the evil in its earlier stages. This aspect of the question loses none of its gravity when we reflect that the schoolgirls of one generation become the mothers of the next. The nervous organisation and the nervous failings of the mother tend largely to be transmitted to her offspring; and there are but too serious reasons for dreading lest the precocious stimulation and premature exhaustion of nervous energy which educational fashion is now apt to entail upon so many schoolgirls should be visited with more dire results upon their children.

The whole subject is one of national importance. It deals so directly with our position among the nations of the future that it cannot be dismissed lightly unconsidered. It comprises problems so difficult and involved that it cannot be settled offhand. And it is capable, if rightly dealt with, of yielding results so grand and gratifying as to be well worthy of the ungrudging expenditure of the time, the labour, and the money which are needed for its adequate solution. National feeling is being aroused, and the question is beginning to be asked whether, in carrying out what was confessedly a novel departure in State education, we have not been too exacting in our demands, too stringent in the application of generalisations. Let the evidence be collected and discussed fairly and dispassionately, as becomes the subject. Let us be grateful for warnings whose value must be proportionate to their timeliness, and still more grateful if the fears to which they have given rise should turn out less serious than had been supposed. If mistakes have been made, let us acknowledge them and see to their repair, bearing in mind that repentance is much less bitter as it is less costly than remorse.

In this matter, as in the great "drink question," the object of the profession has been to avoid extremes. We would not shut up the schools any more than we would advocate drunkenness; but we would not hold silence while a well-fed child was being overworked, or an ill-fed one worried into disease, any more than we should refuse to prescribe alcohol as a medicine for a patient whom we believed to need it; and both, as regards mental work for the child and the use of alcohol by the adult, we preach the golden mean of moderation. What moderation consists in is a question which can only be decided on the individual merits of each case; but to do so is not impossible. It involves the outlay of some trouble, and requires the habit of looking things honestly in the face; and, not being a fixed quantity, from time to time it will require a certain amount of re-adjustment. But most things in this world involve trouble in the doing of them; and no good work can be accomplished without it.

SEASONAL REGIMEN.

The standard work on the practical physiology of the seasons yet remains to be written. Popular opinion on the subject comprises a number of old saws, each of which—as is the case with most of its class—either contains a paradox within itself, or is flatly contradicted by another of its fellows; together with a variety of general impressions, as that fat may be freely eaten in cold weather, while its ingestion in summer (save in the form of cream and with strawberries) is provocative of biliousness, and that to change heavy clothing for light unless hot weather has been in force for some time is to incur the risk of chill; while the practical outcome of precept, action and example, is seen in the way in which people suffer during the rare real summers whose absence it is their custom annually to deplore. No doubt fashion is largely responsible for the torments of mankind in such matters, but ignorance, real or assumed, makes possible the subservience to fashion's rule. It can scarcely be doubted that a wider knowledge, and more honest efforts to appreciate the knowledge which we already superficially possess, would make the fashion of our daily lives throughout the year as much pleasanter as it would be more healthful and health-giving. The whole subject is as wide as it is interesting, and it is impossible to do more than hint at one or two of those mistakes which have been emphasized by the unusual weather through which we have been lately passing. Summer-tide means for us, primarily, a rise of external temperature, an increased supply of heat; and one resultant of the altered relations of the heat exchanges proceeding between our own bodies and surrounding media is a diminished heat loss, which means a lessened need for heat production in proportion. The three great factors concerned in maintaining the body at a constant temperature are tissue-metamorphosis, nervous adjustment, and radiation and conduction. In warm-blooded animals metabolism is lessened by increase of external temperature; *i.e.*, the great source of heat production becomes less active in proportion as the need for its activity diminishes. Less rapid tissue-change means less waste, and so less repair—in other words, less need for food, especially that of a readily oxidisable kind, and an appetite, therefore, less demanding: just as the same kettleful of water may be made to boil at Cayenne with a smaller expenditure of fuel than would be required at St. Petersburg. On these premisses only, a typically healthy warm-blooded animal should maintain its weight and perform its work as well in summer, though with a diminished food-supply, as in winter. There are, however, other factors which require attention, while the humanity of the present century is rarely of the typically healthy type. In addition to a higher temperature, summer brings sun-light, increased both in quality and in amount, and one of the special attributes of sun-light is its power of stimulating tissue-change in organic bodies; so that while our metabolism is lessened by mere heat, it is, on the other hand, increased by the influence of the sun's light rays; whence it follows—that, in order to ensure that amount of tissue-change requisite to the maintenance of health generally, and of the normal bodily temperature in particular, less violent exercise, or less of it, will suffice in bright sunny weather, and that exercise will be carried on in the shade with less fatigue than in direct sunlight; facts which are as important and as applicable to the healthy as to the sick and the convalescent. When we notice how a continuance of hot weather tells on young children, we must not forget that the little child in average health is always active, and that its muscular activity indeed is usually more marked in the summer

weather, which, in our climate, affords such special temptations to facilities for out-door exercise. Children of larger growth are apt to overdo their opportunities in the same direction. During the darker months a man will spend his evenings in an easy chair by his own fireside, in his library, or at his club; in summer-time, after an equally hard day's work, he occupies the lengthened hours of daylight with more or less violent exercise on the tennis lawn, or the river, or he toils like a labourer in his garden, "getting three days' work out of one," and not rarely succeeds in attaining something of that result which inevitably attends the operation of burning the candle at both ends. Many go far towards neutralising the benefits of their holiday by an excess of muscular exertion to which the changed surroundings and the sense of freedom tempt them, but for which the previous months of sedentary life have not afforded an appropriate training. Direct and prolonged exposure to excessive sunheat has, of course, special dangers of its own; and just as the effects of insolation are shown chiefly by disturbance of nerve-function, so it is those in whom the activity of the nervous centres has been most developed, as in highly educated adults, and those in whom it is most susceptible, as in children, that its effects are more readily produced, and are most disastrous, other conditions of bodily health and vigour being equal.

Summer feeding is a question of importance; but the hints which Nature thrusts upon us from all sides for our guidance, are too commonly disregarded; although, when they have been followed, mankind has arrived empirically at the same practice, which theory can do no more than reiterate and justify. We may take it that, except in those cases of special muscular exertion, the proteid elements of our food may be considerably lessened with advantage. At the same time a larger amount of water must be ingested to compensate for the increased exhalation from the cutaneous surface, and to furnish by its evaporation an efficient agent in maintaining the temperature of the body at its proper level; while we must not forget that this free flushing of all the organs of the body itself favours metabolic changes, and so will somewhat augment the demand for more substantial nourishment. Further, since a certain volume of both ingesta and excreta is necessary to the due performance of their functions by the stomach and intestines, it is desirable to substitute for that part of the nitrogenous dietary which has been omitted something which, while not being necessarily assimilable, shall provide the requisite bulk, and which may also usefully serve as a vehicle for introducing water into the economy. Such conditions are secured by the fruit and vegetables with which summer provides us generously and *àpropos*. Vegetable tissue is rich in water and contains an appreciable quantity of inorganic salts, while its cellulose, though not assimilated by us, affords bulk to the intestinal contents without stimulating to an unduly rapid peristalsis. Without adopting the creed of the vegetarians in its entirety, omnivorous man may with undoubted advantage assimilate his dietary to theirs, to an extent somewhat greater than is usually practised. Healthy living is under all circumstances and for all people very largely a matter of habit and custom; but no one who has experienced the case and comfort with which, week after week, a good day's work may be accomplished under a tropical sun when the mid-day meal consists of nothing more substantial than a slice of bread and half-a-dozen bunches of grapes, will deny the advantages which accrue from a liberal infusion of the vegetable element into a hot weather dietary. In England we can never enjoy the flavour of an orange, ripened to perfection on the tree, and shaken, with the dew upon it, from the bough during the stroll before breakfast; but during the summer months we can add to that meal, with economy both of health and purse, some at least of the garden fruits whose best uses we are apt to overlook, as well as the small saladings which make an intermittent appearance at the table. At luncheon again, fruit—always sound and not over-ripe, of course—and salad will advantageously form the staple of the ménu; and the habit of eating fruits with cream or milk enables us to introduce into the system a good supply of light and easily assimilated nourishment with more ease and pleasure than attends the ingestion of some of the grosser forms of food. Dinner is, for most of us, best taken when the brunt of the day's work is over, and should be the most substantial meal. But at dinner fruit is almost invariably offered at the wrong time. The dessert which appears on the table from the beginning, "to lure the appetite from course to course," might well take the place of the soup with which the meal commences. Certainly the most unphysiological and undesirable time for attempting the digestion of raw fruit is at the end of a substantial meal; and it is not the digestive powers only which would benefit by a reversal of our customs in this respect. Fashion and tradition, however, are forces not to be modified at once; and perhaps it will not be until the unremunerative character of some of our older branches of agriculture has driven the English farmer to adopt fruit growing on a large scale, that we shall allow ourselves to appreciate the advantages of that dietetic programme which, year after year, Nature patiently unfolds before our eyes. Come when it may, we need not fear that our countrymen of that age will suffer in mind or in body by the change—in temper or in temperance—though the status of their national roast beef be somewhat jeopardised thereby. They were wise and genial human sprites whom the witty scholar, Thomas Randolph, made to find their recreation *inter poma, lac, et vinum*.

ARMY MEDICAL DEPARTMENT REPORT FOR 1882.

[First Article.]

Possibly not many of our readers would care to make a study of this report, for it is now two years old, and events follow each other so rapidly, that even the story of Lord Wolseley's Campaign has lost much of its interest for medical men. The unavoidable shortcomings of the Army Medical Department in the Egyptian War have been studiously forgotten and condoned; and possible improvements in organisation have been carefully avoided, in the interests of economy.

But it is worth while to examine the successive

reports as they appear, for we always gather from them a notion of the difficulties with which Army doctors have to contend; and we learn to comprehend the enormous strain to which the Department is subjected when it is suddenly called upon, with its peace establishment, to meet the emergencies of war, to say nothing of its multiplied duties when epidemics upset the balance of disease in tropical climates.

We have also to recognise the difficulties of medical men, called upon to arrest preventable diseases *which cannot be prevented*, and preventable diseases which public opinion will not suffer to be controlled. In the report for 1882 we find the very nature of the Egyptian Campaign preventing sanitation from preceding the advance of troops; and in the prevalence of syphilis at various stations, we notice the indifference or the dislike of the public to measures of prevention. But in addition to the work thrown upon the Medical Department by undue economy, weak legislation, and the operations of war, we are told, in the present report, to look for a fresh source of disease and inefficiency in the composition of the Army itself. We are reminded that ours is a short service Army, and that our boy soldiers are victims to enteric fever to an extent formerly unknown. Acute observers are of opinion that "there are grounds for supposing that changes in the constitution and organisation of modern armies have greatly tended to increase the prevalence of enteric fever. Armies are composed of younger and less acclimatised men than they were. Under the short service system a large body of men of the ages most liable in all countries to enteric fever, are being subjected also to another predisposing cause of this fever, in that they have periodically to undergo those constitutional or physiological changes, commonly called 'Acclimatisation,' or the vicissitudes of field service in tropical or sub-tropical climates." We may remark that "enteric fever" pervades the whole report for 1882. Other topics of interest crop up, but only to be replaced by remarks on this destructive disease. Indeed "the Authorities" seem to have become impressed with a vague sense of coming danger, or else it is by a happy accident that the report has ceased to be "a Blue-book," and now flaunts the emblem of sickness in its yellow coloured binding. We shall have to notice enteric fever, as it is recorded in the various returns from home and abroad; but we must take things in due order and first give a glance at the statistical report for the whole Army.

We find that in 1882 the Army at home and abroad numbered 174,557 warrant officers, non-commissioned officers and men, and that the admissions into hospital of this force were 190,880, and the deaths, 2,145. The death-rate, calculated per 1,000 of the average strength was 12·06. It ranged from 6·94 in the United Kingdom to 88·90 in Egypt; while in India it was as low as 12·82 per 1,000.

War and epidemics derange statistics dreadfully, and although we note that on the average of 1872 to 1881 the death-rate for India was 19·22 per 1,000, we should not jump to the conclusion that sanitation had made gigantic strides in India during 1882. There is little difference indeed in the total death-rate of the whole Army during the last ten years. We have said it was 12·06 per 1,000 in 1882, and it was 12·66 on the average of 1872 to 1881.

If we look at the influence of age on mortality, we come to the conclusion that the soldier's life has many risks. The deaths among soldiers under 20, averaged 3·86 per 1,000, while in the healthy districts, the civil male population of the same age gave a death-rate of 5·83. So the soldier *begins* the race of life with every chance in his favour, but he rapidly deteriorates; and between the ages of 30 and 35 soldiers at home die at the rate of 9·59 per 1,000, while at the same age civilians in healthy districts give a death-rate of only 8·36. We observe that no less than 3,389 men were discharged as invalids in 1882. It is no direct business of ours perhaps, but it is impossible not to wonder at the future of these invalids. They have no pensions, they are presumably unfit to resume the occupations which they left when they entered the Army, and private charity and benevolence can hardly support for many years such a constant supply of cripples. It seems rational to suppose that any Reserve Army which may be formed in the next ten years, may be equalled in numbers by a disorganised corps of broken down men, who cannot work; and although we trust that the teaching bestowed upon them in the service may be sufficient to make them resigned to misfortune, and obedient to authority, yet we cannot help suspecting that society is nourishing a dangerous crew, unless indeed, the invalids are so utterly crushed by disease, as to form only a harmless body of helpless, hopeless paupers. We pass on now to the statistics for the year's recruiting. The number of recruits inspected during the year was 45,423, of which 19,294 were rejected as unfit. Out of every 1,000 inspected, 595 were labourers, and of 27,020 labourers, no less than 11,416 were unfit for soldiers. We notice that the causes of rejection number 41. It may be that the list of causes could be reduced without danger, but the proportion of men objected to for defective vision, disease of the heart, want of height or chest measurement, does not lead us to imagine that visions of glory have been the temptations which induced numbers of young men to attempt to be converted into soldiers. Every now and again there is an outcry of want of soldiers, and we never know whether to be patriotically glad or sad when we are told that the ranks are getting speedily filled up. Martial enthusiasm seems to increase so rapidly in company with national distress, and the stagnation of agriculture and trade. The tables for the age, height and weight of recruits for 1882 are not complete, but we do not attach much importance to these returns as affording causes for rejection. We have learned that the War Office can play fast and loose with age, height and weight when *numbers* are required to swell the lists of an Army on paper. Secretaries for War who can direct their medical officers to be *more strict* when too many recruits offer, can equally well assume the power to order them to be *less strict* when the recruits are too few. Such returns do not teach us much. They inform us of the number of boys and men passed into the service in a given year; but they do not tell us, that in the opinion of the medical officers who inspected these boys and men, they were likely to make efficient soldiers. The last statis-

tical return we need notice is that for vaccination. It gives the rates of attacks of small-pox to strength during the year. These were among men ·35 per 1,000, among women 1·05, and among children ·45 per 1,000. The high proportion among women is fairly attributed to the want of power to enforce re-vaccination in the married quarters.

THE INTERNATIONAL MEDICAL CONGRESS.

MEETINGS OF THE SECTIONS.

IX. Section of Dermatology and Syphilis.

The Ætiology of Lupus.

On Monday, August 11th, Professor Doutrelepont, of Bonn, opened the discussion on this subject, by reading a paper in which he stated his belief that lupus is really a tuberculosis of the skin. Not only are the histological characters of the lupus nodules and the miliary tubercle very similar, but the specific bacillus of tuberculosis is found in both. The clinical course of the two diseases also presents, as he thought, some very marked points of resemblance, the slow course, for example, of some forms of phthisis, accompanied with many relapses. But the most important and most direct proof has been found in the inoculation of small pieces of lupus tissue into the cornea of rabbits, and the growth of distinct tubercle at the point of inoculation.

Dr. Leloir, of Paris, also read a paper dealing with the same points, and quoted a case of undoubted lupus of the bones, in which the disease resembled tuberculosis. He, too had inoculated animals with lupus and thereby produced tuberculosis.

Professor Kaposi, of Vienna, said that before the time of bacteria it used to be remarked how unusually free from tuberculosis lupus patients were. (He had seen 1,200 cases of lupus in 20 years, and never seen any connection between the two diseases, although some patients had been covered with the lupus for many years.) Now, however, lupus, which was a perfectly clear and distinct clinical entity, had been confused with tuberculosis. Real tuberculosis of the skin, of which he had seen 15 cases, was an entirely different disease, in which the actual miliary tubercles were seen plainly in the most superficial layers of the skin, and which was always rapidly fatal.

Professor Pick, of Prague, had long since been led to suspect a close relationship between lupus and tuberculosis, but could not establish a satisfactory clinical identity. The discovery of giant cells at first promised to establish their connection, but the theory of their specificity was afterwards disproved. The discovery of the bacillus tuberculosis had had a more satisfactory result. Morrison had found that the bacillus was always present in abundance in certain stages of the disease, and that this was the case even where no tuberculous condition of other organs was present. Observers are, however, divided as to whether the bacillus is causal. Professor Pick considers that it is, and thinks that tuberculosis of the skin may exist as lupus vulgaris, as tuberculosis cutis of Kaposi, or in possibly many not yet discovered forms which may differ exceedingly, just as syphilides and gummata differ exceedingly, and which it may take a long time to distinguish and classify, as was the case with lupus, and the serpiginous eruptions of syphilis. Although tuberculosis cutis is not lupus, lupus might still be and probably is a tuberculosis.

Professor Neisser, of Breslau, vigorously opposed Kaposi, the value of whose statistics he disputed, since the cases had not been examined with a view to settling this question. There was a slow and a galloping syphilis, and there might be similar conditions in tuberculosis of the skin. He considered that the slow course and frequent recurrences in lupus were very like the course and relapses of tuberculosis, and this latter too, like lupus, might last for years. Kaposi seemed to simply disbelieve in the bacillus tuberculosis, but with the present weight of scientific evidence on its side, Kaposi certainly would have to undertake the proof that lupus was *not* a tuberculosis in order to support his position.

Dr. Unna, of Hamburg, agreed with Doutrelepont, and thinks with Pick that there are a series of bacillar diseases of the skin, all containing the bacillus tuberculosis. He knows of four such affections at the present time, viz., lupus vulgaris, tuberculosis cutis Kaposi, lupus papillaris Aubert, and scrofulous eczema, followed by caseous glands. He finds the bacilli are obtainable in quantity by partially digesting hardened specimens and examining the precipitate of what has fallen.

Professor Edward Lang, of Innsbruck, said that the murderous disease described by Kaposi, did not correspond to ordinary mild often curable cases of tuberculosis. There was probably some form of skin tuberculosis which did so correspond, just as there were cases of carcinoma which were rapidly fatal, and cases which dragged on for decades.

The Specific Sensibility of the Skin.

Dr. Goldscheider gave an interesting address on the specific sensibility of the skin. He strongly supported Helmholtz's theory that every nerve, however excited, gave rise to only one specific perception in the cerebral ganglion cell with which it was connected. His investigations had shown him that there were only certain points which were capable of feeling heat, while a completely different and complementary set perceived only cold. It was immaterial how these points were excited, whether mechanically, or by temperature change, or electrically, the effect was the same. This fact of course refuted the old theory of perception of heat and cold by simple increase or decrease of the amount of heat in the nerve. These temperature nerves, when excited, give rise to no pain, nor do they possess any sensibility. Only certain "pressure points" possess acute specific sensibility, and outside these there exists a diffuse indefinite perception. The points at which pain is appreciated are also quite distinct and very sensitive to various irritations. These pressure and pain points are always complementary to the points at which heat and cold are perceived. The touch nerves, like them, are always arranged in areolæ, and hence the necessity of passing the finger over any bodies which we are feeling until an areola is met with capable of appreciating the shape and surface of the particular body. All these functions improve notably with education, as seen especially in the case of blind people. But there are many areas normally destitute of all appreciation of one or more of these different modes of sensibility.

The Ætiology and Pathology of Lepra.

On Tuesday, August 12th, Dr. Armauer Hansen, of Bergen, spoke at length on the ætiology and pathology of lepra. He exhibited patients to show the difference between the tubercular form and the macular. The former was almost always fatal in nine or ten years, the latter was often cured. The anæsthesia and atrophy which follow are effects of the healing process not of the leprosy, and necrosis of the affected parts is always secondary to injury. The paralyses too are local. There are never any traces of spinal lesions to be found clinically or microscopically. He insisted that lepra was not an hereditary but a specific contagious disease; the recurring crops of nodules showed its auto-inoculability; and since the growths tend to heal it must be specific. There is, moreover, no anatomical correlation between the parts affected, as in the metastasis of neoplasms. The cause of the disease had long been obscure. Years ago he had noticed peculiar brown cells which were always present in microscopic sections of lepra. In 1871 he described minute moving rods in the contents of a breaking down tubercle, and immediately after Koch's discovery he found the bacillus lepra by applying the same methods. He has never found them in anæsthetic patches, but Ahning has found them in anæsthetic nerves. The speaker and Professor Neisser have both cultivated them. Inoculations on rabbits and cats (Hansen), and on fish (Köbner and Hansen), had been unsuccessful, but Neisser had produced

a new growth by inoculating a dog. No animal has, however, been lepraized as yet. He does not believe in the heredity of a contagious disease; a disease may be congenital without being hereditary, for example small-pox. Heredity and the transmission of such a disease as syphilis, are entirely different matters; the latter may develop late, is incapable of atavism, &c. Relationship even, with leprous people, is by no means always present. The inhabitants of a valley become in time all more or less related, and the members of one family naturally come into closer contact with each other than with outsiders, hence the apparent frequency of the spread among relations. Isolation is necessary, for although the disease is spontaneously curable, we cannot cure it; but the effect of isolating the cases in Norway has been effective in reducing the number of lepers by nearly one half in 20 years.

Professor NEISSER agreed in Hansen's views as to contagiousness and heredity in lepra. The spores which Dr. Hansen had spoken of were probably vacuoles.

Abortive Treatment of Syphilis.

Professor PICK, of Prague, read a paper on excision of the primary sore in syphilis. He confined his remarks to *hard* chancres, and distinguished carefully between those cases in which the glands were indurated, and those in which they were not. Where the glands are affected they must also be excised; but in such cases, almost without exception, whether excision is practised or not, general symptoms make their appearance. The conditions under which the operation may be performed are only partially known. Simple excision of the chancre where the glands are affected will never give success, and no excision avails when the deep glands are swollen. Pick considers the effect is but slight, mostly only a delay in the appearance of the general symptoms. The operation has, however, served to show that the indurated sclerosis is not the expression of general syphilis. The lymphatics have been recently found to be much enlarged in these cases, and Pick believes that the syphilitic poison passes into the organism through these, and not, as Auspitz believes, entirely through the blood.

Dr. UNNA, of Hamburg, believed that syphilis extended not by any one path, but by the blood vessels and lymph vessels, as well as by simple contiguity of tissue.

Professor NEISSER, of Breslau, observed that although it was not yet certain by what path the syphilitic virus entered the system; still, since it was a bacterial virus, there was no theoretical reason why it should not be prevented from entering by a timely destruction of the bacteria.

Professor BERGH, of Copenhagen, gave accurate statistics extending over some years, and showing the comparative worthlessness of the operation as a protective measure.

Drs. LELOIR and BARTHÉLEMY, of Paris, quoted most favourable cases in which excision a few hours after the first appearance of the chancre failed to prevent infection, and the latter stated that French opinion was now decidedly opposed to the procedure.

Dr. MARTINEAU, of Paris, in opposition to the German speakers, regarded the chancre as a manifestation of general infection, and considered it therefore to be manifestly useless to excise it.

The Treatment of Syphilis by Mercurial Injections.

Professor LIEBREICH, of Berlin, found that certain conditions were requisite in any mercurial compound which was to be spontaneously injected, viz., it must not precipitate albumen, must be indifferent to the connective tissue of the skin, must not be decomposed by an alkaline solution, must be easily broken up, so that with sulphur, sulphide of mercury is precipitated. Sublimate forms insoluble compounds with albumen, and is only absorbed when these are broken up. Tannates and citrates of mercury also unite with albumen, and reach the blood in complicated combinations. A body which fulfils all these conditions is found in the formamide of mercury, which is easily prepared by precipitating the oxide by carbonate of ammonia, and dissolving it in formamide. Amides of a number of other fatty acids also work well. If injected in quantity they form sloughs in the bowels during elimination, as does the sublimate, showing that they can work efficiently, the mercury in the compound being simply masked by the amide. They cause neither pain nor irritation of the tissues, and the dose is somewhat less than that of sublimate. It is, above all, important that the course of injections must be several times repeated: it is impossible to be sure of curing by one course alone. In the midst of the injections the case sometimes ceases to improve; the original vigour, however, can be rapidly restored by giving a good diet, with plenty of chloride of sodium, the salt and chloride of ammonium both assisting powerfully as "help cures."

Dr. MARTINEAU, of Paris, had used injections exclusively in the treatment of syphilis for the last few years, and believed that it was the only reliable method assuring a cure and causing no stomatitis or other alimentary troubles. In no case was the disease itself cured, merely the manifestations; and in doing this, mercury injected subcutaneously occupied less than half the time required by the other methods.

There was a general consensus of opinion among the after speakers that the injection of mercurials was a valuable method of treating syphilis, but by no means the only one. No one method suited all cases.

Dr. NEISSER thought that the injections should be smaller and more frequent, and considered that the formamides were eliminated too quickly.

Dr. DOUTRELEPONT, of Bonn, said he did not believe formamide to be absolutely the best form for injection. All salts, when injected in a sufficient therapeutic dose, might cause stomatitis.

Dr. SHOEMAKER, of Philadelphia, after prolonged experiments on the various methods of injecting mercury, had come back to the simple solution of sublimate in water, as the most effectual and least irritating.

Dr. WULFF, of Strasburg, had made and injected the formamides five years ago. He always used them perfectly freshly made from triturated solutions; they then worked quickly and well.

Dr. UNNA advocated the use of keratinised mercurial pills, which dissolve in the alkaline juices of the small intestine, leaving the stomach untouched; in this way the irritation caused by injection may be avoided.

Dr. BARTHÉLEMY, of Paris, always used the peptones for injection, and found that they acted quickly, but believed that pills were by far the best and simplest method for a continued treatment.

Professor KAPOSI found injections useful, but considered that inunction was by far the quickest and most vigorous method of cure.

Most of the speakers considered that although statistics were a valuable help in deciding the relative merits of the different methods of cure, especially the statistics of venereal hospitals for prostitutes, yet the judgment of the relative merits of different methods depended mostly on the good clinical observation of the individual experimenter.

Inoculation of Syphilis in Animals.

Dr. MARTINEAU had successfully inoculated a monkey with syphilis, and produced a distinct chancre, erosive and ulcerative syphilides of the skin and pharynx, and hypertrophic papular syphilides of the scrotum and thigh.

Dr. PICK had seen the monkey which Professor Klebs claimed to have syphilised. He was only acquainted with syphilis in the human subject, but the eruption which broke out on the monkey looked to him more like a varicella accidentally inoculated than like any syphilitic eruption in man.

REVIEWS AND NOTICES OF BOOKS.

A Defence of Harvey; by GEORGE JOHNSON, M.D., F.R.S. London: Smith, Elder and Co., 1884.—This little book is the outcome of Dr. Johnson's Harveian oration, delivered in 1882, being a continuation of the vindication of Harvey's memory against charges of plagiarism and scientific dishonesty. It may be remembered that certain Italian writers affirmed that, without making any acknow-

ledgment, Harvey had derived his inspiration, if not his facts, from the writings of Cesalpino. To those who heard Dr. Johnson's oration the matter might have appeared finally disposed of, any further defence seeming somewhat like fighting the battle twice over and slaying the slain. From the brochure before us, however, we learn that Professor Scalzi had undertaken to reply to the oration of 1882. His lack of faith in the efficacy of his arguments, and the validity of the claims he attempts to raise for the memory of Cesalpino may be inferred from the fact that his reply, although delivered in Rome and greeted with applause, was never by its author forwarded to England. Professor Scalzi's arguments are that Cesalpino was the first to use the word circulation, that he described the passage of the blood into *capillamenta*, a word which is now translated *capillaries*, and that he is credited with the true explanation of a vein swelling on the distal side of a ligature placed on a limb. Dr. Johnson submits these assertions to scathing criticism and shows conclusively that the context of the passage in Cesalpino is sufficient to disprove the suggested translation of *capillamenta*, and further that the term itself is derived from Aristotle who believed in the filamentous ending of arteries in nerves. After numerous quotations from Cesalpino's works, Dr. Johnson remarks that "it is evident that neither Harvey nor any one else either did, or could, ascertain the course of the blood from a study of his inconsistent and unintelligible physiological writings." The defence will be welcome to all who revere Harvey's memory, it is marked throughout by sound logic and great research, and its occasional asperity of tone may well be forgiven, if not applauded, when we remember that Professor Scalzi had not the courtesy to forward his reply to the "chiarissimo Professor Johnson," although attempting to make capital out of Harvey's silence with regard to Cesalpino.

West African Hygiene; by Charles Scovell Grant, M.D., Univ. Dublin, &c. London: Edward Stanford, 1884. Sm. oct., pp. 61.—This little pamphlet is intended more especially for the use of Europeans, not members of the medical profession, who are called upon to reside on the West Coast of Africa. The title of Tropical Hygiene would, with a few additions to the subject matter, be an even more applicable one, for the directions for the preservation of health in Africa are equally suited to the resident in Panama or British India, and the more severe diseases of that portion of the globe of which Dr. Grant treats are unfortunately to be found in nearly every part of the tropical world. Dr. Grant's remarks on prophylaxis are as good as they well can be. We notice that he lays special stress upon the danger of over-eating. To many this would seem unnecessary, yet it is the error to which almost everyone resident for the first time in the tropics is prone, and the one which it is almost the most important of all to guard against. We cannot, however, agree with Dr. Grant's recommendation of German beer. There seems to be a growing idea among Europeans on tropical stations that it may be drunk freely with impunity. Men who would look with horror upon Bass or Allsopp, will nevertheless drink four or five bottles of "lager" daily, "because it is so light." Yet we venture to think that, although it has a lower percentage of alcohol than the former, few beverages are more ill-suited to those who are in any way predisposed to liver derangement. The Papaw (*Carica papaya*) is highly recommended both as a fruit and a digestive, a recommendation in which we cordially agree. It is curious how little it is used in many parts of the tropics. In the West Indies alone it seems to be properly appreciated. In the Straits Settlements and India it appears but rarely at table, while in Java and the Malay Islands there is an idea among the Dutch that it is absolutely harmful. We have eaten it in many parts of the world, and regard it as one of the pleasantest and most wholesome of all tropical fruits. Dr. Grant's advice is tersely and clearly put. Bearing in mind the apparently unaccountable variations of the temperature of the body in hot climates it is perhaps a little too much to say that a rise to "99° Fahr. indicates impending mischief," but on the whole, the hints conveyed in this little pamphlet may be safely followed by any intending resident in the tropics.

ABSTRACTS AND EXTRACTS.

NEUROLOGY.

Paralysis Agitans. — Professor Charcot observed (*Gazette des Hôpitaux*, June 3rd), that for his lecture at the Salpetrière he should profit by the presence in his wards of several cases of an affection remarkable for its tenacity and for its progressively fatal termination, whatever may be done for it. It belongs to the category of diseases known as neuroses, in which at the autopsy after death no lesion of the nervous centres can be detected; and it is an implacable affection *par excellence* which is never cured, nor even ameliorated. Parkinson's disease, so called from him who so well described it in 1815, consists of two fundamental elements—a peculiar form of muscular rigidity and a trembling—which constitute its entire symptomatology. Sometimes one of these predominates, the other being merely accessory; and this is another reason for preferring the name Parkinson's disease, for in a certain number of these cases the trembling is a mere nothing. Moreover, patients do not in general like to be called paralytic; and in fact there is here no paralysis properly so called, for the dynamometric power is generally not diminished. Parkinson's disease may present itself in three different forms:—(1) When the rigidity and the trembling exist in an equal degree; (2) when the trembling alone characterises the disease; (3) when the rigidity predominates, the trembling either not existing at all or in a very slight degree. The rigidity is quite peculiar, being distinct from spasmodic contraction, and produced according to certain rules or laws. It invades all the muscular system, progressively and symmetrically—predominating sometimes on one side to a certain degree, "Seated, this patient has the absolute immobility of a statue, with the exception of a slight tremor in the left hand. The head is a little inclined forwards, and the muscles of the neck are so immobilised that she always looks straight forward, although by a prolonged effort of the will she can turn her head a little. The features are motionless, the physiognomy expressing a certain amount of hebetude, although the woman possesses all her intelligence. The look is fixed, the eyelids rarely descending. Deglutition being somewhat slow, while the salivary secretion continues normal, the saliva not unfrequently flows from the mouth. The upper limbs exhibit a rigidity analogous to that of muscles in a state of semi-flexion of the joints; but movements are possible within certain limits, as the articulations are quite free. The hands present a peculiar deformity owing to the predominance of the rigidity in the flexors—so that the fingers are semi-flexed on the metacarpus, as in holding a pen. Although the rigidity exists likewise in the lower limbs, the patient can walk after a fashion. Sometimes it is sufficiently great to simulate that observed in spasmodic paraplegia; but the two affections may be easily distinguished from each other, if it were only by the fact that in the latter reflex tendons are exaggerated, while in Parkinson's disease they remain normal. Moreover, while the rigidity in spasmodic paraplegia is a spinal phenomenon, that of this disease recognises no nervous lesion. Perhaps, if M. Pierret's researches are to be relied on, there may exist a sclerous lesion of the muscles —a lesion which he regards as of a rheumatic origin. When standing erect, she exhibits quite a special attitude, having the head somewhat bent forwards, the trunk inclined upon the pelvis more or less, according as the disease is more or less advanced, with all the limbs in a state of semi-flexion, and the hands applied to the thorax or abdomen — the patient then presenting a truly wooden rigidity. When she is made to walk, her feet are raised slowly and heavily from the ground, and walking, very slow at first, becomes gradually accelerated, with a tendency to propulsion, or what has been termed festination. Turning round is accomplished with great difficulty, and only by making a long circuit. In fact, these patients resemble mere automatons which we are obliged to arrest in their walk, under pain of seeing them come into contact with the first obstacle they meet with. An equally curious

phenomenon is that of retropulsion, which may be easily produced by drawing the patient slightly backwards by her dress or shawl, when she will be set walking backwards with a quickness which is rapidly accelerated, and would end in a fall if she were not arrested. In this patient the trembling is very slight, and scarcely exists anywhere, except in the left hand. It consists generally in this disease in small, rapid and short oscillations confined usually to the extremities, and only rarely manifesting themselves in the trunk or head, and then only by propagation. In the hand, it is only the fingers that suffer from the agitation, all of them beuding at the same time, and then recovering themselves, the thumb alone acting independently. It is the same with the toes, so that there is a rhythmic trembling of all the extremities, with short and rapid oscillations, which only ceases while the patient is asleep. A certain number of such patients can, by an effort of the will, arrest the trembling when they wish to execute some motion. The trembling varies in different diseases, for example, in sclerosis the oscillations become more and more considerable until the patient is unable to carry anything to the mouth; in chorea the oscillations become actual gesticulations; in post-hemiplegic hemichorea they are replaced by disordered movements; in athetosis, which is only a variety of hemichorea, the fingers in their trembling agitation resemble the tentacula of an octopus. In Parkinson's disease, sensibility is but little marked, sharp pains being rare. Its subjects complain rather of uneasiness and constant cramp, feeling a desire of incessant change of positiou, and suffering much from excessive heat. They are always too hot, even when their central temperature remains normal. The disease affects both sexes, with a slight predominance in men, and generally appears at from 40 to 60 years of age, although M. Siridey has met with a case in a girl 17 years of age. The most frequent cause is sudden fear, the action of which is in all probability favoured by some predisposition, such as arthritism or nervous heredity. To conclude, the disease is related to the large neuropathic family by the heredity of transformation, and sometimes also by a heredity of similitude. But the general rule is, that the psychical functions remain intact. Thus, I see every year in this hospital from 30 to 40 cases of paralysis agitans, and yet have never met with any psychical disturbances, and it has beeu the same in private practice, so that I regard any such cases that have been noted as mere exceptions. The course of the disease is fatally progressive, the head bending more and more on the chest, and the trunk ou the pelvis."

Pseudo-Hypertrophic Paralysis.—Dr. G. S. Middleton, having had the somewhat rare chance of examining the muscular and nervous systems after death in two cases of pseudo-hypertrophic paralysis, has recorded the results of his investigations in the *Glasgow Medical Journal* for August. He was unable to find any departure from the normal either in the nerve centres, or in the nerve trunks or peripheral nerves. In the muscles he noted a great irregularity in the size of the fibres in different places. The most prominent feature was infiltration with fat, the fat cells being large and enclosed in tubes of connective tissue arranged in rows parallel to the muscular fibres. There was a very marked increase of connective tissue, most marked where the fat was least abundant, the fibres being mostly parallel to the muscular fibres; the nuclei were numerous and many of them were large; the walls of the vessels too were decidedly thickened. In the muscles least invaded by fat the condition variously called hyaline degeneration, and coagulation necrosis was well seen. The fibre so affected presents, by transmitted light, a vitreous-like appearance, and breaks with a vitreous-like fracture; the fibre has a granular aspect. It was noted that this change was found mostly in muscles showing very little other sign of disease, aud Dr. Middleton not unnaturally asks whether this can be the earliest stage, preceding the other changes. Bone lesions have so rarely been described in connection with pseudo-hypertrophic paralysis, that it seems worth while to note that at a recent meeting of the Philadelphia Neurological Society, a report was read of the case of a girl of seventeen, who had suffered from this disease from childhood, and who presented a curious affection of the elbow joint. Owing apparently to atrophy of the epiphyses, there was much greater movement in the joint possible than in an ordinary healthy person, and the attachments of the head of the radius and upper end of the ulna were loosened. The spine showed a slight degree of scoliosis. Dr. J. Hendrie Lloyd, who reported the case, thinks that it may be an expression of that faulty development which overtakes in some defective births all tissues.

Irregularity of the Pupil in the Insane.—Dr. Mosso, of the Turin Manicomia, describes the results of the examination he has made of the pupils in 300 insane and 100 sane persons. Since Baillarger called attention iu 1851 to the frequency and diagnostic value of inequality of the pupils in general paralysis of the insane, other observers have shown that the same circumstance is observable in many other affections of the uervous centres; but in the present paper Dr. Mosso wishes to draw attention to the frequency of irregular shape of the pupil in insanity, and its occasional occurrence in the sane. Of the 300 insane, the pupil was found rotund or sub-rotund in 60 per cent., oval in seven per cent., irregular in 25 per cent., and very irregular in three per cent. In the 100 sane persons, it was found to be irregular in nine. The general conclusions drawn are: (1) That in the insane pupillary irregularity is of frequent occurrence, and is usually bilateral. (2) In diseases of the nervous centres, irregularity and inequality of the pupils have the same pathological significance, irregularity being in fact the first stage of inequality. Dr. Mosso only puts forward these observations tentatively, and asks for their corroboration by other inquirers.—*Lo Sperimentale*, December.

DERMATOLOGY AND SYPHILIS.

Chancre of the Tonsil.—According to Dr. Taylor, (*New York Medical Journal*, May 24th, 1884), this lesion, although not common, is much less rare than was once supposed. He uarrates four cases which have come under his own observation, all of which originated in depraved habits, and quotes one of like nature recorded by Dr. Bumstead. Dr. E. Wigglesworth gives the case of an enthusiastic medical student who became thus infected by attempting the mouth-to-mouth inflation of the lungs of a still-born child. Schirajew reports two cases, iu one of which a mother was infected on the left tonsil from her infant, who had been infected by its nurse. Spilmann gives the case of a woman in whom the lesion was traced to contact with the nursing bottle of a syphilitic child. Hulot gives four cases, of which three were due to kissing a syphilitic child or relative. C. Boeck details four cases of tonsillar syphilis, two of which were traced to the use of eating and driuking vessels, and the third to a kiss. The diagnosis must be made from mucous patches and syphilitic ulcerated sclerosed tonsils, in neither of which conditions is the lesion so sharply confined to one side, nor accompanied by such well-marked adenopathy; further, the history of the case will often establish the late origin of such lesions. The main diagnostic points are—(1) The details of the mode of infection, either from syphilitic sores, primary or secondary, chiefly about the mouth or face, and mostly by kissing; from infection by some article, such as feeding bottle, cigar, pipe, cup or the like; or from indulgence in bestial practices. (2) The slow unilateral development of the chancre with well-marked and extreme enlargement of the corresponding glands. (3) The limitation of the lesion to the affected side. (4) The difficulty in deglutition and even pain, which is referred to one side. (5) The history of the evolution of syphilis; the absence of chancre from other parts, especially the genitals; and the much less indurated condition of the ganglia seated elsewhere, those at a distance being often not affected until near the date of the evolution of secondary manifestations.

Syphilisation.—We had thought that the wonders which were at one time expected to be wrought by syphilisation had been consigned to the limbo of exploded fallacies, but it seems that the veteran syphilographer, M. Paul Diday, of Lyons, still has his expectations, since we

find him laying down (*Lyon Médical*, July 6) the following propositions: "If, in spite of numerous experiments, the existence of syphilis in the ape still remains but a doubtful fact, that is, because in him the disease only prevails with a weak intensity. Being capable only of an attenuated syphilis, is not this animal predestined to be the cause of the attenuation of human syphilis? This vaccination against syphilis, possibly, thanks to him, will be applicable in my opinion, first, preventively to prostitutes, to certain nurses, and to certain individuals, who, shortly after coitus, have discovered or learnt that their companion was the subject of contagious syphilitic lesions; secondly, semi-preventively, at the commencement of a chancre, and that with or without its auxiliary excision." (Our respected ancestor is thus at some remote period also to become our benefactor.)

The Diagnosis and Treatment of Syphilis.—Dr. Detmold, as reported in the *Boston Medical and Surgical Journal*, February 28th, after pointing out that syphilis manifests a decided preference for the bodies of such bones as are not covered with large masses of muscular or fibrous tissue, states that, above all others, the favourite seat of osteal secondary syphilis is the anterior surface of the tibia. A chronic local periostitis is set up, and as an invariable result of this, there is œdema over the bone. The peculiar feature of this œdema is its permanency, for it continues throughout the rest of the patient's life, and constitutes an ineffaceable and certain sign of syphilis. It is true, of course, that œdema over the tibia may be the result of injury or of other causes: "but when this œdema is found in both legs, and no local cause can be assigned for it, there can be no reasonable doubt that the patient has had syphilis." The treatment which, in Dr. Detmold's hands, had yielded the most satisfactory results, consists in the external use of a lotion of corrosive sublimate. The patient is made to rub one grain of mercury bichloride, dissolved in half-an-ounce of water, upon his body every night and morning, applying it to each of the extremities in turn. No salivation, and no inconvenient local effects upon the skin, had ever been produced; but after its long continuance in some cases, griping stomach-pains had been complained of.

Treatment of Syphilitic Condylomata.—Salicylic acid and boracic acid are both very good remedies. Formerly, we often used to remove the larger warts of that kind with the scissors, and then cauterised the wound; but since we have employed the following powder, which is dusted three times a day over the new growths, we have never had occasion to have recourse to any other remedy: ℞. Hydrarg. Muriat. mit. gr. xxx, Acid Boracic., gr. xv, Acid Salicyl. gr. v. M. Under the use of this powder the condylomata almost visibly dwindle away.—*Philadelphia Medical Reporter*, June 14.

Sweating Feet.—A much simpler means of treating this affection than that recommended by Hebra, consists (*Betz, Memorabilien*, 1884, No. 3) in bathing and thoroughly washing the feet in a solution of two to five per cent of carbolic acid, repeating this at first daily and afterwards two or three times a week. Well-washed stockings are then to be put on which have been dusted with a powder composed of salicylic acid, three parts; benzoic acid, two parts; and talc powder, ninety-five parts. The interior of the shoes must also be thoroughly dusted with this powder. The stockings when removed must be placed for twelve hours in carbolic acid water, and then thoroughly washed. In this way the bacteria which cause this fetid secretion may be destroyed, and without such a disinfection a cure is not possible. Dr. Duhring observes in the *Philadelphia Medical Times*, June 14th, that this affection, in which nothing can be seen except a macerated state of the skin, is tolerably common, and consists in a functional disturbance of the sweat apparatus. A saturated solution of boracic acid often exerts a beneficial influence, also tannic acid in solution or powder and salicylic acid. The following powder may also be used—Zinci oleati ʒii, talci amyli aa ʒiii. Tincture of Belladonna in a lotion may also be applied with good results in some cases.

Dermatitis Herpetiformis.—Under this title Dr. Duhring read a paper at the meeting of the American Medical Association (*Medical Record*, May 10), upon a disease of the skin, of which he had only met with fifteen cases. It shows itself in a variety of ways—by patches of an urticarial or erythematous character, by herpetic vesicles, by blebs, by pustules, and by papules. All these lesions tend to take on a herpetic type, and they may all be present at one time, or appear in succession. The disease is remarkable for the multiformity of these lesions; and the different eruptions are accompanied with violent itching and burnings. The treatment of the disease, which may be regarded as a neurotic affection, is very unsatisfactory; and it may continue for years. It may occur in both sexes, and in women independently of pregnancy. The pustular variety of the disease is the same as that described by Hebra, under the name, impetigo herpetiformis.

Lupus Hypertrophicus of the Nose.—In dealing with a case of lupus of the nose, Professor Billroth observed that it belonged properly to the dermatological clinic, but that he had retained it in his own in order to show how this form of lupus is now treated. The patient having been put under chloroform, the diseased substance is scraped away by the sharp spoon, after which caustic potash is applied right down to the healthy tissue. In this way the patient at once gets rid of his malady without any pain, and the danger of relapse is as far as possible guarded against.—*Allgemeine Wiener Medicinische Zeitung*, June 3.

Faradization in Ringworm.—An obstinate case of ringworm on the forearm having resisted all known remedies, the Faradic current was applied as an experiment, the positive pole being applied to the elbow and the flat negative electrode passed repeatedly over the seat of the disease. The itching, which was intense, ceased immediately, and a clear exudation like minute drops of sweat appeared on the surface. A second application, made two days afterwards, left nothing of the ringworm except desquamated skin. A mild emollient ointment was used between the applications of the battery.—*New York Medical Journal*, March 1st, 1884.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XIV.

The Biological Laboratory.

No department of the Exhibition is perhaps less visited or more important than the Biological Laboratory, under the charge of Mr. Watson Cheyne, and his assistant, Mr. Joseph Lister. An exhibition, such as the present one, with the high patronage it has enjoyed, and its unequalled success, both as regards the numbers of visitors, and the general interest evinced by them in matters of health, alone can afford the desired scope for the proper display of a subject of this magnitude. Obviously no greater incentive to safeguard health can be imagined than a study of the life history of the organisms, whose entrance into, and development within the body constitutes *disease*, and of the power of chemical agents in destroying them. Nor can any objects be conceived more likely to convey a powerful lesson or more! surely point a moral, than the ocular demonstration of the germs which work such disaster amongst us. Hitherto the germ theory of disease has rested on too slight and unsubstantial a base even for the medical profession. There have not been means of demonstrating germs; of differentiating them; of isolating one variety from another. There has been a lack of evidence as to the specificity of the organisms, several different kinds being present in one disease or organ, so that investigators have found it difficult to separate cause and effect. Further, the knowledge of the existence and life history of germs will never be of much service to humanity so long as it is confined to the medical profession only. Hence the importance of the present laboratory in connection with the International Exhibition at South Kensington, serving as it does to bring before vast numbers of the public the germs themselves, and expose in tangible reality the existence, specificity and characteristics of each.

The study of the laboratory will teach before all things the value and importance of absolute cleanliness, for without cleanliness the results now obtained would have been impossible; indeed no small part of the progress recently made in this branch of study has depended on advances in the methods of securing absolute cleanliness, both of the instruments and media, before the cultivation experiments have been commenced. Now, however, it is possible to isolate one bacterium from another, and study its peculiarities with ease and certainty. Sterilisation—as this process of purification is called—is effected by heat. The vessels to be used in any experiment are previously heated to a temperature of 150° C. (302° F) for three hours; the cultivating media are steamed for half-an-hour on three successive days, one such steaming being found to be insufficient as a protective. It is thought that bacteria exist in two forms:—first as *active agents*, which are readily killed by a heat of 212°, and second as *passive agents* (spores) which can resist heat for any length of time. The first steaming destroys all the active agents, leaving only spores; the latter develop into active agents between the first and second steaming, and are destroyed by the second steaming; the third time makes doubly sure, by destroying any others which may have escaped destruction on the two previous occasions. When it is desired to cultivate a particular form of bacterium, a little bacteria-containing fluid is mixed with some cultivating medium and then spread very thinly on a piece of glass plate and covered with a suitable cover. In process of time, the bacteria begin to grow; if there are several varieties (as is usual), each form developes in its own peculiar manner and is easily recognised; a portion of that which it is desired to cultivate is then transferred from the glass plate into a test tube or other suitable vessel, and treated *secundum artem*. On the glass plate, on which the original fluid to be tested was grown, there will generally be found more than one variety; sometimes several varieties will be found; but being widely spread out, the varieties are separated, and in the second or third cultivation one particular variety can generally be obtained for experimental purposes, quite pure and unmixed.

It is in this method of cultivation that the *specific* characteristics of certain bacteria, and by inference, therefore, of the whole group, have been demonstrated. Thus some bacteria produce colour—blue, green, violet, or fluorescence; and they can easily be separated and made to *breed absolutely true*. The bacteria of milk fermentation can be isolated, and either that leading to the production of lactic, or that of butyric acid can be cultivated as may be desired. Coming to more pathogenic forms, we find exhibited the specific bacilli which produce tuberculosis, anthrax, typhoid fever, osteomyelitis, pneumonia, and erysipelas. Of these, the tubercular, anthrax and the erysipelas bacilli need only be inoculated in order to produce their respective effects. The typhoid bacillus has not yet been successfully inoculated, probably because typhoid fever is a disease peculiar to the human species; but, as found in typhoid stools, and in typhoid ulcers, it can be cultivated artificially, and it is found to possess characters by which it can readily be recognised and differentiated from other forms. The bacillus of osteomyelitis must be injected in some quantity; and in order that the characteristic lesions follow, one of the bones of the animal experimented upon must have been injured, that is either bruised or broken. To produce pneumonia artificially the animals are made to inhale a spray containing the bacillus, or it has to be injected into the pleural cavity. Some cultivation experiments have also been made with the bacillus of anthrax; it may be so attenuated as not to kill when inoculated into an animal, but whether the animal is thereafter protected from the natural disease, does not appear.

In order to carry on these cultivations, various media are used, simple meat infusion, gelatinised meat infusion, skimmed milk, bread and potato infusions. These are, of course, all sterilised before being used and neutralised. Some germs are found to grow better in one infusion than another, some require a rather higher temperature than others, some grow best on the surface of the cultivating medium, while others thrive only when completely buried in it. In all this there is nothing but a confirmation of the generally accepted doctrine of constitutional receptivity, some persons appearing to be but little affected by a disease, or epidemic which is fatal to others; in other words, germs grow more readily in one constitution than another.

The importance of the subject can hardly be overstated. It is rather humiliating to English scientists that the best work in this field has been done in Germany, thanks to the apathy of the home Government in matters scientific on the one hand, and to agitation and to ill-judged restrictive legislation on the other. Even as regards cholera, a disease which affects English colonial interests so largely, the greatest advance that has ever been made in its pathology, has been made by a German Commission, specially sent out by the German Government to study the disease. At last, and only when the discovery of the materies morbi seems really to have been accomplished, does our own Government wake up to its responsibilities and take steps to study the disease. It is perhaps not an entirely unmixed advantage that the gentlemen selected for the task have already expressed adverse views on Koch's great discovery. If they are converted to Koch's doctrine, it will be greatly in its favour. If they are not converted, we fear there will be a feeling that its study was approached with bias and foregone conclusions. Meanwhile, however, let us not make too much of the germ theory of disease or imagine it final; for while of great interest to have discovered the materies morbi of a disease, the knowledge will avail little unless it can be made subservient in saving life. Let us at least hope that steps will be taken to make the laboratory a permanent institution, and that opportunity will be given to English medical men (not inferior to that enjoyed by foreigners) to make themselves familiar with these uncanny and unwelcome little parasites.

GENERAL CORRESPONDENCE.

HOWARD'S AMBULANCE CARRIAGE.

[To the Editor of the Medical Times.]

SIR,—Since arriving in London last week it has come to my knowledge that various carriage builders are respectively advertising themselves as "Patentees," "Sole Manufacturers," as "Manufacturers to the London Ambulance Service," &c., &c., of Dr. Benjamin Howard's Ambulance Carriage.

As this ambulance, with or without modification, is used exclusively by the London Ambulance Service, largely by the Metropolitan Asylums Board, and increasingly throughout the United Kingdom, I think it important the profession should know that, in consequence of special provision made by me when I presented this ambulance to the London Ambulance Service and the British public, no part of this carriage is, or can be now, patented by anybody, and that all representations which have been made of monopoly of any kind in connection with its manufacture are untrue and fraudulent.

I am, Sir, yours &c.,
BENJAMIN HOWARD.

London, August 25th, 1884.

SPINAL CURVATURE.

[To the Editor of the Medical Times.]

SIR,—Will you permit me to state that the quotation upon which Mr. Churchill has based his remarks, published in your issue of Saturday last, is not taken from my paper read at the Congress upon School Hygiene at the International Health Exhibition, and does not correctly express what I have said or written regarding the origin of deformities. As to the causes of defective eyesight I have never offered—nor do I consider myself competent to offer—any opinion.

I am, Sir, yours &c.,
NOBLE SMITH.

24, *Queen Anne Street, W. August 27th*, 1884.

VACCINATION STATISTICS.

In connection with the articles and correspondence which have recently appeared in this Journal, Dr. Collie has favoured us with the following table of statistics which has not hitherto been published. It shows the relation of vaccination to age and mortality in 915 cases which came under his care in the Homerton Fever Hospital in the Smallpox Epidemic of 1876-7.

Degree of Vaccination.	Discrete Smallpox.					
	Under 16.			Over 16.		
	Total.	Died.	Mortality per cent.	Total.	Died.	Mortality per cent.
Unvaccinated	20	...	...	2	...	...
Said to be Vaccinated	8	...	...	29	...	...
No evidence	14	2	14·14	8	...	...
Bad	16	...	...	34	...	...

	17	17	...	23	23	...

Total number of cases, 915.—(1) Unvaccinated, 131 cases. Mortality, 53 per cent. (2) Badly vaccinated, 396 cases. Mortality, 26 per cent. (3) Fairly vaccinated, 388 cases. Mortality, 2·3 per cent.

MEDICAL NEWS.

University of London.—Intermediate Examination in Medicine.—Examination for Honours.—Anatomy :—

First Class.—James Edwin Thompson, Owens College (Exhibition and Gold Medal). John Rose Bradford, B.Sc., University College (Gold Medal). Walter George Spencer, St. Bartholomew's Hospital. James Jackson Clarke, St. Mary's Hospital. Henry Grabham Lys, London Hospital. James Wheatley, King's College. *Second Class.*—Henry Claxton Bowman, Owens College. William Frederick Clarke, Guy's Hospital. *Third Class.*—Sidney Robert Alexander, Guy's Hospital. Thomas Arthur Helme, University of Edinburgh and University College. William Henry Breffit Brook, St. Bartholomew's Hospital.

Materia Medica and Pharmaceutical Chemistry :—

First Class.—Thomas Arthur Helme, University of Edinburgh and University College (Exhibition and Gold Medal). Walter George Spencer, and John Anderson Smith, St. Bartholomew's Hospital (both obtained the number of marks qualifying for the Exhibition and Medal). Kaikhosro Nasarvanji Bahadhurji, University College. William Henry Breffit Brook, Arnold Lyndon, and Charles Wheeler Forrest Young, St. Bartholomew's Hospital (of equal merit). Frédéric François Burghard, Guy's Hospital; William Permewan, and Charles Edward Sunder, University College (of equal merit). Frederick Nathaniel Brown, and William Thomas Gardner, St. Bartholomew's Hospital; and Frederick Sherman Toogood, University College (of equal merit). *Second Class.*—Hugh Smith, Guy's and London Hospitals. Edmond Fauriel Trevelyan, St. Bartholomew's Hospital. *Third Class.*—Arthur Pearson Luff, B.Sc., St. Mary's Hospital. William Barltrop Featherstone, Queen's and Mason Colleges, Birmingham; Julius Hamel, and Sydney Ernest Holder, University College; Henry John Macevoy, B.Sc., St. Thomas's Hospital; and John Ernest Nevins, Guy's Hospital and Liverpool School of Medicine (of equal merit).

Organic Chemistry :—

First Class.—Charles Wheeler Forrest Young, St. Bartholomew's Hospital (Exhibition and Gold Medal). Arthur Pearson Luff, St. Mary's Hospital (obtained the number of marks qualifying for a Medal). Frédéric François Burghard, Guy's Hospital. *Second Class.*—John Rose Bradford, University College. Henry John Macevoy, St. Thomas's Hospital. Sidney Robert Alexander, Guy's Hospital; Frederick Nathaniel Brown, St. Bartholomew's Hospital; Ernest Paul Alphonse Mariette, King's College; and George Rowell, Guy's Hospital (of equal merit). *Third Class.*—Charles Frederick Seville, Owens College; Walter George Spencer, and Edmond Fauriel Trevelyan, St. Bartholomew's Hospital (of equal merit).

Physiology and Histology :—

First Class.—John Rose Bradford (Exhibition and Gold Medal), and Herbert Henry Brown (Gold Medal), University College. *Second Class.*—Frédéric François Burghard, Guy's Hospital. Walter George Spencer, St. Bartholomew's Hospital. *Third Class.*—Arthur Pearson Luff, St. Mary's Hospital. Kaikhosro Nasarvanji Bahadhurji, University College. Sidney Robert Alexander, Guy's Hospital. Albert Lindow, King's College; and Charles Frederick Seville, Owens College (of equal merit). John Anderson Smith, St. Bartholomew's Hospital.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, August 21st, 1884 :—

Samuel King Alcock, Sytch House, Burslem; Owen Cole Coker, 149, Uxbridge Road, W.; Charles Joseph Heath, Cromwell Road, S.W.; Edgar Alfred Hughes, 91, Onslow Gardens, S.W.; Jno. Oliver Pemberton, 4, Lawrence Terrace, Tidal Basin; Frederick Cecil Holman Piggott, Ormond House, Richmond.

The following gentleman also, on the same day, passed the Primary Professional Examination :—

Samuel Gordon Smith, University College Hospital.

Army Medical Department.—The following were the successful Candidates for Commissions as Surgeons in Her Majesty's British Medical Service at the examination held on August 11th, and following days. The marks shown are those which were gained in order of merit :—J. R. Forrest, 2,475; M. W. Russell, 2,395: W. R. de Morinni, 2,370; B. F. Zimmerman, 2,355; A. F. Stace, 2,340; A. Stables, 2,295; J. F. E. McCraith, 2,285; E. A. C. Smith, 2,265; W. M. Hewson, 2,210, G. E. Moffet, 2,210, equal; H. A. Haines, 2,180; J. D. Moir, 2,175; R. Crofts, 2,150; G. M. Dobson, 2,140; G. E. Hale, 2,130; C. W. Johnson, 2,110; W. E. Berryman, 2,100; A. T. J. Lilly, 2,080; R. Caldwell, 2,075; C. C. Reilly, 2,065; S. E. Duncan, 2,060; J. Maker, 2,030, A. Perry, 2,030, equal; S. M. Cordozo, 2,010; A. de C. Scanlan, 2,000; H. W. James 1,990, R. Trevor, 1,990, equal; H. D. James, 1,970, W. Turner, 1,970, equal; B. O. W. Norfon, 1,960.

Naval Medical Department.—At the competition for Commissions in the Medical Service of the Royal Navy, held on the 11th August and following days, the following were the successful candidates. The marks shown are those which were gained in order of merit :—E. W. von Tunzelmann, 2,375; E. B. Townsend, 2,310; A. G. Wildey, 2,295; P. B. Handyside, 2,200; H. R. Osborne, 2,170; J. M. Rogers, 2,150; C. L. Nolan, 2,135; H. F. D. Stephens, 2,135, equal; F. H. Julyan, 2,095; E. C. Ward, 2,090; W. R. M. Young, 2,085; G. L. Baker, 2,064; H. W. G. Doyne, 2,050; A. B. Murdoch, 2,040; T. Dunlop, 2,030, S. Johnson, 2,030, equal; G. A. Dreaper, 2,000; W. H. O'Meara, 1,940; W. W. Jacobs, 1,910; A. F. Harper, 1,900; H. W. A. Burke, 1,855; E. R. D. Fasken, 1,840, J. C. F. Whicher, 1,840, equal; A. G. Andrews, 1,820, A. S. Nance, 1,820, E. St. M. Nepean, 1,820, equal.

The New Medical Knight.—Dr. William Carter Hoffmeister, of Clifton House, Cowes, in the Isle of Wight, Surgeon Apothecary to the Queen at Osborne, upon whom Her Majesty has conferred the honour of knighthood, became a licentiate of the Society of Apothecaries (London), in 1839, and graduated M.D. at the University of Glasgow in 1840. He became a member of the Royal College of Surgeons in the same year, a Fellow in 1855, and a licentiate of the Royal College of Physicians (London) in 1861. Dr. Hoffmeister has been on the medical staff of the Royal Family for many years, having acted as surgeon in the Isle of Wight not only to the Queen, but also to the late Prince Consort and her Royal Highness the Duchess of Kent. He is surgeon to the Royal yacht squadron, honorary consulting physician to the Royal Isle of Wight Infirmary, a member of the Medical Society of University College, and a Fellow of the Royal Medical and Chirurgical Society, and also of the Obstetrical Society

The Apothecaries' Hall.—At the recent Examination for the Prizes in Materia Medica and Pharmaceutical Chemistry given annually to medical students by the Society of Apothecaries, the successful Candidates were adjudged to be as follows:—First: John Henry Garrett, student of University College, the Gold Medal. Second: Henry Hamilton, student of the Bristol School of Medicine, the Silver Medal and Books.

Admiralty.—The following appointments were made on August 22nd. Staff-Surgeons—W. H. Putsey, to the *Boscawen*, for service in sick quarters at Portland; W. J. Rankin, M.D., to the *Boscawen;* and R. W. Biddulph, M.D., additional, to the *Duncan*. Surgeons—A. H. Kelly, M.D., to the *Valiant;* and J. A. Collot, to the Royal Marine Artillery Division at Portsmouth. Surgeon and Agent—J. Paulin, at Peel, Isle of Man. The following appointments were announced on August 25th. Surgeons—Edward B. Townsend, Alexander G. Wildey, Patrick B. Handyside, Harold R. Osborne, James M. Rogers, Charles L. Nolan, Harold F. D. Stephens, Francis H. Julyan, Edward C. Ward, W. R. Minching Young, George L. Baker, Herbert W. G. Doyne, Thomas Dunlop, Alexander B. Murdoch, Samuel Johnson, George A. Draper, William H. O'Meara, and E. W. von Tunzelmann, to the *Duke of Wellington;* William H. Jacobs, Alexander F. Harper, Hubert W. A. Burke, and Edward R. D. Fasker, to the *Royal Adelaide;* James C. F. Whicher, to the *Impregnable;* Alexander G. Andrews, to the *Asia;* Arthur S. Nance, to the *Indus;* Evan H. St. Nepean, to the *Pembroke.*

Professor Virchow.—A Berlin correspondent of the *Canadian Medical Journal* for July supplies some interesting facts concerning the great Berlin Professor. "The central figure at Berlin is Virchow. With the exception of the years 1849–56, he has been here as student, prosector, and professor since 1839. In 1844 he became assistant to Froriep, whom he succeeded as Prosector of Pathology in 1846, losing the position in 1849 on account of his active participation in the political disturbances of that period. He was, however (not without considerable trouble), reinstated, and shortly after was called to Würzburg as Professor of Pathology, returning to Berlin in 1856. Under his direction the Pathological Institute of the Charité has become the most famous pathological school in Europe; and to name the men who have been his assistants is to go over those of many of the best known teachers and investigators in Germany—Klebs, Recklinghausen, Rindfleisch, Cohnheim, Liebrich, Hoppe-Seyler, to say nothing of the younger men, Orth, Ponfick, Salkouski, and others. After 40 years of teaching, it is but natural that he should have much of the drudgery done by his able assistants, Jurgens, Grawitz, and Israel, who conduct the autopsies and the courses on pathological histology. Students, however, have still the great privilege of hearing him in three different classes. For the first three or four Mondays of the semester, from 7.30 to 10 a.m., he performs an autopsy before the class, giving detailed directions as to methods and the proper modes of observation. On Wednesday and Saturday are held the famous demonstration courses on morbid anatomy, in which the material for the week, often ten or fifteen cases on each occasion, is brought before the students. The time occupied is at least two and a half hours, the first half of which is taken up by some special subject, the pathology of which is well illustrated by the specimens at hand. At 11 a.m he gives each day a lecture on special pathology. Politics and anthropology now absorb the greater part of his time. He is a member of the German Parliament and of the Prussian House of Representatives; and I noticed a day or so ago in one of the daily papers that Virchow had spoken in one of these 38 times during the session. It need scarcely be stated that he is an advanced Liberal. He is also a member of the City Council—not an idle one either, as the copious literature of the "canalisation" (drainage) system of the city can testify. His archæological and anthropological studies are most extensive, and it is upon these subjects that he now chiefly writes. When one turns to the Index of the Berlin Archæological or Anthropological Societies, the figures after his name stand thick and deep, just as they do in a similar index of medical subjects. He has been collaborator with Dr. Schliemann in several of the important works issued on Trojan antiquities. His collection of skulls and skeletons of different races, one of the most important in Europe, will doubtless find an appropriate place in the new Archæological Museum erected by the Government. There are those who grudge him the time he spends on politics and his favourite studies, but surely he has earned a repose from active pathological work, and may well leave section cutting and bacteria-staining to the smaller fry; and when we consider that in addition to the classes above-mentioned, he is President of the Berlin Medical Society, and edits his *Archiv*, now a large monthly journal, it can scarcely be said that he neglects professional duties. On all questions of general, medical, and scientific interest his utterances are not infrequent, and display a judicious conservatism—as witness his sound position regarding the Darwinian theory as opposed to the vagaries of Haeckel. It is satisfactory to note that the attack of gouty nephritis of some eighteen months ago appears to have left no trace. Aged, of course, he is (he is now 63), but there is still a vigour and sprightliness in the wiry frame which bespeak years of continued activity."

The Royal Irish University.—The plans for the Royal University buildings have been approved, and provide for the alteration of the old Exhibition Palace premises, and the addition thereto of a new wing on the ground adjoining Hatch Street. The new building, which will be of one storey, will have a frontage of 200 feet towards Earlsfort Terrace, and 180 feet towards Hatch Street, the extreme depth from Earlsfort Terrace being 240 feet. A chemical laboratory, 120 feet by 30 feet, lighted from the roof and sides, will form a part of the wing, and will occupy a position facing Earlsfort Terrace. Adjoining this spacious apartment will be a corridor extending right and left, off which will be smaller laboratories, stores, and retiring rooms, and an apartment for the study of histology 58 feet by 16 feet. In the centre of the building it is intended to have a large open court 50 feet square, so as to provide abundant light and ventilation to the surrounding premises. The physical laboratory will occupy a position to the rear, and will be 90 feet by 30 feet, and adjoining will be the physiological museum, an apartment 57 feet by 30 feet. Both these rooms will be extremely lofty, and will be lighted both from the roof and sides. Behind these apartments will be the dissecting room, 120 feet by 30 feet. It will be lighted from the sides and from the roof, which will be oaken, and of an ornamental character. In connection with the dissecting room will be a smoking room for students (this apartment being 25 feet by 30 feet), and lavatories, covered corridors, and retiring rooms. Between the new and old building will run a through passage 40 feet in width, and the entrance to the wing will be obtained by a corridor 10 feet wide, forming a continuation of the front corridor of the old building. The frontage of the wing will be constructed of Dungannon sandstone, from the quarries of Lord Ranfurley, and will be of an ornamental character, the style of architecture adopted being that of the Italian school. Rising from the centre of the building will be a large campanile attaining an elevation of 90 feet

from the ground. This will be utilised as a ventilating shaft in connection with which the different apartments will be brought by special arrangement. The alterations of the old building mainly consist of the division of the large apartments into smaller rooms suitable for the purposes of the University. It had been intended to have had the old front taken down and re-built in cut stone, so as to match the interior of the new building, but this project was abandoned, as it was found the expense would have been too great. Some necessary repairs will, however, be executed. It had also been in contemplation to have erected a large clock tower on the northern side, but this plan was likewise given up on the ground of its expense. The estimated cost of the works is 25,000*l.*, of which 18,000*l.* will be expended on the new building. The plans have been prepared by the architect to the Board of Works, Mr. James H. Owen, F.R.I.A., and will be carried out under his personal supervision. Dr. George Moyers, South Richmond Street, is the contractor. The works will be commenced immediately, and will probably occupy about two years.

The Sanitary State of Islington.—In the course of an elaborate report which Dr. C. Meymott Tidy, as the Medical Officer of Islington—a parish of over 300,000 inhabitants—has issued, he says that the death-rate of the district during the past year has been 17·1 per 1,000 of the population. A total of 5,140 deaths had been recorded in the parish, of whom 2,604 were males, and 2,536 females. Of the total deaths, 2,042 cases occurred in the western, and 3,098 in the eastern division. The actual number of deaths in the past year was rather less than the total in the previous year. Considering the increase in the population of the parish, the death-rate of 17·1 per 1,000 was the lowest to be found upon the Islington records. There was one actual death from small-pox within the parish, and in the Metropolitan District Asylums Board's hospitals two deaths of parishioners were recorded. Measles was the disease most severely epidemic during the year; scarlatina was not so seriously epidemic. During the much more severely epidemic years of 1870–69–63–62 and 59 the deaths from scarlatina were respectively 465, 313, 392, 210, and 216. The populations of these years were 209,057, 202,182, 166,922, 161,679, and 143,338, as against 301,283 in the year ending 1883. From diphtheria 70 deaths were certified to have occurred. Only 119 deaths were due to whooping cough, the lowest number recorded since 1870. From diarrhœa there were 162 deaths, as against 149, 216, and 295 in the three previous years. To fever generally 86 deaths were referred, as against 77 and 79 in the two previous years. In 1883 there were only 36 cases of sickness from small-pox, as against 142 and 797 in 1882 and 1881 respectively. Since February, however, of the present year (1884) small-pox had again become seriously epidemic, so much so, in fact, that even should there be a temporary abatement during the summer months, there was every indication that at the close of the year the parishioners would be brought face to face with a still severer outbreak of this dreaded disease. In the circumstances, Dr. Tidy said he regretted that he was no longer able to congratulate the vestry on possessing camp hospital premises, which had, unfortunately, in his opinion, been entirely abandoned. As public analyst of the parish, Dr. Tidy reports that in the twelve months ended December last he examined 113 samples of food, 112 of which were submitted to him by the vestry's inspectors, and one by the public. Of the 112 samples submitted by the inspectors, two samples of milk were adulterated with 20 per cent. of added water in each case, and one sample of so-called "butter" was entirely composed of "oleomargarine," or purified fat. The one sample of food submitted by the public was one of black tea received from the Holborn Guardians, which he certified to be genuine. It was further stated in the report that in the year 1883 661 bodies were received at the mortuary; 371 inquests were held, and 57*l.* 7*s.* 6*d.* was paid for the accommodation afforded the coroner. The proportion of inquests to deaths was about 7·22 per cent. for the whole year. In referring to the sanitary work of the year, Dr. Tidy mentions that 626 visits have been made to the bakehouses in the parish, the Legislature having by the Factory and Workshop Act, 1883, re-transferred their inspection from Her Majesty's inspectors of factories to the vestries and District Boards of the metropolis. "This step," says the Medical Officer of Health for Islington, "will, in my opinion, prove beneficial in every way, but the transferance would have been more readily effected by the re-enactment of the Bakehouses Regulation Act of 1863 than by amending the Factory and Workshop Act of 1878." It seems, from Dr. Tidy's report, that the marriage-rate in Islington in 1883 was 15·5 per 1,000, against 16·1 in each of the two preceding years. The birth-rate was 32·8 per 1,000 of the population, against 34·3 in 1882 and 35 in 1881. This was the smallest birth-rate recorded in the parish since 1858, when the rate was 32·1. The death-rate has already been mentioned.

An International Scientific Association.—Mr. Charles Minot, *Boston Medical Journal*, July 31st, writes to state that there has been an active movement in operation among some of the leading scientific men in America to secure signatures to a memorial addressed to the two great scientific associations meeting this year in that country, having for its object to induce them to consider the advisability of forming an International Association. Another opportunity so favourable as the meetings of the British and American Association, is not likely to recur very soon. Mr. Minot states that in 1881 a proposal was actively discussed in the American Association of inviting the British Association to America, and it was finally determined, greatly as he believes from real modesty, to postpone the invitation, and to issue a large number of special requests to individuals to attend the meeting of the American Association, held at Montreal. The great number who accepted the invitation led to the hope that the British Association would be induced to come over as a body. The matter in the meantime was independently taken up by the Canadians and pushed eagerly and generously towards the great success which has followed. This has given strength to the anticipations of the successful issue that may attend intercommunication of the two bodies upon the matter. At present no definite plans have been formed, as it has been felt that public discussion is necessary before coming to any decision.

International Congress of Surgical and Orthopædic Instrument Makers.—The second annual meeting of the International Association of Surgical and Orthopædic Instrument Makers will take place at Dresden, on September 14th next. Although founded only last year, this association is already represented by a large number of the leading continental and some English and American firms. Its object is to attain by mutual instruction the highest standard of excellence in the improvement of instruments and mechanical appliances, assurance of priority of inventions, and to exclude the intermediate dealers who are strangers to the trade, who from want of technical knowledge furnish instruments of inferior description detrimental to the reputation of the trade at large. In order to attain these objects and to uphold the dignity of the trade, according to the regulations of this association, none but *bonâ fide* instrument makers who have served their full term of apprenticeship to the trade are admitted as members. Members of firms desirous of joining this association and to take part at the forthcoming meeting, are invited to forward their names and addresses to the Secretary, Mr. C. Walter Biondetti, Basle; or to Mr. C. W. Krohne (Krohne and Sesemann), 8, Duke Street, Manchester Square, London, W., both Members of the Committee.

Recent Legacies.—The late Mr. James Lyne Hancock has left by his will, 1,000*l.* each to King's College Hospital and St. George's Hospital; 500*l.* each to St. Bartholomew's Hospital, the Hospital for Diseases of the Chest, City Road, the Royal Hospital for Incurables, Putney, and the London Hospital, Whitechapel. The North London Consumptive Hospital has received a legacy of 1,000*l.* under the will of the late Mrs. Catherine Abram.

Population of Paris.—The complete results of the census made in December, 1881, as far as they concern the population of Paris, have only just been published by the

Prefect of the Seine. Paris had at that time 2,239,928 inhabitants, of whom 1,113,326 were males, and 1,126,602 females. The population of the French capital has increased by 251,122 souls since 1876. The first census ever made in Paris reaches back to the year 1770, and shows the city to have had at that time 720,000 inhabitants. In 1881, Paris numbered 68,126 houses, 32,422 of which were over four stories high. There were 440,022 married men, 446,297 married women, 621,569 single men, and 557,054 girls of all ages. The youngest married man was 17 years and the youngest married woman 14 years of age, both exceptional cases. The number of widowers was 51,735, and of widows 123,251, of whom 2 were 16 and 3 18 years of age. The following figures show the degrees of longevity: —6,386 persons were over 80, 2,747 between 84 and 89, 640 over 90, 198 over 96 years of age. There were, besides, 20 centenarians, including 4 bachelors, 1 married man, 6 widowers, 1 spinster, 1 married woman, and 7 widows. Of the inhabitants of Paris 1,021,996 men and 1,053,804 women were born in other parts of France, and only 348,845 men and 372,576 women in Paris itself. The census of foreigners in Paris, gave 91,872 men and 75,542 women, distributed as follows:—Belgians, 23,981 men and 21,300 women; Italians, 15,703 men and 5,874 women; Germans, 15,441 men and 15,749 women; Swiss, 12,264 men and 8,546 women; English, 4,607 men and 6,132 women; Americans, 2,954 men and 2,973 women; Chinese, 65; other Asiatics, 149. With reference to the various callings followed, the following figures may be quoted. There were 1,102,313 persons (540,288 men and 562,205 women) engaged in industrial pursuits, and 551,678 persons in trade. The garrison and police include 25,482 men, and it is estimated that 8,565 women obtain their livelihood through them. There were 66,720 persons (of whom 37,405 were men) employed in the service of the Government and the municipality. The service of the Church gave employment to 1,858 men; the courts of justice to 16,899 persons; the medical profession to 18,304 men and women; the schools to 9,324 men and 12,794 women. Religious societies claimed 1,569 men and 4,369 women as belonging to them. The artists numbered 42,646, of whom 22,462 were men and 20,164 women. Amongst the class of *savants*, literary men, and journalists 5,684 and 5,500 women. The number of individuals without a calling (amongst whom pupils and students, persons unemployed, beggars, tramps, &c.) was estimated at only 61,692 persons.

Population of Japan.—The population of Japan, according to the Census of 1883, amounts to 37,011,964; and at the end of the year 1883, the three largest towns contained the following number of inhabitants:—Tokio, 299,191 families with 999,623 souls; Kioto, 203,477 families with 840,943 souls; and Osaka 364,254 families with 1,585,696 souls.

An Ultra-Centenarian.—A considerable number of ultra-centenarians have owed their reputation to the absence of official documents. But in the case of one Marie Durand, who died recently at Auberive-en-Royans (Isère) her duly signed baptismal certificate has been produced, from which it appears that she was baptized March 16, 1761, and was consequently, at the time of death, 123 years of age. Her husband died 96 years ago.

Insanity in France.—In the *Revue Scientifique* for April 5th, M. Legoyt gives an interesting review of the statistics of lunacy in France during the period 1871–80. Insanity, he observes, is increasing in France more rapidly than the population; and, in fact, it prevails to a greater extent than the published documents show, for while the number of insane treated in the asylums is known, there are many lunatics not returned at the Census, the number of whom it is impossible to ascertain. The inmates admitted to asylums increased from 11,872 in 1871 to 16,535 in 1880; and the following facts are brought out by M. Legoyt: — (1) There were 5,507 relapsed lunatics admitted, the greater number occurring in the first year of the reputed cure, and especially in the first month. From this period they become less and less frequent, but they are still met with after the cure seemed to be complete, in the ninth, tenth, eleventh, twelfth year and more. (2) Most admissions, in proportion to the population, take place between the ages of 20 and 50, the maximum being between 30 and 40. The ages between 15 and 20 and then those between 60 and 70 and above furnish the fewest. In advanced age women are more frequently lunatics than men. (3) More celibates are admitted than married or widowed persons, viz., one celibate per 2,707 inhabitants, one married per 4,937, and one widowed per 3,936. (4) Distributing the admissions according to the time of the year when they take place, it is found that these increase with the temperature, viz., 22·46 per cent. in winter, 26·42 in spring, in 27·96 summer, and 23·46 in autumn. (5) Among 28,621 lunatics, concerning whom this information could be obtained, 4,056, or 14·17 per cent. inherited the disease from the father or mother, and sometimes both. (6) Of 1,000 cases of insanity, 607 seemed to have been due to physical causes (as age, misery, venereal excess, drinking, emale diseases, epilepsy, or other diseases of the nervous system, blows, falls, &c.); and 393 to moral causes (as domestic sorrows, loss of fortune or employment, death of loved persons, love and jealousy, pride and religious perversion, disappointment, ambition, &c.). These physical and moral causes of insanity are exactly those of suicide, insanity and suicide being, in fact, but two effects of the same cause. Just as in the case of suicides, women are much more subject to the influence of moral causes than men. (7) Of 1,000 lunatics admitted, 174 had been insane for less than a month, 269 for between one and six months, 134 for between six and twelve months, 111 for between one and two years, and 140 for more than two years. In presence of these figures it is not surprising that the cases treated in the asylums present so few chances of cure.

Sheffield General Infirmary.—On Wednesday the new out-patient building was opened. Accommodation of the kind has long been required at the infirmary owing to the constantly increasing demands made upon the space in the institution. Hitherto the poor people attending as out-patients have been received in the main building, but this has caused considerable inconvenience and delay both to the persons seeking relief and the medical staff. It was therefore decided that the new structure should have a separate entrance. Although this plan has been carried out, the new building is, nevertheless, connected with the infirmary by a corridor. The new hall, which is octagonal, is 50 feet in diameter. Radiating from the waiting hall are the physicians' consulting room and one ante-room, surgeons' consulting room and two ante-rooms, ophthalmic surgeons' room and two ante-rooms, one of which is dark. In addition to these is an admission room and large dispensary. The new building has a very neat appearance, and will accommodate a very large number of persons. The entire cost, exclusive of furniture, is under 5,500*l*. The appeal of the Weekly Board for help was rapidly responded to, with the result that only the comparatively small sum of 600*l*. requires to be raised to defray the expenses of furnishing and the making of a new road to the hall from Montgomery Terrace Road.

Successful Removal of the Spleen in a Dog.—Dr. Mercier, of the West Pennsylvania Hospital, Pittsburg, relates (*Philadelphia Medical Reporter*, May 31st) the case of a black poodle, a year old, and weighing about 15 lbs., from which the spleen was removed in 1875. It was gently detached from surrounding parts, leaving only a narrow pedicle, which was divided after being tied with silk ligatures. These were cut off short and allowed to remain in the wound. The incision of the abdomen was closed by six silver sutures. These were removed after two weeks, and the dog continued a house-pet for nine years, exhibiting no change in disposition and acquiring about double of its former weight. He was a good house dog, and in every way a healthy animal. He died suddenly after exposure to severe cold, January, 1884, the only lesion discernible being severe enteritis affecting the lower part of the small intestine. There was not the slightest trace of the spleen, nothing to denote its former locality, no remains of the pedicle, nor anything to show that nature had made the slightest attempt at restitution.

PRECAUTIONS AGAINST CHOLERA. — Writing to the National Health Society (44, Berners Street) with reference to the leaflet entitled "How to Prevent and Oppose the Cholera," which the society has prepared for house to house distribution by local authorities, the Local Government Board have announced that their Medical Department "are now preparing two other papers on the subject for the more immediate use of the Board of Trade and Her Majesty's Inspectors of Factories." These papers will, however, of necessity be somewhat technical, and unadapted for general distribution amongst the poor, which is the special purpose of the leaflet of the National Health Society.

APPOINTMENTS.

BENTHALL, W., M.B. Camb., M.R.C.S.—Honorary Physician to the Derbyshire General Infirmary.

CAIGER, F. F., M.B., B.S., M.R.C.S., L.R.C.P.—Resident House Physician to St. Thomas's Hospital.

COLLINS, E. T., M.R.C.S., L.R.C.P., L.S.A.—House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

FOWKE, FREDERICK WILLIAM, M. and L.R.C.P. Edin., M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Priors Marston District, *vice* Mr. F. W. S. Culhane, resigned.

GLOVER LYON, T., M.R.C.S., L.R.C.P. (Exten.)—Clinical Assistant in the Skin and Ear Department to St. Thomas's Hospital.

GREAVES, C. A., M.B. Lond., M.R.C.S., L.S.A.—Honorary Physician to the Derbyshire General Infirmary.

GREEN, C. D., M.R.C.S., L.R.C.P.—Assistant House Surgeon to St. Thomas's Hospital.

HUDSON, ERNEST.—Senior House Surgeon to the Royal London (Moorfields) Ophthalmic Hospital.

HULL, W., M.B., M.R.C.S., L.R.C.P.—Resident Accoucheur to St. Thomas's Hospital.

JAMIESON, CHARLES, M.B. and C.M. Glas.—Medical Officer to the Finchingfield District, Braintree Union, in the room of Mr. E. Dawson, deceased.

JOHNSTON, G. D., M.R.C.S., L.R.C.P.—Resident House Physician to St. Thomas's Hospital.

KNOX, D. N., M.B., C.M., F.F.P.S.—Surgeon to the Glasgow Royal Infirmary.

LAWSON, R., M.R.C.S., L.S.A.—Assistant House Physician to St. Thomas's Hospital.

MACKENZIE, H. W. G., M.A., M.B.—Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

ORFORD, J., M.R.C.S., L.R.C.P., L.S.A.—House Surgeon to St. Thomas's Hospital.

RICHARDS, WILLIAM, M.B., C.M. Edin.—House Surgeon to the Queen's Hospital, Birmingham, *vice* Charles Sanders, M.B. Lond., resigned.

ROBINSON, H. B., M.R.C.S., L.R.C.P.—House Surgeon to St. Thomas's Hospital.

STONE, F. W. S., M.R.C.S., L.R.C.P. (Exten.)—Non-Resident House Physician to St. Thomas's Hospital.

WITCHELL, E. A., M.B., C.M. Univ. Edin.—House Surgeon to the Stroud General Hospital.

VACANCIES.

COUNTY ASYLUM, SHREWSBURY.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Candidates must be registered practitioners, and not over thirty years of age. Applications, with not more six recent testimonials, to be sent to the Superintendent of the Asylum, from whom further particulars can be obtained, on or before September 1st.

DURSLEY UNION.—Medical Officer to the Third District, *vice* Mr. A. S. Connellan, resigned. Area, 6,410. Population, 2,157. Salary, £80 per annum.

GENERAL HOSPITAL FOR SICK CHILDREN, PENDLEBURY, MANCHESTER.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)

GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN, WESTMINSTER, S.W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London, and Graduates in Medicine of a British University. Applications, with Testimonials, to be sent to the Secretary, on or before September 6th.

HULL GENERAL INFIRMARY.—Assistant House Surgeon. Candidates must be fully qualified. Applications, with copies of testimonials, to be addressed, The Chairman, House Committee, not later than September 2nd.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer. (*For particulars see Advertisement.*)

ST. BARTHOLOMEW'S HOSPITAL.—Dental Surgeon. Applications with Testimonials must be left, on or before September 4th, at the Clerk's office. Further particulars from Wm. Henry Cross, Clerk.

ST. MARY'S HOSPITAL, MANCHESTER.—House Surgeon and Resident Obstetric Assistant. (*For particulars see Advertisement.*)

THE HOSPITAL FOR WOMEN, SOHO SQUARE, LONDON, W.—House Physician. (*For particulars see Advertisement.*)

UNIVERSITY COLLEGE, LONDON.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

DEATHS.

CUOLAHAN, HUGH, M.D., at 9, Grange Road, Bermondsey, on August 20th, in his 67th year.

EVERETT, D., F.R.C.S., late of Worcester, at Sydenham, on August 21st, aged 66.

HAVERS, J., F.R.C.S., at White Hill, Great Berkhampsted, Herts, on August 20th, in his 70th year.

HILLMAR, W., Brigade-Surgeon, A.M.D. (retired), at Beech House, Charmouth, Dorset, on August 19th, aged 51.

PEAR, G., M.D., late of Windsor, at 24, Park Crescent, Brighton, on August 21st, aged 78.

PEELE, RICHARD DE COURCY, Surgeon-Major (retired), at Ludlow, on August 23rd, aged 66.

POPHAM, J., M.D., late of the city of Cork, at Oxford House, Ealing, Middlesex, on August 26th, in his 79th year.

WESTMACOTT, J. G., M.D., L.R.C.S. Edin., of Howley House, Maida Hill, on August 23rd, aged 73.

NOTES, QUERIES, AND REPLIES.

At the Examination of Candidates for Her Majesty's Army, Indian and Naval Medical Services, the following were the questions :—

ANATOMY AND PHYSIOLOGY.—1. Describe the tibia, giving an account of the origin and insertion of the muscles arising from or inserted into it. Describe also the structure of the knee-joint. 2. Describe the abdominal aorta, giving an account of its relation to neighbouring parts. Enumerate its branches, and describe in detail the relation and distribution of those of the cœliac axis. 3. What are the sources of animal heat, and the nature of the mechanism by which it is regulated and distributed? Explain how it is that a mean temperature of the body is preserved under exposure to the influence of either extreme heat or extreme cold. 4. Describe the origin, distribution, anatomical relations and functions of the spinal accessory nerve and its branches. 5. Describe the dissection by which you would expose the parotid gland. Give an account of its connection and relation to the various neighbouring structures.

SURGERY.—1. What are the causes which give rise to extravasation of urine in the perinæal region? Describe the appearance of the parts in the various stages of extravasation; and the treatment; and the consequences of such an injury. 2. Describe the symptoms by which chronic inflammatory swelling of the testicle may be diagnosed from any other enlargement of that organ, and the treatment to be adopted for the relief of the first mentioned condition. 3. Explain generally what is understood by the term "Tertiary Syphilis." What tissues does it most frequently affect; and what should be the treatment under its various conditions? 4. What are the constitutional and local causes, and general characteristics, of gangrene affecting any portion of the lower limb in old age, independent of any severe accident; and what should be the treatment, according to the various stages or conditions of the malady? 5. Describe the conditions known as "Caries" of bone. What bones are most commonly thus affected, and what serious complications may follow when it attacks certain bones? What are the best local and constitutional measures to be recommended under these various circumstances? 6. Describe the appearance and conditions of a knee-joint when the seat of acute sinovitis; the treatment of such a case; and any unfavourable symptoms that may ensue when the acute state has subsided.

MEDICINE.—1. Explain the meaning of "vacciuation." Describe its purpose as first applied to the human race; and mention how, when, and by whom it came to be so employed. Explain what is meant by "primary vaccination," and what by "secondary vaccination" or "re-vaccination;" and describe the regular phenomena which follow each of these operations; also, describe the appearance of a perfect vaccine pustule, and of the scar which is typical of a genuine vaccination, and how its characteristic appearance is brought about. Explain, further, the "rationale" of "arm to arm" vaccination, and mention the age at which primary vaccination is to be doue; and the means necessary to secure its success. Lastly, explain how "sufficiency in amount" of vaccination is to be judged of; and how the operatiou is performed. 2. What are the indications afforded by the opthalmoscope in diseases of the brain, of its membranes, aud of the cranial bones? 3. What are the diseases which may be mistaken for "enteric fever," in the absence of the rose rash? and discuss the points in each case by which your diagnosis would be arrived at. 4. Describe the causation, morbid anatomy, histology, and treatment of "rickets." 5. Describe the causation, phenomena, and morbid anatomy of the various forms of febrile disease usually described as "puerperal fever." What are the indications for their treatment, prophylactic and curative; and on what grounds would you base a prognosis? 6. Name the officinal preparations of "ergot," and the doses of each. What are the chemical principles obtained from "ergot?" and in which of them resides the activity of the drug? Describe the physiological action, the remedial uses, and the mode of administration of the crude drug, and of those of its constituents which have been used.

ZOOLOGY, BOTANY, AND PHYSICS.—*Zoology:* 1. What are the classes of the "vertebrata?" Arrange these classes into two groups, in accordance with the presence or absence of an amnion during development. 2. Describe the stomach of a sheep, and enumerate the more important points of structure which are usually associated with this form of stomach in such animals as possess it. 3. In what order of birds are the wings so imperfectly developed as to be incapable of subserving the purpose of flight. Point out the leading features in the geographical distribution of this order. 4. Select any typical example you please of the "cœlenterata," and describe its structure. 5. Enumerate the principal points of difference as regards mouth-organs and wings between the following order of insects—"coleoptera," "hymenoptera," "lepidoptera." Give an example of each of these orders. *Botany:* 6. What are the essential, and what the non-essential, parts of a flower? Adduce one or more instances of flowers in which the non-essential parts are absent. 7. What is the difference between the fibre of "cotton" and that of "flax?" From what part of the plants yielding them is each obtained? 8. Define the natural order "rannuculaceæ?" Adduce from the pharmacopœia one or more examples of plants referable to this order. 9. What is "cyclosis?" Give some examples of this phenomenon. 10. What is "chlorophyll?" Mention the conditions necessary for its development. *Physics:* 11. What is meant by the "law of sines," as applicable to the refraction of light? 12. What is meant by the "dark lines" on the solar spectrum? How may these lines be accounted for? 13. State the evidence from which it has been inferred that various parts of the earth's surface are slowly undergoing changes of level. 14. What is "river delta?" Mention some of the principal river deltas of the world. 15. Explain the formation of "dew."

Tonsil.—Thanks for your reminder; the letter has been in consequence applied for.

A. B.—Never, that we know of.

COMMUNICATIONS RECEIVED—

Dr. D. B. LEES, London; Dr. CAMERON, M.P., London; Dr. SAUNDBY, Birmingham; Mr. HENRY NATHAN, London; Miss E. FAITHFULL, London; THE SECRETARY OF THE INTERNATIONAL HEALTH EXHIBITION, London; Dr. HOWE, Edinburgh; Mr. HASLEWOOD, Buxton; Dr. DE HAVILLAND HALL, London; THE SECRETARY OF THE NAVAL MEDICAL DEPARTMENT, London; THE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT, London; THE SECRETARY OF THE UNIVERSITY OF LONDON; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Mr. J. APPOINTMENTS FOR THE WEEK.

Friday, August 29 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, August 30.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, September 1.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, September 2.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Arsenic in Wall Papers and Articles of Clothing."

Wednesday, September 3.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m. London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Drinking Water."

Thursday, September 4.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, September 5.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Common Food Adulterations."

ON METAPLASIA.[1]

By PROFESSOR VIRCHOW.

In the first half of the present century medical men looked upon vital processes, both in health and disease, as essentially of a chemical nature. Life was thought to be bound up with certain substances, which existed originally in the body, and especially in the blood, in a fluid condition, and which, by assuming a solid form, made up the various parts of the organism. Even Schwann, in his celebrated cellular theory, adopted the view that cells are formed by a process of crystallization. The doctrines as to these substances and their formation into tissues first came from England where Hewson and John Hunter enunciated the doctrine of plastic lymph, and they were employed with considerable plausibility by Rokitansky in his system of humoral pathology; but they would scarcely have obtained any extensive acceptation had it not been that in physiology also the view had taken firm root that it was the liquor sanguinis (the intercellular fluid of the blood), or as Schulze appropriately termed it the *Plasma*, which was the ultimate cause both of formative and nutritive processes, processes which were accordingly regarded as identical. It is not necessary to point out in any further detail what important results this teaching had on medicine. In reality men had long seen that in every case treatment must, above all, aim at the regulation of nutrition. But it was the higher analysis of individual organic processes which first taught us to turn our attention away from all more or less hypothetical propositions.

When almost a generation ago I made the first step towards the cellular pathology, I put forward, as the basis of the new view, the axiom *omnis cellula e cellulâ*, which stood in distinct opposition to the old teaching that cells were formed of plastic material. For if the cells invariably originate from older cells, and are produced in no other way, all necessity to search for a blastema, or material from which cells are formed, ceases to exist.

It is also sufficiently evident that the nutritive process which goes on in cells already formed cannot be identical with the process by which cells are formed in the first instance, for the object of nutrition is to keep cells alive, whereas the formative process consists in one cell giving origin to other cells. There is therefore a manifest contrast between the nutritive

[1] Address delivered at the International Congress at Copenhagen.

or trophic, and the formative or plastic process, though the same material may be applied in one case to the nourishment of cells, and in another to the production of new cells. All organic activity takes place within cells, never outside them.

It is not necessary here in this assemblage to point out the autonomy of the cell. I will only define somewhat more exactly the notion of autonomous nutrition, by which I mean not the nutrition of the individual, but nutrition in connection with the separate cell. The idea of circulating material which is now used for individual, now for cellular nutrition, has done much to complicate matters, for "interchange of material" and "nutrition" by no means coincide with each other. There are, to wit, many forms of interchange of material which have nothing whatever to do with nutritive processes. Such is the interchange of material in dead parts. When a portion of the organism dies *in situ*, interchange of material by no means ceases; so much material is absorbed into the body from the dead part that the former may be exposed to serious dangers. Secondly, living parts take up and throw off material which is not in any way employed in nourishing them. For instance, during digestion the intestinal epithelial cells, and the cells of the liver absorb fat, which they give up again after a short interval. I have termed this active process "transit interchange," for it has no relation to the nutrition of the cells concerned in it.

Cellular nutrition is essentially a process of restoration; new material replaces that which has been used up, the autonomous cell taking up the nourishment required for its maintenance, which, however, it has first to elaborate within itself. From the nutritive, material, muscle cells form myosin, nerve cells neurin, and so on. We may call this a "plastic" process, but it is in every respect a different one from that to which we used to apply that term. The name "plastic," however, we ought to reserve for the formation of *new* elements, of *new* cells—a process which in old days we used to call assimilation.

But though we may keep up the distinction between nutrition and formation, there still remains a considerable array of phenomena, as to which it is difficult to know to what class to refer them.

Thus *growth* has not the preservation of parts for its sole object, whilst its result is by no means invariably the new formation of living elements. The difficulty depends on the fact that under the idea of growth are comprised two entirely different processes. For instance, in *hypertrophy* the cells, by taking up new material, grow larger and larger, while in *hyperplasia* we find an actual new formation either of cells, or at any rate, as in muscle, of nuclei. Both processes must therefore be kept separate; a nerve for instance grows by "nutrition," a blood-vessel on the other hand by "formation."

But there is yet another group of processes which cannot be treated in such a disconnected manner, and to which I especially wish to direct your attention today, as they are of the greatest practical importance. In their essence they are more closely allied to the plastic than to the nutritive process, for their final result is not so much the maintenance of parts as their organic metamorphosis, in other words the production of new forms of tissue. And yet they are not plastic in the common acceptation of the term, though, at any rate in most cases, new elements may be produced by them. I have, therefore, given them the name of "Metaplasia," and their characteristic is maintenance of cells with simultaneous change in the character of the tissue.

Metaplasias form the basis of important pathological processes, although they are not essentially of a pathological nature; on the contrary, they govern numerous phenomena of physiological life. Indeed, they have not only a considerable significance in the building up of the individual, but they form one of the postulates of the theories which are commonly comprised under the name of *Darwinism*. What embryologists call differentiation, and evolutionists transformation, fall in their chief points, though not exclusively, under the head of Metaplasia. The comprehension of these processes has not only been rendered more difficult thereby, but the processes which tend to produce complete organs have not been sharply enough defined from those whose final object may be the formation of new tissue. To take an example. The formation of bone takes place, as we all know, though comparatively seldom, during embryonic life; but bone is never produced directly from the formative cells of the embryo. First, a transitional tissue is formed, and from that—by Metaplasia—the bone itself, just as in the pedigree of animals which the Darwinians have drawn up, we travel very far down in the line of descent before we meet with animals provided with an osseous system.

The discussion, as to the nature of the tissue from which bone is formed, lasted far into the present century. But all now agree that in the formation of solid bone, its place is first occupied by soft tissue which, after conversion into bone tissue, still remains as a constituent thereof. When I began my studies I was taught that in bone-tissue there was always hidden cartilage, which could again be produced, either by morbid or artificial processes.

It has been very difficult to keep separate the idea of calcification and that of ossification. We know now that there exists calcified cartilage which is not bone-tissue. In ossification not only is lime taken up, but the whole organic basis changes character; solid bone contains chondrin-producing besides lime-producing tissue. Indeed, our present views are opposed to those previously held, inasmuch as it is now a question whether cartilage can as a rule pass into bone by transformation only.

The difficulty of coming to a right understanding on this matter lay chiefly before our time in faulty methods of research. A bone consists in fact not only of bone-tissue, but also of periosteum, of blood-vessels and nerves; more highly developed bones, of marrow and articular cartilage; in other words they constitute a complete organ. But even in this century observers in their researches paid no regard to bone as it exists in the living body or shortly after death; nay, first they *dried* it, and then, and not till then, they examined it. By this method the problem of the formation of bone-tissue (ossification) and that of the

formation of the bone-organ (osteogenesis) were treated as one.

Regarded in this way it is true that by osteogenesis bone originates from cartilage, for *young* bone is entirely formed out of cartilage, but in the later growth we find ossification with periosteum for basis, and at last formation of marrow (medullification) takes place.

How is the marrow formed? As long as men continued to examine dried bone, they looked on marrow simply as a jelly, which filled the bone cavity and medullary canals. Now we know that it is an independent tissue. But of what sort? We recognise three chief forms, red, yellow, and gelatinous marrow, but there is no doubt that these forms are only different conditions under which marrow may present itself. Thus, marrow is a tissue which may occur in *changing* characters, a marked example of Metaplasia.

Not only is marrow, however, subject to the law of Metaplasia; it originates by Metaplasia. The greater portion of this tissue, as it exists in the bones of the adult, was once bone-tissue. The formation of marrow arises by bone-tissue losing its lime-salts, and by bone cells being transformed into marrow cells. The medullary spaces in the midst of bone-tissue are formed in this way. If, owing to morbid conditions, this process goes on to a greater extent than normal, we have *osteoporosis*, and if the transformation proceeds yet further we speak of *osteomalakia*. But marrow may also be formed from cartilage, though this is seldom the case. The Metaplasia, however, which takes place from cartilage to fat is not as a rule direct; for red marrow (vascular and cellular marrow) is first formed, which, after a variable interval, is converted into yellow marrow (adipose tissue).

I may perhaps remark that the hesitation of many observers, as to the extent to which metaplastic processes take place in the bones, appears to me excessive. From this there have arisen the most extraordinary contradictions. All are agreed that in ordinary osteogenesis, the medulla, which has originated from cartilage, also produces the so-called osteoblasts, in other words the ostificers. On the other hand doubts have been raised anew, as to how far, in cases of fracture, the *callus internus* is produced by the ossification of marrow—whether the filling of the medullary canals with compact bone-tissue by osteosclerosis is due to the medulla. In my opinion, in both respects one goes too far. If you examine a transverse section of the epiphyseal cartilage in normal osteogenesis, you will definitely recognise that direct ossification takes place from the cartilage tissue as a starting point, in the same manner as in the diaphysis you see the formation take place from the periosteum; equally obvious in sclerosis is the successive formation of bone from marrow. The only defect in the demonstration is that you cannot see it all take place under the microscope. The investigators who in every organic process demand before all things vivisectional demonstration, appear to me to misapprehend the value of experiment in such cases.

We may pronounce without hesitation that bone-tissue in its widest acceptation is subject to metaplastic transformation, and that a considerable number of the processes in bone-formation and also in various morbid conditions depend on the fact that at certain times the tissue concerned assumes another character. Nevertheless the impossibility of explaining from an entirely nutritive standpoint the changes which go on inside the bone and metaplastic processes, is most evident from the series of investigations on the architecture of cancellous bone-tissue which have been made during the last decade, and which have taught us to what an extent the number and direction of the lamellæ is determined by the weight which is made to rest on the bone and the direction in which the latter meets it.

If, however, we are not satisfied with determining the final result of these processes, but must enquire how such architecture came about, it is evident that the cause is not a new formation of osseous lamellæ, but rather a new formation of marrow, which in certain directions dissolves by Metaplasia the existing bone-tissue, while in other directions it spares it. The process, indeed, is more intricate than I have described, but it is in its principal features rather a formation of marrow than a formation of bone. I am afraid, however, to tire you with a further exposition of it. This introduction must suffice to draw your attention to the metaplastic character presented by many of the processes which go on in bone. Bones form indeed a very happily chosen instance of Metaplasia, for they present a whole series of tissues for consideration—bone, cartilage, periosteum marrow in its three varieties—which can be mutually transformed one into another. These transformations have not, however, always the same significance. The secondary formation of marrow from compact bone-tissue represents the conclusion of the normal formation of bone, and is hence a progressive process. In Osteomalakia, in which the formation of marrow passes beyond the normal degree, the process must be regarded as a retrogressive one.

Next to bone there is no tissue which is so prone to metaplastic transformation as adipose tissue. Its metaplasia, however, is more uniform. Most frequently it is converted into mucous tissue. Thus in cases of injury to the spinal cord, whole layers of fat have been found changed into a jelly-like mass, which some have called colloid degeneration. In this as in other cases there occurs a metaplasia from adipose tissue into mucous tissue, in which the fat disappears from the cells, and the latter do not break down but are converted into mucous tissue. It is a retrogressive movement, in that the fat returns to the tissue like that from which it was formed in the embryo, and like that in which it existed after birth.

This transformation is by no means simple atrophy, such as occurs in general emaciation, in which the fat disappears, but is not converted into large masses of mucous tissue. The formation of it is greatly favoured in parts where, coincidently with the disappearance of fat, there is a solid environment to prevent the shrinking of the contained matter; for instance, in the interior of the bones, in the spinal canal, &c.

When there is partial hyperplasia, we may obtain a fatty tumour (Lipoma.) Lipomata sometimes contain parts which are markedly gelatinous, sometimes they are gelatinous throughout, although formed from adipose tissue. I have shown that in such cases they consist of

mucous tissue and have termed them myxomata. But as mucous tissue is normally a tissue which only occurs in the embryo, one may in a certain sense call a myxoma fœtal fat. Most of the mucous tissue in the fœtus is transformed by Metaplasia into fat; but besides this original primitive mucous tissue, there also exists a mucous tissue formed by Metaplasia, and from this myxomata may be produced by hyperplasia.

Similar experiences are of frequent occurrence in the case of tumours. Thus we know that there are numerous nævi, *i.e.*, congenital abnormalities of the skin, which later on become the starting point for the growth of tumours, either sarcoma or cancer; and these malignant neoplasms may be said in such a case to originate from a fœtal tissue. It is not, however, certain that all nævi are so-called "mother's marks," *i.e.*, congenital formations.

Chondromata, and especially the so-called enchondroma, often start from pieces of cartilage which have been displaced in the course of bone formation. Nevertheless these islets of cartilage, which simply remain lying unchanged in the cancellous tissue at the extremity of a bone, and even in the medullary cavities, are not congenital formations; on the contrary, they do not appear until from the first to the third year of life, and sometimes even later, and they must therefore be regarded as acquired formations.

Professor Cohnheim has applied this and analogous discoveries as the basis of a theory of the development of tumours, which differs from my own teaching in its exclusive character. He has assumed that all tumours grow from the remains of embryonic life, which have lain in the body without undergoing further change. But I think I may venture to say that we have not been furnished with sufficient proofs of such a universal origin. On the contrary, I think it must be admitted that many tumours date from changes which have not arisen until much later on in life.

There is one difficulty which has not hitherto been solved, viz., the fact that the examples of Metaplasia which we know of take place essentially between tissues which we must regard as akin or nearly related to each other, especially such as are richly provided with intercellular substance. The epithelial formations are also subject to Metaplasia, as, for instance, in the transformation of cylindrical epithelium into squamous epithelium, which, as I showed long ago, occurs in the decidua. There is little doubt that even the blood-forming tissues, *e.g.*, the red marrow of the bones, are formed at a later period of life.

It is now contended, however, that dissimilar tissue, tissue of another category, may also originate by Metaplasia; for instance, that in the liver connective tissue can be formed from epithelial tissue. I have not myself seen examples of this, nor, indeed, of the reverse process, Metaplasia from connective tissue to epithelium. There are two objections to such a view. The first is purely speculative, and consists in the fact that in the embryo the epithelial and connective tissues are formed from different layers. I cannot see, however, that this objection has much significance in the case of phenomena, the relations of which must be decided by experience. The other objection proceeds from investigators who think they have observed that epithelium only originates from epithelium. These observations, however, have not been placed beyond the possibility of doubt.

We now come to a question which is regarded by many as of the last importance—the question how far wandering cells, especially white blood corpuscles, may form the starting point of a new formation. Some believe that they possess an absolute metaplastic power, and can give rise to any and every form of tissue. It must, however, be admitted that there are limits even to the metaplasia of white blood corpuscles, which, by the way, are not the only cells that are able to change their position. Certainly, as far as observation goes, one must restrict one's ideas as to the power of the white blood corpuscle to form the starting point of new formations.

To return, I am convinced that even tumours of epithelial structure may arise by Metaplasia from connective tissue, though of course I have not been able to see the process take place under my eyes. The pathological anatomist can only infer Metaplasia from seeing different tissues encamped side by side, no experimental method of solving the problem having yet been discovered.

With these observations I must be content to leave the difficult question as to the possibility of a Metaplasia between dissimilar tissues, without being able to give any more definite answer. At present we can scarcely put forward a satisfactory solution of it. But it will be of considerable advantage if I have succeeded in bringing the question before a large circle, and laid the foundation for the consideration of many processes.

THE NATURAL PRODUCTION OF MALARIA AND THE MEANS OF MAKING MALARIAL COUNTRIES HEALTHIER.[1]

By PROFESSOR TOMMASI CRUDELI.

Gentlemen,—Before entering upon my subject, I must crave the indulgence of those of my colleagues whose language I have borrowed for any Italicisms that I may use, as well as for the foreign accent which must strike their ears more or less disagreeably. Desiring to respond as well as lay in my power to the invitation with which I have been honoured to discuss the hygienic questions relating to malaria, I have chosen the French language as being the one in which, apart from my mother tongue, I could express myself with the greatest ease and precision.

I shall be pardoned also, I hope, for having employed the terms "malaria" and "malarial districts" in place of the more commonly used expressions "paludal miasm" (*miasme paludéen*) and "marshy regions" (*contrées marécageuses*). The substitution is not a happy one from a literary point of view, but I have made it deliberately and for the following reason: The idea that intermittent and pernicious fevers are engendered by putrid emanations from swamps and

[1] An Address delivered at the Eighth Session of the International Medical Congress, Copenhagen, August 12, 1884. Reprinted from *The Medical Record*, New York.

marshes is one of those semi-scientific assumptions which have contributed most to lead astray the investigations of scientists and the work of public administrations. This idea, so widespread and so well established by the traditions of the school, is radically false. The specific ferment which engenders those fevers by its accumulation in the atmosphere which we breathe is not exclusively of paludal origin, and still less is it a product of putrefaction. Indeed, in every region of the globe between the two arctic circles there are swamps and marshes, steeping-tanks of hemp and flax, large deltas where salt and fresh waters mix, and yet there is no malaria there, although putrid decomposition is on every side. On the other hand, in the same parts of the globe there are places which are not and never were marshy, and in which there is not the least trace of putrefaction, but which, nevertheless, produce malaria in abundance. I reject, therefore, wholly the paludal assumption, and in order to express this view in the title of my paper, have been forced to employ terms which to my hearers may sound like Italicisms.

The Italians generally have not this paludal notion, for experience taught them long ago that malaria is produced nearly everywhere ; in marshy districts as well as in those which might almost be called arid ; in a volcanic soil as well as in the deposits of the miocene and pliocene periods and the ancient and modern alluvia ; in a soil rich in organic matters as well as in one containing almost none ; in the plains as well as on the hills or mountains. The word malaria (bad air), which it is the sad privilege of Italy to have lent to all languages to express the cause of intermittent and pernicious fevers, represents then, among the majority of our rural populations, the idea of an agent which may infect any sort of country, whatever may be its hydraulic and topographical conditions and whatever may be its geological formation. This word, therefore, is the one best suited to designate this specific ferment in question, and I have on this account employed it and its adjectival derivatives in order not to resuscitate the idea of the exclusively paludal origin of the morbific agent.

I shall not tarry long to speak of the nature of this ferment, for the studies bearing upon that point, although far advanced, are not yet completed. I may remark, however, that the idea that the ferment is formed of living organisms is a very old one, and has not arisen suddenly because of the modern theories of the parasitic nature of disease. From the time of Varrar (who believed that malaria was made up of invisible mites suspended in the atmosphere) to our own day this theory has been several times advanced by hygienists. Independently of the general considerations which led Rasori, and later Henle, to formulate the doctrine of the *contagium vivum* of infection (long before the progress of microscopical science had revealed the existence of living ferments), there were peculiar circumstances as regards malaria which should have impelled minds to look in that direction, even in times long past.

Some of these circumstances are of a nature to strike every serious observer, and deserve a few moments' attention. How could one maintain, for example, that this ferment is a product of chemical reactions taking place in the ground, when it is seen to remain constantly the same whatever may be the composition of the soil from which it emanates? As long as the paludal theory held sway the chemical interpretation of this identity of the product in every latitude was easy. Rica does not hesitate to admit that when a swampy tract is heated by the sun's rays to the necessary point for the putrid decomposition of the organic matters contained in it, the "chemical ferment," or rather the "mephitic gases," to which is attributed the morbific action, are developed, whatever may be the distance from the equator at which this marshy region lies. But since it has been ascertained that malaria is produced in soils of the most varied chemical composition, *the persistent identity of this product* has become chemically inexplicable ; while it is however readily conceivable, if one admits that malaria is an organized ferment which easily finds the necessary conditions for its life and multiplication in the most varied soils, as is the case with millions of other organisms vastly superior to the rudimentary vegetables which constitute the living ferments.

The same thing may be said of *the progressive intensity of the morbific production in abandoned malarious districts.* This fact has been historically proven in several parts of the earth, and especially in Italy. A large number of Grecian, Etruscan, and Latin cities, even Rome itself, sprang up in malarious territories and attained a high state of prosperity. First among the reasons for this success must be placed the works undertaken with a view of rendering these places more salubrious, which lessened the evil production, *but almost never extinguished it completely.* After the abandonment of these localities, the production of malaria recommenced in a degree which went on increasing from age to age, and which has rendered some of these places actually uninhabitable. This was seen, in the time of the ancient Romans, in Etruria, when it was conquered and laid waste, and in several parts of Magna Græcia, and of Sicily. From the fall of Rome even to the present day, this phenomenon has been manifested in a very evident manner in the Roman Campagna, in certain parts of which, even up to the time of the Renaissance, it was possible to maintain pleasure houses, but which are now uninhabitable during the hot season. In many cases the physical conditions of the soil have undergone no appreciable change during centuries, so that it is impossible to attribute so enormous an augmentation of malaria to an increase in its annual production, itself increased by a progressive alteration of the chemical composition of the soil. But if, on the contrary, it be admitted that malaria is caused by a living organism whose successive generations accumulate in the soil, the interpretation of this fact becomes very simple.

There are, finally, *peculiarities in the local charging of the atmosphere with malaria* which can be explained only in this manner. If the malarial miasm were composed of gaseous bodies emanating from the soil, or rather of chemical ferments formed beneath the ground and raised into the air by gases or watery vapour the charging of the atmosphere with the specific poison ought to arrive at its maximum during the hottest part of the day, when the ground is heated the most by the sun's rays and when the evaporation of water and all chemical actions attain their maximum intensity. But this is very different from what actually occurs. The local charging of the atmosphere is always less strong during the meridian hours than at the beginning and the end of the day, that is to say, after the rising, and especially after the setting of the sun. Now it is precisely at these hours that the difference between the temperature of the lower layers of the atmosphere and that of the surface of the ground is the greatest, and that the ascending currents of air starting from the ground are the strongest. If malaria consists of solid particles contained in the soil, one may readily understand how their elevation *en masse* into the atmosphere should take place especially at these two periods of the day.

All these facts, which can be easily verified if the subject of malaria be studied on the spot and without any preconceived notions, explain the tendency which has always been manifested to attribute this specific

*

poisoning of the air to a living organism which is multiplied in the soil; and they also explain the ardour with which hygienists have applied themselves to the production of the scientific proof.

Unfortunately the investigations undertaken for this end have for a long time been fruitless, for the preconceived paludal theory has led investigators to occupy themselves exclusively with the inferior organisms inhabiting marshes. Among these organisms they studied especially the *hyphomycetes*, which had already acquired so great an importance in dermatology; and their entire attention was concentrated upon the aquatic algæ, without even taking the precaution to determine whether the varieties which they thought to be malarial were found in all malarious swamps, or whether they were capable of living within the human organism. It has thus happened that each observer has indicated as the cause of malaria a different variety of alga, whichever he found to be most abundant in the swampy ground that he had to examine. Thus Salisbury has indicated the *palmella gemiasma*, which is found with us in places perfectly free from malaria, while it is often wanting in malarious marshes in the centre of Italy; Balestra, a species of alga which is as yet indeterminate; Bargellini, the *palmoglœa micrococca;* Safford and Bartlett, the *hydrogastrum granulatum;* and Archer, the *chitonoblastus œruginosus*. There is not a single one of these species the parasitic nature of which has been demonstrated; and as regards the two last named varieties, it can be positively denied that they are capable of producing a general infection, for the diameter of their spores and filaments is greater than that of the capillary blood-vessels.

It was only in 1879 that Klebs and myself, after having been thoroughly freed, by a long series of preparatory studies, from the unfortunate paludal idea, undertook together some investigations in malarious districts of the most varied character, marshy and not marshy. We employed the system of fractional cultivation, making experiments on animals with the final products thus obtained. We felt ourselves justified in recognizing the malarial ferment in the *schizomycete bacillus*. The numerous researches made subsequently by us, and by many other observers, in the soil and in the air of several malarious localities, as well as in the blood and in the organs of men and animals specifically infected, have put it henceforth almost beyond doubt that we really have to do with a schizomycete. Very recently, MM. Marchiafava and Celli have succeeded in demonstrating that the germs of this schizomycete attack directly the red blood-globules, and destroy them, causing them to undergo a series of very characteristic changes which admit of easy verification, and which render certain the existence of a malarial infection.

Several observations made recently in Rome tend to demonstrate that the schizomycete of malaria does not always assume the complete bacillary form described by Klebs and myself; but this morphological question possesses no further interest for the hygienist. For him the essential thing is to know that he has to deal with a living ferment which can flourish in soils of very varied composition, and without the presence of which neither marshes nor stagnant pools of water are capable of producing malaria.

We must not think, however, that all earth containing this ferment is capable of poisoning the superjacent atmosphere. Popular experience, certain modern scientific investigation, and the facts which one can often verify when the soil, which was malarious in ancient times and which has since ceased to be so, is turned up to a great depth, all agree in proving that the ground remains inoffensive as long as it is not placed in certain conditions indispensable for the multiplication of this specific ferment. Up to this point the organism lives, so to speak, in an inert state, and may remain so during centuries without losing any of its deleterious power. There is nothing in this fact that ought to surprise us, since we know that the life and the power of evolution belonging to the seeds of plants of a much higher order than these vegetable organisms constituting ferments, may remain latent for centuries, and may then revive at once when these grains are placed in the conditions suitable for their germination.

Among the conditions favourable to the multiplication of the malarial ferment contained in the soil, and to its dispersion through the superjacent atmosphere, there are three which are absolutely essential, and the concurrence of which is indispensable for the production of bad air (malaria). First, a temperature which does not fall below 20° C. (67·5° F.); next a very moderate degree of permanent humidity of the soil; and finally, the direct action of the oxygen of the air upon the strata of earth which contain the ferment. If a single one of these three conditions be wanting, the development of malaria becomes impossible. This is a point of prime importance in the natural history of malaria, and it gives us the key to most of the methods of sanitary improvement attempted by man.

Let us see first what can be done in this direction without the labour of man. For Nature herself makes localities salubrious by *suspending* for a greater or less time the production of malaria. It is thus that winter brings about in every country a freedom from malaria which is *purely thermic*, for it is due simply and entirely to a sinking of the temperature below the required minimum. Indeed, if the temperature in winter rises above this minimum, there are often sudden outbreaks of malaria. Sometimes during very warm and dry summers, the heat extracts all the humidity from the malarious soil, and thus procures for us a freedom from the disease, which is *purely hydraulic*. This may continue for a long time (as happened in the Roman Campagna during the years 1881 and 1882), but may also be completely destroyed by a single shower. Nature also sometimes renders a district healthy in a manner *purely atmospheric*, by covering a malarious soil with earth which does not contain the malarial ferment, or with a matting formed of earth and the roots of grasses growing closely together in a natural meadow.

In the attempts at purification by suspending the malarial action, which have been devised by man, the same thing has been done; that is to say, it has been sought to eliminate at least one of the three conditions essential to the development of the specific ferment contained in the infected soil. Naturally, they have not thought of bringing about a thermic purification, such as Nature produces in winter, because of the impossibility of moderating the action of the sun; but they have tried from all time to procure hydraulic or atmospheric purifications, and sometimes to combine these together in a very happy way.

The hydraulic systems are very numerous, for the problem which is presented, namely, that of depriving the ground of its humidity during the hot season, necessitates different solutions according to the nature and the bearing of the soil. Sometimes this is done by digging open or closing ditches intended to draw away large bodies of water. At other times a system of drainage is established, by means of which the water is drawn out of the earth, and its level is depressed, so that the upper malarial strata, exposed to the direct action of the air, are deprived of moisture during the hot season. This system of drainage is not a modern invention; the Italian monks understood it as well as, and even better than, we do. In deep and loose soils they used sometimes, just as we do now, porous clay pipes; but when

the subsoil was formed of compact and nearly impermeable matters, they employed a system of drainage, the extent and grandeur of which astonishes us. It is that of drainage by cavities, applied by the Etruscans, Latins, and Volsci to all the Roman hills formed of volcanic tufa, the tradition of which I have found still preserved in some countries of the Abruzzi.

We may sometimes establish a double drainage, from below and from above ; that is to say, drain the subsoil, and at the same time increase the evaporation of water from the surface of the ground. It is well known that clearing off the forests of malarious countries has often proved an excellent means of making lands salubrious which were before too damp ; for, by removing every obstacle to the direct action of the sun's rays upon the ground, we cause an increase of evaporation from its surface, and may thus be enabled to exhaust the superficial strata completely of their water during the hot season. In very moist lands which lend themselves readily to deep drainage, the combination of the latter with a clearing of the surface has, in almost every quarter of the globe, rendered possible a very widespread and sometimes quite lasting freedom from malaria. But, although a nearly universal experience proclaims this fact, there is a school which, following in the footsteps of Lancisi, maintains the contrary opinion, that it is necessary to preserve the forests in malarious districts, and even to increase their extent, since the trees filter the infected atmosphere and arrest the malaria in their foliage. This strange theory was formulated by Lancisi in 1714, on the occasion of the proposed clearing of a forest belonging to the Caetani family, and lying between the Pontine Marshes and the district of Cistema. Lancisi was completely imbued with the paludal notion, and consequently believed that the very severe malaria of Cistema was brought by the winds from the coast marshes, instead of being produced in the soil surrounding the district, which was then covered by this forest. He believed then that the forest acted as a protective rampart, and he prevented its being cut down. But towards the middle of the present century, the Caetani had the woods cleared off from the entire belt of land surrounding Cistema. Twenty years later I was able to show that Cistema had gained greatly in salubrity. I published my observation in 1879, and, naturally, was taken to task rather sharply in the name of the sacred tradition. Happily these recriminations led our Minister of Agriculture to have the question studied by a special commission. This commission, after a conscientious examination, extending over three years, of all the malarious localities in the province of Rome, has just published its report,[2] the conclusions of which are entirely in accord with the facts of universal experience. They were not able to verify a single fact in support of Lancisi's theory, while they found many of the same nature as that of Cistema, and which have resulted in overturning the theory entirely.

It has also been thought possible to practise drainage from above by means of plantations of certain trees which would draw considerable moisture from the earth, a method which might really be serviceable in some malarious districts. But in accordance with the idea that malaria is a product of paludal decomposition, the trees selected have almost always been the *eucalyptus*. It has been maintained that trees of so rapid a growth ought to drain the soil very actively, and also that the aroma of their foliage ought to destroy the miasmatic emanations. I have hitherto been unable to verify a single instance of the destruction of malaria by eucalyptus plantations, but I do not consider myself justified in denying the facts which have been stated by others. There is nothing to oppose the admission that these plantations, when properly made, may sometimes have been of great utility. I maintain frankly, however, that they have not always been so, and that it is necessary to guard against the exaggerations into which some have allowed themselves to fall in recent times. Such exaggerations might have been avoided if, instead of talking about these plantations on the basis of a theoretical assumption, the results only had been studied in places where the eucalyptus abounds. It would then have been known that even in the southern hemisphere, the original home of the eucalyptus, there are eucalyptus forests which are very malarious. This fact has been demonstrated by Mr. Liversige, professor in the University of Sydney, Australia. Among us, also, although everybody was convinced by the statements of the press that the locality of the Tre Fontane near Rome, had been freed from malaria by means of the eucalyptus, people were disagreeably surprised by an outbreak of very grave fever occurring throughout the whole of this colony in 1882, a year in which all the rest of the Roman Campagna enjoyed an exceptional salubrity. If, alongside of these hygienic uncertainties, we place the agricultural uncertainties, we must conclude that it is necessary to contend strongly against this fanatical prejudice in favour of the eucalyptus-tree. These plants are, in fact, very capricious in their growth. In full vegetation, during the winter in our climate, they are often killed instantly by a sharp winter frost, by damp cold, by the frosts of spring, or by other causes which the botanists have not yet been able to determine. At other times, if the winters are very mild, these plants grow too rapidly in height, and then are broken short off by moderately strong winds. It should further be mentioned that these plantations are sometimes very expensive. In fact, if the earth contains too much water, it must be drained under penalty of seeing the roots of the eucalyptus rot. Then, again, if the subsoil is compact, it is necessary to dig deep trenches in order to give room to the long roots of these trees, and often indeed these trenches must also be drained, as is done for olive-trees. The conclusion evidently is that it is better to confine ourselves to hydraulic methods of promoting the healthfulness of a locality, the immediate effects of which are less uncertain. And then, when the local conditions are such as to make it desirable to try the effects of plants possessed of strongly absorbing powers, it is better to choose them from among the flora of our own hemisphere. This is more sure, and will cost the less.

Simple hydraulic methods of purification, even the most perfect, do not, however, produce permanent hygienic effects, since the moisture necessary for the multiplication of the malaria in the soil is so slight that these effects may be compromised by anything whatever, that is capable of restoring a moderate degree of humidity to the ground during the hot season. It has often been thought that a suspension of malarial production would be better assured by suppressing at the same time the humidity of the soil and the direct action of the oxygen of the air upon the superficial strata of earth which contain the ferment. This has been successfully accomplished by the system of overlaying (*comblées*). This consists in covering the infected soil by thick layers of uninfected earth, carried there either by the muddy waters of rivers, or by the hand of man. At the same time the steady drainage of the surface and underground water is provided for. Last year, I advised our Minister of War to undertake in another form an hydraulico-atmospheric purification of the district of the Janiculum surrounding the Salviati palace on the via della Longara, by draining the soil carefully, and covering with a layer of very close turf all the parts of the surface which could not be macadamized. It would seem as

[2] Della influenza dei boshi sulla malaria dominante nella regiona marittima della provincia di Roma. Annali di Agricoltura, No. 77, 1884. Roma : Eredi Botta.

if this system had been rather successful, since there has not been this year a single case of fever in the *personnel* of the new military college, established in the Salviati palace ; while in the Corsimi palace, which is situated on the same side of the via della Longara, but which looks out upon that part of the Janiculum which is still uncovered, there have been some fatal cases of fever.

Furthermore, we have had in Rome, during the past few years, some very evident proofs of the efficacy of atmospheric methods of purification. I will confine myself to the relation here only of the most striking instance, one which has been furnished us in the building up of new quarters of the city. There was much discussion at first as to whether the improvements should be undertaken in the parts where they now are or in the valley of the Tiber, for the uncovered lands of the Esquiline and of the Quirinal were malarious, and, as nearly everybody then thought that the malaria of Rome was carried into the city from the coast marshes, it was supposed that this state of things was irremediable. We opposed to this view the fact of the salubrity of the Viminal, which is situated between the Esquiline and the Quirinal, and which ought to be as unhealthy as the two other hills were the malaria of the latter imported into the city instead of being indigenous. Believing it to be indigenous, we hoped that by shielding the surface of these hills from the direct action of the air (by building houses and paving the streets), the malaria would cease to be produced there. That is precisely what has happened, for the new quarters are very healthy. But the malaria is only held in abeyance, and is not definitely overcome ; for if an extensive excavation is made in these hills, and the contact of the air with the malarious soil is thus re-established, during a hot and damp season, the production of malaria commences anew. A complete atmospheric purification is nevertheless the most stable of all the methods of obtaining a suspension of malarial production, but, unfortunately, its realization is very limited, for it is restricted to inhabited localities and to sodden surfaces.

The ideal method of ensuring freedom from malaria should be to obtain a permanent immunity, that is, to be able to modify the composition of the infected soil in such a way as to make it sterile as regards malaria, without taking from it the power of furnishing products useful for the social economy. But all the elements indispensable for obtaining such a result fail us utterly just here. We do not yet know what ought to be, in general terms, the composition of a soil incapable of producing malaria, yet retaining those properties which are suitable for vegetation. When we have arrived at this first stage, there will still be a long road to travel ; and the most difficult part will be to discover a practical means of imparting this salutary composition to all the numerous varieties of malarious soils.

Scientifically, then, in the present state of our knowledge, we are unable to affirm anything on this point. Practically, we are not much further advanced. It is very probable that the combination of hydraulic purification with a forced cultivation of the soil has sometimes determined changes in its composition by which it has been rendered sterile as regards malaria. If that has happened, it has happened by chance, and we are unable to reproduce the result at will ; for we have not all the data which might enable us to understand how it has come about. Most of the purifications obtained in ancient times, by means of forced cultivation, continued during centuries, have not been definite at all, but the production of malaria has been simply suspended. Hardly was the regular cultivation of the fields interrupted than the production of malaria recommenced. Among the numerous examples that I might cite in this connection, I will limit myself to that of the Roman Campagna. This seemed to have been made permanently healthy under the Antonii, but after the fall of the empire it began again to produce malaria, as if the forced cultivation through so many centuries had never existed.

One might, strictly speaking, be content with such a result, and boldly undertake forced cultivation of all malarious districts, without stopping to ascertain whether the freedom from malaria so obtained would be definite, or whether the production of the poison were only suspended. Unfortunately, one is never sure of arriving at such a result, and no one can say *à priori* whether the forced cultivation of a given malarious tract will render it healthful. It must always ber emembered that the first effect of forced cultivation, which requires an overturning of the soil by means of the plough, the spade, and the pick, is an unfortunate one, from a hygienic point of view, whenever we have to deal with a malarious country. Experience has shown, especially in Italy and America, that this overturning of the soil almost invariably increases the local production of malaria. And this can be readily understood, since the ploughing and the digging in a soil containing the specific ferment increases the extent of surface of the ground in immediate contact with the atmosphere. This first mischievous effect is often gradually weakened by the continued cultivation, and may end by disappearing. At other times, on the contrary, it persists obstinately, and one is often forced in desperation to the resolve to level the ground again and to varnish it, so to speak, with thick sowing of grass, if one wishes to spend or weaken the malarial production.

However, when the local conditions will permit, it is well to try whether, by means of forced cultivation of the soil, it may not be possible to increase the efficacy of the hydraulic method of procuring immunity from malaria, or of the hydraulico-atmospheric method of "overlaying." The moment that it is known that this cultivation has frequently been advantageous, there comes forward a crowd of social reasons which induce us to attempt it, even though we are persuaded that we are about to engage in a game of chance. But to dare to attempt it is not all that is necessary, we need also the possibility of so doing, and just here we find ourselves in a vicious circle from which it is not easy to emerge. Forced cultivation cannot be accomplished without the presence of agriculturists in the region during the entire year ; and the agriculturists cannot remain in the region during the fever season, for they run thereby too great a risk. For the solution of this question there is but one means : *try to increase the power of resistance of the human organism to the attacks of the malaria.* It is to a search after the means of accomplishing this result that I have devoted myself during the past few years.

There is nothing to hope for, as regards malaria, in acclimatization. *Individual acclimatization* is, and always has been, impossible. The malarial infection is not one of those a first attack of which confers immunity from other attacks. It is, on the contrary, a progressive infection, the duration of which is indeterminate, and which is of such a nature that a single attack may suffice to ruin the constitution for life. Collective or *racial acclimatization* certainly existed in the past, at a time when specific remedies for pernicious malaria were unknown ; and even later, when the employment of these remedies was very limited. The acclimatization was due to a natural selection made by the malaria upon successive generations, from which it took away, almost without opposition, all those who possessed but a feeble individual power of resistance to the specific poison, while it spared those who possessed this power of resistance in an extraordinary degree. The first

were, according to the Grecian myth, *the human victims destined to appease the monster, or demon, who opposed the violation of the territory over which he had up to that time exercised an absolute sovereignty.* The second became the founders of the race, and through them, from generation to generation, the collective power of resistance to the malaria was progressively increased. In our own days a like selection may take place among barbarous races, as it does among the cattle and the horses in a malarious region, but it has become an impossibility among civilized nations. By means of the specific remedies which we possess, the use of which is now so general, the lives of a large number of individuals whose resisting powers are very feeble are preserved; and these individuals beget others whose power of resistance to the action of the specific poison is still more feeble. This results, after a number of generations, in the physical degradation of that part of the human race which inhabits malarious countries.

We cannot, therefore, in the future, count upon the assistance of external natural forces to increase the power of resistance of human society against the assaults of malaria. Such an object can be obtained only by artificial means. It has been sought to attain this end by the daily administration of the salts of quinine, of the salicylates, and of the tincture of eucalyptus, each and every one tried in turn. But the salts of quinine are dear, exercise a prompt, though transient, anti-malarial action, and, when administered for a long time, disturb rather seriously the functions of the digestive and nervous systems. The salicylates, when well prepared, are rather dear, and there is as yet no proof that they possess prophylactic powers against malaria. The alcoholic tincture of eucalyptus is useful in malarious regions (as are all the alcohols, beginning with wine) in quickening the circulation of the blood; may it, perhaps, also act as a preservative against light attacks of malaria? Possibly. But it is very certain that it possesses no efficacy in places where malaria is severe. It will suffice to prove this to recall the two epidemics of fever which afflicted the colony of the Tre Fontane, near Rome, in 1880 and 1882. Everybody was attacked, and there were several cases of pernicious fever, although a good preparation of eucalyptus is manufactured in the place and is distributed largely to the colonists during the dangerous season of the year.

Having several times had occasion to observe, in malarious regions, that when recourse was had to arsenic in order to subdue fevers, over which quinine had exerted almost no effect, relapses occurred but rarely; and having been able to satisfy myself that the arsenical treatment sometimes procured a permanent immunity in individuals who are subject to frequent attacks of malaria, I began in 1880 to employ arsenic (arsenious acid) as a prophylactic in certain portions of the Roman Campagna. This remedy was indicated, in an experiment of this sort, not only by reason of its durable anti-malarial effects, but also by its low price, by the beneficial influence which it exerts upon all the nutritive functions, and because it has no disagreeable taste and may therefore be given to everybody, even to children. My first trials in 1880 were rather encouraging, and I felt myself justified in engaging some proprietors and the association of our southern railroads to repeat the experiment on a large scale the following year, recommending them, however, to use arsenic in a solid form as offering an easy and certain dosage. This extensive prophylactic experiment began in 1881, and acquired constantly increasing proportions in 1882 and 1883, which have become still larger this year. An experiment of this kind is not easy to conduct in the beginning. The name, arsenic, frightens not only those whom we desire to submit to its action, but also the physicians, whose exaggerated fears have sometimes rendered the experiments of no avail, since they were conducted too timidly and the doses of arsenic employed were altogether insufficient. But some intelligent men, especially M. Ricchi, physician-in-chief to the southern railroads, were able speedily to triumph over these obstacles, and to place the experiment on a firm basis. The general testimony of all the facts which they have collected tends really to prove that, when the administration of arsenic is begun some weeks before the presumed season for the appearance of the fever, and when it is continued regularly throughout the whole of this season, the power of resistance of the human organism to malaria is increased. Many individuals gained thereby a complete immunity, others a partial immunity, that is to say, they were sometimes attacked by the fever, but it never, even in very malarious districts, assumed a pernicious form, and was easily subdued by very moderate doses of quinine. Last year, for example, in the district of Borino, where the malaria is very severe, M. Ricchi experimented upon seventy-eight employés of the southern railroads, dividing them into two equal divisions, one of which received no prophylactic treatment, while the other was submitted to a systematic arsenical treatment. At the end of the fever season it was found that several employés among the first half had been attacked by fevers of a severe type; while thirty-six of those in the second division had enjoyed a complete immunity, the three others having been attacked, but so lightly that they cured themselves by quinine without seeking medical aid.

Facts of this sort are very encouraging, and the more so as the general health of those submitted to the prophylactic treatment was much improved. It was found almost invariably, upon the termination of the experiment, that there had been an increase in bodily weight and an amelioration of the anæmia which is so common in malarious districts. But, in order to arrive at such results, it is necessary to be at once bold and prudent. On the one hand it is necessary to graduate very carefully the daily dose, never exceeding at the commencement the dose of two milligrammes ($\frac{3}{100}$ grain) per diem for adults, and never giving the arsenic upon an empty stomach. On the other hand, it is necessary to gradually push the dose up to ten or twelve milligrammes ($\frac{15}{100}$ or $\frac{18}{100}$ grain) a day for adults, in districts where the malaria is very severe, giving the arsenic in such a way that there is never an accumulation of the drug in the stomach. Most of the experiments which have been undertaken this year are being conducted on this plan, and there is reason to hope that they will give satisfactory results.

We must not, however, rest here if we wish to attain promptly the end proposed, namely, that of planting colonies in malarious districts without exposing the colonists to grave danger. Even if we realise perfectly the hope which I conceived in 1880, and if we are enabled to prove that arsenic increases man's power of resistance to the assaults of malaria, we must not imagine that everything is accomplished. It will take a long time before the use of a preservative method of this kind becomes generalised, we have first to contend against the fear which nearly everyone experiences when arsenic is mentioned, and then there will also be difficulty in establishing everywhere a proper control over its administration. In every attempt at the colonisation of malarious regions it will be necessary to combat for a long time the diseases caused by malaria, and we must seek for a method of combating them by a means which is in the possession of everybody, and which shall not be dangerous to the general economy of the human organism. Those who do not know from actual experience the miseries of a malarious country, think only of combating the acute

forms of infection, which often place the patient in danger of death. But this danger, though great, is for the most part imaginary, provided that assistance be obtained in time. But that which desolates families, and which causes a physical degradation of the human race exposed to the attack of malaria, is the chronic poisoning, which undermines the springs of life and produces a slow but progressive anæmia. This infection often resists all human therapeutic measures, and is even aggravated by the use of quinine, which is given during the recurrent paroxysms of fever. Quinine is, when given for a long period of time, a true poison to the vaso-motor nerves. The question, then, is to replace quinine, and the alkaloids which possess an analogous physiological action, by an agent the efficacy of which against chronic malarial poisoning may be greater and the dangers of its employment less.

A happy chance has led Dr. Magliori to the discovery of an agent of this sort, which was traditionally in use by certain Italian families. It is an exceedingly simple thing—merely a decoction of lemon. It is prepared by cutting up one lemon, peel and all, into thin slices, which are then put into three glassfuls of water and the whole boiled down to one glassful. It is then strained through linen, squeezing the remains of the boiled lemon, and set aside for some hours to cool. The whole amount of the liquid is then taken fasting. It is well known that in Italy, Greece, and North Africa, they often use lemon juice, or a decoction of lemon seeds, as a remedy in malarial fevers of moderate intensity; and in Guadaloupe they use for the same purpose a decoction of the bark of the roots of the lemon tree. All these popular practices tend to show that the lemon tree produces a febrifuge substance, which resides in all parts of the plants, but which would seem to be most abundant in the fruit. In fact, among the popular remedies employed against malarial infection, that which I have just described is the most efficacious, for it can be employed with good effects in acute fevers. But it is especially advantageous in combating the chronic infection, which is rebellious to the action of quinine, and in removing or moderating its deplorable effects.

Hardly had I learned of this method of medication, when I hastened to induce some proprietors in the Roman Campagna to try it with their farm hands; and, after witnessing the good results there, I endeavoured to persuade practitioners to make a trial of the same treatment. I was ridiculed a little at first, for they thought it rather singular that a professor should be trying to popularise an old woman's remedy. In reply to that I answered that practical medicine would not have existed had it not known how to treasure up from age to age the facts of popular experience; and I ventured to remark that had the Countess de Chinchon waited until methodical researches had been made into the physiological action of cinchona bark, before popularising the remedy, the use of which she had learned from the semi-barbarous Peruvians, in all probability humanity would still, as regards malaria, be dependent upon the medication practised in the middle ages. Happily these arguments had the desired effect upon certain distinguished practitioners, some of whom, especially in Sicily and Tuscany, have already collected together a tolerably large number of very encouraging observations. One of them, Dr. Mascagni, of Avezzo, tried the remedy in his own person, and succeeded in promptly curing an obstinate malarial fever which had resisted the action of quinine.

Gentlemen, in dealing with malaria we ought always to hold popular experience in high esteem, for we owe much to it. We owe to it the fact that we have been liberated from the paludal idea, and, furthermore, that we have learned that it is often better, instead of trying to prevent the importation, for the most part imaginary, of malaria from distant marshes, to suppress its production in the soil under our feet or in that immediately surrounding us. We owe to it the knowledge, which we now have, that malaria rises up into the atmosphere only to a limited height, so that by placing ourselves a little above this limit in order to eliminate the possibility of the malaria being carried up to us by oblique atmospheric currents, we are enabled to breathe an air which does not contain this ferment, or which contains it only in insignificant amounts; thus one may even sleep in the open air during the night in very unhealthy districts without running any risks. The knowledge of this fact has led some peoples of Greece, and the inhabitants of the Pontine Marshes, to sleep in the open air on platforms raised on poles four or five metres (twelve to fifteen feet) in height. Some people in the Roman Campagna have built houses for themselves on the top of the ancient tombs, the walls of which are perpendicular; the American Indians fasten their hammocks as high up as possible to the trees of the malarious forests; and very recently the engineers of the Panama Railroad had little wooden huts built in the trees in order to procure safety against the terrible outbreak of malaria which occurred during the construction of that iron way. We owe, finally, to this popular experience the discovery of the specific action of quinine, and the consequent preservation of thousands and thousands of human lives. Why should we reject *à priori* and without investigation other useful data which it may yet present to our consideration? If we wish to make progress in this question of rendering malarious countries healthy, we must always hold before our eyes a double object: to find a means of prophylaxis which may be accessible to everybody; and at the same time, to find a means, equally within everybody's reach, to overcome chronic malarial poisoning and its evil consequences. Science is still too far behind to permit us to hope that we shall soon succeed in discovering this second means by purely scientific researches. We ought, therefore, to gather together with great care all the facts which point to the possibility of a solution of this problem, and if the measures to which these facts point seem to be incapable of doing harm, we ought to try them boldly, and not be restrained by a false idea of the dignity of science. The social importance of the problem is too great to allow of its solution being retarded by the fear that scientific men may be accused of having been outrun by the ignorant. True science has none of these puerile susceptibilities; on the contrary, it deems it an honour to be able to seize all the observations of fact, whoever may have been their first recorder, to put them to the crucial test of methodical experiment, and to convert them into a new stepping-stone on the march of human progress.

HYDRO- PYO- AND HÆMATO- SALPINX.

By LAWSON TAIT, F.R.C.S.

Miss E. L. came under my care in October, 1873. She was then 28 years of age, and had been a sufferer from the time menstruation began, at the age of 15. Her menstruation had been fairly regular, but had been always profuse, intensely painful, and was accompanied by the passage of shreds of membrane almost every month. At first she obtained relief when she passed the shreds, but at the time I saw her even when they did pass, relief was not obtained. The uterus then was hard, anteflexed and somewhat larger than normal, as the sound entered three inches. She informed me that for three years she had been from time to time under the care of Mr. Spencer Wells,

by whom a variety of treatment, by pessary and otherwise, had been employed, but only with the result that she became worse instead of better. She had an intercurrent leucorrhœal discharge, which was occasionally very profuse.

I regarded the case at the time as one of chronic endometritis, and I recommended that the uterus should be dilated and the mucous surface destroyed by chromic acid, and this treatment I carried out within the next week. For some considerable time after this she greatly improved, and she could get about in a way she had not been able to do for three years. She came back to me in October, 1874, as bad as ever, if not worse. The menstruation was now scanty, and only small fragments of skin were passed; but her pain during the period was intense, even inducing vomiting, and entirely preventing her from walking. The intercurrent leucorrhœa was very considerable, and therefore I tried intra-uterine applications of strong carbolic acid, with a long list of internal tonics for twelve months, and during that time she slowly improved so much as to be able to endure one of Mr. Spencer Wells' anteflexion pessaries. In October, 1875, the leucorrhœa had almost gone, her pains were very much relieved and she was able to get about for a fortnight in each month, but during the other fortnight she was very easily fatigued and pain was soon brought on by exercise.

She came to me again in April, 1876, after having had three very profuse periods in February, March, and April, but with less pain and more intercurrent leucorrhœa. I therefore resumed the carbolic acid treatment with relief to her throughout June, July, and September. In November, 1877, she again returned to me, telling me she had been fairly well until the previous May, when in June something seemed to go wrong again. Her periods became very profuse, lasting from ten to fourteen days, intensely painful, followed by a profuse yellow and very offensive discharge. The former treatment with some variation was resumed and carried on until December, 1879, but even then, although the treatment was to a certain extent successful, she was totally unable to walk more than a few hundred yards or to stand for more than a few minutes. I did not see her again till September, 1880, when I found that although she had been somewhat better in the spring she was worse in every way. For the previous four months she had been rarely free from menstrual flow for more than a few days at a time, and her last period had gone on for three weeks. Looking back at the experience of the previous seven years, during which I had done my best to relieve her without success, recognising the fact that her existence was a burden to herself, and a serious tax on her relatives, I advised the removal of her uterine appendages. My proposal was discussed at great length with some medical gentlemen who were concerned in her case more as friends than as responsible advisers, and also with a number of her relatives, and it was ultimately decided against. When this decision was announced to me, I declined to undertake any further responsibility in the case, and I asked her friends to place her under some other care.

What happened to her between that time and June, 1883, I do not know, and have never cared to inquire, but I have every reason to believe that many and able efforts were made to relieve her. But this I do know, that whatever was done was fruitless, for she came back to me at the latter date, a woman of 38, but looking more like 60, thin almost to emaciation, with a haggard, pinched face, hair almost white, constantly confined to the recumbent position and never free from pain. She asked me to resume the responsibility of her case and do with her as I thought best. On August 27th I performed abdominal section. I found the contents of the pelvis a good deal matted together, the uterus hard and somewhat above the normal size, both tubes occluded and densely adherent, that on the right side being distended by about two drachms of pus, and in the left a similar quantity of serum. The ovaries were small, cirrhotic, and densely adherent. The operation for the removal of the appendages was a very difficult one, but she made an extremely easy recovery and went home on September 27th. I saw her on the 8th of April last, looking very well, and she was able to walk a couple of miles. She had not had the slightest appearance of menstruation since the operation and had only slight occasional pains in the stumps. I have just had a letter from her (July 14th, 1884), from which I take the following sentences: "I am visiting my married sister, and it is delightful to feel well enough to enjoy the baby and go out to see friends. I often send a grateful thought to you, especially when I contrast my feelings with those I had last year at this time. Everybody says I have renewed my youth."

On looking back upon this case, my feeling of regret is strong that the operation I performed on her last year was not performed ten years before. From what I now know of similar cases I am perfectly satisfied the condition she was in when I first saw her would have absolutely justified the proceeding to which she had ultimately to submit. I cannot, of course, be certain that at that time she suffered from hydro- and pyo- salpinx, but I am certain she was the subject of conditions which led up to them—that she was then the victim of incurable chronic inflammation of the ovaries, and that in all probability what was done to her by Mr. Spencer Wells, by myself, and by others, had only for their effects permanent increase of the mischief even though temporary alleviation was obtained. This case forms, in fact, a typical example of a large class who are subjected to useless and torturing treatment for years without real benefit, and to whom removal of the uterine appendages comes as the only relief after years of distress and treatment at once expensive and unavailing. At the International Medical Congress, Mr. Spencer Wells said he had only seen one case which justified the operation to which this case was subjected, yet he had seen this case, and I expect very many quite similar.

A. H., aged 31, came under my care in December last. She had suffered for many years from irregular and profuse menstruation; sometimes her periods lasted as long as fourteen days. For three or four days before each period she suffered pain so intense as to induce vomiting and render her wholly unfit to follow her usual employment as a dressmaker. She informed me that she had been under the treatment of several institutions in Birmingham and two in London, one of these being Guy's Hospital. She had been repeatedly told that she had chronic inflammation of the womb and a falling backwards of the organ, and for this she had received treatment by pessaries at the hands of no less than seven different practitioners, but in spite of their united efforts she obtained no relief but in fact she grew steadily worse. On examination I found a tender mass running behind and on each side of the uterus precisely of the kind which I have myself on too many occasions mistaken for retroflexion and which I have seen mistaken by others in some dozens of instances. Pressure upon this mass at once induced a dull sickening pain, and the use of the sound revealed the fact that it was not the fundus of the uterus, but in all probability the chronically inflamed uterine appendages which constituted it. I advised her to submit to an abdominal section, but this she declined and she went away again to London. She came back to me in April, ready to submit to anything, and I operated

upon her on May 1st. I found both tubes occluded and distended with serum, and they, together with the ovaries, were firmly bound down behind the uterus. I removed both appendages. She made an easy recovery, and although she is not yet entirely free from pain her menstruation has been completely arrested.

M. J. H., aged 25, was sent to me by Mr. Holmes, of Derby. She had been married five years, had had one child and one miscarriage four years ago, at the sixth month ; after that miscarriage she had an illness which, from the history, was probably an attack of pelvic perimetritis, and she had never been well since. Her periods were very irregular, profuse, and intensely painful. A variety of treatments had been employed without giving her any relief. I could feel the distended tubes on each side of the uterus, and I advised their removal. The operation for this I performed on May 27th, and I found both tubes occluded, densely adherent, and distended with serum. Her recovery was an easy one, and on the 24th June she left the hospital.

M. W., aged 23, was sent to me by Dr. Cunningham. She had been married three-and-a-half years, had had a miscarriage two years ago at the third month, and had never been free from pain after that time. After the miscarriage she had an inflammatory illness, and she had been almost continuously unwell ever since. When pressed upon on the left side, I found the uterus fixed in the pelvis and extremely sensitive to the touch. I advised an abdominal section which was performed June 7th. The contents of the pelvis were all matted together, and the appendages were separated with great difficulty. Both tubes were occluded and distended with purulent serum. She made an easy recovery, and went home at the end of the month.

L. D., aged 27, had been married four years, had one child three years ago. She had never been well since. She came to see me for the first time in February last. Her periods came on every fortnight or three weeks, and lasted for about four days. They were not profuse, but they were accompanied by agonizing pain, which came on three or four days before each period. I found the uterus somewhat fixed and slightly retroflexed, but on either side of it were fixed tender masses, which could easily be recognised as the uterine appendages altered by chronic inflammatory disease. Dr. Gibson, who sent her to me, communicated the information that she had been in the Middlesex Hospital, under the care of Dr. Arthur Edis, who wrote to him to the effect that she suffered from prolapse of the left ovary, retroflexion of the uterus, and cervical endometritis ; that he had replaced the uterus and ovary, inserted a ring pessary, and slit the cervix. Under Dr. Gibson's care she had been using astringent injections and taking bromide of potassium and ergot, but without benefit. Dr. Gibson had found her temperature was subject to occasional exaltations. I wrote to Dr. Edis about the case, and he was kind enough to let me know that she had been in the Middlesex Hospital under his care in November last, that when he had got the uterus replaced it was noticed that the tubes were distended, and that they were responsible for her sufferings. He wrote to me —" I advised trying the ring for a time, and had I had your experience should have proposed the operation you have performed, but I am now only beginning to appreciate it. I quite approve of your treatment, and you are at liberty to mention my name." The removal of the appendages was performed June 7th. As usual they were found densely adherent. Both tubes were occluded and distended with serum, and the operation was a difficult one. She made an easy recovery and went home July 8th.

(*To be continued.*)

ON EPIDEMIC CHOLERA.

By ALEXANDER HAMILTON HOWE, M.D., F.R.A.S.

Madras Medical Establishment.

As the attention of the public and the profession is being now strongly directed to the subject of cholera. I may be permitted to advert to the circumstance that in a work published by me in 1865, I distinctly stated, from a historical deduction extending over many centuries past, that severe epidemic visitations of a general character observe a certain well-defined law of periodic return. In this respect epidemic visitations only follow the universally accepted fact in regard to the regular return of the phenomena in the other departments of physical science. In the work alluded to I further stated that the phase of periodic return occupied a period of eighteen years, subject, however, like all other natural phenomena to an occasional deviation of about one year on one side or the other of eighteen years. That is to say, that they might anticipate (like an ague fit) and appear in the course of seventeen years, or they might procrastinate (also like a fit of ague) and not appear until after an interval of nineteen years. All these circumstances are quite in accordance with the phenomena observed in other departments of Nature.

Now your readers are well aware that the cholera has been prevailing on the shores of the Mediterranean during the years of 1882 and 1883. And now, in 1884, it is not only existing on the shores of the Mediterranean, but spreading more generally throughout Europe, although certainly not to any very alarming extent, and is even exciting apprehension in our own country. This is entirely in accordance with the theory laid down in my book,[1] which I now no longer regard as a theory, but as an established fact.

There are certain circumstances opposed to the reception of this theory by the medical profession. In the first place, the virulence of all epidemics has a tendency to wear itself out in the course of time and become comparatively innocuous until they finally disappear, so far as that particular specific form is concerned, altogether. In the second place, the improved sanitary measures which have been adopted by all the States of Europe must have a tendency to prevent epidemic disease from establishing a footing in those countries where sanitary precautions have been rigidly ordained and enforced. Thirdly, the peculiar state of the atmosphere induced by the periodic cause, and upon which I conceive the disease to depend, is quite beyond the province of the medical enquirer. Consequently the medical critic cannot be considered as a competent judge, and, so far as I am aware, he is as yet unable to establish any other alternative cause.

I do not mean to depreciate or disparage the researches that are being conducted by scientific men with a view of discovering the recondite phenomena upon which they consider cholera to depend. These researches do not at all interfere with the periodic law of return every eighteen years which I have ventured to announce, a law which is as plain and palpable to the peasant as it is to the philosopher, and which warns Governments at intervals of eighteen years to adopt more stringent sanitary regulations than those usually in force at other times.

Since the year 1865 my theory of the periodic return has been on its trial and has been confirmed both

[1] A Theoretical Enquiry into the Physical Cause of Epidemic Diseases. By Alexander Hamilton Howe, M.D. London : Churchill & Co., 1865.

negatively and positively. In the first place, no great epidemic of cholera visited Europe between 1865 and 1883. In the second place, an epidemic of cholera has been prevailing in Europe during 1883 and now again in 1884. In these two ways then I consider that the theory I propounded of an eighteen-year phase of the cholera return has been completely substantiated. I may mention that this phasal theory of epidemics is not altogether new, for Sydenham had already proposed a forty-year phase for the plague. The great objection to the period assigned by Sydenham is that there is no natural phenomenon likely to affect our atmosphere that occupies a period of forty years; whereas every eighteen years there is the recurrence of natural phenomena which are likely most powerfully to affect our atmosphere, which, with the older physicians, I regard as the medium for the dissemination and propagation of the pestilence.

I do not presume to determine what is the proximate cause of cholera All that I have attempted to do is to show that at intervals of about eighteen years certain remote causes come into operation which favour the propagation and spread of cholera, and that these epidemic phases can be foreseen and calculated, and governments and local authorities warned to anticipate, prevent, and eventually stamp out the disease. But if this periodic return of epidemic disease is so very regular as I have described it to be, how is it that it has so signally eluded the observation of other enquirers who have been so sedulously directing their attention to the subject of epidemic visitations? This apparent oversight on the part of medical enquirers is very easily accounted for. Previous to the great epidemic epoch, the plague of London of 1665, plague and pestilence had been frequent visitors of our English towns, and Sydenham distinctly states that it visited England every forty years. But between the plague of London of 1665, called the Great Plague (for there was an occurrence of plague in London in 1683, although perhaps not in so marked a degree) and the appearance of cholera in England in 1831, there occurs a period of no less than 166 (one hundred and sixty-six) years apparently without the appearance of any epidemic visitation whatever. It becomes, therefore, a necessary part of the theory which I have endeavoured to propound, in order that its truth may be fully established, to account for this cessation in the appearance of epidemic visitations during this long period of 166 years. Now this, so far from being evidence of failure of the truth of the theory, is one of the very strongest proofs in its favour. And it is of some consequence to dwell upon this fact, for upon it depends the inability of the great body of medical enquirers to recognise the periodicity of epidemic returns. Previous to the year 1660, and even for several years afterwards, for anything I can discover to the contrary, there existed in England, and I presume in other countries also, a Levant Company. Now we can easily understand how pestilences which usually have their origin in the East would be brought by this Levant Company—in their goods and agents—to England, and disseminated in the other countries of Europe by the same agencies. This fact will sufficiently account for what has been called by Hecker "The Plague of the Middle Ages," and treated by him at great length. But the year 1600 inaugurated a new era in Oriental trade. The English East India Company was formed, the Mediterranean route to India was abandoned, and East India produce and goods and passengers were brought round the Cape of Good Hope.

It is not necessary for me to dilate upon this subject, but I think I have offered a sufficient reason for the disappearance of pestilence, from Great Britain at least, for a long period after the adoption of the Cape of Good Hope route to India. It is hardly possible that the seeds of epidemic pestilence could survive a period of six months, usually at that time consumed in a voyage home from India.

Again, the period which elapsed between the Great Plague of London in 1665 and the cholera visitation of 1831 amounts to exactly one hundred and sixty-six years, that is nine revolutions of the phase of eighteen and a half years, and is quite in accordance with the theory that I have propounded, and is one of the strongest proofs in its favour. Since the year 1831 the chain of sequences in the return of epidemic diseases at the interval I have specified has been quite complete. And why? Simply because the Mediterranean route to India has been resumed, at least ever since the commencement of the present century, and other European countries, such as Russia, have had much more intimate connection with Persia, China, Tartary, and other Oriental countries during the present century than ever they had before. These reasons seem quite sufficient to account for the European pestilences of the Middle Ages, the almost complete disappearance of pestilence during the long period of 166 years, and finally its renewed appearance in our days in the countries of Europe under the form of epidemic cholera, at regular intervals, and the failure on the part of the general body of the medical profession to recognise the periodicity of its return.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

EAST LONDON HOSPITAL FOR CHILDREN.

CHRONIC DISEASE OF KNEE — EXCISION —SOFT FIBROUS UNION—AMPUTATION—REMARKS ON "CONSERVATIVE" SURGERY.

(Under the care of Mr. R. W. PARKER, Surgeon to the Hospital.)

JOHN R., æt. 6½ years, whose father had just died of "rapid consumption," æt. 35, was admitted with chronic disease of the left knee-joint. The leg was much flexed on the thigh, but there was no displacement of the head of tibia on the condyles of the femur. After getting the leg into a good position, it was put into a fixative dressing, and the boy was sent to St. Leonards, where he remained five weeks. He was re-admitted in January, 1883. His general health had improved while at St. Leonards, but the knee remained *in statû quo*. The leg was again greatly flexed on the thigh. He started occasionally in his sleep; the knee was swollen, and painful when moved or handled. There was a sense of semi-fluctuation in the joint, which was believed to be "pulpy" thickening of the synovial membrane.

February 2.—After consultation it was decided to open up the joint and explore. This being done, about one ounce of thick caseous pus escaped; the synovial membrane was everywhere very much thickened, and the cartilage of the joint eroded in many places. A thin layer was removed from the tibia and from the femur, the bone thus exposed appearing somewhat soft and fatty, but not materially diseased; it was very vascular. The diseased synovial membrane was then carefully removed. After ligature or torsion of a few smaller vessels, the whole joint was swabbed out with chloride of zinc lotion. A drainage tube was inserted on each side, and the flaps brought carefully together. The limb was put on an excision splint

carefully padded with carbolised-waxed lint, and fixed with bandages soaked in the same mixture, the whole dressing being impermeable to secretions, the operation being carried out with Listerian precautions.

February 9.—The boy has been fairly easy since the operation. The limb is not painful; the line of incision appears to have healed; there is little discharge; the tubes were shortened. The temperature has varied from normal to 100° F., averaging about 99° F.

February 20.—The line of incision, which appeared to have united by first intention, has widened out considerably, during the past few days especially. As this appeared due to the riding forward of the femur, the whole splint was removed (the boy being chloroformed) and re-adjusted.

March 13.—The femur still appeared to be riding forward; he had chloroform again therefore with a view to the re-adjustment of the splint. There was found to be no union; the line of incision was separating; this was opened up anew, and the granulation tissue between the extremities of the femur and tibia was scraped away; it was pale and flabby and covered with pus. There was little hæmorrhage. After this had been done effectually, the limb was readjusted, good apposition of parts, bony and integumental, being obtained. There was very little reaction. He required dressing about every other day, strict Listerian precautions being taken.

April 7.—Parts again carefully examined; discharge not profuse, quite sweet. A general want of reparative power daily becomes more apparent; there is a hectic fever, and the boy's appetite is variable.

May 21.—The limb began to improve a week or two back; it is still in very good position, and there appears to be some union. The wound is quite aseptic. He sweats very freely; belladonna was ordered, and answered well.

June 30.—One of two small collections of pus have been opened in the hinder part of the leg, evidently gravitation abscesses. Union is taking place. The granulations along the external wound are very œdematous and discharge pus copiously.

July 20.—Condition of the wound much about the same; it appeared now to be quite superficial; antiseptic dressings were therefore left off, and boracic ointment substituted. The general condition was not satisfactory; the boy was greatly emaciated, but it was hoped he would now commence to improve.

October 10.—He was sent into the country *in statû quo*.

February, 1884.—He returned. General health improved; the local condition much as before. There was union, but it was not firm, obviously fibrous at best.

The boy's friends desired to take him home and he was accordingly discharged.

March.—He was re-admitted. He was now 8 years old and still greatly emaciated; the granulations along the line of the excision wound very œdematous and flabby; the limb was very painful when moved.

Amputation was recommended and performed; recovery was exceedingly slow, but complete at last. The lower extremity of the sawn femur looked soft and fatty; the medullary cavity was scraped out and some iodoform dusted in; the flaps were likewise dusted with iodoform. They finally united, and the boy left the hospital for the country with the stump well healed. He was just beginning to make flesh; was free from pain; showed no signs of lung complication, or of lardaceous disease, but was exceedingly anæmic.

Remarks by Mr. Parker.—In this case, at the onset, there was nothing to indicate the want of reparative power, which became so conspicuous during the course of treatment, unless, perhaps, the fact that the disease showed no signs of clearing up. When first seen, there was a good deal of synovial disease, for which Scott's dressing, counter-irritants, strapping, rest in bed in plaster of Paris bandages were tried in turn, and continued for considerable periods; cod liver oil &c., being given internally. Nor at the time of excision did the condition of the bones indicate anything abnormal. Yet after the first week or two the leg showed little or no tendency to repair.

It was, perhaps, not true "conservative" surgery: to persist so long in the attempt to save the limb; on the other hand, it was not easy to decide on the moment for amputation. I was a little influenced, perhaps, by a case which was under treatment about the same time. A boy, sent to the hospital as a case of acute rheumatism, was found to have periostitis of his iliac bone, which, in process of time, destroyed the hip joint and set up an extensive cellulitis of the thigh, with destruction of the upper portion of the femur. After a lengthened illness, and after the knee-joint had shown symptoms of becoming implicated, I recommended amputation at the hip joint as the best means—a very uncertain one—of saving life. The parents objected, they preferred "to take the boy to die quietly at home." After lingering on, he suddenly began to improve in health, and finally quite recovered. The knee-joint has gradually become quite movable, the upper part of the femur has reproduced itself, and the boy has a thoroughly serviceable limb. There is considerable movement about the upper end of the femur, which rests somewhere on the dorsum ilii. One cannot help calling to mind many other cases pronounced hopeless, which, with patience and time, have righted themselves without the final appeal to surgical ablation.

The great difficulty is to know in which cases to wait, and when to proceed to active treatment. Of course, the difference in the probable course of a disease with an acute onset (such as the last-mentioned case) and one in which the onset is very chronic (as in the case related in the text) is always present to the surgeon's mind. Unfortunately, however, it is no sure guide, especially in children. The case I have related appears simple enough "after the event," yet, while it was going on, I felt much puzzled as to the line of treatment which I ought to adopt. Fortunately, the boy finally recovered, and in the contemplation of his maimed limb, he will have the satisfaction of knowing that it was not sacrificed hastily, nor until longer delay would probably have fatally exhausted him.

Medical Times and Gazette.

SATURDAY, SEPTEMBER 6, 1884.

The cholera microbe has definitely transferred its head-quarters from France to Italy, where, if we may judge from the statistics furnished by the daily telegrams in the papers, it has found a soil suited both to its requirements and capacities. For Saturday and Sunday the official bulletins in Italy acknowledged 56 and 81 deaths respectively, and on Monday the fact that cholera had broken out in Naples was an open secret. In the first 36 hours after its recognition, 50 deaths were recorded out of less than 100 cases; and those who are familiar with the insanitary condition of that city will not be surprised to learn that the epidemic there is assuming serious proportions.

In France the number of fresh cases is steadily decreasing; at Toulon the average number of deaths is not above one per diem, and it is not much higher at Marseilles. Perpignan and Carcassonne at present share the credit of providing the largest number of deaths. Considerable alarm, not to say consternation, seems to have been caused at Madrid by the news that cases of cholera had occurred at Alicante and Novelda in the province of Alicante. The first cases occurred in a family who had come from Cette in a ship *viâ* Algiers, and had been quarantined for a week at Alicante before being allowed to land.

The failure of Italy to exclude the cholera by means of her quarantine precautions and other similar forms of sanitary fencing, is but another proof of the folly of regarding State sanitation as all-sufficient, and personal hygiene as consequently unnecessary, or at least unimportant. The lesson would be a striking one did it go no further; but no one can have read those graphic reports from Spezzia and other infected towns, describing the panic which prevailed, and which so intensified the terrors of the situation, without perceiving how largely it was due to a belief that since the cholera had conquered quarantine, it must be invincible. The people had been taught to rely on the efficacy of a system which was to repel disease from their borders; and, happy in the fancied security of such protection, they had little inducement to trouble themselves as to any need for local sanitary improvements. So that, when the dread visitant appeared amongst them, not only was there a rude shattering of old convictions, but there was neither the knowledge nor the training needed for exercising that calm courage which is equal to meeting the foe on his own ground and defeating him by means of his own weapons reversed. No doubt our countrymen have reason to be thankful for the national phlegm with which they are sometimes reproached, for panic is a cause powerfully predisposing to more than one sort of disaster, and a proneness to panic is but a bad preparation for danger. But if we may claim to view the spread of cholera in Europe with a calmness which is something higher than selfishness and more intelligent than ignorant indifference, it is due to the fact that we have learned to realise that a successful issue in struggles of this sort depends on the personal care of health, and that a national hygiene worthy of the name is but the sum of well-directed individual action.

The subject of over-pressure in schools has engaged the attention of the public and of the press to a considerable extent lately. Under the title of "Evening Schools and Over-pressure," the leading journal recently broke fresh ground, and raised questions which will not conduce to the equanimity of those who already find themselves puzzled to adjudicate between the demand for education, the risks of over-pressure, and the claims of parents and employers on the time and labour of the educational material. The State has prohibited all children under 14 years of age from labouring for hire, unless they have (1) reached the age of 10; and (2) passed a certain standard of educational proficiency. The minimum of this standard, as at present fixed, is somewhat lower in England than in Scotland, where it cannot be lower than the 5th standard for whole-time labour, and the 3rd for half-timers. If we accept the doctrine so unhesitatingly asserted by the *Times*, that "it is certain that this *minimum*, instead of being lowered, will ere long be raised, so as, at any rate, to assimilate the labour conditions of England and Wales to those already in force in Scotland," it becomes obvious that the mental strain under which a child has hitherto been successfully "passed on" to labour is likely to increase rather than diminish in the future; and that the cry of teachers and school managers will be for "more time" in which to accomplish the task demanded of them.

With regard to the meaning of this phrase—"more time," it must be remembered, in the first place, that the present system is admitted to "make sufficient demands upon the health and strength both of teachers and children, to say nothing of pupil teachers;" that, in short, it would be as impossible, as dangerous to the health of those concerned, and as unpopular, to demand an attendance for more hours each day, or more days each week, as it would be to attempt to shorten the already brief holidays allowed in Elementary Schools. "More time," therefore, would resolve itself into the devotion of a greater number of years than hitherto to the schooling of each individual child. Compulsory attendance in England begins, as it is, at 5 years of age; and of all the children liable to school-attendance between that age and 7, nearly eighty per cent. are already entered on the school register; and in this connection it is noteworthy that of *all* the children whose names appear on the registers, nearly ten per cent. are those of infants *under five years* of age, who attend school "voluntarily"—which means, we take it, by the wishes of their parents. On turning to the other end of the attendance lists, it appears that of children between 11 and 13 years old, some 75 per cent. only attend school regularly; but if this percentage is to be raised, it will mean depriving the parents of one or possibly of two of the years during which, at present, the earnings of their children are available. The parents will not be willing to relinquish that which they now often regard as the too-long delayed return upon the outlay involved in rearing their infants, clothing and keeping them, and paying the school-fees. And if the *minimum* requirements for the coveted "labour certificate" are to be raised, the child will be likely to fare but badly between the increased difficulty of passing the necessary standard, and the urgency of the parents that this standard shall be passed at the very earliest age possible.

The only adequate solution of the difficulty appears to lie in adopting the method which has found favour on the Continent—that is, in "lengthening out the period of half-time attendance, and in extending and perfecting the system of evening schools." It is clear that each portion of this plan is complementary to the other; but in England there appear grave reasons to apprehend considerable difficulty in securing such an

attendance at the night schools as shall, from the educational point of view, make good and justify the allowance of "half-time." As the facts stand, the average of attendance at night schools has fallen by 62 per cent. since 1870, and the average of those present at examinations by no less than 68 per cent.; while from all parts of the country comes the story that the night schools are dwindling so rapidly in number that they are already spoken of by one inspector as "practically extinct." This is not hopeful intelligenee for those who see in the judicious combination of half-time and night school work for the older children the only practicable means of meeting "the changing requirements of successive codes" without incurring overpressure.

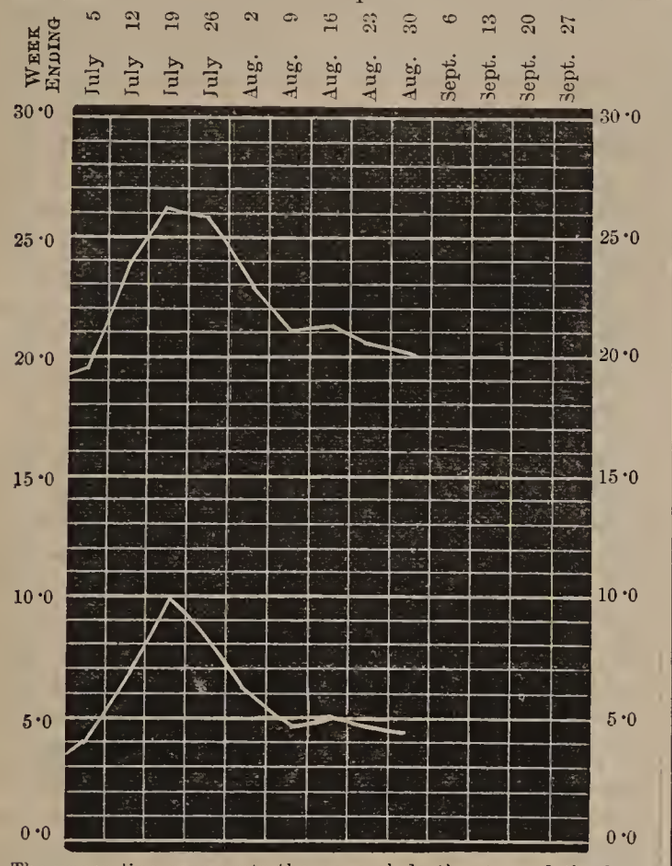
There are two other points in the article from which we have quoted which deserve attention. It is incidentally suggested that the efficiency of the evening schools might be secured by providing such stipends as would induce the best of the day-school teachers to undertake the work. If this means "to induce the day-school teachers to undertake the" evening work in addition to that demanded of them during the day, the proposal is both cruel and short-sighted. The present work of the day teachers is not so easy as to allow of their working double-tides without injury to themselves and a lowering of their average efficiency. And as regards the causes of the admitted failure of the evening-school system, we believe that Mr. Wilkinson goes to the root of the difficulty when he writes, "The 'hobbledehoys' of the period are most impatient under restraint. They are their own masters at sixteen years of age. They earn more than enough to meet all their legitimate wants, and their surplus time and money they prefer to spend in amusement rather than in improvement. A 'free and easy' evening school would probably be a financial success, but a well-ordered evening school cannot be put up with." We are tempted to ask who and what is answerable for the "impatience of restraint" displayed by those hobbledehoys who were once infants exempt from compulsory attendance? Is there some essential quality lacking in the School-board fare? And by teaching even only one or two subjects thoroughly up to a certain stage, rather than by attempting a broad-cast smattering of several, is it not possible to make knowledge so far attractive to "half-timers" as to induce a fuller voluntary attendance at the evening classes during the later years of life? It seems to us that the salvation of the evening schools depends upon an enlightened treatment of the day scholars.

The question of an adequate water supply presses us on all sides, and not least heavily in relation to the towns situated in the valley of the Thames. The results of an exceptionally long and dry summer prove only more plainly than before the folly of dealing with a scientific problem after an unscientific and piecemeal fashion. We drain deeply and broadly, so that the showers rush into the brooks scarcely moistening the roots of the plants on their way; we riddle the natural reservoirs of the great water-bearing strata, and cover the surface with a maze of streets and houses for the myriad population which clamours for plenty of pure water, and yields an abundance of foul sewage. In a recent letter to the *Times*, Mr. F. R. Condor reminds us that between 1827 and 1849, the water level beneath London was depressed by 98 feet; and, citing the lowering of the water in a gravel bed of some three thousand acres in extent, near Oxford, by about 16 feet, remarks that each foot of that fall probably represented the stored-up rainfall percolating in a year. Again, while the flood discharge of the Thames at Hampton is some 400 metric tons per second, its *minimum* summer flow is only about one-twentieth of that amount; and on this lower quantity the needs of the vast population in its neighbourhood begins even now to tell.

It has frequently been proposed to meet the difficulty by storing the excess of the flood volume of the river in capacious reservoirs, whence it might be released to meet domestic and sanitary demands, and for the requirements of navigation. The Thames Valley, however, does not lend itself kindly to the purpose. Land is dear; and it has been estimated that to store one inch of the rainfall of the Thames Valley (an amount equivalent to the total annual supply of the existing London water companies) would entail the expenditure of at least 5,000,000*l*. And this, while doubling the cost per head of the water supply for domestic and sanitary purposes, would afford but little aid to navigation or towards the prevention of floods. The project for bringing an aqueduct of sea-water from some spot on the South Coast to London, for which the necessary Act of Parliament has been obtained, may, if successful, secure an efficient flushing of the sewers, and help to cleanse the lower reaches of the river. But it would seem that the real solution of our main difficulties in this matter lies—as might have been anticipated—in treating the problem as a whole; in dealing fairly with the real sources of supply, and in a wise conservancy of the natural subterranean reservoirs; rather than in hurrying water out of the soil—first making our rivers unmanageable and then attempting to control them.

The general and the zymotic death-rates last week both exhibit a further fall, but the total number of deaths was nevertheless 88 above the corrected average of that week for the past ten years. When we add that the number of births was 145 below the corrected average, we shall have afforded sufficient data for an idle person, with a turn for figures, to calculate the probable date of the entire extinction of London as the habitation of human beings. The deaths from measles, whooping cough, and scarlet fever, all showed a decline in numbers, as did also those from diphtheria; but it is impossible to help noticing that of the 23 deaths which occurred from this malady in the 28 large towns, no less than 16 were recorded in London. There was a difference of nearly 43° between the highest and lowest temperatures during

the week, which perhaps accounts for the fact that the deaths from bronchitis and pneumonia exceeded the



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the first nine weeks of the current quarter.

corrected average. It is worth mentioning that two deaths occurred during the week in one of the Metropolitan hospitals from hydrophobia.

Burnley, which formed the subject of an investigation by the Local Government Board in 1873, has been again inspected and reported upon, this time on account of its abnormally high death-rate from fever, by which term is probably meant typhoid fever exclusively, though the point is not quite certain. Positive conclusions as to the cause of the fever could not be attained, owing to the length of time that had been allowed to elapse before the enquiry was instituted, but certain facts in regard to excremental nuisances and defective drainage were made very evident. The favourite method, and a very objectionable one in the eyes of Dr. Airy, the author of the recent report, of dealing with excreta, appears to be to have a large earthenware tank sunk into the ground at the back or side of the privy, with which it communicates by means of an earthenware cone placed under the seat. Six inches from the level of the top of the tank is an overflow pipe leading to the sewer, which should convey the surface fluid away, whenever the holes placed at its entrance to the tank are not so much blocked up as to prevent this. The tanks are covered over with a stone slab, and the chief objection to them is that, being but seldom cleaned out, the decomposition which takes place within them keeps the air in a fœtid state and is a constant source of danger to the neighbourhood. Pail closets are also used, but to a less extent, and they are not emptied sufficiently often to be free from objection. Burnley has an abundant water supply and a good system of sewers, and there does not seem to be any reason why the present objectionable and inefficient privies should not give place to properly constructed water-closets. The provision for dealing with infectious cases is most meagre and not good of its kind, consisting of a row of four small two-storied labourers' cottages, which have been made to communicate by holes knocked through the party walls, so that setting apart one cottage for the caretaker, there are in all six rooms available, none large enough to accommodate more than one person, and all communicating with each other, so that different classes of infectious disease could not be treated at the same time.

A pamphlet on the Sandefjord Sulphur Bath, by Dr. C. A. Knutsen, has lately been placed in our hands. Sandefjord is a small town in the South of Norway, possessing many recommendations in the shape of readiness of accessibility, good accommodation, and beautiful surrounding scenery. The pamphlet appears to have been written in order to make known to the members of the Congress the properties of the natural waters of this little town. Besides the bath, there are sulphureous waters to be taken internally, and much stress is laid upon the use of poultices and inunctions in the local treatment of disease. Rheumatism and rheumatic pains are amongst the affections most amenable to this line of treatment, whilst very good results are said to have been obtained in syphilis. After making due allowance for the natural enthusiasm of the writer of the book, it must be admitted that considerable benefit has probably been derived from the treatment advocated in it.

That degraded form of competition which results in the adulteration of various articles of diet, calls for some preventive more effectual than mere reprobation of the practice is ever likely to prove. But while we feel a natural satisfaction on learning that a well-merited punishment has overtaken the perpetrators of a form of fraud whose effects are practically illimitable, there is some reason for congratulation when, at the same time, we are able to derive a therapeutic hint from the very measures which are under condemnation. Certain "articles" which are in use amongst some of the cheaper New York coffee houses, have been found on analysis to be so grossly adulterated that the manufacturers are to be prosecuted. Dried blood appears to be one of the ingredients which enters largely into the compounds sold under the name of "coffee-essence." It is probable that few would prefer, or would care to pay the price of coffee for drinking such a substitute; but if dried blood can be so manipulated as to make a passable third-rate coffee, it is at least possible that genuine coffee (or the nearest approach to it now obtainable in England) may serve as a good vehicle for the administration of those preparations of pure dessicated blood which undoubtedly possess a real therapeutic value in certain debilitated conditions of the system. The drift of recent legislation on the subject has, unfortunately, been all in favour of coffee adulteration in this country. We should be

thankful for all mercies, and perhaps it is some consolation—a kind of set-off to the nationalization of a vitiated taste in coffee-drinking—to feel that we have been forced into familiarity with a beverage which is, by virtue of its mongrel composition, only the better fitted to serve as the disguise of a remedy which is valuable, but not too appetising or attractive in itself.

The following is the list of officers for the ensuing session of the West London Medico-Chirurgical Society:—President, Mr. F. Lawrance; Vice-Presidents, Dr. Alderson, Dr. Travers, Dr. Thudichum, Dr. Pickett; Council, Mr. Barnes, Dr. Clippingdale, Mr. Swinford Edwards, Mr. Hemming, Mr. J. R. Lunn, Mr. Potter, Mr. Walker, Dr. Hart Vinen, Mr. R. F. Benham, Mr. C. B. Keetley, Dr. Owles, Surg.-Major Scriven; Treasurer, Mr. Alfred Cooper; Secretaries, Dr. Campbell Pope, Mr. Gunton Alderton. The meetings are held on the first Friday in each month, at 8 p.m., at the West London Hospital.

Dr. John Popham, who died a few days ago at Ealing, in his 78th year, was, up till two years ago, a well-known and highly esteemed practitioner in Cork. He was a graduate in medicine of the Universities of Cambridge and Dublin, having been one of the most distinguished students of his day in the latter. For more than forty years he was Physician to the North Infirmary, Cork, and was also Chemical Lecturer at that Institution. He contributed several papers to the medical journals, one of which, on the "Climate and Diseases of the City of Cork," succeeded in making more than a local reputation for itself, and was translated into German.

Dr. Eustace Smith's new work, which bears the philosophical title of "A Practical Treatise on Disease in Children," is almost ready for publication. It will appear simultaneously in America and England, and may count upon a large circle of readers.

An argument commonly used by the anti-vivisectionists is to the effect that, not content with experimenting on the brute creation, the vivisector will ere long be treating human beings in the same fashion. Whatever be their individual opinion on the subject, it must have afforded some satisfaction to the readers of the *Morning Post* to have this question raised so plainly and so frankly as it was put before them by Miss Burton in her recent letter to that paper. Premising that "M. Pasteur's refusal of human subjects and yet going on with animals, having perfectly succeeded with them," is, to her mind, "very shocking." Miss Burton propounds a question at which she knows one-third of the public will be dreadfully shocked, while two-thirds will quite agree with her, though "few will have the courage to say so." She wants a plain answer to the plain question—Why a doctor may not go to a condemned cell and say, "John Smith you are to be hanged in forty-eight hours, for the murder of your wife and innocent children. I am permitted to make you an offer which you are to think over for twenty-four hours, and are not obliged to accept. There is an operation to be performed in the hospital the day after to-morrow. It is useless to use animals for it, because their bodies are not in the least like ours, and the results are not much, if any. If you like to accept the risk, you may. It will be to my interest that you suffer as little as possible, and to the honour and glory of my profession if you survive the operation. If you recover you are granted a 'free pardon' until you repeat your crime (of murder or brutal violence) when you will belong to us as a subject without choice. If you die you do not die a felon's death, nor leave the shame upon your innocent posterity; for, as you took life, so you have freely offered yours for the benefit of mankind, and expiated your crime before God and man."

In the form which it is made to assume, this question appears scarcely as "plain" to us as to its author. We do not recognise the class of operations habitually performed "in hospitals" for which "animals are useless," and for which, nevertheless, no human patients are, under the present conditions, forthcoming. It may be true that, were such a plan enforced, "the vivisector would only be using up virulent material that has to be got rid of at any rate;" but unless we are admitted to a fuller knowledge as to how, and with what object, this material is to be "used up," we are not justified in endorsing the thesis that the substitution of one criminal in lieu of "whole hetacombs (the phraseology here employed again lacks something of the accuracy so necessary to scientific discussion) of harmless, innocent, faithful, intelligent creatures," would "give a certainty instead of producing little or no result."

"Anæsthetics would, of course, be used as much as possible"; and, under the circumstances, Miss Burton thinks that "no man condemned to be hanged on the morrow would refuse such a chance as this." Yet, if the terrible and deterrent weight of a capital sentence were liable to be thus reduced, it does not seem clear that such a course would "materially diminish crime." And having regard to the nature of the operations incidental to that kind of experimental research for which the living human body, if available, would be of the greatest value, we could not soberly promise the subject of such experiment that its result, physically and mentally, would be such as to "give a man a chance of beginning a new and better life"—in this world, at all events.

Stripped of its errors and extravagances, the question nevertheless contains an outline of that which must, in one form or another, have suggested itself to the mind of every one who has honestly, thoughtfully, and reverently endeavoured to master for himself the ethics of experimental physiology. It is a question which may, at some not distant day, demand an answer; but it is one to which we may feel thankful that the medical profession can never be called upon to reply alone. Miss Burton says that she does not believe much in changing men and women, but has great faith in forming children, and has "no sickly philanthropy at all for the 'human brute,' who has all England's tenderest sympathies now-a-days." It would seem that Miss Burton is a vivisectionist—if we may

apply to her that much-abused term without discourtesy—spoiled only through lack of an inadequate acquaintance of the subject. If she will undertake a thorough and impartial consideration of the question, she will realise that the right practice of experimental physiology involves no lessened respect or sympathy for the animals whose cause she pleads so eloquently, and for which she has worked so well.

The condition of our English graveyards is not even now, in every instance, all that can be desired; but it is something to be able to lay the flattering unction to our souls that these matters are not always better managed abroad, even in those lands in which the temporal power of the Church is held to be greater than in our own. The sanitary condition of a city situated upon one of the great natural highways of commerce cannot be a matter of complete indifference to the rest of the world; and though it may be "well known that Panama itself has a very trying climate, and is a very dirty city," it does not follow that ordinary folk are prepared for the horrible yet soberly-stated revelations which have of late been published respecting its two most conspicuous and potent sources of disease, viz., the condition of the cemeteries and of the water-supply.

Writing in the early part of 1882, Dr. Heffenger stated that the annual death-rate of the city of Panama was at least eighty-eight per thousand, and that of these deaths one-half was due to malarial (yellow?) fevers, and one-fourth to small-pox. The largest cemetery, which is the immediate property of the bishop, was built by the Spanish Government nearly two hundred years ago upon a boggy piece of land about a mile to the westward of the city. It consists of three hundred and sixty-five niches arranged in three tiers, forming a hollow square. Only the wealthy can indulge in this ultimate luxury, and upon the demise of one of the favoured sons of fortune, the body is placed in one of the niches and sealed up by a suitably (?) inscribed tablet, so to remain—as long as cadaveric rent is paid to the Church. Should, however, the relatives of the deceased fail to keep up this payment, the coffin and its contents are tossed into the swamp, just to the rear of the cemetery, "where at all times may be seen the unsightly remnant of ancient and recent dead, old Spanish hidalgos, proud doñas, fair señoritas, and new-born babes, lying in a promiscuous heap of putrescence ten feet high, their white, staring, tongueless skulls mutely protesting against such barbaric desecration of the dead."

It is further stated that in September, 1882, an earthquake loosened the walls, and cracked many of the *bovedas*, or niches, which in the climate of Peru are veritable ovens, filled with putrescent humanity—so long as rents are paid. A letter published in the *Panama Star and Herald*, in April of the present year, from Dr. Wolfredhelson, a late Member of the Panama Board of Health, shows that the conditions portrayed have been in no way improved, and appears to justify his prediction that the old Church would prove too strong for the young Board of Health. While the Jewish, the Chinese, and the "foreign" cemeteries are in excellent order, the condition of the two native cemeteries—that owned by the bishop, and rented in niches to the rich, and that used for the general burial of the poor—is in every way and wholly loathsome. With regard to the general cemetery it need only be pointed out that it covers but three-quarters of an acre of ground, for an increasing population of twenty thousand people, and that in the necessary process of interment it is dug over at least once every year. Nor is the air the only medium by which the poisonous influence of these so-called cemeteries—seldom has the term resting-place been applied less aptly—is diffused. Within a hundred feet of each of them are wells from which water is drawn and sold for drinking purposes throughout the city, and from which washerwomen draw their supplies "for cleansing and infecting" the soiled linen of the inhabitants.

We feel and express no sympathy with the morbid minds which find their pleasure in the mere unveiling of horrors such as these. At the same time, an evil is not the less an evil because we may choose to ignore the fact of its existence and persistence; even in matters sanitary, perfection is not necessarily maintained simply because it has once been won; and while we are sometimes tempted to hug ourselves in the smug belief that we have done and are doing all that is required, it is as well to be reminded now and again of the depths to which we might sink were we to become oblivious of our ideal, or to relax our efforts after its attainment. All the great questions of practical sanitation are stirred by the pathetic commentary of the local press on the state of things which has just been sketched:—"This whole isthmus wants sanitary reform, at once, to make it a fitting place for human beings to live on, and to prepare it for the great future that lies before it. Let us hope that some plan of combined wisdom and hygiene will bring about such an ending. Humanity and science demand it." What is the power that will undertake and effect it?

At the meeting of the British Dental Association at Edinburgh last week, a discussion was raised, by some remarks of Mr. Brownlie, of Glasgow, on the fees for operations, and the absurd system of giving advice, where no operation was indicated, for nothing. This was universally condemned by all the speakers, but the remedy is in the hands of the dentists themselves, as was pointed out by the President-Elect, Dr. Cunningham, of Cambridge. The question thus raised is, however, capable of wider application than to dentists only. In all the departments of our profession, the public are willing to pay, or at any rate do pay, at a very much higher rate for manual dexterity than for advice pure and simple. Indeed, the inconsistency and absurdity is much more obvious in the case of medicine and surgery than it is in dentistry. Thus a man will pay two guineas for a consultation on which the whole future of his life depends, for instance, whether he is to leave the country on account of a supposed or real delicacy at his chest, and a hundred guineas for the removal of an eye that is hopelessly lost. So long as

the profession by its silence virtually expresses its approval of the doctrine implied by this scale of fees as to the relative value of scientific discrimination in the one case, and the extremely slender manipulative dexterity required in the other, we must not be surprised if the public fail to take a more enlightened view.

The Sub-Committee of the International Collective Investigation Committee commenced their labours at their first meeting on Wednesday last.

When medical experts, chosen in our hap-hazard way, express discordant opinions in our courts of justice, it is customary to refer to France and Germany as models of the mode in which medico-legal testimony should be dealt with. As regards the former country, however, there does not seem to be much more satisfaction felt with the results of the procedure in force than among ourselves. A project for the reform of this is now before the Senate, and the Society of Legal Medicine of France has appointed an influential committee, in order to communicate its opinions as to the necessity of such a reform to the Commission of the Senate, to whom the Bill in question has been referred. These opinions are stated at length in the *Annales d'Hygiène* for April, by the reporter of the Committee, Professor Brouardel, and are well worthy the attention of those interested in the matter. We have only space to quote his conclusions, indicating remedies for what he considers the most unsatisfactory state of things which prevails in France, as well as among ourselves, viz., that there is no security against the employment of incompetent persons for this important office. The conclusions are :—1. The Society of Legal Medicine suggests that if, in spite of the inconveniences signalised in this report, the Commission admits that the evidences of the experts may be contradictory, it should accept the logical consequence of such a system. This would be the establishment of a Superior Medico-Legal Commission, analogous to the *superarbitrarium* tribunal of Berlin, having the duty of judging scientifically questions of an exclusively scientific character which may have given rise to differences of opinion between experts. (The tribunal at Berlin at present consists of Professors Virchow, Hoffmann, Bardeleben, Quincke, Skrzecka, Eulenberg, Schröder, and Von Bergmann.) 2. But the Society believes that such a reform would prove incomplete, unless the conditions for the instruction of experts and those for the practice of legal medicine undergo modification. It requests the Commission to direct the attention of the competent authorities to the following points, which, in its opinion, are alone capable of protecting the interests of society and those of the accused. (*a*) Special instruction of experts by appropriate professional teaching. (*b*) Proof of such instruction having been undergone to be furnished by a diploma, conferred by the Minister of Public Instruction, after an examination by the Professors of the Faculty of Medicine, viz., a diploma for medical experts and one for chemical experts. (*c*) An increase in the tariff of fees. Dating from 1811, the present payments are acknowledged by all as insufficient, and likely to become much more so when a more onerous system of studies shall have been imposed on candidate-experts, and upon experts themselves, by the modifications in the operative procedures rendered necessary for the control of their researches.

In the course of the last few weeks the phrase "Total Abstinence" must, in some localities, have acquired a baleful significance signally repugnant to those who are in the habit of preaching the doctrines of teetotalism. While farmers were spending five pounds a-week and more in the cartage of water for their stock, the labourers and their families have been in a still worse plight. There are districts, some even within little more than an hour's railway journey from the Metropolis, in which the water supply of villages as well as of isolated cottages is drawn from a few scattered shallow apologies for wells which have no right to the full meaning of the name, and which are dependent on the influx of surface water only. But there are many other places where even "wells" do not exist; where all the water for drinking and cooking and for cleansing purposes is obtained from the pond at the back of the house or on the village green, a shallow depression in the impervious soil, whither various odds and ends of rubbish gravitate, and to which the ducks and geese of the neighbourhood enjoy an ancient right; while, in hot weather especially, the pigs gain a forced admission to its freedom.

During seasons of average humidity the water baled from such a source is used persistently, despite the occasional discovery of a newt or other small deer of more objectionable character in the contents of the bucket; despite its muddiness and its repellent colour; and despite the evil odour which becomes more noticeable as it increases in "body," and as the shrinking volume of the pool reveals the slimy relics which strew its bottom. But, in such a summer as this has been, there comes at length a time when the green-brown mixture of the mud puddle is exhausted; and then the household must beg or buy its supply from some more persistent pool on another farm, or send, some miles perhaps, to the nearest stream or spring which has not failed. For such labour the mother has no time to spare from household duties; the children are at school, or working in the fields, and it is only towards evening, and after a hard day's sultry labour, that the father or the elder sons are available for fetching, with irksome toil and in limited amount, the water which can barely be a sufficient and assuredly not an abundant supply for the family necessities.

From one point of view it might seem mistaken to pity such people for being, even by circumstances like these, compelled into familiarity with water which is probably far purer than any to which they are accustomed. But the conditions of the luxury, both present and antecedent, are not such as to extend the popularity of water as a beverage; while it certainly favours the consumption of much over "drawn" tea and pot-house beer (*arcades ambo* in the opinion of competent authorities) as substitutes. The British farmer is reputed as a long-suffering grumbler; the English labourer suffers much, and his real grievances

do not quickly reach the public ear. In the present instance the complaints of both are only too well founded, and demand attention. Much might be done by sinking wells in properly selected spots, by deepening and fencing in those which already exist, and by careful measures for husbanding the water-supply; and good results might be achieved by intelligently carrying out the suggestion that wealthy landlords and sanitary authorities, etc., should supply Abyssinian tube-wells on hire to those districts in which water is scarce and where the geological configuration is favourable to their employment. If the state of things which we have sketched, and which in sober reality exists, is disgraceful, the drought of 1884 will at all events have accomplished some good by exposing the extent of the evil and by emphasizing the immediate need of cure.

This is the season of Congresses. Last week it was the Hygienic Congress at the Hague; this week it is the turn of the Red Cross Conference at Geneva, where the first conference of the sort was held just twenty years ago. Surgeon-General Longmore is the representative, as on former occasions, of our Government, and, with the exception of Esmarch, almost all the Continental leaders in military surgery are present. On Tuesday evening, a practical demonstration of the use of the electric light on the battlefield was given, in presence of a large audience.

THE CHOLERA FUNGUS.

The fact that Koch and his colleagues have as yet failed to observe the process of sporiferation in the bacillus, to which so much attention has been directed of late, shows that its life history is still incomplete and that we know it as yet only in its mycelial stage. Though many of the fungi may reproduce themselves for indefinite periods without emerging from this phase of their existence, and even in the *Torula* no conjugation or other sexual phenomena have ever been observed, there is reason to believe that under certain conditions sporiferation will take place. Moreover, the form which the mycelium, sporiferous or not, assumes, depends greatly on the medium in which it grows, and many of the forms referred by systematic cryptogamists to distinct genera, or even to different orders, are of this kind. Not only may oïdia, penicillia, mucors, &c., thus spring from a common origin, but it is highly probable that many of the schizomycetes are but degraded or early phases of organisms of higher grades.

In 1866, contemporaneously with the description by Professor Pacini of a bacillus, which appears to have been none other than that which is now associated with the name of Professor Koch, Professor Hallier, of Jena, published a remarkable account of a fungus which he had found in the stale rice-water evacuations of two cholera patients. This fungus had in the stools the appearance of a uro-cystis, but when cultivated in different artificial media it assumed those of four oïdia, viz., mucor, penicillium, tilletia, and achlya (?) Remembering that the parasitic fungi of cereals frequently appear as uro-cystis, he watered with the choleraic fluid rice plants growing under the most favourable conditions. Whether as a consequence or a coincidence these plants were soon blighted and their tissues permeated by like fungoid growths. But further than this he could not proceed, or recommence the cycle of metamorphoses; and though his observations cannot be questioned, it has generally been held that the association of this fungus with the cholera stools was accidental, and that the disease in the rice plant had no direct connection with either.

But if the startling accounts of alleged discoveries contained in a letter recently received from Drs. S. Maurin and Lange, who have been pursuing their researches on cholera at Marseilles since the departure of the other Commissioners, be not entirely the product of an over-heated imagination, we may have to rehabilitate the credit of the German botanist. MM. Maurin and Lange assert that on the fourth or fifth day after evacuation a mucor appeared on cholera stools and on them only, in the form of mycelium, the filaments of which were constricted at points, to which were attached capsules containing large numbers of spores. The slightest movement suffices to rupture the capsules and to discharge the spores, which, if deposited in putrid organic matter, germinate, giving rise to a mucor of another kind. It again bears spores, from which are produced the bacilli of Koch. These in a putrescent medium and exposed to the air develop into the mucor first described. They assert that the mucor No. 2, which is anaërobic, or one which does not require the presence of oxygen, is the immediate agent in the causation of the disease, and that the bacilli which in due course are derived from it, and consequently appear in the evacuations, are, as Koch found them, perfectly harmless as such.

Another striking contrast between the bacillus and the mucor which springs immediately from it is that while the former is, as Koch found, incapable of resisting the feeblest acid, the mucor defies most of the reagents commonly fatal to low vegetable life. It was not killed by a ten per cent. solution of sulphuric, hydrochloric, or carbolic acids, nor by a temperature under 150° C. (302° F.), though higher temperatures or a ten per cent. solution of tincture of iodine cause it to fall to pieces. This recalls the utter failure of disinfectants in 1866 to check the spread of cholera in Erfurt, Stettin and Leipzig, though used in such profusion that at Erfurt the very wells reeked of carbolic acid. MM. Maurin and Lange state that a specimen of this mucor, nourished in oil of turpentine and intended for presentation to the Academy of Medicine, was observed by themselves and others to continue its development unchecked, bear conidia, and to scatter its spores throughout the fluid. Should these observations be even substantially verified they will elucidate to a degree which we can but faintly realise the perplexing phenomena of the ætiology and propagation of cholera. We must, however, in justice to Professor Hallier, add that not only did he make no fewer than forty-four separate series of experiments, which were perfectly consistent in their results, but that his observations were confirmed by Dr. Thomé and Professor Du Bary, two of the most eminent mycologists of Germany.

ARMY MEDICAL DEPARTMENT REPORT FOR 1882.

[Second Article.]

The second section of the report, in addition to the statistics regarding recruiting and vaccination, to which we have already referred, is devoted to the consideration of the sanitary conditions of the home stations of the Army. The average annual strength of the non-commissioned officers and men was 86,847. The daily average of men non-effective through sickness was 409,204. The average sick time to each soldier was 17·20 days, and the average duration of each case was 20·18 days. The rate of constantly sick was 47·12 per 1,000. This gives a heavy list of non-effectives, but diseases which civilians would hide are not passed over in the barrack-room, and the soldier really unfit for duty is sent to hospital. We notice particularly that "including gonorrhœa and its sequelæ, the admission rate for all forms of venereal disease amounted to 246·0 per 1,000, and the rate of constantly sick from these diseases to 10·86 per 1,000." Of course we find the admissions into hospital varying according to the protection afforded or neglected by legislation. In 14 stations under the Act, 41,783 men gave 78 victims, and 45,064 men at non-protected stations furnished 124. We believe the public conscience is very tender, however, and requires that there should be no interference with the delicacy or the modesty of prostitutes, and we must expect in future reports, an increase of venereal disease in the British Army. Passing on to particular stations, we notice everywhere an attention to sanitary improvements with one or two notable exceptions. One is at Gravesend where we are informed "The Gravesend hospital has been reported on unfavourably for *several years*, as unsuitable both in construction and position." We suppose it is a question of money. Everybody is willing that sanitation should be attended to, but the coin to effect big reforms cannot always be found. We should like to know whether annual sums are distributed to each district which *must* be spent but not exceeded? If such an arrangement exists, we can understand why the Gravesend hospital has not been rebuilt, while minor improvements of less importance have been immediately completed. We see that the disposal of "sewage" gave trouble at the Curragh. A sewage farm attempts there to meet the ever present difficulty, but it fails, as the sewage poured upon the land is not sufficiently absorbed. We do not wonder at the perplexity of the authorities who say, "The subject is under consideration, but as there is no fall for the fluid, it seems difficult to find an outlet for its disposal."

We have said that "enteric fever" was prominent throughout the whole report for 1882, and we see that at Aldershot it is stated "there has been an unusual amount of enteric fever, more than for any period during the last 20 years, and no case could be traced to sanitary defects, but it was observed that in the quarter ending 29th December, 1882, all the cases with one exception occurred in corps recently returned from Egypt. During the year, 25 cases and 10 deaths are returned, and of these 22 admissions and 3 deaths are attributed to service abroad. Enteric fever prevailed at many other stations, and only in Dublin do we find sanitary defects given as the probable causes of the outbreak. The germ theory must account for the greater number of these attacks; and if the germ is originated by insanitary conditions, there is every reason to suppose that an epidemic of enteric fever may be imported from tropical climates of even a more virulent character than any which owes its undoubted origin to home sources. Among other febrile diseases we notice the prevalence of erysipelas at Aldershot, and here again the cases could not be referred to any sanitary defect.

We are sorry to observe that in the home districts sufficient accommodation was not provided for married soldiers. The report says, "A family of four or five children are sometimes found to be occupying one room, but it is right to add that the overcrowding has not been frequent."

REVIEWS AND NOTICES OF BOOKS.

WHARTON AND STILLÉ'S MEDICAL JURISPRUDENCE.[1]

The appearance of the fourth edition of this well-known and popular work is an evidence that an old favourite has not been forgotten, but is holding its own well against all comers. This edition consists of three large octavo volumes of some 750 pages apiece. It is clear therefore that, in the very limited space at our disposal, we cannot attempt anything like such a review as the size of the work would merit. When, however, a book reaches a fourth edition, it may be generally accepted as a proof that there is not much necessity for criticism; the public has expressed its verdict, and there is no need for more.

The first of these volumes is edited by Dr. Francis Wharton, a doctor of laws, not of medicine, and is devoted entirely to the consideration of mental unsoundness, considered first in its legal relations, afterwards psychologically. The two most important points in which law and medicine come into contact in regard to the state of the mind are in reference to the capacity to make a will, and in the matter of insanity as a plea in criminal cases, and accordingly we find a good deal of attention bestowed upon both these departments. Some remarks under the latter head, suggested by the trial of Christina Edmunds, seem to us to be of especial interest. The writer, noticing the very scanty medical evidence for the defence which had been produced, attributes it to our system of leaving the medical evidence for the defence to be provided entirely by the defendant, so that, as he says, under this system a poor man has no chance. Again he objects to the practice, adopted by the Home Secretary in this case, of referring to two independent medical inspectors after the trial for a report as to the condition of the patient, a report given and often adopted without any sworn testimony, though it may be in direct opposition to the con-

[1] Wharton and Stillé's "Medical Jurisprudence." Fourth Edition, 3 vols. Philadelphia: Kay and Brother, 1884.

clusions arrived at by the judge and jury at the trial. Objectionable as the system is in theory no doubt, yet in practice we find that it works very well, and a good many insane persons have escaped the gallows in this way, notably so on two recent occasions. The chief fault we should find with the plan is that the inspectors are appointed at the wrong time ; their investigation and report ought to be completed *before* the trial and not *after* it, but we fear that we shall have to wait some time for so useful a reform as this.

In the second half of the volume, in a long chapter, the author deals with general moral insanity, which he refuses to recognise as entitled to separate consideration apart from mental disease. The Guiteau case is dealt with in a footnote by long extracts from the judge's summing-up and from one of the daily papers, which leave no doubt as to Dr. Wharton's views as to Guiteau's sanity. This, by the way, is treated of under the head of politico-mania. Other forms of monomania, such as pyromania, kleptomania, erotomania, oikeiomania and pseudonomania, are each in turn alluded to, but to none will the author grant a separate entity, when unsupported by other evidence of mental disease. Not even dipsomania will the author admit to be more than a physical disease ; he regards it as "but a type of other appetites for excessive food, drink and stimulus. These appetites spring from the animal nature, and if they are yielded to in excess, brutalize him who yields to them, making them the sources of great domestic and sometimes cruel wrong. From the very nature of such indulgences they are to be controlled chiefly, if not exclusively, by the fear of results. Hence it is to such men the greatest mercy that the law should be firmly expressed. To declare them emancipated from the law on the ground that dipsomania is a moral insanity, is cruel to them as taking away the only barrier between them and ruin." We are not altogether prepared to subscribe to these doctrines, and would prefer to make some distinction between the inebriate, whose craving for drink appears to be irresistible, especially when there is an inherited tendency to the condition, and the simple drunkard.

The second volume deals with the poisons, and is edited by Drs. Robert Amory and E. S. Wood. In an introductory chapter they discuss the evidence of poisoning, and the method of making an examination of the dead body at some length. The classification of Orfila is followed out in the main, the poisons being divided into irritants, narcotics, and narcotico-acrids. Throughout, the volume bears traces of the most careful revision ; and the numerous references to, and quotations from, the important cases of the last few years testify to the pains that have been bestowed upon it in order to bring it up to date. In this respect there is only one thing we have to complain of, and that is that the cadaveric alkaloids have not been deemed worthy of a separate chapter. In all cases of alkaloidal poisoning in the future, the prosecution will doubtless be confronted with the theory that any alkaloids present are of the nature of ptomaines. The appendix contains between fifty and sixty of the most important cases of poisoning that have been recorded either in America or in Europe, in many instances reported at great length. The one feature in which this volume differs from almost every other work on the subject is that, being addressed to lawyers, it makes no mention of the subject of treatment. This is much to be regretted, and we think unwise, for it is certainly the business of the advocate in a criminal charge of poisoning to be familiar with the ordinary treatment that would be adopted in such a case. For although it would be no defence to a charge of murder by poisoning to say that the deceased would have recovered with better treatment, yet it often supplies some essential evidence ; and even if it would seem to have no importance in the case, we should bear in mind the fate of the medical witness who appealed to the judge to know if he was bound to reply to a question as to what his treatment had been, and got the unanswerable remark, "Yes, unless you have reason to think that your treatment killed the patient."

The third volume is edited by Dr. Francis Wharton, and consists of four books. The first of these deals with pregnancy and infanticide, and we may note in passing that as regards protracted gestation, the author regards 276 days as the normal period, and would allow a margin of four weeks as the limit to which prolongation may occasionally extend. This limit is not universally adopted throughout the States, for we observe that in Pennsylvania, if a married woman has a child within a year of the possibility of access on the part of her husband, there will be a presumption that the child is legitimate. The second book deals with questions regarding the sex, with sterility, impotence, and rape. On the latter subject the possibility of a rape being committed on a person whilst under the influence of an anæsthetic is considered at some length, and a case in point is fully reported. The third book includes wounds and injuries, death by violence, and the signs of death. The remaining half of the volume is occupied with the legal aspect of some of these points, such as rape, homicide and infanticide, and a few other points, including a very good chapter on medical malpractice, and another on insurance. The volume concludes with a section on defects of vision, in which is given a long extract from the writings of Joy Jeffries on colour vision. In bringing this necessarily very brief review to a close, we would express most emphatically the high opinion we entertain of the work. Although it is addressed rather to lawyers than to medical men, yet those who take an interest in medical jurisprudence will find it full of valuable and useful information. The printing and binding are all that could be desired.

Post-nasal Catarrh and Diseases of the Nose causing Deafness; by Edward Woakes, M.D., London, Senior Aural Surgeon to the London Hospital, &c. H. K. Lewis. 1884, pp. 212.—The range of diseases to which the naso-pharynx is subject is comparatively small and it cannot be said that any have been altogether neglected by the writers of the several treatises upon nasal disorders, or even by the authors of the general surgical text-books. In his present work, Dr. Woakes presents, however, some remarkable physiological theories in explanation of the various morbid conditions occurring in the throat and nose, in addition to his views as to the diagnosis and treatment of the diseases themselves. A part of his book, the introductory chapter, has already appeared before the public, the main points contained in it having been presented to the International Congress in

1881. It consists of observations upon the correlating and reflex functions of the sympathetic system; and it is precisely these observations which form the text for the author's subsequent explanations of the various naso-pharyngeal phenomena of which he treats in the following two hundred pages. In his remarks upon chronic catarrh he makes known his views upon this point with unmistakable clearness. He would "emphasize the fact that chronic catarrh, whether nasal, or pharyngeal, or both, is essentially a neurosis. To avoid ambiguity associated with this term, I would point," he says, "to the superior cervical ganglia of the sympathetic chain as the specific seat of this neurosis." His belief upon the subject, roughly summed up, would appear to be this: that as all parts of the body are placed, as it were, in telegraphic communication with each other, it is probable that any force influencing any one part must of necessity cause some molecular change in some other part, through the particular ganglion or chain of ganglia with which these parts are in nearest relation. The subtle influence of *chill*, therefore, affecting, say, the lumbar spine, may be telegraphed from one set of ganglia to another, radiating its influence from each, until it arrives at a point of "lesser resistance," such as the nose, in which it may call forth the pathological changes grouped together under the name of a cold in the head. This apparently scientific explanation is so attractive at first sight that one is almost tempted to accept it without enquiry as to the facts upon which it is based. "The central fact in connection with this subject is one . . . to the effect that gunshot wounds of the brachial plexus . . . cause the subject of them to fall down, consciousness being sometimes, but not always, momentarily lost." Coupling this with the well-known fact that pressure exerted within the middle ear, either from within or without, produces similar symptoms, the author arrives at the conclusion that it is all owing to the correlating influence of the lower cervical ganglion, through the branches which it sends to the vertebral artery. Assuming the correctness of his view that influences affecting any part of the sympathetic nervous system may affect any other, it becomes difficult, except by means of his *locus minoris resistentiæ* theory, to account for this strict localisation of so severe a nerve shock as we must assume to be caused by a gunshot wound. The evidence afforded by vivisection appears to us not less difficult of acceptance when we take into consideration the profound disturbance which must occur, even in a lowly organised nervous system, in the simple (?) process of exposing the inferior cervical, or any other sympathetic ganglion to the gentle titillation of the experimental physiologist's needle. Where phenomena are of necessity so difficult to prove, or even to explain, it may perhaps be said that we must be content with the theories that we have until some more daring investigator tempts us to others that we know not of, and our contentment may be confirmed by the reflection that our practice must still be guided solely by the *facts* at our disposal, theorize we never so wisely. Turning then to the practical side of Dr. Woakes' book, we find many useful hints for the guidance of the "Catarrhally Predisposed," prefaced by an alarming account of the pre-catarrhal state and the complex chemical changes which produce it. Clear instructions are given for the practical examination of the nasal and pharyngeal cavities, while the various morbid conditions, and occasional anatomical peculiarities to which they are subject are fully dealt with. A chapter on post-nasal vegetations should be especially noted as one of the most complete accounts at present published of a condition which is far too frequently overlooked in practice. The presence of these troublesome appendages in the vault of the pharynx gives rise not unfrequently to a permanent expression of countenance unbecoming to either sex, and quite preventable by an early recognition and treatment of the disease. The book is closed by a chapter on nasal stenosis and its treatment. Although the confident tone which pervades the theoretical part of his work may cause irreverent merriment on the part of his all-practical readers, and notwithstanding the polysyllabic magnificence of the periods in which many of his most common-place facts are related, we have no hesitation in recommending Dr. Woakes' book as a useful treatise upon a subject of more than ordinary interest.

Specificity and Evolution in Disease; by W. J. Collins, M.D., B.S., B.Sc. Lond., &c. London: H. K. Lewis, 1884.—This pamphlet, which is a reprint of a paper read before the Abernethian Society, St. Bartholomew's Hospital, in the early part of the present year, deals with a question which is not merely of great interest, but of great practical importance. Are the so-called "specific" qualities of a disease, such as small-pox or typhus, immutable in their character, always pre-historic in their origin, eternal in their unchangeableness? Guided by the light of analogy and of what we have lately learned with regard to the ætiology of several of the infectious maladies, few would be prepared to answer such a question in the affirmative. On the other hand, our ignorance is still so profound, and such knowledge as we do possess on the subject is so fragmentary and ill-assorted, that we are not yet justified in accepting as proven the full-blown theory of the evolution of disease, as Dr. Collins would put it before us. Specificity may not be the power which the older writers almost revered; nor are we yet convinced that the *same poison* "may produce different diseases in different individuals;" that "the chief (if not the only) element in determining specificity is. . . . the predisposition of the individual;" or that "predisposition may be so strong that, apart from contagion, it may develop disease *de novo;*" simply because, although evidence is adduced in favour of these not improbable propositions, its weight scarcely yet amounts to proof. The subject is too large, and such facts as we possess are too few and too isolated to allow of our accurately gauging their proportions. Research is most important, for facts are above all, and in the first place, needed. Argument is useful by stimulating enquiry, and, so long as it does not limit free-agency, by pinning us down to what we have no right, at present, to regard as more than hypothesis. The author complains of the generally loose employment of the word *specific;* he himself appears to use the word "poison" in the several senses of morbid germ, *materies morbi* (particulate or otherwise), cause of disease, origin of disease, the disease itself, and a something which is not essential to the disease (as developed *de novo*, for instance,) a sort of pathogenic phlogiston; which invests certain passages with some obscurity. The *brochure* is interesting and suggestive; it undoubtedly contains several germs of considerable value, and it will be well alike for patient and practitioner in the future if their careful culture result in the evolution of a creed presenting the specific characters of originality and unquestionable truth.

Handy Guide to Public Health; by Thos. Whiteside Hime, M.B., B.A., Medical Officer of Health of Bradford, and formerly of Leeds. London: Baillière, Tindall, and Cox, 1884. pp. 207.—This is a mere compilation, but such a compilation as was greatly needed. Here, in a volume not much bigger than the visiting list, we have a complete digest of sanitary law, and a mass of useful facts, figures, and formulæ. The former is all that could be desired; the whole of those clauses of the Public Health Act, 1875, which in any way concern the Medical Officer of Health are printed in full, with notes critical, suggestive, and explanatory, mostly taken from the annotated editions by Glen and others, which, as the editor of this *pocket* guide observes, are indispensable in the library; abstracts of all other sanitary laws or sanitary clauses of factory and such-like Acts down to the bakehouses regulations, which were passed on the last day of the Session of 1883; and a chronological arrangement of all the sanitary legislation, Local Government Board circulars, parliamentary papers, returns, reports, &c., with the numbers by which they are distinguished, which will be found almost the most useful feature of the book. The rest of the work gives the impression of hasty preparation. It consists of tables, &c., on the metric system, statistics, facts and figures relating to water, sewage, dietetics, meteorology, and a number of other subjects gleaned from Parkes, Glaisher, &c. Some are such as could not be spared, a few are of doubtful utility, and might be replaced by others more recent and trustworthy, and we miss much that would agreeably enhance the value of the work, but one sentence, following an obsolete table of Letheby's for estimating the dilution

that milk has undergone from its specific gravity, is so extraordinary that we can only think Dr. Hime has failed to convey his meaning:—"Any sample indicated as bad by the lactoscope (of Professor Feser) and densimeter, the examination only taking a few minutes, should be sent to the analyst." As the words stand, they suggest the opening by the Medical Officer of Health of samples which had been sealed in the presence of the seller, a procedure at once unjustifiable and illegal, and which would at once put him out of court. Probably Dr. Hime had a vague notion of those frequent unofficial examination of milks from all the dairies in a district which some analysts make unknown to the seller, following any suspicious indications by taking fresh samples with all the formalities required by the Act. As so many prosecutions have miscarried from omission of a single word, even from the incantation to be uttered while the sample is being taken, or of the form referring to subsequent decomposition, these should not have been left out of an abstract, however short.

Report of the Delancey Fever Hospital, Cheltenham, for the Year 1883.—The institution with which this report deals is a small hospital for infectious diseases partly on the pay system, patients being received gratuitously only from the Cheltenham General Infirmary, those in the public wards pay two shillings per day (the guardians paying for paupers), and those in the private wards five shillings. The total sum received last year from or on account of patients was 389*l.* 10*s.*, from the Urban and Rural Sanitary Authorities 100*l.* each, from dividends 207*l.* 16*s.* 11*d.* out of a total income of 1,293*l.* 4*s.* 10*d.* The cases admitted last year were nearly all scarlatinal, but during the ten years it has been in existence, small-pox has broken out in Cheltenham on twenty separate occasions, though every case having been removed within 48 hours, and the other members of the family re-vaccinated, the disease has never taken on an epidemic character. There is no compulsory notification or power of removing fever cases in Cheltenham, and of the 48 or 49 scarlatina cases received last year, only two were sent in by the guardians and seven by the Local Authority. If the poor could be induced or compelled to avail themselves of its benefit as freely as the well-to-do classes have done hitherto, it might be as successful in the repression of other fevers as it appears to have been in that of small-pox.

Water and Water Supplies and Unfermented Beverages; by John Attfield, Ph.D., F.R.S., &c. International Health Exhibition Handbooks. London: 1884.—More than half of this agreeably written handbook is devoted to a description of the natural history, the chemical and physical properties and the varieties of water; the remainder being occupied with chapters treating of aërated drinks, tea, coffee, cocoa, chocolate, and milk. If there is nothing original, new or striking in the compilation, it is nevertheless to be warmly commended for clearness of exposition, and for the considerable amount of reliable information condensed in a small volume sold at a cheap price.

ABSTRACTS AND EXTRACTS.

SPONDYLOLISTHESIS.

A recent number of the *Archiv für Gynäkologie* (Band xxii., Heft. ii.), contains a valuable and interesting paper by Dr. A. Swedelin, of St. Petersburgh, on a case of labour with spondylolisthesis. He begins by expressing the opinion that this deformity is not so rare as was at one time supposed. In his case the patient was healthy until the age of 17, when she fell backwards in such a manner that the edge of a table caught her in the lower part of the back. Soon after the fall she suffered from pain in that region, which, in spite of treatment, continued severely for half a year; and in the course of this time a backward inclination of the trunk was acquired, the patient feeling as if without this inclination she would fall forward. About a year after the fall she noticed greater prominence of the iliac crests, and protuberance of the lower belly. She was married at 25 and soon became pregnant. At about four months' pregnancy she consulted her medical man who found retroversion of the gravid uterus. He twice reduced the displacement, but it each time returned, and at four and a half months' pregnancy she miscarried. In her second pregnancy retroversion again occurred at the beginning of the fourth month, and this time was successfully corrected by a Hodge's pessary. The presence of pelvic deformity having been ascertained, labour was induced at the 36th week, and terminated successfully, the child, a male, as big as one at full time, being born without assistance. The mother recovered well and was afterwards carefully examined and measured. There were no deformities elsewhere than in the pelvis. The patient stood upright with the knees slightly bent, complete extension of them being painful to her. The gait at first glance presented nothing peculiar, but when carefully watched was seen to be of the "rope dancer type," one foot being put down almost exactly in front of the other and the heel of one foot occasionally striking the other as it passed it. The figure of the patient presented the peculiarities pointed out by Neugebauer as characteristic of spondylolisthesis. "Shortness of stature, especially diminution in the trunk, and therefore apparently disproportionate length of leg; a deep lumbo-dorsal hollow in the spine, sinking of the thorax into the false pelvis; wider separation than normal of the hip bones as compared with the trochanters; the presence in the lateral contour of the trunk of an angle above the iliac crests; width of the hips above owing to greater separation of the innominate bones; but smallness of the buttocks each being bounded by a deep lateral hollow; projection backwards of the upper part of the sacrum, and of the posterior superior iliac spines." The sinking downwards of the thorax leads to the formation of a very marked cutaneous fold, running parallel to the lower ribs, which Neugebauer calls the thoraco-pelvic fold. Dr. Swedelin's case was further complicated by slight scoliosis. The sacrum was also bent, so that its third spine was unusally prominent. This our author attributes to the pressure of the body-weight in sitting. Neugebauer's description of spondylolisthetic subjects as seen in profile also applied exactly to Dr. Swedelin's case: "characteristic saddle-shape of the loins; shortening of the trunk; coincidence of increased lumbar lordosis with diminished pelvic inclination; flattened buttocks; pendulous belly; abnormal visibility from the side of the mons veneris; apparent uprightness of trunk." On palpation the muscles of the lumbar spine could be felt as thick rolls on each side, and between them the last dorsal and upper two lumbar vertebral spines could be felt indistinctly, and the third and fourth lumbar spines not at all; the fifth lumbar spine could be very plainly felt above the base of the sacrum. The upper eleven dorsal spines were easily made out. The pelvis externally looked very large, the ilia well developed, the crests almost horizontal, the spines strongly projecting. The symphysis pubis was high, and the pubic arch narrow. The base of the sacrum was apparently displaced backwards. Above it the last lumbar spine was felt, and in a line with it two other bony projections, one on each side, evidently the inferior articular processes of the last lumbar vertebra. By abdominal examination the spine could be so easily palpated in the interval left by the separation of the recti

that the inter-vertebral substance could be distinguished from the bodies of the vertebræ. It was made out with certainty that the outline of the projecting vertebral mass was not gradually lost in the structures attached to it at the sides, but was sharply defined, leaving an angular hollow on each side. Internal examination gave at first no indication of narrowing of the pelvis; and the finger, pressed up as usual towards the sacral promontory, would fail to detect any. But when the finger was passed up in the axis of the pelvic inlet, then it encountered the displaced lumbar vertebra, sharply projecting, not merging into lateral masses at the side; below it an angular hollow, bounded by the surface of the last lumbar vertebra and the upper part of the sacrum. Both the true and the diagonal conjugate diameters were shortened, the diagonal measuring 10 centimetres, the true, or rather apparently true, conjugate $7\frac{1}{2}$ centimetres, and the transverse diameter of the outlet was only 7·5 centimetres. There was therefore no doubt that the case was one of spondylolisthesis, produced in the way Neugebauer has described, viz., by fracture of the inter-articular part of the vertebral ring." Dr. Swedelin gives complete measurements, which we need not quote further. He then considers the obstetric management of these cases; and has collected and examined from this point of view every case of labour with spondylolisthesis that he could find. The first point of interest in his own case, clinically, is the occurrence of retroversion in each pregnancy, which the author attributes to increased pelvic inclination, bringing the intra-abdominal pressure to bear on the anterior surface of the organ, aided by the deformity which prevented the uterus from righting itself. The course of labour in these cases has before been studied, and on the basis of the recorded cases, by Schwing and by Perroulaz; but Swedelin has been able to collect a larger number of cases than either of these authors. He draws the following conclusions as to the course and management of labour in the spondylolisthetic pelvis—(1) Slight degrees of narrowing of the pelvis by olisthesis, in which the conjugata pseudo-vera (that is, the measurement between the internal surface of the symphysis and the anterior surface of the olisthetic vertebra) exceeds 9 centimetres ($3\frac{1}{2}$ inches) do not as a rule cause any hindrance to the parturient process; (2) Moderate contraction, conjugata pseudo-vera of $7\frac{1}{2}$–9 centimetres (3–$3\frac{1}{2}$ inches) permit labour at term without very great difficulty; (3) Higher degrees, 6·5–7·5 centimetres ($2\frac{1}{2}$–3 inches) cause labour to be attended with great danger to the child, but the prognosis for the mother is favourable; (4) Extreme contraction of conjugata pseudo-vera when it is under 6·5 centimetres ($2\frac{1}{2}$ inches) will not allow the head to pass without diminution in its size; (5) In multiparæ the prognosis of an approaching labour is worse in proportion to the difficulty of the preceding one. From these propositions Dr. Swedelin deduces the following therapeutical rules—(1) With a conjugata pseudo-vera under 7 centimetres premature labour should be induced in the 32nd week; (2) With a pseudo-conjugate of between 7 and 8 centimetres it should be induced in the 36th week; (3) When the dimension mentioned is between 8 and 9 centimetres, pregnancy may be allowed to go to term, but if the patient be feeble, or unfavourably circumstanced, it is better to induce labour in the 36th week; (4) With a conjugata pseudo-vera over 9 centimetres there is no reason for inducing labour; (5) If the patient has been allowed to go her full time, and the pseudo-conjugate is between 6 and 7 centimetres, then the case must be treated according to its individual features, either by craniotomy and cranioclasm, or by Cæsarean section; (6) With a conjugata pseudo-vera below 6 centimetres, Cæsarean section is indicated. Appended to the paper is a valuable bibliographical list of the literature of the subject.

DISEASES OF CHILDREN.

Significance of certain Symptoms in Diseases of Children.—In an interesting paper in the *Deutsche Medicinische Zeitung*, Dr. S. M. Politzer enumerates certain symptoms to which he attaches great importance in the establishment of a diagnosis. Dr. Politzer has had great experience in children's diseases, having been for many years director of the Children's Hospital at Vienna. (1) *If the cry of the child has a decidedly nasal sound*, we should always look for retro-pharyngeal abscess, never omitting when we hear this peculiar nasal or guttural sound to touch the posterior wall of the pharynx with the finger. If abscess is present we feel the characteristic tense, fluctuating swelling. (2) *An expiration, which is greatly prolonged while inspiration is normal and no other disturbance of breathing is present and no dyspnœa exists*, is a sure sign of chorea major. The same may be said of a greatly prolonged, very loud, and forcible expiration, sounding like bellowing. This symptom of bellowing expiration has a typical character, it may happen for many weeks daily at the same hour, recurring every 7 to 10 seconds, and it usually consists of a single prolonged and forced expiration, or of a single expiratory roar. For months sometimes this symptom is the only sign of chorea major. It is easily cured by large doses of quinine, but it is very prone to return and become accompanied by other symptoms of chorea. (3) *The symptom of high thoracic, continually sighing inspiration*, indicates the beginning of debility and paralysis of the heart. This symptom makes its appearance before cyanosis or paleness of the face, weak, thread-like pulse, and coldness of the face and of the extremities develop themselves. Contrary to stenotic respiration, as observed in croup, pneumonia, and œdema of the glottis, this sighing inspiration is not characterised by forced contractions of the diaphragm, and is not of abnormal type, but is accompanied by a laborious rise and fall of the thorax and neck, and instead of a croupy noise by continuous sighing and moaning. No matter how the paralysis of the heart may be produced—by the so-called heart poisons, as quinine, salicylic acid, pilocarpin, and digitalis, or otherwise, the symptom is pathognomonic of the disease, and wherever it is met with precautionary measures should be resorted to. In some cases of acute fatty degeneration of the heart the same symptom has been observed. (4) *Expiration decidedly diaphragmatic and accompanied by a whistling sound of high pitch*, denotes bronchial asthma. A similar symptom is also met with in croup, but here it is associated with stenotic forcible inspiration. The same is observed in capillary bronchitis, but the noisy breathing through the nose, the rapid development of pulmonary emphysema, the sudden appearance and disappearance of intense dyspnœa, and the fact of the latter and the whistling remitting during deep sleep, will prevent error. (5) *The existence of noticeable pauses between the end of each expiration and the beginning of the next inspiration* indicates severe catarrh of the larynx, and proves the absence of croup. In consequence of the enormous aspiration of air in croup, inspiration and expiration follow each other immediately, while in laryngeal catarrh a pause takes place between the two acts, as the physician can convince himself by bringing his ear near the mouth of the patient, or by carefully watching the diaphragm and the neck, both of which are at rest during a pause. (6) The so-called *stridulous expiration*, if present at birth and continuing day and night with rare interruptions of ten or fifteen minutes' duration, and usually considered by anxious mothers and the uninitiated a dangerous and ominous symptom, has neither diagnostic nor any other importance, being perfectly innocent, and generally ceasing of its own accord after the lapse of a few months. There are also some symptoms facilitating the early recognition of certain *diseases of the brain* in children: (1) *A remarkable drowsiness, not accompanied by fever or any*

other symptom, and continuing for a long time (one to three days) often precedes basilar meningitis; vomiting, fixed pain in the head, and even a slow, irregular pulse have not the same great significance as this sleepiness, as they may also happen in other maladies. Certainly, stress must be laid upon the absence of fever, for many infectious diseases begin in children with a peculiar drowsiness, always associated, however, with more or less high fever. (2) *Prominent anterior* fontanelle, if reaching decidedly above the level of surrounding parts, and if tense and of such resistance as not to yield under pressure, proves the presence of an exudation within the cranium, or an increase of the contents of the latter, and is met with in persistent meningitis of the convexity, in cerebro-spinal meningitis of the epidemic variety; in acute, essential, and chronic hydrocephalus (here tense, but not necessarily very prominent); in great tumours; in echinococci; in acute œdema of the brain; and in intra-meningeal apoplexy. In simple congestion, in acute hyperæmia of the brain, the fontanelle is always soft and depressible. If it is very prominent, almost wedge-shaped, and unyielding, without the least trace of penetration, the diagnosis of apoplexy of the new born, and a large intra-meningeal extravasation of blood can be made with certainty. (3) *Remarkably slow motion and long fixation of the balls of the eye, with a vague look into space, accompanied by a peculiar slow opening and closing of the eyelids* is a sign of commencing basilar meningitis. Next, *peculiarities of the cry* in children aid us in diagnosis. (1) *Violent, loud, penetrating cries, lasting two or three minutes, accompanied by great anxiety, as expressed in the face, and setting in almost typically one or one and a half hours after the child has fallen asleep* are a symptom of nightmare, and easily cured by quinine, which should be administered one or two hours before retiring. (2) *Periodical crying, lasting five to ten minutes, and happening several times during the day, but occasionally only at night*, draws attention to spasm of the bladder, if colic and dyspepsia are not present, and is cured by an emulsion of lycopodium, with or without belladonna. (3) *Frequent crying during defæcation, dread of the act, and decided opposition of the child to going to stool*, indicates the existence of fissure of the anus. Constipation should be avoided in such cases, and zinc ointment with belladonna locally applied. (4) *Violent, very painful, and nearly continuous crying, with restless throwing of the head from side to side* on the pillow, and frequent grasping of the head by the hands, are generally indicative of otalgia, and otitis. (5) *Crying, lasting days and weeks, greatly increased on touching or moving the extremities*, accompanied by continuous and enormous perspirations and fever, denotes the presence of acute general rachitis, while the same symptom, without the sweating, but with decided emaciation, proves the existence of hereditary syphilis, and that the case is hopeless. Of a great number of other symptoms, the following only are mentioned by Dr. Politzer, as they are of more common occurrence, and of greater importance. If the children are remarkably weak, and little inclined to moving about after apparently innocent complaints of very short duration, *spinal infantile paralysis* may be expected. The least disturbance of hearing after acute disease must be carefully inquired into, as it might be caused by *circumscribed meningitis* at the base of the fourth ventricle. Depression of psychical activity in small children, after grave infectious diseases, frequently forms the commencement of *acquired idiocy*. Here strychnine has proved an invaluable remedy. Ossification of the bones of the cranium, postponed longer than normal, denotes commencing *rachitis*. An anxious, stiff action in walking, sitting, rising, &c., and pain expressed in the face of children who do not yet walk, when they are lifted or laid down, are met with in commencing *spondylitis*. When children with a very large closed cranium vomit for weeks everything they eat, we have the proof that *acute hydrocephalus* is being added to the former chronic disease.—*Philadelphia Medical Reporter*, July 12.

Infantile Summer Diarrhœa.—Just at the present time, when we have been reading every week of the enormous mortality from infantile diarrhœa, any paper would be read with interest that attempted to deal with this important subject, and especially so when it comes from one who has already shown by his writings on children's disorders that he is entitled to a hearing. Dr. J. Lewis Smith has given his views in the July number of the *Archives of Pediatrics*. After premising that the breast milk is the proper and best food for an infant, he proceeds to discuss what is to be done when this is not to be had. The best substitute he declares to be peptonised milk; this closely resembles human milk in appearance, and its casein is either digested or left in an easily digested state, and not liable to be precipitated in thick curds in the stomach as is the case with cow's milk. Farinaceous food is to be avoided in the case of young infants, as they cannot digest starchy matters; if however these have been previously converted into glucose the objection no longer holds good. Dr. Smith's plan for accomplishing this is to take some wheat-flour, packed dry in a firm muslin bag and placed in water, so as to keep it constantly covered, and let this be kept over the fire for three or four days; at the end of this time the outer part is peeled off leaving a lump behind looking something like yellowish chalk. This should be scraped into a powder; about a tablespoonful of it should be mixed with twelve tablespoonfuls of water and heated. For a child of six months old half a teaspoonful of extract of malt should be added to a tea-cupful of this, and a little salt may be put in. This may be given alternately with the peptonised milk. White of egg or a little raw beef juice may be added if more nourishment seems to be called for. Change of air, when the child lives in a crowded city, is always very beneficial. It will be seen that these excellent regulations are intended for the children of the well-to-do, and not for the poorer classes. In the August number of the same periodical, Dr. Smith gives the following formula as the best for making an artificially humanised cow's milk;—One gill of cow's milk, fresh and unskimmed; one gill of water; two tablespoonfuls of rich cream; two hundred grains of milk sugar; one and a quarter grain of extractum pancreatis; four grains of sodium bicarbonate. This to be placed in the feeding bottle, and then heated for twenty minutes. For the acute thirst that infants sometimes suffer from, Dr. Smith orders ice water with a little whisky or brandy, the rule being to allow two or three drops of the stimulant for each month in the age, every second or third hour.

Acute Yellow Atrophy of the Liver.—This affection is so rare in children, that every case deserves to be carefully studied. Dr. Hyla Greves having met with a typical case in an infant of 20 months has recorded it in the Liverpool *Medico-Chirurgical Journal* for July, and has taken the opportunity to pass in review the symptoms of the disease as seen in children, and to offer some general remarks on the nature of the affection. There is nothing in his case that calls for special notice; the child was ill for some days, and under observation before any symptoms of a serious nature made their appearance. The liver was at the commencement enlarged and not tender; later on, when it began to get smaller, it became very tender. Examination of the liver after hardening showed a marked increase in the connective tissue, especially around the portal vessels; a large number of free oil globules also were present between the cells. In many places all trace of liver structure had disappeared, and the small bile ducts appeared to be choked with epithelium which had undergone fatty degeneration. The course of the disease he divides into two stages: during the first of these there is gastric catarrh with enlargement of the liver; the symptoms in the later stage may be grouped under the head of nervous, including headache, drowsiness, rigors, convulsions, delirium and coma. Hæmorrhages from the mucous surfaces are common, the pulse and temperature often remain normal or subnormal until late in the disease, the liver decreases in size and becomes very tender, vomiting is almost constant and the urine is acid, the urea and phosphates being greatly diminished, and albumen, leucin and tyrosin frequently present. As to the pathology of the disease the following are the considerations which he puts forward in support of the theory that it is a general disorder. The epithelium of all the glands in the body shows some parenchymatous degeneration, and the muscles of the heart and some of the voluntary muscles are in a similar state. The resemblance

of the disease both to yellow fever and to phosphorus poisoning supports the idea of its being not a local disease. The almost absolute identity with some cases of icterus gravis suggests the notion of some general blood poison, and the discovery of micro-organisms in the liver and in the blood during life points in the same direction.

Spina Bifida.—Professor Demme has collected all the cases of spina bifida which have been treated in the Jenner Children's Hospital at Berne up to the year 1882 From out of a total of 36,148 patients, there were 57 cases of spina bifida—31 female and 26 male children. In two of the cases, two earlier children of the same family, and in three cases, one previous child had suffered from the same deformity. In 29 of the 57 cases, the deformity occurred in the first born child; in 17, the second child; in 11 cases later children. In 13 cases besides the spina bifida, there was club-foot, in 3 cases hare-lip, in 1 case ectopia vesicæ. In 31 of the cases the parents were quite strong and healthy, and nothing untoward during pregnancy occurred to account for it; in 16 of the cases, one or both parents appear to have been rather weakly; in 2 cases the mother was the subject of hare-lip, in 3 cases the father had congenital talipes. In 5 of the cases, the tumour was situated in the cervical region, in two in the cervico-dorsal, in 13 cases in the dorsal region, in 2 of the dorsal cases there were two tumours; in 17 cases in the lumbar region; in 11 cases in the lumbo-sacral region; and in 7 cases in the sacral region. A careful examination of the 57 cases showed that in 3 cases, the hydro-meningocele, was apparently not associated with division or defect of the vertebræ, but consisted in a prolapse of the membranes through the inter-vertebral foramina. In 19 cases, the meningocele had escaped through defect of certain of the vertebræ, and in the remaining 35 cases, in addition to the meningocele, there was also myelocele. The majority of the simple hydro-meningoceles occurred in the cervical and dorsal regions, while on the other hand the great majority of cases which occurred in the lumbar and sacral regions were examples of hydro-meningo-myeloceles. 17 of the 57 cases were complicated with more or less hydrocephalus —no case of Rachischisis anterior (cleft of the bodies of the vertebræ) had, as yet, been seen at this hospital—25 of the 57 cases were operated upon, of which 15 died, 7 cases recovered, 3 were discharged incurable. Of the 32 cases not operated upon, 11 died between the 8th and 14th days, 9 between 15th and 22nd days, 5 between 23rd and 30th days, 3 between three and four months; one at five months, one at eight months, one at twelve months and one at the end of the second year. Death took place in the 32 non-operated cases either from marasmus, or rupture of the sac, or through suppurative arachnitis, or from inter-current diseases such as broncho-pneumonia or capillary bronchitis. From the foregoing statistics, Professor Demme draws the following conclusions as to prognosis and probable effects of treatment. Antiseptic treatment notwithstanding, the operative treatment of mylo-meningocele has always been less favourable than that of pedunculated meningocele. The differentiation therefore between the two forms is of great importance from the operation point of view. The following are the diagnostic points (though not absolutely reliable) of a hydro-meningocele:—(1) absence or inability to detect, a cleft, or smallness of the cleft into the vertebral canal; (2) a thin pedicle; (3) transparency of tumour; (4) absence of umbilication of the tumour; (5) absence of paralysis of limbs, rectum or bladder.—*Twentieth Report of the Jenner Children's Hospital in Berne.*

Hæmaturia as a Symptom of Renal Cancer.—Dr. Leibert, of New York, after relating a case in point, the chief interest of which lay in the fact that the infant, aged ten months, died within three weeks of the appearance of the first symptoms—severe and unexplained vomiting, and diarrhœa—collects together 50 recorded cases of primary "cancer" of the kidney in children under ten years of age, for the purpose of testing the value of hæmaturia as a symptom of this disease. He quotes from various treatises the diagnostic value which authors attach to hæmaturia, and the wide divergence justifies his statement, "that the contradictions in respect to hæmaturia in renal cancer increase with the number of works on the subject." Of the 50 collected cases, in nineteen hæmaturia occurred, whereas in 75 cases in adults, this symptom only occurred in 23 cases. *Thus the symptom is more common in children than in adults.* The relative frequency of its occurrence is not without interest; in the first year of life it occurred only twice in 12 cases; in the second year of life, three times in 8 cases; in the third year of life three times in 6 cases; in the fourth year, four times in 7 cases; in the fifth year, three times in 7 cases; in the sixth year, once in 3 cases; in the seventh year, twice in 3 cases; and in one case in the eighth year of life. According to these figures then, the symptom is commonest in the third, fourth, and fifth years of life. Apart from the more frequent occurrence of febrile diseases, it is not improbable that the numberless accidents to which these ages are subject may contribute something to this result. The symptom appears to come on in the early stages more frequently than in the later stages; not infrequently, it is the earliest appreciable symptom; it is generally sudden and unexpected in its onset; in only four of the 50 cases was it accompanied by pain; the hæmorrhage is often profuse. The question is discussed whether the early onset of hæmaturia, common in renal cancer, can be regarded as at all diagnostic. In nearly all cases, the hæmorrhage is profuse and unaccompanied by colic. When there is pain, the pain ceases so soon as the hæmaturia comes on. In nephrolithiasis, on the contrary, the pain is usually during or subsequent to the bleeding, which is never profuse, and there are generally other signs of existing pyelitis. In cancer cases, at first there is no pain on pressure; in the latter there is generally pain or pressure in the region of the kidneys or ureters. When the hæmorrhage ceases, if other signs of pyelitis are absent, and there is no sediment of any kind in the urine, Gerhardt teaches that the case is probably one of renal cancer. The absence of wasting is nowise diagnostic, for this only sets in after the tumour has become diagnosable by its size.—*Jahrbuch f. Kinderheilkunde*, Vol. xxi., Part 3.

The Relation of Over-Nutrition after the Acute Fevers of Childhood to Bone Disease.—Under this heading Dr. Jacobi (*New York Medical Journal*, August 9th) draws attention to the facts, known to the laity as well as to physicians, that children not only appear very tall after having gone through a severe illness, and particularly through a severe infectious disease, but that they are really taller than before the sickness, and that they grow very rapidly for a short time during and after such infectious disease. The growth or tallness is not only apparent from the patient having become thin, but by measurement it can be shown that there is an actual increase of stature. The body becomes taller by an elongation of the bones; the bones grow by a rapid proliferation of the cartilage which separates the epiphysis from the shaft. If the bone grows, it must be in consequence of a nutritive process, which may become an irritative process in that neighbourhood. And the question arises whether high fevers, and infectious fevers particularly, have not the effect of producing such irritative disorder as proves under certain circumstances a cause of increased nutrition. Observation showed that after all cases of infectious disease in particular, the epiphyses and adjoining cartilages were very hyperæmic; and where there was much blood there was at least an opportunity for over-nutrition. Thus it is that after most infectious fevers not only the epiphyses are apt to grow thicker, but also the diaphyses to grow longer, in consequence of the nutritive irritation of the cartilage (and periosteum). In cases in which the nutritive disorder, the hyperæmia, was not limited to its physiological condition—where it was a little more than physiological—it became pathological. In most cases the over-nutrition and the resulting growth ceased after a while and returned to the normal state; but in others they were carried to such an extent as to become pathological and to cause necrosis. Dr. Jacobi has seen quite a large number of cases of this description. Such over-nutrition of the epiphyses is the cause of one of the forms of so-called "growing pains." Growing pains occur very frequently after a severe illness, and especially after a severe attack of an infectious fever, and are due to a local hyperæmia which may proceed to inflammation. The other

forms of "growing pain" are either rheumatic or neuralgic in character.

Tuberculosis.—Professor Demme, in Berne, defines tuberculosis of children like that of adults, as a specific infection disease, associated with the entrance of Koch's bacillus into the affected organ. In order that this infection take root, a soil favourable to the development and propagation of the bacillus is necessary, thus supporting the view of individual predisposition to tubercular disease. This predisposition can be transmitted from generation to generation. Thus, of 366 cases of primary visceral tuberculosis, this hereditary predisposition was found in 71·8 per cent.; in 823 cases of joint and bone tuberculosis, in 69·6 per cent.; in 692 cases of lymphatic glandular tuberculosis, in 65·4 per cent.; and in 51 cases of lupus, the hereditary tendency was found in 37·2 per cent of the cases. This individual predisposition can further be acquired through certain external life influences, especially through suffering from infectious diseases, such as measles, and more rarely whooping cough. Thus of individuals, not the subject of any hereditary taint, who had suffered from measles, 6·8 per cent. got tubercular pneumonia; 8·1 per cent. joint tuberculosis; 8·7 per cent. lymphatic glandular tuberculosis; and 3·9 per cent. lupus. As to the mode of entrance of the bacilli into the organism, that by inhalation or by ingestion was by far the commonest at all ages; nevertheless, in any given case, the difficulty of locating the first tubercular starting-point rendered this observation, seeing the smallness of the figures, not very reliable. As regarded the extremities as places of possible entrance for the bacillus, it appeared that eczematous and impetiginous eruptions, so common in childhood, and the subsequent localization of the bacillus in the bones of the extremities after possible injury, ought certainly to be reckoned with. As a rare mode of infection, Dr. Demme records four cases (without hereditary tendency) in which milk of tubercular (Perlsucht) cows appeared to be the source of infection. Two cases of congenital tuberculosis are also given.—*Twentieth Report of the Jenner Children's Hospital in Berne.*

The Treatment of Hysteria in Children.—Seeing the number of cases of hysteria which are computed to date from childhood, estimated by one observer at one-fifth of all the cases, and by others at an even higher proportion, Dr. Forchheimer has thought it desirable to call attention to the importance of treating hysteria in childhood. This he has done in an admirable article in the *Archives of Pediatrics* for June. The first point is, that neuropathic parents will have children liable to the same complaint; such children should be educated under the guidance of a medical man. He would take care that the child had plenty of exercise of a proper kind, massage and shampooing when the child was quite young, gymnastics, riding, swimming later on. Exercise in the open air must be insisted upon, and the child must be removed from its parents; the importance of this last point it is impossible to exaggerate. It would be well that the attendant chosen should undertake the teaching of the child, but if he must be sent to school, it should be a large school where there were lots of other children, and the hours were not too long. The study of music should be absolutely forbidden, for Dr. Forchheimer believes that all musicians are more or less neurotic. The diet should be carefully chosen, albuminous food, easily digested, starchy material, young vegetables and fruit, cooked, or if raw quite ripe. Medicine is not often beneficial, but some preparation of iron might be indicated. This is entirely preventive treatment; should a child have had an attack with symptoms of hysteria, the plan recommended by Weir Mitchell in adults is to be adopted. The child must be removed from friends and relations; and have a nurse, who will at first leave the child to itself as much as possible, even without toys; a strict milk diet should be ordered and massage combined with daily galvanism. As the child gets better, the restrictions may be lessened.

Antipyrin in Children's Practice.—As the result of numerous trials of this new anti-febrile substance in children at the Erlangen polyclinic, Professor Penzoldt (*Berliner Klinische Wochenschrift*, July 28) arrives at the following conclusions:—(1) It is to be regarded as a very suitable means for diminishing the temperature in the febrile affections of children. (2) In proper doses it effects a diminution by several degrees during several hours. (3) The diminution of the pulse does not always correspond to that of the temperature. (4) Its influence upon the general condition of the patient is usually favourable. (5) Vomiting only sometimes attends its employment; but when this persists the antipyrin must be given in an enema. (6) The proper dose to begin with is as many decigrammes as the child is years old, repeated three times, at intervals of one hour. If this dose does not suffice for the production of a decided effect, then it must be increased decigramme by decigramme. In an enema we may give at a single dose from 3 to 6 times as many decigrammes as the child has years. (7) After long use of it the child's system sometimes gets accustomed to the remedy.

Ephemeral High Temperature in Young Children.—In a paper published under this title, in the *New York Medical Journal*, July 19, Dr. H. N. Read, after relating several cases in which the maximum temperature ranged from 103·5° to 106°, while the patients were quite well in twenty-four hours or less, remarks on the analogy presented by such cases to those of abnormally high temperature occasionally observed in adults, as a sequence of injury to the nervous system. The points in favour of such sudden and ephemeral pyrexia in infants being due to disturbed nerve inhibition, and not to interference with the other heat-controlling factors (tissue metamorphosis, and heat conduction or radiation) are briefly, non-interference with the secretions of bowels and kidneys, &c., in proportion to the degree of fever; the skin more moist and natural than in ordinary fever; marked disturbance of the nervous system; and the ready subsidence of the high temperature on the exhibition of a nerve sedative—chloral being *the* remedy to administer. The chloral treatment of these cases is also recommended by Da Costa and by Wilson.

Cystic Hygroma of the Neck.—Dr. Plath, of Stettin, records a case successfully treated by free incision after punctures, several times repeated, had failed, the last of which appears to have set up inflammation and suppuration within the sac. The child, about one month old, was well nourished and otherwise healthy. The hygroma was situated below the jaw, around the neck, reaching as low down as the manubrium sterni, and was multilocular. The day following the last tapping, there was a little redness of the skin, the child was feverish and restless. There being no improvement at the end of a week, it was decided to incise the cysts, which was accordingly done, and a quantity of healthy pus from one, and semi-coagulated reddish brown fluid evacuated from another; they were then irrigated with a 2½ per cent. carbolic solution, and then filled with iodoform gauze. There was very little reaction, and the places were quite healed within the month.—*Jahrbuch f. Kinderheilkunde*, Vol. xxi., Part 4.

Congenital Absence of Left Wing of Diaphragm.—The specimen was obtained from the body of a coloured infant. The stomach, the left lobe of the liver, the greater part of the small intestine, and the cæcum were all in the left pleural cavity. The left lung was the size of a hickory nut, and emphysematous; the right lung was well developed. —*New York Medical Journal*, April 12th, 1884.

Feeding Children on Masticated Food.—Dr. Vanderbeck, Professor of Hygiene in Philadelphia, calls attention, in the *Medical Reporter*, August 16, of that city, to the fact that in the far south of the United States, and especially in Texas, it is a common practice for mothers to chew the food for their children, spit it out, and feed them with it. These people, too, are so firmly set in their ways, that any remonstrances are likely to be indignantly opposed. He asks for information from the practitioners of those parts whether, apart from the disgust such a practice should excite, the health of children so fed suffers, and whether their comparative mortality is greater.

Mental Alienation in Young Children.—Professor Max Leidesdorf, in a paper which he read at the Vienna Medical Society (*Wiener Medicinische Wochenschrift*, June 28 and July 5), observes that at the beginning of the present century Carus entirely denied the existence of psychical disturbances in children; and that it is only of late years, by means of the works of Brière, Conolly and Maudsley and their successors, that the subject has been placed in its proper position. He has himself for some years past paid much attention to it, in consequence of his having so often found that a proper appreciation of certain cases and certain forms of insanity in the adult can only be obtained by investigations carried back into early childhood. But if it is now certain that psychical disturbance may occur even before the fourth year of age, yet its relative frequency cannot well be determined, the statistics of lunatic asylums simply showing that admissions take place only rarely prior to the eighteenth year of age. By the census of Prussia for 1880 it was shown that there were 66,345 insane, or 1 to 411 adult inhabitants, while there was but 1 insane child to 1,400 children. These statistical returns do not give even an approximative statement of the prevalence of the affection in children; but if we abstract cases of idiocy with or without epilepsy, dependent upon anomalies in the development of the brain, it must be confessed that insanity as it occurs in the adult is rare in childhood. But separate elements of such a condition of a rudimentary and transitory nature are frequently met with in the form of shortly lasting attacks of depression or excitement, alarm, and hallucinations. Professor Leidesdorf has often met with, in children not more than 5 years of age, transitory but frequently recurring conditions of depression, the causes being generally hereditary predisposition, loss of blood (*e.g.*, in pertussis), or preceding severe diseases, such as typhus, measles, scarlatina, &c. He refers to the case of a girl 5 years of age, who, although damaged hereditarily, was, as regards her intellect, in quite a normal and satisfactory condition, and yet was frequently seized on going to bed with attacks of groundless alarm, which lasted an hour or so, but leaving her in a normal condition. Sometimes, too, a hypochondriacal disposition is observed in children 4 or 5 years old, and this is especially the case when parents pay an exaggerated attention to their children's health, magnifying every trifling ailment into a serious disease, and managing by their excessive care to transfer their own anxiety to those who are the objects of it. On other occasions it is the witnessing severe illness, or on the death of relatives, which saddens the child; and Professor Steiner refers to the case of a boy 8 years of age, who, having seen a sister die of phthisis, from that time was the victim of the extremest fear of becoming a similar sacrifice. On the other hand, Professor Leidesdorf has met with examples in boys from 6 to 8 years of age of great or even maniacal excitement with destructive impulse, which however lasted only for some hours. In one case, the maniacal attack came on at the same hour every evening; but after some months the disposition entirely disappeared. A more frequent form of transitory psychical disturbance is hallucination of a disagreeable or terrifying nature, a typical form of which is well known to children's doctors under the name of *Pavor nocturnus*. Children from 3 to 8 years of age, in a perfectly normal condition, after some hours sleep are suddenly awakened, a prey to the greatest anguish, with pallid face and fixed look. The entire body is bathed in sweat, they utter loud screams, do not recognise those who surround them, and are the victims of hallucinations, which sometimes take the forms of dogs or serpents threatening them. These attacks sometimes come on at the same hour. At the end of an hour or less they fall asleep again, and on awakening are quite unaware of the occurrences of the night. Another type of transitory psychical disturbance is constituted by natural somnambulism, a condition which presents a great similarity to certain disturbances of consciousness which are sometimes met with prior to, or after, fits of epilepsy. These attacks of somnambulism occur not only at night in the midst of sleep, but also in the daytime. Peter Frank relates a case of this somnambulism brought on in a little girl through the operation of sudden fear, and Professor Leidesdorf gives interesting particulars of another girl, 7 or 8 years old, who was liable several times a day to hypnotic attacks, during which she exhibited many actions remarkable for the regularity of their execution. At the end of some months these attacks entirely disappeared. Besides these transitory conditions other psychoses may be observed in children 5 or 6 years old, which persist with variable intensity during the rest of life. To these belong the *ideas of constraint* (*Zwangsvorstellungen*), which are psychical representations entirely independent of the will, and which those surrounding the child take for simple creations of the fancy. Dr. Leidesdorf's experience in this matter has been gathered in part from children 7 or 8 years old, and in part from adults, who suffering from these images traced them back to early childhood. These manifestations differ from delirious ideas, as, contrary to what happen with these last, their subjects are quite aware that they have to do with an abnormal condition. The patient tries to repel these ideas, but in the struggle between the will and the ideas it is the latter that is always victorious. Some adults have been tormented by this condition from their earliest childhood, and have found their studies and occupations greatly interfered with; so that this double mental exertion, a part of which consists in withstanding these images, may at last tire them out into alienation. Prolonged mental affection in the proper sense of the word, such as we meet with in the adult, is very rare in children under 14 years of age, and on account of its rarity Professor Leidesdorf cites some cases from his own and others' practice for which we have not space. The more grave forms of neuroses are frequently accompanied by psychical disturbances, which last as long as the neuroses themselves. This is observed in epilepsy, chorea, and infantile hysteria. Hysteria, accompanied by psychical disturbance, is met with in children from 5 to 14 years of age; and, according to the author's observations, it is the gravest form of hysteria which usually attacks children. Another form of disturbed mental condition observed sometimes in young children is a disposition to simulation, a remarkable case of which is related, and another quoted from West. Professor Leidesdorf terminates his paper by some observations on moral insanity which, in its rudimentary stages, is not unfrequently met with in children.

GENERAL CORRESPONDENCE.

THE ÆTIOLOGY OF SPINAL CURVATURE.

[To the Editor of the Medical Times.]

Sir,—It is true my quotation from your editorial summary of Mr. Noble Smith's lecture on Postures in School, &c., was not taken from the paper read at the Congress upon School Hygiene, because I limited my criticism to that part of the lecture which attributed the causation of spinal curvature to muscle fatigue, brought on by the alleged too strict discipline at school, as "walking in file," and "sitting up." I will now quote the exact words which formed the basis of my remarks, as I wish to express correctly what was said and written. "Marching in file is very necessary work for soldiers . . . but it is not a proper routine exercise for girls." "They (schoolmistresses) try to keep their pupils straight, but then their plan defeats its object, and they produce the very evils that they are attempting to avoid." "Enforced 'sitting up' is probably the commonest cause of spinal curvatures." I must again express opinion that the spine suffers much more from laxity of school discipline than the reverse. I observe that Mr. Keetley, in the *British Medical Journal* of this week, also "challenges the gentlemen who advocate the muscular origin of scoliosis."

I am, Sir, yours, &c.,

FREDERICK CHURCHILL.

South Kensington,
2nd September, 1884.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, August 28th, 1884:—

Howard Davies, The Ash Grove, Pontypridd; Hanway German, Maywood, Sevenoaks; Charles Robert Mortimer Green, St. Simon's Vicarage, Morpeth, P.C.; Tamiz Uddin, 3, Pump Court, Temple, E.C.; Henry Gordon Oliphant Wharry, 6, Gordon Square, W.C.; Edward Wood, Oaklea, Lansdown Rd., Tottenham.

The following gentleman also, on the same day, passed the Primary Professional Examination:—

George Julius Congdon, Guy's Hospital.

Admiralty.—In accordance with the provisions of Her Majesty's Order in Council of April 1, 1881, Fleet-Surgeon William Shute Fisher, B.A., M.B., has been placed on the retired list, with permission to assume the rank and title of retired Deputy Inspector-General of Hospitals and Fleets. Staff-Surgeon John Buckley has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet. The following appointments were made on Saturday, August 30th:—George W. Low, Surgeon, to the *Alexandra*, additional; Mr. Albert P. Wells, to be Surgeon and Agent at Douglas, Isle of Man; Mr. J. Claque, to be Surgeon and Agent at Castletown, Isle of Man. The following appointments were made on September 3rd.: Surgeons—Charles W. Hamilton and Henry Harris, to the *Alexandra*; Edward Ferguson, to the *Rapid*; John Ottley, to the *Vernon*; William H. O'Meara, to the *Repulse*.

Army Medical Department.—Deputy Surgeon-General Francis Holton, M.B., retires on temporary half-pay. The date of appointment as Surgeons of the Surgeons on Probation named in the *Gazette* of August 26, 1884, is August 2, 1884, and not as therein stated.

King's College Hospital.—The Queen has given a donation of 100*l.* to the funds of this hospital.

Hospital Saturday.—The last meeting of the Board of Delegates of the Hospital Saturday Fund, prior to the eleventh annual street collection, which will be made on the 6th inst., was held on Saturday last at the central office of the fund, 41, Fleet Street. Mr. J. M'Gregor presided. There was a full attendance of delegates. The secretary (Mr. R. Frewer) reported with regard to the workshop collection carried on since May last, with the sanction and support of the principals in 20,000 industrial establishments of the metropolis, and which formed the main and most important branch of the work of the fund, that it was likely to produce this year a sum considerably in excess of the amount realized in preceding years. A circular, signed by Mr. S. Morley, M.P., the president, and Mr. H. N. Hamilton Hoare, the hon. treasurer of the fund, had been sent to each of those 20,000 firms reminding them of the near approach of Hospital Saturday, on and after which the sums collected would have to be paid. A result of this reminder was the receipt of many applications for more collecting sheets and boxes. Among those who had received the collection sheets were the whole of the metropolitan railway—the companies having termini—and dock companies, the Post Office authorities, the City and Metropolitan Police the Fire Brigade, the Railway Clearing House, and, for the first time, the Salvage Corps. Mr. Noble, the manager of the Midland Railway Company, had made two further applications for sheets, as the number at first supplied was found to be wholly inadequate. Fifteen hundred specially printed sheets, distributed according to the instructions of the central office, had been supplied to the Post Office authorities. The Chief Commissioner of the Metropolitan Police had intimated his willingness that the police should afford protection and all necessary assistance to the lady collectors at the different stations as in previous years; and Major Bowan, of the City Police, besides promising that the police under his control should give especial attention to the lady collectors, had undertaken to place constables on duty at the central office from midday on Saturday next until midnight on the following Monday, when it was expected the counting would be completed.

International Health Exhibition.—A special demonstration was given on Tuesday afternoon in the Hygiene Laboratory by Mr. Cassal, F.I.C. (the public analyst for High Wycombe), on arsenic, in connection with the manufacture of articles for household use. After alluding to the isolation of arsenic as an element by Brandt, in 1773, specimens of metallic arsenic and of its oxide were shown, and it was demonstrated experimentally how volatile they are. In the state either of fine dust, of metallic particles, or of the volatile gas, they are highly poisonous. As they are used not only in the manufacture of wall paper of other colours besides green, in calico printing, in gloves, stockings, carpets, &c., and even in fly-papers, it was pointed out how important it is to have convenient tests for its presence so as to avoid the use of articles in which it has been introduced. In the case of paper or material that can be torn up and worked into a pulp, the warming of it with hydrochloric acid, or with sulphuric acid and common salt will free the chloride of arsenic if there is much arsenic present, and the dark colour produced by this is at once manifest. How easily any one may do this was illustrated. A more delicate test, known as Marsh's, is the employment of hydrosulphuric acid. It was shown to be by no means complicated, but it can hardly be called adapted for popular use. Mr. Cassal especially mentioned that in many household books such things as orpiment and realgar are recommended for various uses. They are, however, only names of compounds of arsenic, and should be avoided. A second demonstration in the Hygiene Laboratory was given by him on Wednesday, when the subject was "Examination of Drinking Water." The object was to show simple tests by which people may themselves examine their own drinking water in relation to its more markedly dangerous pollution. Hard waters, that is those which contain much salts, are injurious, and the simple test for them is the fact that they decompose soap. With a soap solution of known strength the hardness of different waters can be told by the amount of solution that has to be added to produce a permanent lather. The poisonous metals most frequently met with are lead and iron, for it is a fallacy, though a popular one, that much iron in water is beneficial. Sulphate of ammonia will show if either of these are present, as a dark tinge is produced in the water. The addition of hydrochloric acid will reveal which of the two is the cause of the colour, as it dissolves the lead precipitate but not the iron. As a test for organic matters present, a simple way is to evaporate the water till a residue is left, and submit this to ignition. The production of a dark colour indicates the presence of carbon, and a smell as of burnt feathers the presence of nitrogen. Permanganate of Potass (Condy's fluid) is a good and simple test, but the strength used should be known, or unreliable results will follow. As a test for ammonia, which should not be present in large quantities, "Nessler's test" is excellent, and this can be had of chemists of the standard strength. A complete examination of water requires, of course, a skilled analyst. The practical illustrations which accompanied the demonstration were clear and showed the simplicity of the processes.

Hospital Accommodation.—At a meeting of the Metropolitan Asylums Board on August 30th, a discussion took place on the subject of the precepts issued by the Board. It arose upon the receipt of a letter from the Guardians of St. Mary, Islington, containing a resolution passed by that body declaring "that taking into consideration the enormous and continual increase in the precepts of the Metropolitan Asylums Board, the amount of such precepts having nearly quadrupled since 1880, and also that one-half of the accommodation in the hospitals under the jurisdiction of that Board is at present unoccupied, this Board earnestly protests against any further hospital being erected by the Metropolitan Asylums Board, fully believing such a course to be quite uncalled for, and therefore an unnecessary burden on the ratepayer, this Board is of opinion that the Hampstead Hospital is a very desirable place for a fever convalescent hospital, and could be used accordingly, and that the proposed hospital at Winchmore is not required."—Mr. C. H. Galsworthy, the chairman, said he hoped Islington was not going to follow the example of the

City Union, from whom, a year or so ago, they received many resolutions condemnatory of the action of the managers—resolutions which were about as inaccurate as this one. After a great deal of trouble they had assembled a conference of guardians, but eventually the whole thing collapsed. The resolution sent by the Islington Guardians was not only misleading, but absolutely untrue. Speaking of the precepts of the managers generally, it stated that they had quadrupled since 1880. Such was not the case; and as to the statement that one-half of the hospital accommodation was not used, that was the old nonsense of which they had had so much. At the present time it might be so, but if fever increased at the present rate, they could not say how long this might be. As the resolution of the Islington Guardians had been sent to all the local bodies throughout the Metropolis, he should depart from the usual course of moving that it be simply acknowledged, and propose—"That the letter from the Guardians of the parish of St. Mary, Islington, be acknowledged, and that it be pointed out to the Guardians that the statement contained in their resolution regarding the precepts of this Board is entirely erroneous, that the expenditure of the Board in the year ended Lady Day, 1881, was 249,482*l.*, that the estimated expenditure for the year ended Lady Day, 1883, was 572,439*l.*, and that a very large amount of the increase in the amount has been caused by the establishment of the camp at Darenth to meet a severe epidemic of small-pox in the metropolis." Mr. Robins seconded the resolution, which was adopted.

Cholera Prevention.—At the meeting of the International Congress of Hygiene, a new view was put forward respecting Mahomedanism and the cholera, by Dr. Zoeros Bey, who quoted the passage in the Koran, declaring that "cleanliness is an article of faith." Mahomet had ordered prayers five times a day; but no prayer was acceptable which was not preceded by ablutions and accompanied by movements not unlike gymnastics. For a hot country and an indolent people these were eminently hygienic measures. Armed with the 8th and 9th chapters of the fifth book of the Koran, the sanitary reformer could work unhindered in any Mahomedan country. Bad hygiene in the East was the result of ignorance and opposed to religion.

Prevention of Blindness.—At the International Congress of Hygiene a few days ago, the report was read of the Commission appointed at the last International Congress to adjudge a prize of 80*l.* to the author of the best essay on diseases of the eye, offered by the British Society for the Prevention of Blindness. Four German, one English, and two French essays had been sent to compete for the prize, which was adjudged to one of the German works. The first prize was awarded to Dr. Ernest Fuchs, Professor at the University of Liège. A prize of 40*l.* from the French Society for the Prevention of Blindness was adjudged to the second best essay, also written in German, and the English essay came third on the list.

Total Abstinence.—Mr. Joseph Livesey, who died at Preston on September 2nd, in his 91st year, had throughout his long life devoted himself most intensely to the temperance movement, of which, in the form of total abstinence, he may be said to have been the founder, having on the 1st September, 1832, drafted for the signature of himself and six others the first teetotal pledge. From that date for a period of about 50 years his labours and sacrifices on behalf of his favourite cause were without parallel, comprising the delivery of thousands of lectures and addresses, and the circulation of millions of pamphlets, tracts, and leaflets, the last of these being his annual temperance address on New Year's Day, 1881.

Corporal Punishment in Board Schools.—At Southwark Police-court, on August 29th, Thomas Atkins, head master of the Addington Road Board School, Lambeth, appeared before Mr. Bridge on a summons charging him with unlawfully assaulting and beating Alfred James Sheridan, aged seven, one of the boys attending his school. Mr. Blanchard Wontner was counsel for the defence. Complainant's mother stated that the boy came home and complained to her that he had been thrashed for nothing by the defendant with a stick. She examined him, and finding several severe bruises, she went to the defendant's house to complain, and he ran away and locked himself in. She then gave information to the police, and had the boy examined by the divisional surgeon. Alfred James Sheridan, a weakly-looking but intelligent boy, stated that he was called by the assistant master to "stand out" when another boy snatched his book and they had a scuffle. Then the defendant came and beat him with a pointer. Dr. Evans, divisional surgeon of police, said that he had been called to examine the complainant, and he found several severe bruises on the hips, such as might have been inflicted by the pointer produced. In answer to Mr. Bridge, he stated that they were bruises which must have been caused by considerable violence. On cross-examination by Mr. Wontner, witness expressed the opinion that the pointer said to have been used by defendant was not a proper instrument to be used for inflicting corporal punishment on a schoolboy. Mr. Wontner said that the defendant had inflicted no more punishment than was demanded by the boy's disobedience, and called the assistant master, who told the magistrate that the defendant was a most amiable and kindly teacher, and stated that the boy had stopped the whole school by his conduct, and had three times distinctly refused to leave his seat at the request of the head master. In answer to Mr. Bridge, this witness admitted that the defendant dragged the boy off his seat and gave him a little of the pointer on the way. The Rev. William Henry Tickel also gave the defendant a high character for kindliness and considerate conduct as a teacher, and said that his management of the school was most effective. Mr. Bridge asked if any representative of the School Board was present to state what were the regulations with respect to corporal punishment, upon which a gentleman in court stated that there were no such regulations excepting that no teacher save the head master was allowed to inflict corporal punishment, and the matter was left entirely to his discretion. Mr. Bridge, in giving judgment, said that nobody could be more convinced than he was of the evil that might be caused by the conviction of a schoolmaster for punishing a child improperly. He was one of those who believed that corporal punishment judiciously inflicted was a very necessary and wholesome punishment for boys of a certain character, but the question which he had to decide in the case was whether the boy had been properly flogged. He did not say one word as to whether the boy did or did not deserve corporal punishment, but what he had to determine was whether the chastisement inflicted was such as a schoolmaster ought to give. In his opinion, the complainant had been subjected to more punishment than his offence demanded. A schoolmaster stood in relation to his pupils in the position of a parent, and for disobedient boys he should have a cane or a birch, to be used by him, not in temper or anger, but in a cool and collected fashion for the purpose of maintaining discipline. In this case the instrument used was not such as ought to have been employed for the punishment of a delicate boy of the tender years of the complainant, and had not the master received a good character, he would have subjected him to a severe penalty. As it was, he thought the justice of the case would be met by the imposition of a fine of 20*s.* and 2*s.* costs.

Sanitary Prosecutions.—At the Stratford Petty Sessions, on Wednesday, William Lester, a builder, of Ashville Road, Leyton, was summoned at the instance of the Leyton Local Board for that he did, between July 21 and Aug. 21 last, erect a house in Ashville Road and occupy it without constructing a covered drain for the effectual drainage of the said house to connect with and empty into the sewer of the Leyton Local Board, which was within 100 feet of the house in question. Mr. Vincent, the clerk to the Leyton Local Board, who appeared to prosecute, said that these proceedings were taken under the 25th Section of the Public Health Act, which looked upon this offence as a very serious one, the penalty imposable being £50. The defendant had submitted plans for the building of the house in question in which a perfect system of drainage was shown, but the house was now finished and there was no means of drainage whatever, so that anything thrown on the ground would have to soak through. The main sewer ran down

the centre of the Ashville Road, and with this the drains should be connected. The house was found occupied by the defendant himself, who, when told the requirements of the local board, said he would at once move out and have the work performed, but he had not done so. Mr. Dawson, the surveyor of the local board, gave formal evidence in support of the charge, and stated that when he spoke to the defendant he said he was trying to raise the money to get the drains put in, but if he did not he would leave the premises. The house in question was perfectly uninhabitable. There was no system of drainage and no water was laid on. Water had to be obtained from the houses opposite. Defendant had built property in the same road, and had received notices from the local board in respect of that, and he had complied with the notices, so that he well knew the requirements of the board. Defendant admitted the offence, but pleaded that he was in financial difficulties, having lost a considerable amount of money. He had built the house for a person who did not take it, so he occupied it himself; but assured the Bench that in so doing it was with no intention of infringing the Act. He had five children, but now he had removed these from the house, and as soon as he could raise the money he would have the work done as required by the local board. Mr. Vincent pointed out that the defendant did not remove his children till he had received the summons. Mr. Powell said this appeared to him to be a case of poverty, and asked Mr. Vincent if they would give the defendant time to do the work. Mr. Vincent said they did not object provided the defendant had the work done. They took action because the house had been occupied without any system of drainage; if the house was unoccupied the work could be done at the defendant's leisure. Ultimately defendant promised to quit the house at once, and then Mr. Vincent agreed to an adjournment for a fortnight. Defendant had to pay the costs of the day, £1 17*s.* 6*d.*

The Sanitary Institute.—The autumn Congress of the Sanitary Institute of Great Britain, which has the Duke of Northumberland for its President, will be held this year at Dublin, and the programme of the proceedings has been issued. The President of the Congress is Sir Robert Rawlinson, C.B., who will open the Congress with an inaugural address on Tuesday, the 30th instant, and the proceedings will last until the 4th of October. The Congress is divided into three sections—the first, "Sanitary Science and Preventive Medicine;" the second, "Engineering and Architecture;" and the third, "Chemistry, Meteorology, and Geology." Of the first section, the president is the Registrar-General for Ireland, Mr. Thomas W. Grimshaw, M.A., M.D. In the section of "Engineering and Architecture," the president is the Engineering Inspector of the Local Government Board for Ireland, Mr. C. D. Cotton, C.E.; and the president of the section of "Chemistry, Meteorology, and Geology" is Mr. C. A. Cameron, M.D., the City Analyst and Superintendent Medical Officer of Health for Dublin. The sectional meetings and the general meetings will be held at Trinity College, where the opening address will be delivered on Tuesday evening by Sir Robert Rawlinson. On Wednesday morning the actual work of the Congress will commence with the address of the president of the first section, and the remainder of the day will be taken up with the reading of papers and their discussion, while a *conversazione* will be held in the evening. The business of the second section will be taken on Thursday, October 2nd, and in the evening a lecture will be delivered to the Congress by Dr. Alfred Carpenter on "Education by Proverb in Sanitary Work." On Friday, after the third section, the closing general meeting of the Congress will be held. Arrangements for excursions will be made for the Saturday.

A New Commission on the Cholera.—The Academie de Médicine has just appointed a new Commission or Committee of its members for the purpose of drawing up a report on the measures which should be adopted against the cholera. The names of those chosen are as follows:—MM. Brouardel, Rochard, Proust, Pasteur, Noel Gueneau de Mussy, Fauvel, Marey, Besnier, and Legouest. In the meantime the discussion on the general subject of the cholera pursues its weary course in the Academy.

The Monument to J. B. Dumas.—M. Pasteur has just communicated to the Academie des Sciences a letter from His Majesty Don Pedro, the Emperor of Brazil, expressing a wish that his name should be entered for 1,000 francs on the subscription list for the monument to be erected to the memory of the great chemist, J. B. Dumas.

Items from Vienna.—Hofrath Prof. v. Bamberger has met with a severe affliction, which has excited general sympathy, in the loss of one of his sons, Richard Bamberger, a medical student, who, three weeks ago, set out on a long pedestrian excursion, and has never since, in spite of numerous searches, been heard of.—Wilhelm Ritter v. Braumüller, of Vienna, died recently in his 77th year. He was the head of the great publishing firm Braumüller and Co., which has held for so long a period the most distinguished place in relation to medical and scientific literature. He was an honorary doctor of Würzburg, Knight of the Third Class of the Order of the Iron Crown, and the possessor of numerous other tokens of the esteem which his remarkable undertakings had won for him. His name will always hold a high position in the history of medical literature and of the book-selling trade.

German Medical Students in the Summer Session of 1884.—The following return has just been published:—There were in the entire number of Medical Faculties of the German Universities 7,190 students, viz., 6,780 Germans and 410 Foreigners, distributed as follows: Berlin, 1,154 (1,065 G., 89 F.); Munich, 848 (804 G., 44 F.); Würzburg, 706 (671 G., 35 F.); Leipzig, 608 (573 G., 35 F.); Greifswald, 459 (454 G., 5 F.); Breslau, 421 (415 G., 6 F.); Freiburg, 365 (352 G., 13 F.); Bonn, 289 (286 G., 3 F.); Halle, 282 (277 G., 5 F.); Heidelberg, 267 (202 G., 65 F.); Marburg, 210 (200 G., 10 F.); Königsberg, 267 (243 G., 24 F.); Tübingen, 224 (216 G., 6 F.); Strasbourg, 191 (156 G., 35 F.); Göttingen, 189 (176 G., 13 F.); Giessen, 181 (181 G.); Kiel, 175 (171 G., 4 F.); Erlangen, 171 (163 G., 8 F.); Jena, 162 (154 G., 8 F.); Rostock, 71 (71 G.).

Notes of Practice.—Under this heading Dr. C. P. Clark contributes to the *New York Medical Journal* for June 7th, 1884, some of the results of his therapeutical experience. "Most of us old doctors" he writes, "follow methods which we know for certain to be sound and valuable, but which are neither generally taught in books or schools, nor generally followed or even known of by the profession at large. . . . However derived, to go down to our graves without putting them on record is to leave important truth to perish with us, and thus somewhat fail in duty to the generations. . . . In opposition to the stereotyped warnings of the text-books, the best of all treatment for that often wearing and wearying affection *varicocele* is said to be a weakish truss; pressing upon the spermatic veins, the pad takes the place of the deficient valves, and supporting the superincumbent columns of blood, not only greatly or entirely relieves the sufferer, but by continued application frequently effects a permanent cure of the real malady as well as of the many non-resistent diseases which its discomfort seems often to make the patient believe he is labouring under. When the bars of honour in our profession are still further let down, and the 'go-as-you-please' principle becomes our law, I propose to advertise a list of the cases of Bright's disease, heart disease, dyspepsia, hypochondriasis; in fact almost everything but reflexion of the womb and fissure of its os, that I have cured by the gentle pressure of a truss in the spermatic veins where they pass over the pubic bone. I was my own first case." *Powdered rhubarb* applied thickly twice a day is an effectual remedy for the superficial indolent-irritable ulcerations which occur about in-growing toe-nails, stumps, over varicose veins, and the like," but it may be that iodoform deserves to supplant it." For *tinea tarsi* and *porrigo favosa* full doses of chlorate of potass, *e.g.*, about a drachm per diem for a child, acts like a charm even in severe cases: it renders the scalp-shaving, poulticing, &c., usually adopted in the latter disease quite unnecessary. The compound *tincture of iodine*, given internally, effects a speedy cure in the intolerable itching of acute lichen and of urticaria. In prurigo and other like itchments of the skin it exercises

no such virtue. Aided by a calomel ointment it is of value in acne simplex, but it is not masterful. *Opium* is admittedly a valuable adjuvant to iodide of potass in the treatment of exophthalmic goitre; but opium, in doses of perhaps one grain per day, is also most useful in uncomplicated bronchocele. The *liquor ferri subsulphatis*, diluted with water to one half strength, is an almost sovereign remedy in diphtheria, applied locally with care and thoroughness twice a day. It is not a caustic, but "it is a mighty astringent, and seems to operate in the silly way of puckering the life out of the diphtheritic deposit and sucking or squeezing the bad juices out of the living parts adjacent." It is not claimed as a specific, but only that it is a very good thing. *Phlyctenular corneitis* owns a similar origin to that of the eczema or "cold-sore" often seen on or near the lip in evident intermittents; and for it quinine is the grand remedy, the more effective the earlier employed. "The attending photophobia is charmingly controlled by wiping the moistened outer surface of the upper eyelid with a stick of nitrate of silver till a good smarting is produced. The persistent and distressing giddiness of which now and then a patient otherwise apparently well complains, is successfully treated by the *compound tincture of bark*. *Phelgmasia dolens* is effectually controlled and speedily cured by opium, combined with a little calomel or other mercurial, given to the point of making the patient quite comfortable. Infants should always be fed from a spoon or cup, not from a bottle. "This is the only way to keep them from being overfed, which, with the refusal to them of a free supply of water that idiots still practice, kills three-fourths of the hand fed children that die. Always water should be offered before milk is given, otherwise to quench thirst, and not from hunger, they will drink more of the latter than they can digest, and a bellyful of trouble will ensue."

Manufactured Pills.—From a paper by Dr. French, in the *Philadelphia Medical Reporter*, we extract some observations of interest. In all cases in which medicines can be administered in the pill form he thinks that "manufactured" pills are greatly superior to the pills prepared in ordinary dispensaries, and especially in regard to powerful remedies which can in this way be more exactly given in small doses. Their soluble coat too preserves the pills from oxidation, and he refers to instances in which the contents of phosphorus pills have been found soft and unaltered after having been made for one or more years. These pills are found of great convenience in country practice owing to the exactness of their composition and easy portability. Speaking of the numerous cases of dyspepsia met with in city practice, Dr. French observes that when these cannot be relieved by dietetic and hygienic remedies alone, they require the drugs given them to be in the "most pleasant and unobjectionable form, as there is no class of patients so prone to find fault with their medicines." A very useful pill in such cases is made of aloin, grain $\frac{1}{3}$, strychnia $\frac{1}{60}$, given at bedtime, which produces a mild and thorough laxative effect, unloading the stomach and bowels, removing the fœtid breath, the furred coating of the tongue, and the cerebral congestion. Too active cathartics are very objectionable. Pepsin and bismuth, which are frequently combined for dyspepsia, should always be given in pill form, as they undergo decomposition in mixtures. The dyspepsia arising in malarious districts is well treated by pills containing quinine, or a combination of quinine, iron, and arsenic. Iron is a most valuable remedy in dyspepsia, when given towards the termination of a course of treatment. Active business men, brain workers, and the subjects of mental anxiety and overwork, frequently suffer from what is termed "nervous indigestion." Phosphorus, in small doses, given immediately after meals, is the proper remedy, and this should be given in the manufactured pills as the combination of phosphorus by ordinary dispensing is a difficult matter in producing uniform diffusion. When prescribing medicines so powerful that from a two hundredth to a twenty-fifth of a grain is given, the exact amount in each pill, unless many are prepared together, can scarcely be secured. These pills also form an excellent means of administering medicines to children.

Professor Schweninger.—The Berlin correspondent of the *Allgemeine Wiener Medizinesche Zeitung*, in his recent letters, draws attention to the remarkable silence observed by the Berlin medical press as to the career and proceedings of Professor Schweninger, who having succeeded in curing some of the ailments of Prince Bismarck and his son, which had resisted the efforts of distinguished members of the Faculty, has become not only an indispensable and prized member of the Bismarck family, but has been through its potent influence installed in the Faculty Ordinary Professor of Diseases of the Skin, without the Faculty having been consulted upon the matter. The extraordinary thing seems, that this body has not resisted the appointment beyond publishing the simple statement that it has had nothing to do with it. This is somewhat in contrast with the spirited conduct of the Paris Faculty, when the Emperor Napoleon III., then in his zenith, sought to place a distinguished Berlin ophthalmologist in the Faculty *proprio motu*. That Faculty unanimously declared that it would resign, and the appointment was abandoned. A Bismarck is formed of a tougher and more unyielding substance, and no doubt will have his way in the matter. The worst of it is, that in the present case there seems to be nothing in the new professor's history that will confer any honour on the Faculty. He was originally a privat-docens of pathological anatomy at Munich, and assistant to Prof. Buhl, and also became an assistant of the now famous gynæcologist, Geheim-Rath Schroeder, when professor at Erlangen. For some reason not stated he was excluded from the Munich Faculty, and finding success in practice impossible there, he repaired to Berlin, where he succeeded in ingratiating himself into the Bismarck family. The Chancellor, in gratitude for the benefits derived from his services, obtained for him the title of a royal professor, and the Minister of Instruction has since bestowed upon him the Chair of Dermatology, which, rendered vacant by the death of Bärensprung some twenty years ago, has never since been filled, but only provisionally provided for. What are the qualifications for it of its new occupant is not stated; but it is somewhat singular that all these proceedings, which have of course occupied a good deal of time in their transaction, have called forth no statements from the Berlin medical press, although some of the political journals have freely alluded to them, and it is said that they are about to be brought before the parliament.

Exploring for Bullets.—Dr. S. J. Allen, in a paper read at the Vermont Medical Society, stated that during four years active service in the American civil war, he was very seldom able to localise the position of a bullet by means of a probe; which indeed he considers only of service for determining the direction the ball has taken from its point of entrance, and whether it has entered a cavity. Used beyond this it will do harm. But successful exploration may almost always be made by means of the smallest sized exploring needles, which may be repeatedly passed in, in different directions, without any danger and with little or no pain.

Rattlesnake Bite.—A fatal case is fully reported in the *New York Medical Journal*, July 19th. J. R., a professed "snake-charmer," was bitten on July 13th, at 4.30 p.m., by a Mexican "diamond snake" (*Crotalus adamanteus*), said to be nearly ten feet long. The bite was inflicted on the dorsal aspect of the right hand, between the first and second metacarpal bones. The man at once drank a pint of whisky, and a surgeon made three incisions, laying the wound open. Half an hour later the man fainted; then he vomited the whisky, and at once drank a quart more. Two hours afterwards the ambulance surgeon found him wearing an anxious expression, and covered with a cold, clammy sweat, and extremely restless. His mind was clear, his pulse was rapid, feeble, and barely perceptible; respirations hurried and laboured. The hand was swollen to the wrist, of a purplish colour, cold to the touch, exhaled a peculiar odour, and was bleeding freely from the incisions. The patient complained of agonising pain, extending up the arm, of a feeling of great constriction across the chest, and of a terrible pain near the umbilicus. Being put to bed in the hospital half an hour later, he began to have

involuntary evacuations of the bowels—at first solid, then solid and liquid fæces, and finally pure, arterial-coloured blood. This purging continued for two hours before abating, and was accompanied with constant vomiting, first of the contents of the stomach, and then of blood, also bright red in colour. The swelling extended up the arm to the elbow, and became darker in colour; the axillary glands were swollen and very painful; the voice husky and weak; the tongue dark-red and dry; the pupils were dilated and sluggish. The restlessness and other symptoms increased; there was constant thirst, and agonising pain in the arm, extending up over the chest and stomach, as well as over the back, in the region of the kidneys. Ten minims of Liq. Ammoniæ, and about ʒ ij. of whisky were given *sub cute*, the vomiting and purging precluding the administration of anything by the mouth or rectum. By noon on the 14th, the prostration was more marked; the swelling had extended to the trunk, and was dark-bluish in colour, owing to effusion of blood; this discoloration was also present on the right side of the chest. There was no delirium, and the mind remained clear up to the time of death, which took place at 8 p.m., the heart ceasing to beat several seconds before the respiration stopped. During the day, about a pint of milk and frequent draughts of hot tea had been taken. There is no note of the temperature, or of the renal secretion. At the autopsy made forty hours after death, there was found great extravasation of blood into the tissues of the arm, extending about the shoulder, and over the right side of the body, down to the groin in front, as if from severe bruising. Both lungs were congested, especially in the upper lobe—and œdematous. The heart was pale and flabby, but contained no clots. About an ounce of blood was found in each pleural cavity, and half an ounce of serum in the pericardium. The stomach was greatly congested and partly filled with blood; the right kidney one-third the normal size, the left much larger than normal. The spleen was normal; the liver congested, but otherwise normal. The brain was heavy and healthy, with slight congestion and extravasation, and evidences of an old pachymeningitis. "Death seems to have been due to syncope, from septicæmic gases entering the right auricle by way of the vena cava."

Women-Doctors in Russia.—Quoting from a Russian correspondent's letter, the *Revue de Thérapeutique* (August, 15) states that the question of women-doctors in Russia is exciting general attention, popular opinion setting in strongly against its recent prohibition by the Government. A Royal Commission has been issued to reconsider the subject, and it is a remarkable circumstance that the male medical practitioners of Russian origin are unanimous in recommending that women should be taught, while those who are of German origin, and who are very numerous at St. Petersburg, are just as unanimous against such teaching. Controversy on the subject is at the highest pitch, and at the present time he would be considered a bad patriot who pronounced against Æsculapius in petticoats. Something surely should be done, for in some parts of Russia a 100 kilometres may be traversed without meeting with a single doctor; and, indeed, with the exception of the two capitals, the want of doctors is urgently felt over the whole empire. The duration of life is only 26 years, which is explained by the fearful mortality of young children, 60 per cent. (and in the North, 75 per cent.) dying under five years of age. The result is that in each year more than a million and a half of young children disappear; so that of 8,000,000 boys born between 1856 and 1860, only 3,700,000 reached the military age, *i.e.*, 21, and of these nearly a million of conscripts were found unfit for service. Statisticians calculate that throughout the empire there dies a human being every eleven seconds. It is true that a birth takes place every eight seconds, whence results the consoling conclusion for the future that there is an annual increase of 1,220,000 individuals, or more than 3,000 per diem. From this progression the optimists infer that by 1954 the Empire of the Czars will comprise nearly 200,000 inhabitants.

Bisulphide of Carbon as a Disinfectant.—Calling to mind the much greater efficacy of the combustion of bisulphide of carbon than that of ordinary sulphur in extinguishing chimneys on fire, M. Pierre Vigier suggests (*Gazette Hebdomadaire*, August 15) that it would probably prove a far more active disinfectant of rooms and hospital wards. It is cheap, costing only a franc per kilo, is very inflammable, burning to the last drop and emitting torrents of sulphurous and carbolic acids. Dr. Dujardin Beaumetz is now conducting experiments in disinfection at the Cochin Hospital, and M. Vigier suggests that he should try the efficacy of the bisulphide by burning two or three kilogrammes in a closed room in which infectious germs have been deposited. After being exposed to the fumes for 24 hours, they should be examined to ascertain whether their vitality has been destroyed.

Chlorodyne.—The death of Dr. James Collis Browne, the inventor of chlorodyne, at the age of 66, on August 30th, is announced. The deceased was well known for his experiments in the construction of racing vessels, as well as for the above invention.

Errata.—In our report of the Bradshawe Lecture, the following misprints should be corrected:—Page 248, col. 1, line 12, *for* "insufficient," *read* "sufficient." Page 280, col. 2, line 12 from bottom, *for* "invented," *read* "perverted." Page 281, col. 1, line 33 from bottom, *for* "motbid," *read* "morbid"; line 29 from bottom, *for* "materials," *read* "material."

APPOINTMENTS.

Fottrell, W. J., L.K.Q.C.P.I., L.R.C.S.I.—Resident Surgeon to the Jervis Street Hospital, Dublin, *vice* Chance.

McCaw, James Matthew, M.B. and C.M. Edin.—Assistant Medical Officer and Dispenser of Medicines at the Workhouse and Infirmary, Woolwich Union, *vice* Mr. W. E. Boulter, resigned.

Richards, W., M.B., C.M. Edin.—House Surgeon to the Queen's Hospital, Birmingham, *vice* Charles Sanders, M.B. Lond., resigned.

Spicer, R. H. S., M.D.—Medical Officer and Public Vaccinator to the North Molton District, South Molton Union, Devon, *vice* James Flexman, resigned.

Williams, John, M.D. St. Andrews, M.R.C.S. Eng. and L.S.A. Lond.—Medical Officer to the Swinton and Clifton District, Barton-upon-Irwell Union, *vice* Mr. W. B. Shearman, resigned.

VACANCIES.

Devonshire Hospital, Buxton, Derbyshire. — House Surgeon. (*For particulars see Advertisement.*)

Faversham Union.—Medical Officer to the First District, in succession to Dr. W. E. B. Atthill, resigned. Area, 7,123 acres. Population, 8,332. Salary, £92 per annum.

Gloucester County Asylum.—Assistant Medical Officer. Salary, 100 guineas per annum, with board, lodging, and washing. Candidates must be duly qualified, registered, unmarried, and not over 30 years of age. Applications and testimonials to be sent to the Medical Superintendent, on or before September 15th.

Grosvenor Hospital for Women and Children, Westminster, S.W.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London, and Graduates in Medicine of a British University. Applications, with Testimonials, to be sent to the Secretary, on or before September 6th.

Manchester Royal Infirmary.—Resident Surgical Officer. (*For particulars see Advertisement.*)

Rhuyader Union. Medical Officer. (*For particulars see Advertisement.*)

Somerset and Bath Asylum. — Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Candidates must be single, not more than 30 years of age, and have had previous experience in a public asylum. Applications, stating age and experience, with not more than four recent testimonials, to be sent to Dr. Wade, Superintendent, County Asylum, Wells, Somerset, on or before September 10th.

South Molton Union.—Medical Officer to the Eleventh District, in succession to Mr. Robert Henry Scanes Spicer, resigned. Area, 8,376 acres. Population, 1,143. Salary, £28 per annum.

St. Mary's Hospital, Manchester.—House Surgeon and Resident Obstetric Assistant. (*For particulars see Advertisement.*)

St. Thomas's Hospital.—Curator of Museum. (*For particulars see Advertisement.*)

The Hospital for Women, Soho Square, London, W.—House Physician. (*For particulars see Advertisement.*)

University College, London.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

University of Aberdeen.—Examiners in Medicine. (*For particulars see Advertisement.*)

DEATHS.

BROWNE, J. C., M.D., late H.M. 98th Regiment, at Ramsgate, on August 30th, aged 64.
GARRARD, G. S., M.R.C.S., at Kington, Herefordshire, on August 27th, in his 59th year.
LYDALL, W. H., L.R.C.P., late of 19, Mecklenburgh Square, London, at Exmouth, Devon, on August 28th, aged 46.
MICHAEL, Surgeon-Major, D., F.R.C.S., at 1, The Circus, Bath, on August 29th, in his 52nd year.
PEARL, G., M.D., late of Windsor, at 24, Park Crescent, Brighton, on August 21st.

NOTES, QUERIES, AND REPLIES.

AN ULTRA-CENTENARIAN.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Under this heading a paragraph appears in this day's journal, asserting that a French woman had died aged 121 years, and that "her duly signed baptismal certificate had been produced." Signed *by* whom, and produced *to* whom? is the question that naturally arises. Since the appearance of Mr. Thoms's critical work on "The Longevity of Man," one has learned to disregard all stories of centenarianism that are not vouched for by *public* documentary evidence. This case of Marie Durand probably belongs to the "enormous gooseberry" season of some provincial newspaper.

August 30th, 1884. I am, Sir, yours, &c., J. D.

COMMUNICATIONS RECEIVED—

Mr. H. A. KNUTZEN, London; Mr. JAMES DIXON, Dorking; Mr. JOHN F. POPHAM, London; Dr. SIDNEY COUPLAND, London; Dr. WILLOUGHBY, London; Mr. J. T. W. BACOT, Seaton, Devon; Dr. W. R. GOWERS, London; Mr. T. W. HIME, Bradford; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Dr. PHILIPSON, Newcastle-on-Tyne; Dr. A. H. HOWE, London; Messrs. BROWN, GOULD, & Co., London; Dr. F. CHURCHILL, London; OUR EDINBURGH CORRESPONDENT; Dr. J. MITCHELL BRUCE, London; THE HON. SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; Mr. CHARLES E. CASSAL, London; THE SECRETARY OF THE INTERNATIONAL HEALTH EHHIBITION, London; Mr. STEVENS, London; Dr. Isambard Owen.

BOOKS RECEIVED—

Handbuch für Madeira, von Prof. Dr. Paul Langerhaus—Twentieth Report of the City Hospital, Boston—Thirty-eighth Report of the Commissioners in Lunacy to the Lord Chancellor—Annual Report of James Murray's Royal Asylum, Perth—The Philosophy of Mr. Herbert Spencer, examined by the Rev. James Iverach, M.A.—Spaltpilze im menschlichen Blute, von Dr. G. V. Hoffman—Dementia Paralytica, von Dr. Franz Tuczek—Cerebral Localization in relation to Insanity, by J. M. Carnochan, M.D.—Report on the Sanitary Condition of the Wandsworth District during the year 1883—Report on the London Water Supply during the year 1883—Report on the Borough of Portsmouth for the year 1883.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—New York Medical Journal—New York Medical Record—The Edinburgh Clinical and Pathological Journal—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—Louisville Medical News—Weekblad—Maryland Medical Journal—The Girl's Own Paper—The Sunday at Home—The Leisure Hour—Friendly Greetings—National Anti-Compulsory-Vaccination Reporter—The Archives of Pediatrics—The Polyclinic—The Edinburgh Medical Journal—The Veterinarian—The Sanitary Journal, Ottawa—The Bath Argus—Archives Géuerales de Médicine—The Monthly Homœopathic Review—The Boy's Own Paper—The Glasgow Medical Journal—The Birmingham Medical Review—The Brighton Times, August 29—The Analyst—Centralblatt Therapie—The Philadelphia Medical Times.

APPOINTMENTS FOR THE WEEK.

Friday, September 5 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Common Food Adulterations."

Saturday, September 6.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.: Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, September 8.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, September 9.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London' 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY)' 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Air and Air Analysis."

Wednesday, September 10.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Common Poisons."

Thursday, September 11.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, September 12.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Methods of Food Analysis."

STUDENTS' NUMBER.

IT is a custom of long-standing with Medical Journals in this country to devote one of their September numbers to the interests of those who are intending to enter the medical profession. Considering how large this class is, and how important the functions that its members will one day have to undertake in the commonwealth, it will be admitted that no means should be neglected of giving them the fullest and most accurate information as to the arrangements for their future education and examination. At the same time, a Medical Journal has its obligations to its ordinary readers, for whom it is to be feared a Students' Number in its typical form is little else than waste paper. In the present issue we have attempted, as far as is attainable, to combine the two purposes, including all such information and advice as may be necessary to guide the intending student and his parents, while casting it in such a form that it may be expected to be of some interest to the ordinary reader. The choice of a Medical School may be considered the most important problem to be decided by the aspirants to a medical education, and it is hoped that the original articles on the London and Provincial Schools in England, which have been specially written for this number by members of their respective staffs, will be of essential service in this respect, while we doubt not that they will be read with interest throughout the profession, by the friends, fellow-students, and past pupils of their authors. The information as to the requirements of the Examining Bodies, which do not as a rule concern the student until he has joined his chosen school, has been thrown into the form of synoptical tables, with a view both to economising space and to facilitating comparative reference. The Advice to Students, which forms a usual and, considering how freely they are advised in other ways, perhaps a superfluous function of a Students' Number, has been thrown into the form of letters, for the idea of which we must acknowledge our indebtedness to Mr. Hamerton's "Intellectual Life." If this innovation needs any apology, it may be contended, with some amount of justice, that the ordinary leading article hardly offers such scope for that friendly and unpedantic advice adapted to varying conditions and contingencies, as is afforded by the plan we have selected. In conclusion, we must express our deep sense of obligation to the lecturers of the English schools who have so readily complied with our desire to have the advantages of their schools set forth by those who best know them, while at the same time we return our thanks to the authorities of the various universities, corporations, schools, and hospitals who have furnished us with the information necessary to make this number a complete one.

MEDICAL EDUCATION AND EXAMINATIONS IN ENGLAND.

INTRODUCTORY ARTICLE.

There are eight different bodies in England which can grant Licences to Practise Medicine, viz., the Universities of Oxford, Cambridge, London, Durham, and Manchester (Victoria University), the Royal College of Physicians and Surgeons, and the Society of Apothecaries.

(1) The University of Oxford grants degrees in Medicine to those of its students who have resided the requisite number of terms, who have taken the B.A. degree, and have fulfilled certain conditions and passed certain examinations under the following conditions:—

There are two degrees in Medicine—B.M, and D.M. Every candidate must take the degree of B.A. Hence he must matriculate at some College or Hall, or as a non-Collegiate Student, keep twelve terms or three years of residence, and pass the following examinations:—Responsions, or the examination in lieu of Responsions, held annually shortly before Michaelmas Term; Moderations, Rudiments of Faith or the Substituted matter, and the Final Pass School or one of the Final Honour Schools. Of the latter the School of Natural Science offers many advantages. There are in it two examinations, the Preliminary, and the Final Honour Examinations. The former includes (1) Chemistry, (2) Mechanics with Physics; and the certificates exempt the holder from further examination in these subjects at the First B.A. Examination, and in case he is unable to proceed to Honours reckon as two out of the three certificates necessary for the Pass Degree. The Final Honour Examination includes Chemistry, Physics, Botany, Animal Morphology, Animal Physiology, and Geology. Honours are granted in every one of these subjects separately. Whoever obtains a First or Second Class in the five first named, may present himself as soon as he chooses for First B.M. Examination. A First or Second Class in Botany frees the student from further examination in that subject.

The degree of B.M. may be taken by a B.A. in the twenty-seventh term from matriculation. There are two examinations held annually in Trinity Term (usually in June) after due notice given by the Regius Professor of Medicine, to whom names are (by statute) to be sent at least fourteen days before the week of examination. The examinations are conducted partly by papers, partly by practical work, and partly *vivâ voce*. Conditions and subjects are as follows:—

(I) *First Examination.*—Candidates other than those privileged as above stated may not enter earlier than two years, or eight terms from the date of the first certificate in a Final School, Pass, or Honour. The subjects are—(1) Human Anatomy and Physiology, (2) Comparative Anatomy and Physiology to a certain extent, (3) Botany (exemption see above), (4) Chemistry, and (5) Mechanics with Physics (exemptions see above). Subjects (4) and (5) may be taken together on an occasion other than that at which the remainder are offered.

(II) *Second Examination.*—A candidate may present himself four years or sixteen terms after the date of the first certificate in a Final School, Pass, or Honour, provided two years or eight terms have elapsed from the date of his certificate in the First Medical Examination. Certificates of attendance at some hospital of good repute must be sent to the Regius Professor of Medicine, and be approved by the major part of the examiners. The subjects are—(1) Theory and Practice of Medicine, including Diseases of Women and Children, (2) Materia Medica, (3) Therapeutics, (4) Pathology, (5) Principles of Surgery, and (6) of Obstetrics, (7) Forensic Medicine, and (8) General Hygiene. A paper is also set containing passages from two out of four ancient medical authors (Hippocrates, Aretæus, Galen, Celsus) and from more modern writers in Latin, French, and German; *e.g.*, Sydenham, Pasteur, Koch, approved by the Regius Professor. Candidates are usually required to select two passages, one from an ancient, and one from a modern author.

A B.M. may proceed to the degree of D.M., provided he has passed three years from the degree of B.M. in the study or practice of Medicine. He has to write a thesis on a subject previously approved by the Regius Professor, to read it publicly before him, and then to deliver to him a copy.

Incorporation, under certain conditions, is possible to a Cambridge or Dublin graduate.

(2) The University of Cambridge has an efficient and rapidly increasing Medical School attached to it, and grants degrees in Medicine and Surgery under the following conditions:—

The Degree of Bachelor of Medicine (*M.B.*).—A Student proceeding to this degree must (1) reside in the University the required portion of each of nine terms; (2) pass (or obtain exemption from) the previous examination; (3) pursue medical study for five years, unless he has obtained honours in one of the triposes, in which case four years only are required.

There are three examinations for the M.B. Degree. The subjects of the *First* Examination are—(1) Chemistry and other branches of Physics. (2) Elementary Biology. These two parts may be taken together or separately.

Before presenting himself for the First Examination, the Student must produce certificates of attendance on a course of Lectures in Chemistry and a course of Practical Instruction in Chemical Manipulations. The subjects of the *Second* Examination are—(1) Human Anatomy and Physiology. (2) Pharmacy and Pharmaceutical Chemistry. These two parts may be taken together or separately.

Before presenting himself for the Second Examination, the Student must have attended Hospital Practice during six months, must have practised Dissection during six months, and produce certificates of attendance on Lectures in (1) Human Anatomy. (2) Physiology. (3) Pharmacy and Pharmaceutical Chemistry. The *Third* Examination is divided into two parts. The subjects of the first part are—(1) Principles of Surgery. (2) Midwifery and Diseases peculiar to women. Before presenting himself for this part the Student must have attended the Surgical Practice of a recognised hospital during one year, have attended ten cases of midwifery, produce certificates of proficiency in vaccination, and of attendance on Lectures in (1) Pathological Anatomy; (2) Principles of Surgery; and (3) Midwifery. The subjects of the second part are—(1) Pathology; (2) Principles and Practice of Physic; (3) Elements of Hygiene; (4) Medical Jurisprudence. Before presenting himself for the second part, the Student must have attended Hospital Practice during three years, have acted as clinical clerk for six months, and produce certificates of attendance on Lectures on (1) Principles and Practice of Physic; (2) Physiological actions and Therapeutic uses of Remedies; and (3) Medical Jurisprudence. After the Third Examination, an Act has to be kept, which consists in reading an original thesis, followed by a *vivâ voce* examination on the subject of the thesis, as well as questions of a more general nature connected with medicine.

The Degree of Bachelor of Surgery (*B.C.*).—A Student is admissible to the Examination for this degree at any time after he has passed the first part of the Third Examination for the M.B. The subjects of the Examination are—(1) Surgical Operations and the application of Surgical Apparatus; (2) The examination of Surgical patients. Before admission to the Examination, certificates are required (1) Of attendance on Surgical Practice for two years, and of having acted as Dresser or House-Surgeon for six months; (2) A course of instruction in Practical Surgery. Before admission to the Degree of B.C., the candidate must also have passed the second part of the Third Examination for the Degree of M.B.

The Degree of Doctor of Medicine (*M.D.*) may be taken three years after the M.B. An Act has to be kept, by reading a Thesis on some subject chosen by the candidate, but approved by the Regius Professor of Medicine. In addition an ex.empore essay has to be written on some subject relating

to Pathology, Physiology, the Practice of Medicine, or State Medicine. A Master of Arts of four years' standing can proceed direct to M.D., provided he produces the same certificates and passes the same examinations as for M.B.

The Degree of Master of Surgery (*M.C.*).—A candidate for this degree must have passed all the Examinations for B.C. two years previously. The subjects of the Examination are:—(1) Pathology; (2) Principles and Practice of Surgery; (3) Surgical Anatomy and Surgical Operations; (4) Clinical Surgery and a short extempore essay on a Surgical case or topic relating to Surgery.

(3) The University of London, which has its head-quarters in Burlington Gardens, W., grants degrees in Medicine and Surgery (M.B., B.S., M.D. and M.S.) after a very complete and arduous series of examinations. These degrees have achieved a high reputation throughout the country, and the student who has received a good preliminary education, and is confident of being able to devote the requisite time to the curriculum, and has not had the advantage of residing at one of the older universities, cannot consult his future prospects better than by competing for the London degrees. He must first pass the Matriculation Examination which is held in London and in certain provincial centres twice a year, in January and June, no other preliminary examination being accepted by the University in lieu of it. The candidate must have completed his sixteenth year, and the fee for the examination is 2*l*. The subjects of the examination are: (1) Latin. (2) Any two of the following languages:—Greek, French, German and either Sanskrit or Arabic. (3) The English Language, English History and Modern Geography. (4) Mathematics. (5) Natural Philosophy. (6) Chemistry. It is scarcely advisable for the student who has already entered on his medical studies to think of passing this and the succeeding Preliminary Scientific Examination, as his medical studies must necessarily be suspended for that purpose, no medical studies being counted by the University until the student has matriculated. Both examinations ought to be passed before entering as a medical student, though many of the London Medical Schools now give facilities for the study of the subjects included in the Preliminary Science Examination. These subjects are: (1) Inorganic Chemistry; (2) Experimental Physics; (3) General Biology. The candidate must have completed his seventeenth year, and the fee is 5*l*. The examination is also held in a few of the northern cities, except in respect to the practical examinations in Biology, which must be carried on at the University. The passing of this examination involves a very complete and practical knowledge of the preliminary sciences which cannot be acquired without special instruction. Further particulars, both of this and of the matriculation examinations, may be obtained from the Registrar of the University, and information as to the arrangements made at various institutions for preparing students for them, will be found in our advertisement columns.

The requirements of the University in respect to the later examinations—the intermediate examination in Medicine, and the M.B., B.S., M.D. and M.S. Examinations will be found concisely put in the synoptical tables at page 377 of this Journal, and more fully in the calendar of the University, as well as in the extracts from it specially printed for the use of students, and to be obtained from the Registrar.

(4) The University of Durham grants degrees and licences in Medicine and Surgery, particulars of which may be gathered from our synoptical tables. In respect to residence required of its students, it stands midway between the older universities and the University of London, one year's study at the University College of Medicine, Newcastle-on-Tyne, being required of candidates for all its degrees, except the M.D. degree for practitioners of 15 years' standing.

(5) The newly constituted Victoria University, which has its head-quarters at Owens College, Manchester, grants the degrees of M.B., M.D., and Ch.M. Candidates must have completed four years of medical studies, two of which must be passed at one of the colleges in connection with the University. The examinations are very similar to those of the London University; but further particulars may be gathered from our synoptical tables.

(6) The Royal College of Physicians of London, in Pall Mall, may be regarded in two aspects, in its relation to the consulting physician, and in its relation to the general practitioner. All who aspire to physician's practice, whatever their degree, will find it necessary to take the membership of the College in the hope of subsequently being deemed worthy of election to its fellowship. It does not fall within our present scope to describe the conditions on which these valuable diplomas are conferred. Full particulars, however, with regard to the Licence—the general practitioner's diploma—will be found in our synopsis. It constitutes a qualification to practise all the three branches, Medicine, Surgery and Midwifery, and students cannot be too strongly counselled to lay out their studies with a view to securing a diploma, the value of which is so generally recognised. They must at the same time consider it obligatory on them also to obtain the membership of the Royal College of Surgeons, and it is to be hoped that before long arrangements will be made by which the two diplomas will be obtainable by means of a single conjoint examination. Both Colleges require evidence that the student has passed one of the many Arts examinations recognised by the General Medical Council. These include the various local and entrance examinations of the British Universities, the Arts Examinations of the Apothecaries' Halls of London and Dublin, and the Preliminary Examinations of the Scottish Licensing Corporations and of the Irish College of Surgeons, the Examinations of the College of Preceptors and of the Civil Service Commissioners, and those of various Indian, Colonial and Foreign Universities and Colleges. Some of these examinations must have been passed under certain conditions, particulars of which may be obtained by application at the offices of the General Medical Council, No. 315, Oxford Street. If the student has passed none of these recognised preliminary examinations, he should not delay to present himself for one of them, and he will probably find the most convenient to be that of the Apothecaries' Society, particulars of which are given in a succeeding paragraph.

(7) The Royal College of Surgeons of England, like the College of Physicians, grants two diplomas, a lower and a higher one, the Membership and the Fellowship. The latter, however, differs from the higher diploma of the physicians, in that it does not practically disqualify from general practice; indeed, it is possessed by many hundred practitioners throughout the country, and the student who cannot spare the time required for a university degree, but is ambitious enough to desire to raise himself above the generality of practitioners, should lay himself out for taking the Fellowship of the College of Surgeons. It is not necessary here to particularize the requirements of the College for this diploma, but it may be stated that the candidate must have passed a preliminary Arts examination which includes Greek as one of its subjects, and he must be prepared to spend a third winter at his anatomical studies, and to devote considerable attention to the study of Comparative Anatomy. The examinations, especially the first, are sufficiently severe.

The Membership of the College is the diploma taken by the vast majority of English, and by many Scottish and Irish students. The curriculum at the various hospitals is arranged to fulfil the requirements of the College for this diploma, an abstract of which will be found in our synoptical tables. The candidate it will be observed, must pass not only one of the Arts examinations recognised by the Medical Council, but also the elementary examination in Anatomy and Physiology held at his school. This is a new regulation, and as it cannot fail to induce the student to fully utilize his first year, will no doubt exercise a most beneficial effect on primary medical instruction. By the large majority of students the first examination for the membership is taken in the April or May following their second winter session. They are then able to devote themselves to their hospital work, with the view of passing the final examination at the end of their fourth year. If the candidate is not successful in satisfying the examiners, he is referred under certain conditions, with which, it is to be hoped, none of our readers will find it necessary to make practical acquaintance.

(8) The Apothecaries' Society of London, which occupies an interesting old building behind the Ludgate Hill Station of the Chatham and Dover Railway, confers a qualification to practise medicine, entitled the Licence of the Apothecaries' Society, granted after passing two examinations, a primary and a final. Each examination is divided into two parts, written and oral; the former is held every Wednesday, the latter every Thursday throughout the year. Both in the primary and final, the candidate is examined on the living subject, on healthy and morbid specimens respectively. The primary may be taken at the end of the second winter session, and the final at the end of four years from the commencement of medical studies, of which it may be noted only three winter and two summer sessions need be passed at a recognised hospital. The Licence is a cheap diploma, costing only 6*l*. The candidate must have passed an Arts examination, a special one being held by the Society itself three times a year, which is recognised by the Medical Council and other licensing bodies. The following are the particulars :—

Examination in Arts.—This examination will be held at the Hall of the Society on Thursday, Friday, and Saturday, January 8, 9, 10; April 30, May 1, 2; September 10, 11, 12, 1885.

Syllabus of Subjects for Examination in Arts. (a)

1. *The English Language*—Including grammar and composition; writing sentences in correct English upon a given theme; writing correctly from dictation; explaining the construction of sentences; pointing out the grammatical errors in sentences ungrammatically expressed; giving the derivation and definition of words in common use.

(a) The examiners recommend the study of one of the following:—English: Angus's, Adams's, or Mason's Grammar, and Earle's Philology. English History: Bright's History of England, and Green's "Short History of the English People." Mechanics: Wormell's or Newth's Natural Philosophy, or Girdlestone's Mechanics. Chemistry: Roscoe's Elementary Chemistry.

2. *English History*—The general facts of English History, and special questions on the reigns of Charles II. and James II.

3. *Modern Geography*—Including the elements of physical geography.

4. *The Latin Language*—Including translations from the original, and grammar. January Examination: Æneid 7 and 8. April Examination: Quintus Curtius. Alexander in India (Pitt Press). September Examination: Cicero, pro Milone.

5. *Mathematics*—Arithmetic, including vulgar and decimal fractions. Algebra, including simple equations. The First Two Books of Euclid, or the subjects thereof. (b)

6. *Elementary Mechanics*—Of solids and fluids, comprising the elements of Statics, Dynamics, and Hydrostatics.

7. (*a*) *Greek*—Homer, Odyssey 5 and 6. Grammatical questions. (*b*) *French*—Lazare Hoche, by E. Bonnechose (Pitt Press). Translation from English into French. Grammatical questions. (*c*) *German*—Das Jahr, 1813, by F. Kohlrausch (Pitt Press Edition). English into German. Grammatical questions. (*d*) *Elementary Chemistry*—Inorganic.

METROPOLITAN SCHOOLS OF MEDICINE.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

St. Bartholomew's Hospital was founded in 1123, and the first medical treatise due to its opportunities of observation is the "Breviarium Bartholomæi" written about 1380. From scattered remarks of the author, John Mirfeld, it appears that some medical instruction was even then given by the Hospital Staff. In the sixteenth century a few members of the Universities studied under the Physicians, while the Surgeons had apprentices, but it was not till the reign of Charles II. that any regulations were made with regard to the Hospital as a School of Medicine. Two years after the Great Plague a library was formed for the use of the students. One of these was Edward Browne, of Trinity College, Cambridge, son of Sir Thomas Browne, and a manuscript note-book of his studies is still extant. Dr. Caius, though never on the staff, lived within the Hospital walls and took interest in its work, and six members of his college have since been elected Physicians to the hospital, one being the immortal Harvey, who held the office for 34 years.

Since 1660 the history of the Medical School has been one of continued improvement. In 1724 there was added a museum, and in 1734 a regular dissecting room. The Physicians had before this lectured on Anatomy outside the hospital in Monkwell Street, where Dr. Terne's lectures, delivered early in Charles II.'s reign, were remarkable for their fulness and lucidity, but from the time of Edward Nourse, who was elected Surgeon in 1745, the teaching of Anatomy passed into the hands of the Surgeons.

In 1765 Percival Pott, whose name every medical student associates with two well-known surgical affections, gave the first full course of lectures on Surgery. John Hunter was one of his pupils. Dr. William Pitcairn and Dr. David Pitcairn gave lectures on Medicine. In 1787 lectures on Physiology were first given and these were soon followed by lectures on Chemistry. Abernethy soon appeared upon the scene and his genius for teaching trebled the number of students, so that during his time the anatomical theatre was twice re-built.

The Governors of the Hospital have always shown a wise liberality towards the school, and they had already seven times added to its accommodation and conveniences during the nineteenth century, till, in 1876, the regular increase for several years in the number of students made it desirable to re-model all the school buildings. The question was discussed as to whether this re-building should provide for a moderate further increase, or whether provision should be made for as many students as it was ever likely the practice of the hospital could instruct. The more extensive scheme was wisely adopted with the result that, while the School is the largest in London, it has abundant accommodation for all its present members and for a very large future increase. Full accommodation was made for an annual entry of 200, a number which it is not probable will be reached for many years to come.

The out-patient practice of the Hospital is the largest in the United Kingdom, and the enormous advantage of this to the students is shown by the fact that they have opportunities of receiving instruction on examples selected from more than 160,000 cases of medical and surgical affections in the course of the year. The total number of beds under the control of the staff is 750,

and the 75 beds just added in the new Convalescent Hospital will materially increase the clinical advantages of the students by making it possible to admit a larger number of urgent cases into the beds vacated by convalescents.

It would be impossible to conduct so large a practice without the aid of a great body of competent students. After passing their Anatomical and Physiological Examination and receiving a systematic course of instruction in the rudiments of practical Medicine, Surgery and Midwifery, students are eligible for hospital appointments: clinical clerkships, dresserships, out-patient clerkships and dresserships, ophthalmic gynæcological, and *post-mortem* clerkships, about 140 such appointments being made every three months. Four House-Physicians, ten House-Surgeons, an Assistant Chloroformist, two Ophthalmic House-Surgeons, and two Midwifery Assistants are chosen annually from the most diligent students when duly qualified. The holders of these appointments receive rooms and an honorarium. They also receive all the fees for *post-mortems* and inquests upon persons brought dead to the Hospital. Every two years three Casualty Physicians are appointed, and though the appointment is open, former members of the Junior Staff have usually been appointed. Each Casualty Physician receives 100*l.* a-year. The House-Physicians and House-Surgeons are under the direct control of the Physicians and Surgeons, and during the absence of their Seniors have the advantage of being the sole medical authorities of the Hospital.

Besides these clinical opportunities, an industrious student at St. Bartholomew's has a succession of Scholarships and other prizes to stimulate his application to his work. At entrance there are two science Scholarships of 130*l.* each, and one Scholarship in Arts of 50*l.* In the first year two Scholarships of 50*l.* one of 30*l.*, and one of 20*l.*, with a prize in Anatomy, are offered for competition. In the second year, three prizes and a Scholarship of 50*l.* In the third year, two Scholarships of 30*l.*, a Gold Medal, and three prizes, and in the fourth year a Scholarship and Gold Medal of the value of forty guineas. A student of distinction, when qualified, may obtain one of the junior teaching posts. Three Assistant Demonstrators of Anatomy, two of Physiology, and an Assistant Medical Tutor are appointed every two years. All these are paid offices, and, with the private tuition to which they lead, enable a man of ability to support himself in London while he is considering his future course of practice, or while preparing himself to compete for higher posts at St. Bartholomew's or elsewhere.

The College of St. Bartholomew's Hospital, in which students can reside with many of the advantages of residence at a University, occupies the side of the Hospital looking into Duke Street, Smithfield. Each student has two rooms, and there is a common hall. The College is presided over by the Warden, who has usually also discharged the duties in the School at large, which are elsewhere associated with the title of Dean. The earliest use of the word "Warden" at St. Bartholomew's is in 1182, when one Alan is so described, and the title was happily revived in 1843, when Sir James Paget was elected head of the College. The general discipline of the School is in charge of a special Committee which sends every month for all students who have been irregular in their attendance. The Committee is always ready to receive every explanation and to make full allowance for slowness of apprehension or occasional thoughtlessness, but persistent idleness is not permitted and *aut disce aut discede* is the alternative offered to every student who persists in neglecting his studies.

Lastly, as to fees. The principle rigidly adhered to at St. Bartholomew's is that the fee for a perpetual ticket shall cover everything required for qualification. The library and the chemical laboratory and chemicals are free to every student. The only extra-payment of any description is the small fee for a ward-dressership. Forty such dresserships are given away as prizes by open competition every year, so that an exemption from this payment is within the reach of every one who chooses to work for it. The prize dresserships thus afford a widely diffused and very useful stimulus to the exertions of the students of the first year.

These are the main features of St. Bartholomew's. The graces of its antiquity, its vast modern opportunities for observation in Medicine, Surgery, and Pathology make it a place to which both its teachers and its students are devotedly attached, and all are actuated by a desire to be worthy of its past reputation and to extend its fame in the future.

CHARING CROSS HOSPITAL AND MEDICAL SCHOOL.

(By a Member of the Staff.)

The Charing Cross Hospital and School of Medicine occupy a prominent position in the very heart of London, in close proximity to the spot from which they take their name, which is associated with so many memorable events in the history of our country. The Hospital proper compactly occupies a mass of buildings which lie between King William Street, Chandos Street, and Agar Street; and the apex of the triangle is aptly completed by the Westminster Ophthalmic Hospital, which is also open to Charing Cross students. Across Chandos Street, and connected with the Hospital by means of a subway, stands the Medical School, an entirely new building within the last few years. To those students who are anxious to avail themselves fully of the many and unique advantages presented by the Metropolis over other cities, as a place of medical education, the central situation of Charing Cross Hospital will at once commend itself. Not only is it easily reached from all parts of London and the suburbs—no small matter when lectures commence at nine in the morning, but the neighbourhood in which it stands might be taken as the very type of all that is Metropolitan, for every character of patient, every class of disease and injury, come daily under observation. Some of the greatest arteries of traffic pass its very doors. The river is within a hundred yards of it. A walk of two minutes brings the student to Trafalgar Square, Pall Mall, St. James's Park, and all the imposing grandeur of Royal palaces, Parliament, and the Clubs. Behind the Hospital stretches a very different region—the great districts of St. Martin's and St. Giles's, with Leicester Square, Drury Lane, and Seven Dials. From each of these fields of life and of disease comes a constant supply of material for medical relief and medical study.

The character of the instruction given at this School reflects very accurately these advantages of its situation. It has come to be essentially a school for training the general practitioner, a place where the student who enters the profession with a love for Medicine as the healing art, can enjoy to the full the pleasures and benefits of practical training and experience. Whilst sending up to the Universities a number of distinguished pupils who worthily maintain the reputation of their hospital amongst other schools, Charing Cross especially rejoices in preparing men for an honourable and useful career in family practice and in the public services. The hospital which can claim a Huxley amongst its former pupils, is not less proud to point

to a Livingstone, a Fayrer, a Guyer Hunter, and to the many younger men who have taken and who now hold the highest places in the Medical Department of the Army and Navy, or the highest professional positions in London and the provinces.

The Committee and Staff of Charing Cross Hospital thoroughly appreciate the character and the traditions of their School, and strive earnestly to maintain them. They avail themselves of the obvious advantage that attends the moderate size of the institution, to make themselves intimately acquainted with the character and abilities of every pupil, and to give him both the amount and the kind of individual attention which he specially requires. In a school of 120 to 150 students this is quite practicable. This care is especially practised at the commencement of the student's career. The first importance is attached to the soundness of his grounding in the great natural sciences of Anatomy, Chemistry, and Physiology, which are taught practically and tutorially as well as by systematic lectures. The chemical laboratory is thoroughly complete. The dissecting room is probably unique of its kind in London, situated in the roof of the building, large, light, elegant, and sweet. Dissecting goes on here in summer as well as in winter. The physiological laboratory is intended to be a second dissecting room, open all day, and fully provided with material and the means for studying it. During his first year the student is allowed to whet his appetite for Medicine and Surgery by occasionally visiting the hospital and holding minor appointments: his second winter is entirely devoted to the completion of his scientific knowledge, and to preparation for his first examinations, which will enable him to proceed untrammelled to professional work proper.

Having passed his primary examination or examinations, the student has his attention directed to Surgery, Medicine and Midwifery, as well as the related subjects of Pathology, Therapeutics, and Forensic Medicine. Here an important change in the right direction has been made within the last three years, by the establishment of regular Chairs of Practical Medicine and Practical Surgery. By this means a vast amount of instruction which was given casually by the different officers of the hospital, and of which the students no doubt did not always take full advantage, has been systematized, and indeed rendered compulsory. Physical Examination, Clinical Chemistry and Microscopy, Minor Surgery and Bandaging, and Practical Pathology are now studied in regular courses, in which the demonstrative and tutorial system is closely followed. A proper groundwork being thus laid down, the student undertakes his work in the wards and out-patient rooms with intelligence and profit. Another advantage of the moderate size of the school is now seen. Every student obtains (and that in proper order) a clinical post, without more than that amount of difficulty which enhances its value in his eyes, the appointments to clerkships and dresserships being made in order of merit, as tested by the previous performances of the men in the school and at the public examinations. Every pupil is required to hold an out- and in- door clerkship, and an out- and in- patient dresserships, each extending over a period of three months; besides which he is encouraged to fill similar posts in one or all of the special departments, and to serve as pathological assistant. An interesting feature in this connection is the arrangement by which the students virtually keep the professional records of the hospital. The "cases" of the out- as well as of the in- patients are carefully preserved, and they are entirely taken by the clerks under the close direction of their superiors. Instruction and work thus go hand in hand. The greatest importance is attached at Charing Cross to the training in the out-patient department. The officers believe that this is an unrivalled field for the students to observe just that kind of general practice which every man has to meet when he enters the profession for himself.

At the same time all the important specialties are represented. The students attend the gynæcological practice in rotation. The lying-in institution is efficiently organised. There are departments for diseases of the skin, of children, of the ear, and of the teeth, where instruction is not only freely but systematically given. The students have the invaluable privilege of attending the practice of the Westminster Ophthalmic Hospital. The Dental Hospital of London is within three minutes' walk, in Leicester Square, and the lecture hours have been especially arranged to enable dental pupils to take full advantage of the instruction at both institutions.

The students of Charing Cross Hospital have abundant opportunities of occupying with advantage the time not actually devoted to classes or hospital work. The large library and reading room is always open. They may study in the museum, which is rapidly increasing in the number, variety and value of its contents. And when work is over they are encouraged in every way to enjoy their relaxation after a wholesome fashion. The Students' Club is a social bond which confers upon the members the right of belonging to all the sub-institutions of the hospital—to the Foot-ball and Cricket Clubs, to the Medical or Debating Society, and to the society for organising entertainments to the patients in winter. Charing Cross Hospital has the honour of having been the first to establish a Volunteer Army Hospital Company, and a number of the students are now fully equipped with uniform, accoutrements, and stretchers. By these and similar means the life of the student at this School is made as bright and happy as possible.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

"London is the capital of England, and the capital of London is Leicester Square," so a popular French guide-book for tourists used to inform its readers. To the inhabitants of modern residential London, the metropolis may be said to centre in Hyde Park Corner; and the most conspicuous object at Hyde Park Corner, since the happy removal of the Iron Duke and his charger, is the façade of St. George's Hospital. It is singular to reflect, so magical has been the growth of the great city, that the noble charity which now occupies the very focus of the western residential districts was founded, not more than 150 years ago, to give poor patients from London the advantage of treatment in the clear country air.

As it stands at present, enlarged, rebuilt, and added to, with the populous industrial quarters of Westminster, Pimlico, and Chelsea but a short distance away, the hospital is fully employed in meeting the wants of its own neighbourhood, and furnishes ample material for instruction in all varieties of disease and all branches of medicine and surgery.

Private munificence has enabled it to establish a branch in the country beyond Wimbledon, to which convalescent patients are drafted as soon as their state permits, leaving the wards of the central hospital free for such cases as require a serious exercise of medical or surgical skill. Of the 351 beds of the establishment at Hyde Park Corner, all of which are available for the purposes of the teaching staff, 205 are given to surgical cases, 146 to medical ones; and special wards are set apart for diseases of the eye and diseases of women. In addition, the whole of the out-patient department

has been organised for the purpose of clinical instruction, to an extent hardly possible except under the peculiar circumstances of a West End hospital, so that students have full opportunities of becoming familiar with the minor as well as the major ailments they will be called on to treat. Special out-patient departments have been arranged for diseases of the eye, of the skin, of the throat, for diseases peculiar to women, for orthopædic and for dental surgery, and in all of these instruction is systematically carried on.

The school buildings, containing the lecture theatres, dissecting room, laboratories, library and museum, are compactly and ingeniously arranged, and immediately adjoin the hospital, so that the student loses no time in going to and fro. Busts of John Hunter, of Brodie, and of other past celebrities of the School, adorn the main corridor. The well-known pathological collection, which was commenced by Sir Benjamin Brodie and the late Mr. Cæsar Hawkins, is housed in a lofty hall in the school precincts. It has recently been entirely rearranged and recatalogued on a new system with the view of affording students every facility in consulting it. Among the historic relics shown in connection with the museum are the skin of the cow from which the first vaccine lymph was taken by Edward Jenner, the anatomical table and chair of John Hunter, and the famous coin that nearly proved fatal to Brunel the engineer. Commodious reading and writing and refreshment rooms, where luncheon and dinner are served at a fixed tariff, complete the arrangements of the school buildings.

As is well known, the School of St. George's has long borne an especial *cachet*, as one particularly affected by the "bene nati, bene vestiti,"[1] among aspirants for a diploma. In rougher days, when a pilot coat and an absence of collar were the outward marks of the typical medical student, curious tales went the round of the city schools, how the St. George's men dissected in white kid gloves, and wore evening dress when they attended the Surgeons in the wards. A process of levelling up has long since taken place; the student of Albert Smith's day is as extinct as the Dodo, and the prowess of St. George's men at Lillie Bridge and Kennington Oval has finally extinguished the legend of the white kid gloves; but the School, owing perhaps to its peculiar position, still retains a good deal of its ancient characteristic, and draws a large proportion of its students from the universities and public schools. The existence of an important school of medicine in so favoured and so accessible a spot does not fail to be appreciated by the London residents, especially those of the western districts, whose sons are enabled to prosecute their studies while living at home, without the loss of time and health involved in long daily journeys by omnibus or underground rail. A pleasant walk through park and gardens brings the student from Kensington, or Bayswater, or Notting Hill to the scene of his morning's work, and the proximity of the Victoria stations places the hospital in direct connection with all the southern and western suburbs.

The most important money prizes offered to students at St. George's are:—The William Brown Exhibitions of 100*l.* per annum, tenable for two years, and of 40*l.* per annum, tenable for two years, and the Brackenbury prizes in Medicine and Surgery, value 32*l.* 6*s.* each. In addition, the Treasurer's prize, the Thompson medal, the Brodie and Acland Clinical prizes, the Henry Charles Johnson prize in Anatomy, the Pollock prize in Physiology, Sir Charles Clarke's prize, and three general proficiency prizes, of smaller value, are annually competed for.

[1] The remainder of the All Souls' formula is scarcely applicable to the school of Chambers and Young, of Hunter and Brodie.

An exceptional value attaches to the hospital offices which are open to students of St. George's, both on account of the length of the term of office, and of the magnitude of the charge which is placed upon the officers. No extra fee is asked for any office whatever, and all are awarded as the result of open competition. After passing through the usual dresserships and clinical clerkships, which are an obligatory part of the curriculum, the intending house-surgeon or house-physician is called on to compete with his fellows for the post of Assistant to the Registrar. The successful competitor then passes six months in systematically observing and recording the cases in the wards under the Registrar's supervision; alternating his work, on the surgical side, with a period of assistantship in the ophthalmic department. Having completed this first six months' work, he obtains by another competition the office of Assistant House-Surgeon or House-Physician, and spends a second period of six months in attending on the out-patient department under the instruction of the Assistant Physicians and Surgeons. From the subordinate position he passes at the expiration of the six months into the full House-Surgeoncy or House-Physiciancy. These offices are held for twelve months, and the officers are provided with board and residence in the hospital.

The hospital appoints at one time two House-Surgeons and two House-Physicians, who share the heavier duties of their office week and week about. Each House-Surgeon will therefore have on an average about 90 cases, and each House Physician about 70 cases under his charge, the entire responsibility of which rests upon him in the absence of the visiting Physicians and Surgeons. He is called on further to deal with such urgent cases as arrive, and to attend the visiting officers, to whom he is attached, upon their rounds of the wards. By a tacit custom, moreover, he is expected to aid in instructing the clinical clerks, dressers, and other students who accompany him on his morning rounds. The value of two years of such training and work as this, before entrance into ordinary practice, it would be difficult to over-estimate, and it is not surprising that the competition for these posts is keen.

A further office of great value is open to the house officer on completing his term, that of Obstetric Assistant. The Obstetric Assistant, who attends to the outdoor midwifery department as well as to the gynæcological ward, and holds his office on an annual tenure, is given a salary of 100*l.* a year, with board and residence.

For those who wish to devote themselves to hospital work for a further period, there are open the Medical and Surgical Registrarships, and the Curatorship of the museum, each with an honorarium of 50*l.* a year; and the Demonstratorships of Anatomy, Physiology, Physiological Chemistry, Histology, and Practical Pathology in the School, to all of which a salary is attached. From the men who have served in these last-mentioned posts the staff of the hospital is almost uniformly recruited. The old practice of canvassing a large Board of Governors for hospital appointments, with all its discreditable incidents, is happily a thing of the past, as far as St. George's is concerned. Appointment to staff offices is made by a select standing committee, sedulously guarded from communication with the candidates; that to junior offices is determined by the recommendation of the Medical School Committee, who are intimately acquainted with the merits of the applicants. A student entering at St. George's with the view of eventually becoming attached to the staff and joining the higher ranks of London consulting practice, thus knows that his course is clear before him, and that his prospects depend entirely on his own exertions.

GUY'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

The medical school of Guy's Hospital is provided with every requirement for giving the students a thorough and complete education. There are two large theatres, the Anatomical and the Chemical Theatre. In the former are delivered the lectures on Anatomy, Physiology, Medicine, Surgery, Midwifery, Mental Diseases. Adjacent to this are class-rooms, one of which is fitted with all the appliances in splints, bandages, models of dislocations, &c., for the classes in Practical Surgery. Another is a large room suited for the practical classes in Histology, Zoology, and Botany, and in this also are held the various written examinations for testing the students' knowledge, and for the award of prizes. Two other rooms are used as histological laboratories. The dissecting room has been enlarged from time to time, and is now a spacious and lofty room, lighted entirely from the top and well-ventilated; and connected with it is a smaller room with every arrangement for special demonstrations on the dissected subject. Dissection is now carried on both summer and winter, as for several years the subjects have been perfectly preserved for long periods by the injection of glycerine and arsenic. The students' work in the dissecting room is supervised by three demonstrators, and two assistant-demonstrators. Special demonstrations are given regularly during the winter session, and students who are candidates for the various anatomical examinations are divided into classes, systematically taught and tested from time to time by written examinations. In the Chemical Theatre are delivered lectures on Chemistry, Physics, Medical Jurisprudence, and Materia Medica, as well as clinical lectures in Medicine and Surgery. It is fitted with appliances for lecture experiments, and close by are the lecturers' private laboratory, and a laboratory arranged for large classes of Practical Chemistry. In all these various departments, besides the lectures and classes prescribed by the examining bodies, special classes are held for the examination of the Royal College of Surgeons and for the examinations of the University of London. Students find further opportunities of study in the Library, containing upwards of 5,000 volumes, which is open to all students, and from which books may be taken out for a limited period by special arrangement, and in the Museums, which are situated in different parts of the Hospital. On either side of the Anatomical Theatre are two large rooms forming the Pathological Museum. This contains not only the various morbid specimens arranged according to the physiological systems of the body, but also a unique collection of 800 wax models, the work of the late Mr. Joseph Towne. These comprise not only a complete series of models of diseases of the skin, illustrative of typical forms, but several models of rare or anomalous forms of skin disease; a large number illustrative of other conditions, such as gout, tumours, &c., and finally some accurate representations of typical visceral lesions, such as cerebral hæmorrhage, pneumonia, phthisis, which are of service in the lectures on Medicine and Pathology.

The Anatomical Museum also contains a collection of wax models by Mr. Towne, numbering over 200. They include perfect representations of dissections of every part of the body, and a number illustrating the anatomy of the lower animals, and the development of ova. This Museum also contains a complete zoological collection of typical specimens of the several divisions of the animal kingdom. The Materia Medica Museum contains specimens of all the drugs in the Pharmacopœia, with their several preparations; as well as others commonly used, though non-officinal. All the Museums are open to the constant inspection and use of the students.

Having passed through his earlier studies, the student at Guy's Hospital gains a thoroughly practical aquaintance with his profession by study in the wards, the out-patients' rooms, and the *post-mortem* room. The Hospital contains, besides general medical and surgical beds, special wards for diseases of women, and for diseases of the eye, a large operating theatre, an electrifying room, and spacious out-patient rooms in which arrangements are made for the study of diseases of the skin and of the ear, as well as those mentioned above. The *post-mortem* room has been quite recently built, and offers every advantage for the demonstration of morbid anatomy.

Every part of the Hospital is systematically utilized for clinical study, by the appointment of students for periods of two, three, or six months as reporters, clerks, or dressers. One of the earliest appointments is that of surgical clinical clerk, in which the student, having a certain number of beds allotted to him, keeps an accurate record of the cases therein, being guided and assisted by the Surgical Registrar. He then learns to observe the more obvious facts of ordinary surgical cases. Subsequently he takes the junior dresserships, dresser in the surgery, and assistant-surgeon's dresser, for three months each, and then becomes qualified for the office of medical clinical clerk, whose duties are of a similar kind to those of the surgical clinical clerk, and are superintended by the Medical Registrar. All the students in turn undertake the above appointments; but there are several other offices, *post-mortem* clerks, extern obstetric attendants, assistant-surgeons' clerks, and others in special departments, such as clerks to the obstetric physician, and dressers in the aural and dental departments. These appointments are distributed by a special committee of the staff, according to the merits of the candidates, as judged of by their previous work in the dissecting room, at lectures, in the earlier appointments and at examinations. In a similar way a selection is made for the more responsible appointments, surgeon's dresser, clinical assistant, dresser in the eye wards, resident obstetric assistant, house surgeon and house physician. These are appointed entirely according to merit, and without additional payment; the last three reside in the Hospital, free of expense, and the surgeon's dressers also for a short time during their period of office.

As an incentive to careful study, the medical school offers several prizes and scholarships. There are two open scholarships of 125 guineas each, the Arts Scholarship for classics, mathematics, and languages; and the Science Scholarship for chemistry, physics, botany, and zoology. Prizes are offered at the end of each year in the subjects of the year's work. In the first year 50*l.* and 25*l.* In the second year 25*l.* and 10*l.* (Joseph Hoare Prizes). In the third year 25*l.* and 10*l.* In the fourth year 25*l.* and 10*l.*; and certificates to candidates who have done creditable examinations. In addition there are the following special prizes:—Two gold medals given by the Treasurer for clinical medicine and clinical surgery respectively; the Gurney Hoare prize of 25*l.* for clinical medicine: the Mackenzie Bacon prize of 10*l.* for medical ophthalmoscopy; the Beaney prize of 30 guineas for pathology; the Burdett prize of 10*l.* for hygiene; the Sands Cox Scholarship of 15*l.* per annum for three years for physiology; the Michael Harris prize of 10*l.* for anatomy.

The Pupils' Physical Society, which meets once every fortnight during the winter session for the discussion of medical subjects, also awards five prizes of 5*l.* each, and one of 10*l.* for papers and essays presented to it, and for excellence in debating.

KING'S COLLEGE AND KING'S COLLEGE HOSPITAL.

(By a Professor of the Medical Faculty.)

King's College was founded by Royal Charter in the year 1829 and opened in 1831. Its foundation was undoubtedly due to the creation in 1826 of what was then called the "University of London," in Gower Street, and the fear that the new institution, while widening the bases of a purely secular education, would, by definitely displacing theology from the curriculum, refuse to religious training any recognition in education. The leaders of the Church of England at that time naturally became alarmed, and at once took action to form a teaching institution in which definite religious training on the principles of the Church of England should be combined with a full and thorough theoretical and practical scientific education. The Duke of Wellington placed himself at the head of the movement, and the first meeting of its supporters was held at the Freemasons' Tavern on Saturday, the 21st of June, 1828. The constitution of the College as it now exists was then determined on, viz., a principal to superintend the general discipline, professors and tutors for the various branches of literature and science, a council to conduct the general affairs of the institution, composed of a number of life governors and official governors and some elected members, with the Archbishop of Canterbury as visitor, and His Majesty the King as patron. At all times the College has been resolutely kept aloof from all special parties in the Church, and to this determination was due the first important secession from the list of its founders, that of Lord Winchelsea and many of the Ultra-Protestant party, in 1829. A virtual "Conscience Clause" has always been in operation, and students of all creeds, some not even Christians, have been freely admitted.

The foundation was intended to be on a large scale, and probably 150,000*l.* has been spent on the building and establishment of the College, without any professorial endowment, so that the incomes of the teachers have always been, and still are, dependent on the fees paid by the students only. In the year 1831, on the opening of the College, it consisted of a department of general literature and science, a medical department, and the school. Rooms for a certain number of resident students, then a new feature in London colleges and medical schools, were part of the original plan, and this feature was more fully developed as the College grew older. At present rooms are provided for about thirty students. The first principal was the Rev. William Otter, M.A., afterwards Lord Bishop of Chichester; the first head-master of the school was the Rev. Dr. Major, and among its first professors in science were the Rev. T. G. Hall, in mathematics, the Rev. H. Moseley, in natural and experimental philosophy, Nassau Senior, in political economy, Charles Lyell in geology, and Daniell in chemistry. The actual work of the College was opened on October 8th, 1831, introductory lectures were given on botany, by Professor Burnett, and on chemistry, by Professor Daniell, and the lecture rooms were soon well filled. The first lecture on the separate opening of the medical session was delivered by Professor J. Henry Green, F.R.S., in October, 1832, and the following list contains the names of the eminent professors who formed the first medical staff, with the subjects on which they lectured:—Herbert Mayo, F.R.S., General and Descriptive Anatomy, Physiology, and Pathological Anatomy; Richard Partridge, Practical Anatomy and Dissections; Gilbert Burnett, F.L.S., Botany; J. F. Daniell, F.R.S., Chemistry and Chemical Demonstrations; Bissett Hawkins, M.D., Materia Medica and Therapeutics; Francis Hawkins, M.D., Principles and Practice of Physic; Thomas Watson, M.D., Forensic Medicine; Robert Ferguson, Midwifery, and the Diseases of Women and Children; J. H. Green, F.R.S., Principles and Practice of Surgery. For the lectures, being all then required by the College of Surgeons and the Apothecaries' Hall, the total fees were 54*l.* 12*s.*

In 1833, the second year after the opening of the Medical Department, the number of matriculated students was 77, and of occasional students, 233. Frequent class examinations were instituted from its very commencement, and all students, occasional as well as matriculated, were expected to attend them. A regular register of attendance on lectures and examinations was also kept. Students were earnestly recommended to devote themselves for some time to the general studies of the College, before they entered on a more exclusively professional course of instruction, and it is worthy of notice that a course of instruction in medical Latin is specially mentioned in the first medical prospectus. It was not for many years after this that passing a preliminary examination in arts was made compulsory on every medical student by the Examining bodies, and this great reform was always strenuously urged by the medical authorities of King's College. On the 18th May, 1832, the Lord Bishop of Llandaff presided at the first distribution of prizes, in the Medical School, and among the successful students were the late Mr. John Soden, of Bath, and Mr. Edward John Chance, of London. In 1833 the Leathes Endowment Prize was instituted, Messrs William Harris, Leacock, and Edward Tweddell Atkinson being the first prizemen; and in 1839 the late Dr. Warneford began his munificent endowments towards scholarships and prizes by founding the Warneford Prize, which was taken by William Allen Miller, who afterwards succeeded Professor Daniell in the Chair of Chemistry. The first scholar in 1842 was George Johnson, the present professor of clinical medicine in the College. In 1836 the Institution in Gower Street had been incorporated by charter as "University College," and in 1837, mainly owing to the rivalry between the two bodies, the present University of London was founded as an Examining body, granting degrees, and power was given to it to affiliate the two Colleges and other colleges of higher education.

Meanwhile, there had been some important changes in the teaching staff of King's College. In 1835 David Don, F.L.S., had succeeded Professor Burnett in the Chair of Botany, and Dr. Paris followed Dr. Bissett Hawkins as Professor of Materia Medica, but in 1836 the greatest alterations previous to the establishment of King's College Hospital were made in the professoriate. On the resignation of Professor Herbert Mayo, the Chair of Anatomy was divided, Professor Partridge devoting himself to descriptive and surgical anatomy, whilst Dr. Robert Bentley Todd was appointed Professor of general anatomy and physiology; Dr. Royle succeeded to the Chair of Materia Medica; Mr. Arnott and Dr. Thomas Watson took charge of the teaching of surgery and medicine; Mr. Fergus followed Dr. Watson in forensic medicine, and a new Chair of Comparative Anatomy being made, T. Rymer Jones was elected as the first professor. It was during his tenure of the professorship of medicine in this College that Sir Thomas Watson's celebrated and classical lectures were given, and so materially assisted in increasing the reputation of the young school.

The chief drawback to the thorough and efficient medical education contemplated by the founders of the College, and anxiously desired by the teachers, was the want of a hospital for the purposes of clinical teaching. The students were obliged to obtain practical instruction and ward work at the existing hospitals under other authorities, who looked with some jealousy and

distrust on such of their surgeons and physicians as were attached to the new institution. For the due development of the Medical School it had therefore become a matter of urgency that a hospital should be obtained, and that the eminent teachers at its head should have proper scope for their practical skill as well as their acknowledged theoretical efficiency. In the year 1839, King's College Hospital was opened on the site of the old St. Clement Danes' Workhouse, in Portugal Street; 120 beds were at once made available for teaching purposes and its position, in one of the poorest and most densely populated parts of the Metropolis, was especially favourable for the reception of the worst and most varied forms of disease. In consequence of the creation of the hospital further changes took place in the teaching staff; and Dr. Watson and Mr. Arnott, electing to remain at the Middlesex Hospital, resigned their professorships and became merely consulting physicians. Dr. George Budd undertook the lectures on medicine and Mr. William Fergusson was elected professor of surgery. The first members of the hospital staff were—Surgeons, Richard Partridge, William Fergusson; Physicians, Robert Bentley Todd, M.D., and George Budd, M.D. Robert Fergusson for diseases of women and children; Physician Accoucheur, Arthur Farre, M.D.; Assistant Surgeons, William Bowman, John Simon; Assistant Physician, William A. Guy, M.B., and Arthur Farre, M.D., for diseases of women and children; Surgeon-Dentist, John Tomes. The first House-Surgeon was Henry Lee and the first House-Physician Henry Elton.

A more distinguished staff of officers could not possibly have been brought together. Farre, Simon, Bowman, Guy, and Tomes are still living, and we need only point out how fully their subsequent career has testified to the wisdom of the Council's selection. The sparkling originality and successful teaching of Partridge, the thorough kindliness and extensive erudition of George Budd, who has so recently passed away, are household words among all old King's men. But undoubtedly among the first teachers Todd and Fergusson are the names that will be the longest kept in memory, and will be first recalled when the old hospital is spoken of, for in 1861, the present building, with its 220 beds, took the place of the former makeshift.

Robert Bentley Todd gave the whole of his life-work to King's College and King's College Hospital, for in 1836, at the early age of 27, he began to lecture on Physiology, and he only resigned his office of clinical physician at the close of 1859, just six weeks before his death. His name will always be identified with the "alcoholic" treatment of disease, in favour of which perhaps even now the last word has not been spoken. We prefer to remember him as the accurate clinical observer, the correct diagnostician, the fearless exponent of unpopular views, and the earnest and convincing teacher. Probably no man was ever more truly loved and admired by his pupils than Robert Bentley Todd. William Fergusson was well known as a successful demonstrator of anatomy, and a bold operator in Edinburgh when he was appointed the surgical head of King's College Hospital. He was less successful as a teacher, perhaps, than as an operator, yet those who daily attended to Fergusson's maxim "Learn with your eyes as well as your ears" will place him on a higher level in this respect than those who only casually heard him. Imbued with the teaching and example of Liston and Syme, he was at his best in the operating theatre conspicuous for the brilliancy and ease with which he performed the most difficult and unusual operations, he at the same time simplified his act by always leaning to what he called "conservative" surgery. His self-command and temper, unperturbed by any unforeseen circumstances, were peculiarly striking. As a result of the teaching of the exceptional staff then at the head of King's College, it may be mentioned that alumni of this school have been elected to appointments in every medical school in the Metropolis, with one exception only.

Since 1861 new chemical and physiological laboratories, and an enlarged dissecting-room have made King's College a well appointed and even an almost ideally complete medical school. With the new developments in medical education, King's College has kept pace. Special teachers and professors have taken charge of the teaching of biology and physics, whilst tutorial and practical instruction has been largely increased for the requirements of the preliminary examinations at the University of London and the Royal College of Physicians. On the death of Sir William Fergusson, in 1877, it was thought desirable to strengthen the surgical staff, and Mr., now Sir Joseph, Lister was induced to resign his appointment at Edinburgh, and to accept a clinical professorship and the post of surgeon at King's College Hospital. This appointment at once gave an impetus to the study and practice of scientific surgery at the hospital, and the wisdom of the Council's choice was shortly apparent in a considerable increase in the number of entries of students in the Medical Department. By thus becoming the head-quarters of antiseptic surgery, King's College Hospital has increased its attractiveness, not only for its own students, but also for the practitioner, from whatever country he may come. The medical students at the College, probably from being under more direct discipline, and drawn to a large extent from the relatives of the clergy of the Church of England, have been in a very large proportion public-school men, and we question if the failures are so great as Sir J. Paget's well-known averages. Athletics have always been assiduously cultivated. In the foundation of the Inter-Hospital Athletic sports King's College men took a great share, and for many years produced winners in all the principal races, whilst the Inter-Hospital Cricket matches were mainly due to their initiative, and for the first two years they held the champion cup. An athletic club has recently been formed, and a large piece of land taken by the Council close to Wormwood Scrubbs Station for lawn tennis, cricket, and football. Entrance exhibitions in science and literature, to the amount of 250*l.* per annum, have been placed at the disposal of the Council by the munificence of the late Dr. Warneford, Mr. T. G. Sambrooke, and the Cloth-workers' Company, and besides many endowed and class prizes, medical scholarships to the value of 130*l.* are awarded annually. The residents at the Hospital are elected by competition, and have rooms and commons free, and the registrars are endowed officers. A marked point in the tenure of the resident appointments is the absence of a resident superintendent, so that in the absence of the visiting officers the house-surgeons and house-physicians are in sole charge, and the names of the eminent men who have held these offices show how good a training is secured by giving them such responsibility and scope for learning medicine and surgery. Selected students are made Associates of King's College each year, and Honorary Fellows have been elected since 1847, as a special mark of distinction.

THE LONDON HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

Every hospital and medical college has some advantages and peculiarities that offer attractions to those about to begin their medical education, and the variety of choice tends to embarrass rather than help

one who has to select an *alma mater*. In pointing out the advantages offered by the London Hospital and Medical College, the writer desires above all things to avoid the disparagement of other hospitals and schools.

The especial attraction of the London Hospital is that, owing to its great size and position, it offers, in excess of every other medical school, an enormous amount of clinical material available for study and teaching purposes. In order to appreciate the importance of this fact we must point out that to gain a thoroughly competent knowledge of our profession two things are essential, namely: good systematic teaching, and abundant opportunities at the bedside, and in the dead-house, of acquiring a large practical experience and insight into disease in all its many and varying forms. No didactic teaching of medicine and surgery, however good, can make a fully equipped practitioner of medicine. Such teaching may lay the foundation for acquiring knowledge, which will up to a certain point be of the greatest value and assistance to the student, but the structure will be dwarfed and incomplete unless accompanied by large clinical opportunities. Such teaching may make a scholar, but it will not make a successful doctor; for medicine is an art as well as a science, and must be learned by studying nature, diseased and distorted though it be, and not from books and lectures. Books and lectures can never develop and ripen the habits of observation which are essential to a true knowledge of disease. These can only be gained by long and patient study at the bedside and in the *post-mortem* room. It is not sufficient to *walk* the hospital, that is, to accompany the teacher in his visits to the wards, but the student must have the training and responsibility of individually watching patients day by day, and of recording their conditions, and of personally adapting the appliances of surgery under supervision before he is qualified to treat the diseases and injuries he will afterwards be called upon to deal with. Hence the failure of some teaching establishments, with hospital opportunities insufficient for the number of students. Such establishments turn out students who may be successful at examinations such as test only book knowledge, but when the education of these students is supposed to be complete they find it has really to commence. This is evidenced by the fact that a number of legally qualified men come each year to the London Hospital from British and other Universities to supply the deficiencies of their medical education, and eagerly fill the subordinate appointments open to junior students.

The London Hospital stands in the midst of the large manufacturing region of East London, quite close to the Docks, and in the centre of a densely populated, but poor neighbourhood. It is the largest general hospital and contains nearly 800 beds. The beds are fully occupied, and last year 7,976 patients passed under treatment in its wards. The great size of the hospital and the number of patients necessitate a proportionately large number of offices, which afford the greatest educational opportunities to the student. He can, as a rule, hold all the appointments in turn, without waste of time in waiting for them. And though the number of students has undergone a remarkable increase during the last few years, there is no likelihood, owing to the great size of the hospital, of this special feature being lost. There are the following resident appointments:—five House Physicians, five House Surgeons, a Resident Accoucheur, and two Resident Maternity Pupils. All the resident officers are provided with rooms and board entirely free of expense, and all these offices are open to the full students of the hospital without additional fee. At some colleges a salary is attached to the resident offices, but the holder is required to pay for his board and lodging, or the student is required to pay an extra fee for the privilege of holding office, both of which often mean expense to the student. The fact that the resident offices are entirely free, and entail no expense on the holder, is especially important to realise, as it enables any good student, to whom the expense of his education is a great consideration, and who would otherwise be compelled, as soon as he has obtained his diploma, to seek some means of subsistence, to hold these appointments, which are simply invaluable in the experience and knowledge they confer.

Every student is *required* to act as in-patient clinical clerk, dresser, and *post-mortem* clerk, for a certain period, though usually this period is voluntarily exceeded. As already stated, there are no extra fees for dresserships. The physicians and surgeons take every opportunity of making use of the large number of patients in the wards for the instruction and training of the students. The out-patient departments are on a scale proportionate to the size of the hospital, and last year there were 64,256 out-patients. In the out-patient departments the students are instructed in elementary medicine and surgery, by the physicians and assistant physicians, and the assistant surgeons, so that when their ward work commences, they have the requisite training to enable them to perform their duties. There are special departments for diseases of the Eye, the Ear, the Teeth, and the Skin, and the number of patients attending in these departments is so large that the student who avails himself of his opportunities cannot fail to obtain a competent knowledge of the more or less specialised branches of medicine. There is also a completely equipped Obstetric department, with wards and an out-patient department for the study and treatment of gynæcological cases, and a maternity department, for the attendance of parturient women at their own homes. The opportunities of obtaining practical experience in midwifery are simply unlimited.

The arrangements of systematical lectures and teaching are as complete as possible. In the winter session there are lectures on Anatomy (Mr. Frederick Treves), Physiology (Mr. McCarthy), Chemistry (Dr. Meymott Tidy), Experimental Physics (Mr. Page), Medicine (Dr. Stephen Mackenzie), Surgery (Mr. Rivington). In the summer session the following courses are given:—Midwifery and Diseases of Women (Dr. Herman), Morbid Anatomy and Pathology (Dr. Sutton), Toxicology (Dr. Meymott Tidy), Medical Jurisprudence and Public Health (Dr. Sansom), Materia Medica (Dr. Prosser James), Practical Chemistry (Mr. Page), Botany (Dr. Francis Warner), Comparative Anatomy (Mr. C. W. Mansell-Moullin), Practical Histology (Mr. McCarthy), Practical Surgery (Mr. Reeves), Operative Surgery (Mr. Rivington). Besides these lectures, there are courses of lectures on Ophthalmic Diseases (Mr. James Adams), Aural Diseases (Dr. Woakes), Diseases of the Throat (Dr. Morell Mackenzie), Anatomy and Pathology of the Teeth and Dental Surgery (Mr. Ashley Barrett). In the winter and summer session Mr. Jonathan Hutchinson, Emeritus Professor of Surgery, gives two short courses of lectures on Clinical Surgery.

The standards of the Examining Boards have of late years advanced, and, in order to meet an evident need, special Tutorial Classes have been instituted for all the examinations, and especially for the Preliminary Scientific and Intermediate M.B. London Examinations, and for the Primary Examination for the Fellowship of the Royal College of Surgeons. Great care is taken with the teaching in the department of practical anatomy, and the supply of subjects is always so large that the new student can count on getting a "part" at once instead of wasting several weeks at the commencement of the winter session before settling down to dis-

section. The advantages of a large supply of subjects cannot be overrated. A sound knowledge of anatomy can be obtained in the dissecting room, and in the dissecting room only. When work commences in the department of practical anatomy at the beginning of the coming session, some twenty bodies will be available for use on the first day of the session. At the London Hospital every student can dissect the entire body twice during his first two winter sessions, and facilities are offered to gentlemen preparing for the higher qualifications for undertaking special anatomical work. Dissecting is also carried on during the first two months of the summer session. The ample supply of bodies is taken advantage of during that session for the teaching of operative surgery in an exhaustive manner.

Though the hospital is situated in a neighbourhood that has a somewhat evil reputation (not by any means, from a sanitary point, deserved) the writer knows by experience, having lived there when himself a student, that residence there is healthy and cheerful, if not *élite*. Good lodgings, at reasonable charges, are easily obtainable. At the present time, however, a student may live at any part of London he prefers, or in the suburbs, the numerous railways, with conveniently situated stations, bringing him quickly to the hospital.

The material wants of the student are not neglected. There is a Students' Club, where refreshments of all kinds can be had, and a Resident College in contemplation.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

The first stone of this Hospital was laid in the year 1845, by the late Prince Consort, and the Institution was enlarged in 1865, when the Prince of Wales opened a new wing. This year the Princess Louise conferred a similar distinction on a second wing, containing 70 additional beds, which was built through the liberality of the late Mr. J. F. Stanford, who left 25,000*l.* for structural improvements. The Hospital is managed by an open Board of Governors (President, Lord Carlingford), who meet every Friday at 4.30 p.m.

It contains 270 beds, 130 of which are devoted to medical, and 140 to surgical cases. Two wards are appropriated to the diseases of children, and one to those of women; beds are also provided for ophthalmic, aural, and cutaneous cases. During the past year relief was afforded to 2,322 in-patients, and 25,000 out-patients and casualties. Among some of the early teachers on the medical and surgical staff who have now passed away, may be mentioned—Sir James Alderson, late President of the College of Physicians, Dr. Francis Sibson, Dr. Tyler Smith, Mr. Coulson, Mr. Ure, Mr. Toynbee, Mr. Gascoyen, Dr. Murchison, and among those who have retired from active work in the Hospital and School—Messrs. Samuel and James Lane, Mr. White Cooper, Dr. Graily Hewitt, Dr. T. K. Chambers, Dr. Markham, Dr. Burdon Sanderson, Mr. Ernest Hart, Mr. Spencer Smith, and Dr. Farquharson, M.P.

The Hospital is situated in one of the most pleasant and open districts of London, and by its nearness to the Great Western Terminus, and to the Praed Street, Bishop's Road, and Edgware Road Stations of the Metropolitan Railway, students are enabled to live conveniently at short distances from it. A Students' Club has lately been founded, and the club rooms are situated in the basement of the Mary Stanford Wing, and comprise a library, reading-room, and dining-rooms. The Medical School has been constructed with careful attention to ventilation, and in the additions recently made to the school buildings, every sanitary requirement has been amply supplied.

The School, in 1883, was considerably enlarged, at a cost of 6,000*l.*, and many additions were made in the Physiological and Chemical Laboratories. During the present year the past and present students of the Hospital have subscribed largely towards a fund for thoroughly fitting up the physiological laboratories for the double purpose of advancing the interests of the School and of commemorating the services of three of their late teachers, Dr. Sibson, Mr. Lane, and Mr. Gascoyen. During the past year some alterations have been made in the teaching staff. Dr. Waller has been elected to the Chair of Physiology, and Dr. Crichton Browne to that of Psychological Medicine. The Medical Tutor, Mr. Pepper, after six years' service, has resigned his appointment into the hands of Mr. Silcock.

One open scholarship in natural science, of the value of 100*l.*, and four of the value of 50*l.*, tenable for one year, will be competed for on Tuesday, September 23rd, 1884, and following days. Subjects: — Inorganic chemistry and experimental physics, with either botany and vegetable physiology or zoology (as defined in the syllabus of subjects for the preliminary scientific examination in the London University calendar). There will be a practical examination in addition to the paper in all the subjects. Candidates must not have completed a full year of study at a London Medical School. No candidate will be allowed to hold a scholarship or exhibition at another Medical School in London. The successful candidate in each case will be required to enter at the Hospital as a perpetual pupil immediately after the examination.

In addition to the above, at the same examination, a scholarship of a hundred guineas is offered for competition to such students of Epsom College as are sons of medical men. Names of intending candidates should be forwarded on or before Saturday, September 20th, to the Dean.

Also in addition to the above, scholarships of 30*l.*, 25*l.* and 20*l.*, are offered annually for first, second, and third years' students respectively.

Besides the clinical instruction and lectures given in the wards daily, distinct clinical lectures will be given on Wednesdays throughout the Academical year, at 3.30 p.m., in the Anatomical Theatre. All the Medical Appointments in the Hospital, including the five House Surgeoncies, are open to its pupils without further fee, an advantage of the highest importance to the student, and a valuable addition to the scholarships and prizes. Preference is given to the qualified perpetual pupils of the Hospital. *Post-mortem* examinations are made by Mr. Silcock, the Pathologist, at 2.30 p.m., as opportunities occur. About 300 inspections are made annually. Surgical operations are performed on Wednesdays at 1.30 p.m. The Medical Society meets on alternate Wednesday evenings, during the winter session, at 8 p.m., for the exhibition of pathological specimens, the discussion of clinical cases, and the reading of papers on medical, surgical, and collateral subjects by the students. The museum is open to students; it contains about 3,000 specimens, illustrating healthy and morbid anatomy. Special classes are held for the preliminary scientific and intermediate M.B. of the University of London, and for the F.R.C.S. examinations.

The session will open on Wednesday, October 1st, at 3.30 p.m., with an introductory lecture by Dr. Lees. On the same evening Dr. Alfred Meadows will take the Chair at the Annual Dinner of the Past and Present Students. On Thursday, October 2nd, a *conversazione* will be held at 8.30 p.m., in the Hospital and new school buildings

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

Although unable to boast of great antiquity, the Middlesex Hospital has during the major part of the 140 years of its existence taken a prominent share in the work of medical education. During most of this time its sphere was confined to clinical instruction, and in the interval that elapsed between the foundation of University College and the building of University College Hospital, it was for this purpose resorted to by the students of the Medical Faculty of that College, amongst whose professors were some of the leading members of the Middlesex Hospital Staff. Then came the decision to found a medical school in direct connection with the hospital, which was carried into effect in 1835, so that the session now to be opened will be the fiftieth of the independent existence of this medical school. The buildings, erected in a corner of the hospital garden, originally comprised a laboratory and class room, library, lecture theatre, dissecting room and museum. The dissecting room was narrow and encircled the theatre, but more than 30 years elapsed before any material alterations were made. At length, owing to the increasing number of students and the needs of education, these became imperative. New class rooms were added, the old theatre removed, and the present dissecting room constructed on its site, and a new spacious theatre was built. At the present time the accommodation is sufficient for its purpose ; but the hope may reasonably be entertained that the buildings may be further extended at no distant date.

Systematic lectures are delivered here regularly throughout the winter and summer sessions, the largest courses being Chemistry and Anatomy, each four times a week ; Physiology, Medicine and Surgery, each three times, the other winter courses including Practical Surgery, two and three times, and Pathological Anatomy, twice a week. In the summer session the lectures comprise Practical Chemistry, Botany, Practical Physiology and Histology, Materia Medica, Midwifery and Forensic Medicine, each three times a week ; and shorter courses of Comparative Anatomy, Psychological Medicine and Public Health. Many of the hospital staff hold lectureships, but the subjects of Chemistry, Physiology, Materia Medica and Psychological Medicine, are taught by lecturers not upon the staff. It will be seen that the school is essentially a *medical* one ; and that the fact is recognised that instruction in preliminary scientific subjects is not a duty that should be imposed on a medical school. Although this fact may prevent the enrolment of students intending to graduate at the University of London, unless they have previously passed the preliminary scientific examination, it is, in the present writer's opinion, a limitation founded on a right principle. The stress laid by the University on a preliminary scientific training implies that this should be full and thorough ; and it is needless to multiply centres of scientific study, which require for their equipment not only a large amount of material, but a staff of specially trained teachers. The endeavour to teach science in every medical school tends to defeat the object of the University and hampers the medical curriculum by encouraging the student, to his own detriment, to combine these two distinct phases of his career. In declining to institute special lectureships in Science, the Middlesex Hospital School declares that its primary object is the medical curriculum, and this it endeavours to make efficient and complete.

The opportunities for gaining practical knowledge in the various subjects have been considerably extended of late years. In addition to the anatomical demonstrations, and the practical classes in Physiology, Chemistry and Surgery, there have been instituted classes on Practical Medicine and Midwifery. In Morbid Anatomy, besides the daily work in the *post-mortem* room, the pathologist gives demonstrations every week, and the microscopical examination of diseased tissues has been included in the course of Pathological Anatomy. The continued advance in this direction is one of the most notable features of the present educational system, and one of which the value might be more fully recognised by examining boards. Mention should also be made of the fact that this school has for very many years recognised the importance of tutorial teaching ; and although the duties of the tutor's office have been materially modified, in accordance with its special needs, it is still retained, and ably directed with much profit to the students. Respecting the museum, which is particularly rich in morbid specimens, and to which of late a series of dissected anatomical preparations have been added, it may be said that it is put to good service as a means of education. This valuable collection has hitherto lacked a printed catalogue, but this want will now no longer exist, as the work, upon which much labour has been expended, will probably be published at the opening of the present session.

But the work of the class room and laboratory is subsidiary to that of the hospital, and this school is fortunate in being attached to a hospital that possesses advantages, both natural and acquired, if we may so phrase it. Occupying a central position, it is a building without pretension but remarkably free from the straggling irregularities that often disfigure such edifices, and bewilder the visitor. Nothing could well be devised on a more simple plan than this building, with its two wings and uppermost floor devoted to wards, and the central block to the rooms and offices of the resident staff ; whilst annexed to the eastern wing are the special wards and out-patient department, now made continuous with the block devoted to the Nursing Home. The wards, which contain mostly from twelve to twenty beds, are thus assigned : six to medical cases, nine to surgical (exclusive of three special female cancer wards), and one to gynæcological cases ; and besides these there are several small special wards. The hospital is always well supplied with patients. It cannot be said that there is not here ample scope and opportunity for clinical work ; nor is there any lack of encouragement in its pursuit. The visits are made by each member of the staff three or more times a week ; and in addition to this instruction, surgical and medical clinical lectures are delivered by each in turn throughout the session. The number of Dresserships and Clinical Clerkships is sufficient to enable every student to hold these necessary offices each for a period of six months ; and there are (at present) twelve resident appointments open for competition annually.

During the summer very extensive structural alterations have been carried out in the out-patient department, from the acquisition of property at the south-eastern angle. The block of new buildings is also intended to increase the accommodation of the resident staff, to supply additional wards, and extend the Nursing Home. The new out-patient department and casualty rooms, and the special departments in connection with the hospital, will be thoroughly reorganised, and the facilities for instruction proportionately improved.

As to the various class-prizes and scholarships obtainable by students, reference must be made to the prospectus. It may merely be mentioned that here, as elsewhere, there are entrance scholarships, two in general subjects and one in science open for competition at the end of September.

**

Nor would a sketch cursory as this is be complete that did not include mention of the Students' Medical Society, a society that has the distinction of being the oldest of its kind in London. The meetings are held once a fortnight during the winter session, and encouragement in the preparation of papers, exhibition of specimens, &c., is given by a system of prize-awards. The president is a member of the hospital or lecturing staff, but all the other officers are elected by the students from among themselves. The meetings are well attended and have considerable educational value.

Lastly it may be added that the school adheres to the time-honoured custom of prefacing its winter session with an introductory lecture on the 1st of October, a ceremony which is followed in the evening by the less formal gathering of past and present students at dinner. The same social feeling amongst those who in past times have been connected with the school is promoted by the Middlesex Hospital Club, established many years ago, the members meeting annually at dinner in the spring.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

(By a Member of the Staff.)

St. Thomas's Hospital appears to have been first founded early in the 13th century, but it remained little more than an almshouse until the year 1553, when it was endowed with lands as one of the Royal Hospitals by Edward VI., and placed under the Lord Mayor and commonalty of the city of London as perpetual Governors. The endowment was from time to time enlarged by bequests and donations, and in 1693 the fabric of the hospital, then situated in Southwark, was rebuilt. The building was considerably enlarged at different times, but the whole was at length sold, in 1862, to the Brighton Railway Company, and after a temporary sojourn in the Surrey Gardens, the well-known extensive buildings on the Albert Embankment were opened in 1871.

Apprentices appear to have been received at the hospital as early as 1561, but it was not till 1718 that the first lectures, those of William Cheselden, were given. In 1768 St. Thomas's Hospital was united with Guy's, so far as the attendance of students on the surgical practice of the two hospitals was concerned. About the same time the anatomical and surgical school, in connection with St. Thomas's Hospital, was founded, and was subsequently carried to the height of its reputation by the labours of the two Clines, Astley Cooper, and Joseph Henry Green. Meanwhile, the lectures on Medicine, Materia Medica, Midwifery, and Physiology were delivered at Guy's Hospital, and no physician of St. Thomas's was allowed to share in them. But in 1825 the "United Hospitals" were severed, and a complete school set up in both. The majority of the students clung to Guy's and St. Thomas's school began to sink. The establishment of the Aldersgate Street private school, under Tyrrell and Lawrence, materially aided in this declension, as did also the secession of Dr. Elliotson to the newly-established University College, and the foundation of a fresh school at King's College, where for a time the surgical lectures were given by Mr. Joseph Henry Green, although a surgeon of St. Thomas's. Owing to the unprosperous state of affairs, in 1842 the Governors came forward to reorganise the school, and the aid of Mr. R. D. Grainger, whose popularity had been established in the Webb Street private school, was obtained. Mr. Joseph H. Green also rejoined the school; and Dr. Marshall Hall, Dr. Hodgkin, Dr. Martin Barry, Dr. Gregory, and Mr. Benjamin Travers contributed to its efficiency. This state of affairs continued until 1858, when the Governors gave back the management, and its attendant risks, into the hands of the lecturers. For some years it was maintained with difficulty, and at much self-sacrifice on the part of the staff, during what may be termed a transitional period, in the hope, now realised, of its once more developing into an institution worthy of its old traditional glories.

The present hospital contains in all 572 beds, and consists of six blocks appropriated to the reception of patients; with one for the administrative and other offices, and one for the Medical School. The ward blocks, though connected by corridors, stand apart, so as to afford free exposure in all directions. Generally, each ward affords accommodation for 28 beds, which are placed against the piers between the windows, so as to secure thorough ventilation. Of the whole accommodation of the hospital, about 180 beds are appropriated to ordinary medical cases, and 230 to ordinary surgical cases. There are also special wards for the reception of diseases peculiar to women; for diseases of the eye; for venereal affections; for children, and for infectious diseases. The out-patients' department is extensive and well arranged to meet the large demands upon it of the poor and crowded districts in its vicinity, and every facility is afforded for the treatment of different forms of medical and surgical casualties and diseases. Clinical instruction is given to the students both in the wards and out-patient rooms in all branches of medicine and surgery, including the diseases of the eye, ear, skin, throat and teeth, and in vaccination. Clinical lectures are delivered weekly during the session. During the twelve months ending December 31st, 1883, the number of patients admitted into the hospital amounted to 4,450. In the same period, 22,374 out-patients have been treated, and in the maternity department 2,130 women have been attended at their own homes. Casualties to the number of 52,919 attendances were treated during the same period.

The school buildings stand at the southern extremity of the hospital, from which they are quite isolated. They contain ample accommodation for large classes of students. The museum is one of the most important in the metropolis. There is a large reading room and library for the use of the pupils. In addition to these are the various lecture rooms, the dissecting rooms, the laboratories for Practical Physiology and for Practical Chemistry, and the *post-mortem* rooms.

Two Scholarships in Natural Science, of the value of 100*l.* and 60*l.* respectively, are awarded annually, while over 250*l.* in scholarships and prizes, besides several medals, are yearly offered for competition to students who are undergoing their curriculum at the hospital.

Three House Physicians, two Resident and one Non-Resident, and an Assistant House Physician, two House Surgeons, an Assistant House Surgeon, and a Resident Accoucheur are selected every three months from gentlemen who have obtained their professional diplomas; they hold office for three or six months. One House Physician, the Assistant House Physician, and the Assistant House Surgeon, are non-resident, but the other Officers, together with the Dressers and Obstetric Clerks, are provided with rooms and commons during their period of attendance in the hospital, free of expense. An Ophthalmic Clinical Assistant is appointed for six months with a salary at the rate of 50*l.* per annum, with board but not residence; the appointment is renewable for a limited period. Clinical Assistants in the special departments for diseases of the skin, throat, and ear are appointed every three months. Clinical Clerks and Dressers to in-patients are selected to the number of at least 100 in each year. Two Hospital Registrars, at an annual salary of 100*l.* each, are appointed in each year, and there are several other appointments.

UNIVERSITY COLLEGE AND HOSPITAL.

(By a Professor of the Medical Faculty.)

The Institution now known as "University College" was opened as the "University of London" in 1828 on the most unsectarian principles, with the object not only of affording a liberal education of a high class order, but also of conferring degrees. The "Medical Faculty" commenced work on October 1st, and is a month older than any of the other faculties. Having thus a history of little more than half a century, this College has during that period exerted a remarkable influence upon the progress of education in this country, as well as upon many social and other questions of importance. Such an influence has been particularly evident in the improvement of medical education to which it has so largely contributed, as well as in the advantages which it has afforded for the acquisition of scientific knowledge and training. Before University College was founded, medical education in England was in a very low state; but the medical school set a pattern of teaching that raised this branch of education throughout the whole country, and it has continued ever since to occupy a leading position. In 1836 the name was changed to "University College," the power to confer degrees having been transferred to a separate merely examining institution, since known as the "University of London."

At first there was no hospital connected with the College, and arrangements were made with Middlesex Hospital for clinical study. The first portion of the present hospital was opened on November 1st, 1834, and it was subsequently enlarged, but it cannot be denied that until a comparatively recent period the number of cases in the hospital was inadequate to supply the large number of students with sufficient practical work. Nevertheless, it must be noted that the cases were systematically used for clinical instruction, and also that the out-patient departments have always been thoroughly utilized for this purpose. At present the hospital contains 208 beds, which, with the out-patient practice, afford a large field for clinical instruction and study. All the important "special" branches connected with medicine or surgery are now recognised as separate departments, and are systematically taught by members of the staff. Although University Hospital is thus very thoroughly worked for clinical purposes, yet, not only for the sake of the students, but also taking into consideration the vast number of artizan, labouring, and poorer classes for whom this hospital is most convenient, and its proximity to important thoroughfares, crowded with shops, and having a large vehicular traffic, as well as to numerous manufactories of various kinds, and to some of the most extensive and busy railway stations in London, it might be considerably enlarged with great advantage to all concerned. It may be mentioned that the hospital contains a very efficient system of baths, which are of great service in the treatment of patients, and which were established through the efforts of the late Dr. Tilbury Fox, for many years physician to the skin department.

On July 9th, 1878, the first stone of the extension building of University College was laid by Earl Granville, and the new north wing was opened on October 1st, 1880. This additional building afforded most important facilities for the study of physiology, zoology, and comparative anatomy, and chemistry, and the present arrangements for teaching these subjects are probably unsurpassed, even if equalled.

The history of the progress of University College is intimately associated with the names of the eminent men who laboured within its walls as professors, or did no less service as members of the medical or surgical staff of the hospital. Many acted in both capacities. The professors who inaugurated the work at the College consisted of Mr. (afterwards Sir) Charles Bell (Physiology), Dr. Jones Quain (Anatomy), Dr. Conolly (Practice of Medicine), Mr. Samuel Cooper (Surgery), Dr. Anthony Todd Thomson (Materia Medica), Dr. David Davis (Midwifery), Dr. Grant (Comparative Anatomy), Dr. Lindley (Botany). Dr. (afterwards Sir Robert) Carswell was the first Professor of Pathological Anatomy, and Dr. Turner of Chemistry. Taking these subjects individually their history is briefly as follows:—The Chair of Physiology was occupied by Dr. Sharpey from 1836 until 1874, and this eminent physiologist always attracted a large number of students. He was succeeded by Dr. Michael Foster, and on his removal to Cambridge, Dr. Burdon-Sanderson was appointed to the Chair, which he held until recently, when his valuable services were transferred to Oxford, and Professor Schäfer took his place. In anatomy Dr. Jones Quain was followed by Mr. Richard Quain, who had previously taught practical anatomy, and then came Mr. George Viner Ellis, who held the chair from 1850 to 1876; on his resignation Professor Thane was appointed. The Professorship of Medicine has been held in succession by Drs. Elliotson, C. J. B. Williams, Walshe, Jenner, Russell Reynolds, and Sidney Ringer. Associated with the Chair of Surgery are the names of Mr. James Moncrieff Arnott, Mr. Erichsen (who held it from 1851 until 1866), and Mr. Marshall. Dr. Garrod followed Dr Thomson as Professor of Materia Medica, and occupied the Chair for some years. His successors have been Drs. Sydney Ringer, and Frederick Roberts. Since the resignation of Dr. Davis the Chair of Midwifery has only had two occupants, namely, Dr. Murphy and Dr. Graily Hewitt. Associated with Pathological Anatomy are the names of Drs. Walshe, Jenner, Wilson Fox, and Charlton Bastian. Connected with Chemistry or Practical Chemistry are the names of Drs. Graham, Fownes, and Williamson. The Chair of Comparative Anatomy and Zoology, and that of Botany, have each only had two occupants, Drs. Grant and Lindley, the professors appointed at the opening of the College, having held office until 1874 and 1860 respectively, when they were succeeded by Professors Ray Lankester and Oliver. A Professorship of Medical Jurisprudence and Toxicology was instituted in 1849, and was held until 1860 by Dr. Carpenter, followed by Drs. G. Harley, Maudsley, and Poore. The Chair of Ophthalmic Medicine and Surgery, established in 1852, was occupied by Mr. Wharton Jones until 1881, when Mr. John Tweedy was appointed.

A branch of medical education which has of late years undergone special development at University College, is that of hygiene and public health. Professor Corfield was appointed to the newly instituted Chair in 1869, and since that time the subject has progressively increased in interest and importance. The arrangements for imparting instruction in its various departments are now, through Professor Corfield's efforts, of the most complete character. Successful classes for the teaching of operative surgery and practical surgery have been in operation at University College for several years.

Passing now to the Hospital, the original staff consisted of Drs. Elliotson, A. T. Thomson, and Carswell as Physicians; Messrs Samuel Cooper, Liston, and Richard Quain, as Surgeons; and Dr. Davis as Obstetric Physician. At a subsequent period assistant-physicians and assistant-surgeons were appointed, who gained promotion as vacancies occurred. It must suffice merely to mention the names of those who have successively held the several posts. Associated with the Medical Department, in their order of appointment, are the names of Drs. C. J. B. Williams, John

Taylor, Walshe, Garrod, Parkes, Jenner, Hare, Russell Reynolds, George Harley, Wilson Fox, Sydney Ringer, Charlton Bastian, Frederick Roberts, Gowers, Vivian Poore, and Barlow. The Surgical staff includes the names of L. B. Potter (whose early death from a dissection wound was a great loss), Syme (for a very short period), Moncrieff Arnott, Morton, Erichsen, Marshall, Cadge, Statham, Henry (now Sir Henry) Thompson, Berkeley Hill, Christopher Heath, Marcus Beck, Arthur E. Barker, and Godlee. In the Obstetric Department Dr. Murphy succeeded Dr. Davis, and he was followed by Dr. Graily Hewitt, while Dr. John Williams was appointed Assistant-Obstetric Physician in 1872, and is now Physician in this department. Mr. Wharton Jones held the post of Ophthalmic Surgeon from 1850 until 1881 ; Mr. Streatfield served for many years as Assistant-Ophthalmic Surgeon, and now holds the higher post, Mr. Tweedy being Assistant-Ophthalmic Surgeon. The Skin Department was first established under the control of Dr. (Sir William) Jenner, who was then one of the physicians ; subsequently it became a separate speciality, which has been successively in the hands of Drs. Hillier, Tilbury Fox, and Radcliffe Crocker. Mr. Ibbetson was Dental Surgeon for many years, and was followed by Mr. Hutchinson.

It will thus be seen that the names of many who have stood out prominently as leaders of the profession have been associated with University College Hospital as members of its Staff, and some of the most eminent are still on its Consulting Staff, although not actively engaged in its work. The name of Liston cannot be passed over without reference, and the death of this great surgeon, in 1847, was a loss to the Hospital that was deeply felt. It may also be noted that several of the members of the Staff have contributed to medical literature publications which have gained a firm standing in the profession, and are recognised as standard works. It may not be uninteresting to observe that within a recent period the high offices of President of the College of Physicians, and President of the College of Surgeons have been held at the same time by members of the University Hospital Staff, namely, Sir William Jenner, and Messrs. Erichsen and Marshall.

In connection with University Hospital it is only right that special allusion should be made to clinical instruction, which has always been a prominent feature in this Hospital, and has been carried out systematically. It may truly be said that every member of the Staff takes an active interest in this work. Every physician and surgeon receives the title of "Clinical Professor," and there is a special Holme Professor of "Clinical Medicine" and "Clinical Surgery." The Professorship of Clinical Medicine has been held successively by Drs. Walshe, Parkes, Jenner, Russell Reynolds, and Wilson Fox ; that of Clinical Surgery by Messrs. Liston, R. Quain, Erichsen, and Christopher Heath. Several years ago classes were commenced for the more elementary instruction in Clinical Medicine and Surgery, and these have now become so developed and systematised that a most complete practical training may be obtained by any student who chooses to avail himself of the privileges afforded him. Those who conduct these classes are called "Assistant Professors," or "Assistant Teachers," and they work along with and under the superintendence of the Holme Professors.

Owing to the constitution of University College the students attending the medical faculty, as in the other faculties, have come from various parts of the world, and have belonged to different races and creeds. Some of its most distinguished students have hailed from distant colonies, and from India. Their number has varied considerably at different times, and in this respect the College has experienced some checks in its progress. In the first session the number was 165, a remarkable number to start with, but it rapidly rose until in the session 1838–39 it amounted to 494, the highest which has ever been reached. With occasional rises there was on the whole a gradual decrease until the years 1865 and 1866, when the numbers fell to 161 and 163 respectively. After this there was a rapid growth of the medical school in point of numbers, and this has been maintained until the present time, University College in this respect holding its position as one of the leading schools of medicine. Moreover, a large number besides, who are not strictly medical students, attend the scientific classes, in order to prepare for the Preliminary Scientific Examination of the London University.

Although not in any way officially connected, there has always been some sort of traditional association between University College and the London University. A large proportion of students enter with the view of preparing for the degrees granted by this University. Of those who take these degrees, a considerable number come from University College ; the names of its students are usually conspicuous in the Honours lists, and they have also taken a large number of the exhibitions, scholarships, and medals granted in different subjects. Of late years students preparing for medical degrees at the older Universities—Oxford and Cambridge—seem to have recognised the educational advantages to be obtained at University College and Hospital, and are entering for part of their curriculum in increasing numbers. Many students from this College have taken high positions in the public services. It may also be noted that it has trained numerous eminent men who now hold prominent positions on the Staffs of other medical schools and hospitals, both in London and in the provinces.

University College offers to its students considerable advantages in the way of scholarships and prizes. These amount to about 630*l.* annually, exclusive of twelve gold medals and thirty silver medals awarded in the different classes. The appointments at the Hospital are also free, and are awarded according to merit, there being competitive examinations for the higher resident posts, which are usually keenly contested.

A most successful Students' Medical Society has flourished at University College for a great many years, and it has done very good work. There is also a well-established Christian Association. Of late years more attention than formerly has been paid to physical exercise, and now athletics, cricket, boating, football, &c., have their several clubs. There is at present a disposition to develop more the social element among the students at University College, and to increase their *esprit de corps*, which has not always been what it ought to be. A very successful dinner of past and present students was held last October, but this year it is anticipated that its success will be far greater, as it is to be presided over by Sir William Jenner, whose almost unrivalled clinical teaching will never be forgotten by those who were privileged to benefit by it, and who is justly held in such high esteem and respect by the whole profession, as well as by the rising generation of medical students.

WESTMINSTER HOSPITAL AND MEDICAL SCHOOL.

(By a Member of the Staff.)

Westminster Hospital owes its origin to a meeting which was held at St. Dunstan's Coffee House on the 14th of January, 1715, nearly 170 years ago, and first opened its doors at a small house in Birdcage Walk, under the name of the "Publick Infirmary for the Sick and Needy." At this time the only hospitals which existed for the medical and surgical relief of the

sick poor were St. Bartholomew's and St. Thomas's, both having been established and carried on by the religious houses of their respective neighbourhoods, and created royal hospitals soon after the suppression of the monasteries in 1537. Westminster is remarkable as being the first hospital in London which trusted for its support to the voluntary contributions of the public. Guy's Hospital, founded by the munificence of one individual, was not established until a few years later.

After four years' work in Birdcage Walk as an institution for the administration of medical relief, the hospital was opened for the reception of in-patients, with 30 beds, and with an entrance from Petty France. So rapidly did its usefulness develop, that in 1724, having been in existence little more than nine years, it opened its wards in Chapel Street, with 60 beds. At this time the celebrated and courtly Mead, Queen Anne's Physician, whose monument is in Westminster Abbey, was physician to the hospital, and two years later Cheselden, the teacher of John Hunter, was appointed its lithotomist, a post which he held for fifteen years. His portrait hangs in the Board room of the hospital. In 1733, the removal of the hospital to a larger building again became necessary, and a warm discussion arose among the governors as to the comparative eligibility of a house in James Street, and of Lanesborough House at Hyde Park Corner. The majority considered the latter site too far from the poor of Westminster, and determined to purchase the building in James Street, which was opened early in 1734. The minority, with a portion of the medical staff, were dissatisfied with this decision and determined to purchase the lease of Lanesborough House, which in their opinion "on account of the strength of the building and the airiness of the situation was much more convenient to answer the ends of charity." This is the origin of St. George's Hospital.

In James Street, the Westminster Hospital did its work for nearly 101 years, but the building having become dilapidated and the accommodation insufficient the requisite money was collected and a very eligible site was obtained in the Broad Sanctuary, under the very shadow of the grand old Abbey. The new building was well and solidly constructed upon a block of concrete, and was remarkable for its thoroughly efficient drainage and ventilation. The removal of the patients from the old hospital to the new was effected on November 14th, 1834. Westminster had for some years enjoyed a great reputation for its clinical teaching, and at this time its surgeons were Mr. Lynn, Sir Anthony Carlisle, Mr. Guthrie, and Mr. Anthony White; and its Physicians Sir G. L. Tuthill, Dr. Bright, and Dr. Hamilton Roe.

The removal of the hospital to a new building stimulated a portion of the staff to establish a medical school in the same year, but it was not until 1849, that this school became intimately connected with the hospital. Its buildings were then constructed on a site leased for a period of 40 years from the Commissioners of Her Majesty's Woods and Forests. It unfortunately happened that after only three years' occupation, twelve months' notice was given to terminate the lease, the ground being required for the Stationery Office. In the following year, therefore, the school buildings were transferred to the ground at the rear of the hospital. They have been added to from time to time by the erection of light and commodious laboratories, &c., but at the end of 30 years, the requirements of the school have outgrown the space at its disposal. A larger site has recently been obtained next to the Westminster Town Hall, five minutes' walk from the hospital, and upon it, school buildings affording the most complete accommodation will be immediately erected from the plans of Mr. Salter.

To return to the hospital. About seven years ago a sum of nearly 18,000*l.* was expended in repairing and improving the building. Sanitary science was, in 1834, little understood, but in forty years a great advance was made in this respect, and changes of an expensive kind became urgently necessary if the hospital was to offer to its patients and to its students the full benefit of the new knowledge. Towers were built to provide sculleries and water closets outside the wards with cross ventilation, separate cisterns, &c. Bath rooms and lavatories were built. The floors of the wards were relaid and covered with oak parquetry and polished. Chloroform and consultation rooms were added to the operation theatre. The greater part of the hospital was raised another story, affording domitories for the nurses in front, day-wards for the convalescent patients at the ends of the building, and separate wards at the back quite outside the hospital, but approached by a covered way, to which infectious cases can at once be removed from the wards. Healthy and airy as the hospital was before these alterations were made, the condition and appearance of the wards are now much improved, and in the surgical wards, the improved sanitary arrangements and the polished floors together have reduced the cases of erysipelas by more than one half.

Westminster Hospital with its 200 beds and extensive out-patient department, affords in a complete form all the material that is required for a practical medical education. Its size is a very convenient one and it combines the advantages of a general and a special hospital, as it has separate departments for all the specialties which may be legitimately so considered or which require special instruction. These departments are devoted to *obstetric*, *dental*, *ophthalmic*,[1] *aural*, *orthopædic*, *skin*, and *throat* diseases, in all of which it is important that the student should have opportunities of study.

The medical school is proportioned to the size of the hospital, so as to maintain all the advantages of a small school and especially that personal supervision and guidance which every student requires but which is very difficult if not impossible in a large school, and at the same time to secure for every student in rotation clerkships and dresserships both to out and in patients. In the more strictly school subjects also it is hardly necessary to point out the great advantage of personal supervision, aided as it is at Westminster by regular tutorial instruction, and by taking great pains with the students individually in all manipulative work and especially in practical histology.

For another year the Medical School work will be carried on in the present buildings, but it is promised that the new school will be ready to receive the students before October 1st, 1885. Afterwards the rearrangement of the out-patient rooms, on the ground now occupied by the school buildings, will be immediately undertaken, and the result cannot fail to be of great advantage to patients, students, and staff.

The return of Westminster men who have passed their examinations, the prize list, and the importance of the appointments that have been gained all show a high average of success, and it may not be out of place to mention that the first place at the last two examinations for the Indian Medical Service has been occupied by a Westminster man.

Wolverhampton General Hospital.—Fees for hospital practice: — six months, 6*l.* 6*s.*; twelve months, 10*l.* 10*s.*; perpetual, 22*l.* 1*s.* Some members of the Staff receive resident pupils.

[1] Westminster students have also the advantage of being allowed to attend the practice of the Royal Westminster Ophthalmic Hospital.

PROVINCIAL SCHOOLS OF MEDICINE.

UNIVERSITY OF OXFORD.

(By Two of the Science Teachers.)

There is not a complete Medical School at Oxford, but there are excellent arrangements for the study of the so-called Preliminary Sciences—Biology, Chemistry, Botany, and Mechanical Philosophy. Many of the Colleges (Balliol, Merton, Exeter, New College, Magdalen, Christ Church, Trinity, St. John's, and Keble) encourage the study of Natural Science, under the guidance of special tutors; by a few it is admitted as one of the subjects for matriculation. Scholarships to the annual value of 80*l.* for from four to five years, and Exhibitions of less annual value are given every year by some, from time to time by other, Colleges. Balliol, Magdalen, and Christ Church have private laboratories. At the University Museum the teaching in the laboratories, under the direction of the Science Professors, is most complete. In the Radcliffe Library there is accessible to students a place of unrivalled facilities for the consultation of current and periodical literature, Continental and English, in Mathematics, Science, and Medicine. Regular courses of lectures are given by the professors and tutors, of which a list is issued terminally by the Board of Faculty of Natural Science. In February there is competed for annually, by those who have obtained a First Class in any School or a Scholarship, or Prize, open to general competition in the University, one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of 200*l.* The examination is partly Scientific, partly Medical. The holder must travel abroad, and take the degree of B.M., Oxon.

The *Radcliffe Infirmary* contains 138 beds, and the annual average of in-patients for the last ten years has been 1,265; of out-patients and casualties, 4,686. Surgical accidents and urgent cases are admitted without "turns." There is a special block for children. The members of the staff (three Medical and three Surgical) take pupils for six months' attendance at six guineas, for twelve at ten guineas, and perpetual at fifteen guineas. Advanced students are allowed to act as Clinical Clerks and Surgical Dressers. Practical Pharmacy is taught in the Dispensary. One Medical and one Surgical member of the staff are Clinical Litchfield Lecturers. Attendance at the lectures, given twice a week in Term, and under the authority of the Board of Faculty of Natural Science, is free to members of the University, but does not confer the right of attendance on the general Hospital Practice. Dissection is carried on at the University Museum, under the direction of the Linacre Professor. There is great need for the appointment of a Lecturer in Human Anatomy, in order that students may be certificated for the First M.R.C.S. Examination of the College of Surgeons.

UNIVERSITY OF CAMBRIDGE MEDICAL SCHOOL.

(By a Member of the Staff.)

The course of medical study in the University, and the requirements necessary for the Degree in Medicine have now been arranged in a manner highly advantageous to students entering the profession. Of the increasing popularity of the Cambridge Medical School and the many advantages offered to medical students no stronger testimony can be adduced than that of the yearly list of entries at the different colleges of those intending to pursue medical studies. A glance at the number of entries this year shows that Cambridge is now one of the largest medical schools in England. The arrangements are such that the student can go through the whole course at a very moderate expenditure of time and money. He must enter at one of the colleges, or as a non-collegiate student and keep terms for three years. He can live quite as cheaply as in London, the expenses of residence, lectures, &c., at a college being not necessarily more than 150*l.* per annum, or as a non-collegiate about 100*l.* At most of the colleges scholarships are open for competition in science as well as classics and mathematics. As regards the length of time necessary, it is required of a candidate for the Degree of Bachelor of Medicine that he shall have completed five years of medical study, except he have obtained Honours in any tripos, in which case four years shall be deemed sufficient. It is advisable to take a Degree in Arts, and of great advantage to the student to do this through the Natural Sciences Tripos, as he is enabled to devote his work and energies to the same subjects that will be required of him in the several examinations for the Degree in Medicine, while at the same time he is laying a good foundation of scientific knowledge which will be of the greatest value to him in professional life. The shorter term of four years' necessary study is of no material advantage as it would be unadvisable to attempt to conclude the whole course in so limited time. A brief summary of the course of study recommended is as follows:—A student will do well to enter early, at the age of 16 or 17, prepared to pass his previous examination and additional subjects at the beginning of the October term, if he have not already obtained exemption through the "Local Examinations" in the "Oxford and Cambridge School Board Examinations." It is important to do this as he can then register as a student of Medicine, and at once join the Natural Science and Medical Classes at the commencement of the several courses in the October term. The subjects of the first M.B., namely, Chemistry, Physics, and Elementary Biology, will first occupy his attention, in all of which he will be examined for the first part of the Natural Sciences Tripos. The first M.B. may be passed at the end of his first year, or the following December, and he can then devote himself to the subjects in which he selects to be examined for the Natural Sciences Tripos. In the first part of this examination the student can present himself at the end of his second year. In preparing for the second part he will save time if he selects Human Anatomy and Physiology as two of the subjects in which he desires to be examined, as these are also included in the second M.B. He may enter for the second part of the Natural Sciences Tripos in his ninth term, after which he may take his B.A. degree. During the following long vacation and October term he can continue dissection, preparing to pass the second M.B. in December. A certificate of attendance at a recognised hospital for six months is required of students, previously to entering for the second M.B. This can be obtained at Addenbrooke's Hospital, where regular instruction is given in term time and during the long vacation. Students who pass the second M.B. in December, may with advantage remain on until the end of the following long vacation, studying at the hospital, learning the elements of surgery and medicine and bandaging, and attending the courses of lectures required of them before the final M.B. They are then ready to enter at some London Hospital at the commencement of the October Session, having already acquired some knowledge of the more elementary details of practice. All the lectures for which

certificates of attendance are required before the several examinations may be attended at the University.

The study of Natural Science is carried on at the Museum, where lectures are given on Chemistry, Physiology, Anatomy, and other subjects, and practical instruction is carried on at the numerous laboratories in Biology, Physiology, &c., and dissection at the Anatomical School. Classes are also held in Histology and Pathological Anatomy. At Addenbrooke's Hospital, instruction is given in the elements of Medicine and Surgery, and bandaging. The Museum contains a good series of Pathological preparations.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

(By a Member of the Staff.)

The University of Durham College of Medicine at Newcastle-upon-Tyne has, during the last few years, attracted to itself a very largely increased number of students. The advantages it offers are numerous, and appear to be every year more highly appreciated. Perhaps its greatest attraction, as compared with other Schools of Medicine, is the fact that only one of the four years of medical study need be spent at Newcastle, while the other three may be passed either at the same place or at one or more of the recognised Schools. The required year's attendance may be taken at any time before the candidate presents himself for the final examination for the M.B. Degree. This regulation has attracted many who were already qualified for practice. For "full" students there are many valuable prizes. Four scholarships of 100*l*. each have been presented by the University of Durham, and are awarded, one every year, to the student who passes the best examination in arts at the time of entry or during his first year. Five other valuable scholarships are given for proficiency in various branches of medical study, and silver medals and certificates are awarded in each class. There are eight useful student appointments at the College, and 27 at the Infirmary. At the latter institution the practice is very large and of varied interest, the patients (about 25,000 annually) being drawn from the whole of Tyneside and the densely populated districts in the neighbourhood. Every opportunity is given to students at the College for learning their work. In the chemical laboratories a separate bench is provided for each student, and the department is under the charge of Professor Bedson, D.Sc., Lond. The anatomy is taught as much as possible by individual instruction, under the able personal guidance of Dr. Mears, who until recently occupied the position of Medical Tutor. There are special departments for practical instruction in pathology, dermatology, ophthalmology, gynæcology, diseases of the throat and ear, and minor surgery, and in operations on the dead body. It is expected that very shortly the College will be moved to more commodious and convenient quarters, and it is hoped that a residential hall may also be provided for the better accommodation of students.

THE BIRMINGHAM SCHOOL OF MEDICINE.

(By a Member of the Staff.)

By the association of Queen's and Mason's Science Colleges for purposes of medical education, and by the amalgamation of the General and Queen's Hospitals for purposes of clinical instruction, students of the Birmingham Medical School are enabled to avail themselves of the whole teaching resources, and nearly the whole hospital practice, of the town. The advantages thus offered to the young man about to commence the study of medicine, compare most favourably with those of any other centre of medical education. Students may qualify themselves for admission to the examinations of any licence-granting body except those of the Universities, which require attendance on their own lectures. All the examinations of the University of London may be passed from here. Students can also make two *anni medici* out of the four required for degrees by the University of Edinburgh. Neither College provides accommodation for residence, but lists are kept of gentlemen prepared to receive medical students. Queen's College—the parent institution—is a well arranged building, situated in the centre of the town, close to the various hospitals and railway stations. Here are taught from the usual professorial chairs all the subjects included in the medical curriculum, except Physiology, Chemistry, and Botany; these courses are given at Mason's College. There are complete and well appointed museums of Anatomy, Pathology and Materia Medica, specially arranged for purposes of instruction, also a well stocked library and reading-room for the use of students. The dissecting rooms are extensive, commodious, well warmed and ventilated, and they have been recently remodelled and enlarged. They are under the immediate superintendence of the Professor of Anatomy, who devotes his whole time to Anatomical teaching within the College. The supply of bodies for dissection is always plentiful. Mason's Science College undertakes the teaching of Physiology, Chemistry and Botany to medical students of the town. Its special professors, its rich museums, and its magnificently appointed modern laboratories, offer advantages to the students of medicine which are equalled at few medical schools in the kingdom. Special classes are held for the matriculation and preliminary scientific examinations of London University. The practices of the General and Queen's Hospitals are amalgamated for purposes of clinical instruction, under the direction of the Birmingham Clinical Board; a body elected from the honorary staffs. The hospitals have a total of 400 beds, and 4,500 in-patients and 45,000 out-patients are treated annually. Clinical practice and lectures commence at 9.30 a.m. daily throughout the session, the operating days being, Tuesday, Wednesday, and Saturday. Attendance upon two-thirds of these lectures is insisted upon. There are special Ophthalmic, Obstetric, Gynæcological and Dental departments, each under the care of a specialist. Practical instruction is given in the use of the microscope, laryngoscope, ophthalmoscope, surgical appliances, &c. Practical Pharmacy is taught in the dispensaries of the Hospitals. There is a special Dental department in the College, associated with the Birmingham Dental Hospital and the Clinical Board. By this arrangement students may qualify for the Dental diploma of any of the examining bodies. The Midland metropolis is particularly well off in the matter of special hospitals. There are in the town the Children's (72 beds), Eye (70 beds), Women's (30 beds), Ear and Throat, Orthopædic and Spinal, Small-pox and Fever, Skin and Lock, and Homœopathic Hospitals; the honorary officers of any of which are willing at all times to show their practices to senior students of the School. Besides the ordinary class prizes—medals and certificates—the following are open for competition to students of Queen's College:—One or more annual Queen's Scholarships, value 30 guineas, given to first year's students on entrance; one or more Sydenham Scholarships, value 30 guineas, tenable for three years by the orphan sons of medical men; two Ingleby Scholarships, value about 10*l*., for proficiency in Obstetric Medicine and Surgery, and Diseases of Women and Children; Sands Cox Prize, value 20*l*., for proficiency at the end of curriculum in Medicine, Surgery, and

Midwifery. The Clinical Board also offer prizes of five guineas each in Medicine and Surgery for senior students; prizes of three guineas each in Medicine and Surgery for junior students; and a prize of four guineas in Midwifery. They also fill up, after competition, the following resident appointments twice annually, viz., medical and surgical assistants and two surgical dressers at the General; obstetric house surgeon and surgical dressers at the Queen's Hospital.

THE BRISTOL MEDICAL SCHOOL.

(By a Member of the Staff.)

The Medical School was founded in 1828, but long before that time lectures on Chemistry and Medicine were given, and regular courses of lectures on Anatomy by two of the surgeons to the Infirmary. A dissecting room was soon opened, under the direction of Dr. Riley, in Lower College Green, and another at the rear of 25, King Street, the then residence of H. Clark. Those were times when difficulties were experienced by everyone who wished to pursue medical and surgical studies, as obstacles were thrown in the way of the most necessary branch of training—namely, dissection. Much interest was taken in the lectures given by Dr. Riley, and so greatly did they become appreciated and their value recognised, that he and Hy. Clark were induced to prepare and issue a prospectus of a Medical School, to be opened at premises in Old Park. During the first twenty years of its existence no support or encouragement was accorded the School by the public or the profession; but gradually the claims of the School came to be recognised, and for many years now it has been in a prosperous condition, especially since its affiliation with the University College. Of the pupils who have passed through the School, many have attained high distinction. With its fame the number of its pupils has grown, and with the extension of researches in Medicine and Surgery more perfect appliances for teaching have been secured. During the Session 1883–84, 97 students attended the School.

Students at the School have the privilege of continuing their practical studies in Medicine and Surgery at the Infirmary and Hospital, in connection with which Institutions are valuable scholarships and prizes. The Medical School, together with the Infirmary and Hospital, provide for every detail of the professional curriculum required by the University of London, and students can complete at these Institutions the entire course of study required for the diplomas of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The prizes connected with the Infirmary are Suple's Medical Prize, consisting of a gold medal, value five guineas, and about seven guineas in money; Suple's Surgical Prize, similar in character; Clarke's Prize, consisting of the interest of 500*l.*, given to the most successful student on the completion of his third year's study; Tibbits' Memorial Prize, being the interest of 315*l.*, awarded the student who shows the greatest proficiency in practical surgery; Crosby Leonard's Prize, being the interest of 300*l.*, a surgical prize; the Pathological Prizes, value three guineas each. The Scholarships and Prizes connected with the Hospital are:—The Martyn Memorial Entrance Scholarship, value 20*l.*, awarded to the most successful candidate in the competitive examination in subjects of general education; Clarke Scholarship, a surgical prize of 15*l.*; Sanders' Scholarship, being the interest of 500*l.*, offered for proficiency in Medicine, Surgery, and Diseases of Women; Lady Haberfield Prize, the interest of 1,000*l.*, also awarded for proficiency in Medicine, Surgery, and Diseases of Women. All the Scholarships and Prizes at both Institutions are given annually. The Medical School has a governing body of fifteen members, five of whom are elected by the Council of University College, one member by the Committee of the Infirmary, one by the Committee of the Hospital, three members by the Staff of the Infirmary, three by the Staff of the Hospital, and two by the Faculty of the Medical School.

UNIVERSITY COLLEGE, LIVERPOOL.

(By a Member of the Staff.)

In the old days, when almost every medical man had one or two pupils, it was no uncommon thing in the larger provincial towns for a few of the leading practitioners to collect these young gentlemen and give them short courses of lectures, preparatory to the time when they should proceed to "walk the hospitals" in London or Edinburgh. Even dissecting was carried on in a furtive and incomplete way. In 1834, just half a century ago, a few of these private lecturers in Liverpool agreed to combine their efforts, and thus was founded the Liverpool Medical School. For eleven years its work was carried on in rooms belonging to one of the larger public institutions of the town; but in 1845 the Trustees of the Royal Infirmary erected a building upon the Infirmary grounds, and the school thenceforth became the "Royal Infirmary School of Medicine." Its progress for a long time was very slow, and once, indeed, the attendance was so small that the lecturers entertained serious thoughts of entirely abandoning the enterprise. By degrees, however, it drew slowly ahead, and about fifteen years ago participated in that sort of general revival which visited nearly all the provincial schools. Doubtless this was greatly due to the change which has come over the style of medical practice in the great northern towns; the increasing size and wealth of which has enabled them to support men working at specialties. Pure physicians and surgeons, oculists, aurists, gynæcologists, and dermatologists can now make good livings, and give time for teaching also, where formerly there were none but general practitioners, so immersed in practice that teaching, as we now understand it, was an impossibility with them.

In 1871 the lecturers of the school felt the necessity of improving the building in which they laboured, and by a vigorous appeal to the public succeeded in raising between five and six thousand pounds, which was expended upon additional class rooms and upon a museum and physiological laboratory. Within the last few years the generosity of the Liverpool public has founded the University College. Possessed of a building which, for the present, answers its requirements, and with nine endowed professorships the College has before it a great future. Quite recently the School of Medicine has become allied to it as its medical faculty, while still retaining much of its powers of self-government. The next advance will be the affiliation of the College to the Victoria University, as one of the various colleges of which that body is to be the head. At present the Owens College is the only one, but Liverpool and Leeds will, without doubt, be incorporated ere long, and in due time probably others also, thus completing the great scheme of popular University Education for the North of England. The first examinations for the Victoria Degree in Medicine recently held, show that while perhaps less harassing than those of the University of London they are hardly behind them in point of strictness. The establishment of University College (fortunately in the same grounds as those of the School of Medicine) affords the students of the Medical Faculty the best possible training in

physics, in zoology, and in chemistry, for which the names of Professors Oliver Lodge, Herdman, and Campbell Brown are a fair guarantee. At the present moment a chemical department, which will ultimately cost between 10,000*l.* and 15,000*l.*, is rapidly rising.

The Royal Infirmary, founded in 1749, has through its committee extended a warm support to the school which so long took its name from it. Constructed at a period when sanitary knowledge, and indeed architecture in general was at its lowest ebb, the present building has been felt to be quite behind the times, and the public have recently subscribed 100,000*l.* to build a new one, which, it is hoped, will be soon commenced. Among the list of those who have acted as its surgeons appears the distinguished name of Park, who, next after the Moreaus, introduced the excision of joints. His celebrated case of the sailor, whose elbow-joint he excised, and who was afterwards able to follow his occupation and even to go aloft, was long quoted in surgical text-books. Alanson also was one of its surgeons, who was probably the first to practise amputation by flaps, in contradistinction to the old circular method. Among its physicians was Curric, the friend of Roscoe, and the author of an admirable "Life of Burns," and other literary productions. In the beginning of this century he advocated the use of cold affusion in fever, and drew attention to the clinical value of thermometry. Fifty years after his death his suggestions began to be put in practice.

While it is admitted that a small school possesses certain disadvantages in its inability to afford systematic training in special subjects, it has, on the other hand, certain advantages. It may be claimed for Liverpool that it affords great opportunities in the abundant material for practical Anatomy at the school, and in the extensive surgical work done in the wards of the Royal Infirmary. Abundance of dissection and an unlimited field for dressing, counterbalance the loss of much special work, which the student gains at the great crowded schools, at the expense of having to wait weeks for a part (even then sharing it with another man), and of having often to act as dresser to a very few patients only.

THE OWENS COLLEGE (VICTORIA UNIVERSITY) MEDICAL DEPARTMENT, MANCHESTER.

(By a Professor of the Medical Department.)

The prospectus for the ensuing year contains many and important changes. Additional accommodation, chiefly in the form of laboratories, for the practical study of Physiology, Pathology, and Pharmacy has been provided, the several departments have received their necessary complement of demonstrators, and are now in working order. The anatomical department is presided over by Professor Watson, assisted by two demonstrators, all three of whom devote their whole time to their duties at the College. In the physiological department, which is under the direction of Professor Gamgee, a lecturer on Histology has been appointed, in the person of Mr. Waters, who still retains the demonstratorship of Physiology. This department is also to be extended by the appointment of a second demonstrator and assistant lecturer on Physiology. In the pathological department Dr. Maguire has been appointed Assistant Lecturer and Demonstrator, under the direction of Professor Dreschfeld. The pathological laboratory is open daily, and is well equipped with all requirements for the prosecution of original work in Pathology, especially for Bacteriological Observations. Practical classes are held for Medical and Surgical Morbid Histology, the latter conducted by Mr. A. H. Young. A practical class on Pathology for medical practitioners is announced, and a special course of lectures, by Dr. Maguire, on the Pathological Anatomy of the kidneys, and the Pathology of Albuminuria. In the Materia Medica Department, Professor Leech gives two courses of lectures, one on Materia Medica, the other on Therapeutics; besides an additional course on Mineral Waters. Practical Pharmacy is taught in a special laboratory, with Mr. Elborne as Demonstrator and Assistant Lecturer. The syllabus of Forensic Medicine is now separated from that of Hygiene, and we notice the appointment of an Assistant Lecturer in Forensic Medicine, and Demonstrator of Toxicology (Mr. Beverley), who conducts a practical class under the direction of Dr. Cullingworth. Hitherto the students, as in most medical schools, have attended lectures on the Principles and Practice of Surgery in their second winter session. As there are many objections to this plan, the several surgical classes have been re-arranged, so that henceforth there will be two courses of lectures on Surgical Pathology, one in summer, for second years' students, and the other, more advanced, in winter, for third and fourth years' students, while the class on Practical Surgery has been similarly subdivided, and the lectures on Systematic Surgery are to be postponed until the third winter. Equally important changes have been made in the clinical teaching. Hitherto there has been no direct connection between the Infirmary, the recognised hospital for the clinical teaching, especially of Medicine and Surgery, and the College. The College authorities, recognising the importance of sound clinical instruction, have instituted lectureships in Clinical Medicine, Surgery, Gynæcology, Ophthalmology, and Diseases of Children, selecting for these appointments members from the Staffs of the different hospitals. The importance of this step can scarcely be exaggerated, for thereby have been ensured the utilizing of the vast clinical material of the Manchester hospitals, and a uniform and systematic plan of clinical instruction. The newly-appointed Clinical Lecturers are—for Medicine, Drs. Simpson, Morgan, Leech, Dreschfeld, Ross, and Steell; for Surgery, Messrs. Heath, Whitehead, Jones, Hardie, Southam, and Wright; for Gynæcology, Drs. Thorburn, Lloyd Roberts, and Cullingworth; for Ophthalmology, Drs. Little and Glascott; for Diseases of Children, Dr. Ashby. The duties of the lecturers are to give systematic clinical instruction, according to a definite plan; thus in Medicine and Surgery there are held demonstrations in physical examination and minor surgery respectively, elementary clinical classes, advanced clinical classes, and clinical lectures. We notice, further, special clinical classes and demonstrations in Laryngoscopy (Dr. Simpson), in Aural Surgery (Mr. Wright), in Electro Therapeutics (Dr. Dreschfeld), on Fever cases in the Monsall Hospital Dr. Steell), and on Mental Diseases (Mr. Mould) in the Cheadle Asylum.

SHEFFIELD SCHOOL OF MEDICINE.

(By a Member of the Staff.)

For more than half a century a good school for the teaching of practical medicine and surgery has existed in Sheffield. The large population of the town and district, consisting as it does mainly of a working class ready to avail itself of public charity, and engaged in pursuits provocative of disease; coupled with the unavoidable accidents necessarily arising in connection with large ironworks, collieries, and factories, render the material for the study of medicine and surgery exceptionally large and varied. In the town there are the following medical charities, viz.:—

The General Infirmary (180 beds), the Public Hospital and Dispensary (101 beds); and at these institutions the clinical teaching is mainly carried on, the practice of both being open to all the students of the School, and clinical instruction by the physicians and surgeons being given daily. In addition to the above-named there are:—The Jessop Hospital for Women (with 45 beds and a Midwifery Department), the Fever Hospital, and the Hospital for Sick Children. At the Infirmary there is a large ophthalmic department, and special facilities are afforded for studying this branch of practice. In connection with the Medical Charities there are five house surgeoncies (salaries varying from 130*l.* to 50*l.* a-year), and one clinical assistantship. Five of these posts are held by former pupils of the School. The incorporation of the Medical School with the Firth College, which has recently taken place, will without doubt mark a new era in the medical education of Sheffield, for the students here are now offered not only the best opportunities for the practical study of the profession, but also the greatest facilities for obtaining a thorough scientific training. The teaching now is so arranged as to include not only all the subjects required by the Royal College of Physicians and Surgeons, but also those of the University of London and other Examining Boards.

YORKSHIRE COLLEGE MEDICAL DEPARTMENT, LATE LEEDS SCHOOL OF MEDICINE.

(By a Member of the Staff.)

Whilst the Infirmary Staff has during the last year been very much increased numerically, the School of Medicine has undergone a complete revolution by its incorporation with the Yorkshire College. Since its foundation 54 years ago the school has been a private venture, and has sought no help from the public. It has nevertheless done a very good work; for besides preparing a large number of students for their diplomas, it has enrolled on its charter many who have held, and others who are still holding, leading positions in the medical world. This is not to be wondered at when one recollects that the names of Hey, Teale, Nunneley, Wheelhouse, Clifford Allbutt and others, who would have added lustre to any institution, have formed part of the teaching staff. Instruction in Chemistry, Botany and Comparative Anatomy, was transferred to the professors of the Yorkshire College immediately it was founded ten years ago; but it has since been felt that the welfare both of the School and College would be enhanced if the two institutions were completely incorporated. This has only just been effected, and the coming October will witness the recognition of the School of Medicine as a public Institution, and a department of one of the chief scientific and educational establishments in the country. It is expected that the Yorkshire College will almost immediately be affiliated with the Victoria University, when the Leeds medical students will be able to obtain its degrees in their ordinary curriculum. The subject of Physiology will in future be taught by a professor who will devote the whole of his time to the work of his chair. In the Anatomy course there will be a professor and a paid demonstrator, whose whole time will be given up to the students. The other courses will be given as usual. In the summer, courses of lectures on Ophthalmic Surgery and Hygiene, and a practical course of Operative Surgery will be given, which subjects are additions to the prospectus. The Anatomical and Pathological Museums contain carefully prepared anatomical sections and other specimens of human and comparative anatomy, and a large number of pathological preparations, some of which are very rare and valuable. There are also Materia Medica, Botanical and Dental Museums. The valuable collection of comparative anatomy specimens, when studied along with the geological specimens in the museum of the Philosophical Society, "also open to students," gives every opportunity for the study of this branch of biology. The dissecting rooms and physiological laboratories have been much improved and extended in response to the increased number of students, whose numbers have been almost doubled during the last decade. The library, which contains about 10,000 volumes, is well supplied with standard works on medicine and surgery and allied subjects, and with the leading medical periodicals; it is open to all students of the School, who have the advantage also of using the books belonging to the Leeds and West Riding Medico-Chirurgical Society. Special attention is given to the preparation of students for the higher examinations, the professors of physiology, biology, and chemistry holding classes appropriate to that end. Several valuable prizes are given annually. A House Physician and a House Surgeon are elected from time to time. There are also five Resident Assistant Medical Officers in the Infirmary who continue in office one year. They are chosen from the Senior Students of the School, and are provided with apartments and board in the Infirmary free of charge. They must possess at least one legal qualification.

There are three Resident Medical Officers appointed from time to time at the public dispensary, a stipend with residence being given; for these appointments Leeds Students are frequently chosen.

The Leeds General Infirmary which is close to the School, and in its teaching intimately associated with it, has beds for 320 in-patients; 3,754 having occupied them during the last year. In the out-patient department 20,071 were treated. These numbers show a remarkable increase if compared with the statistics of ten years ago, when 11,551 out-patients were prescribed for. The increase of work in the in-patient department lies chiefly in the fact of the great development of active surgical work; an idea of the extent of which, may be gathered from the fact of 612 major operations and 439 ophthalmic operations having been done in the past twelve months. The "ether record" shows that anæsthetics have been administered 2,000 times in the same period. In consequence of this increase, last year two Honorary Assistant Surgeons were appointed and this year two Honorary Assistant Physicians, who have charge of out-patients. In the General Infirmary are comprised Medical, Surgical, Ophthalmic, Aural and Electrical departments, in each of which special instruction is imparted to students. Clinical teaching goes on daily by the Honorary Physicians and Surgeons, and by the Assistant Physicians and Surgeons in the wards and out-patient rooms. Clinical lectures are also given regularly in the winter and summer sessions. Major operations are performed every Thursday, but minor operations are done daily after the ward visits of the Surgeons. Every Wednesday morning consultations are held in the operating theatre on interesting and important surgical cases, students being permitted and encouraged to attend. A new departure has just been made in the case of Dr. Clifford Allbutt, Mr. Wheelhouse, and Mr. T. Pridgin Teale, who, having served twenty years on the staff, have been appointed Consulting Physicians and Surgeons respectively, with the right of retaining a certain number of beds for special and interesting cases. The Leeds Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum, are other medical institutions which are made use of by the Leeds Medical Students.

The session will be opened on October 1st, by Dr. Michael Foster, F.R.S., Professor of Physiology in the University of Cambridge.

MEDICAL EDUCATION IN SCOTLAND.

INTRODUCTORY ARTICLE.

(By our Edinburgh Correspondent.)

THERE are in Scotland seven *examining bodies* which grant licences to practise medicine, viz., the Universities of Edinburgh, Aberdeen, Glasgow and St. Andrews, the Royal College of Physicians and Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow. An abstract of the regulations and requirements of these bodies will be found in the synoptical tables (pp. 379–380). The two Edinburgh Colleges has recently adopted a conjoint scheme, and will not, as a rule, in future give separate diplomas.

The centres of *medical education* in Scotland are the Universities of Edinburgh, Glasgow, and Aberdeen. Each of these institutions possesses a complete Medical Faculty, attendance on the classes of which, besides qualifying for their respective degrees, qualifies for the examining boards in any of the kingdoms. Each city, moreover, possesses a hospital or hospitals where the necessary clinical and practical instruction can be obtained.

Besides these University Schools, there exist, moreover, in Edinburgh and Glasgow what are known as Extra-mural or Extra-academical Schools of Medicine. In Edinburgh, this school comprises a body of over forty lecturers, whose courses qualify for the examining boards and to a certain extent are recognised by the University as qualifying for their degrees. In Glasgow, the Extra-academical School embraces the Medical Faculty of Anderson's College, and the more recently formed School of Medicine attached to the Royal Infirmary. In Aberdeen no such school exists, all the medical teaching being done under the auspices of the University.

The existence side by side with the University Faculty of an Extra-academical School of Medicine is a matter of the highest importance in relation to the general question of medical education in Scotland. It does not admit of doubt that this co-existence accounts in great measure for the attraction which Edinburgh, during recent years, has offered to students from all parts of the world. Here, the Extra-mural School has existed in a state of high efficiency for many years, and a form of rivalry has existed between it and the University which has been fraught with the greatest benefit to the teaching of Medicine. The possible extent and effect of this competition will be seen when it is stated that a student, besides obtaining at the Extra-mural School all the classes necessary for the boards of Edinburgh, London, and Dublin, may also take out a maximum of four classes, attendance on which will count in the same way as the corresponding classes in the University would do for the University degree. How this tells on efficiency can be readily understood. It is within the nature of things that the occupant of a university chair should now and then prove either unable or unwilling to fulfil its duties in a satisfactory manner. Without the assistance of the Extra-mural School, the teaching of the subject represented by the chair would suffer seriously. No sooner, however, does such a contingency arise, than the student turns to the lecturers outside the academic walls, and among them he never fails to find one at least able and willing to supply all reasonable demands. And not only does the healthy competition of this school provide efficient substitutes for inefficient university professors, and so maintain the standard of medical education, but the mere fact that the number of his students depends in some degree at any rate on his efficiency, serves as a healthy stimulus to the lagging professor, too intent on his *otium cum dignitate*. At no period has the Edinburgh Extra-mural School been in a more healthy and vigorous state than it is at present. On each of the chief branches of medical study there are several lecturers, so that there is abundance of opportunity for selection, while all the special departments, such as the eye, ear, skin, &c., are more or less fully represented. No one can doubt that the high standard of efficiency which the Edinburgh School as a whole has attained, has proved the main attraction to students during the past decade. What are the limits to this efficiency, and what are the weak points in the system of medical education, we shall endeavour to show by-and-by.

In Glasgow, the competitive influence of the extra-mural system is of more recent origin than in Edinburgh. It is beginning to have its effect, and its development ought to obtain every encouragement from the University. No policy could be more shortsighted and suicidal than any endeavour on the part of the University authorities to curb the growth of its less favoured rival. In addition to the healthy stimulus which such legitimate competition brings to bear on the holders of chairs, it cannot fail to develop a many-sidedness in the teaching of Medicine which is apt to be missed under the narrower auspices of a University acting alone. In such a city as Glasgow, with its wealth of material in its hospital and dispensary practice, the rapid development of its medical school is a matter of certainty provided its growth is not stunted by narrowness and jealousy.

In Aberdeen, the absence of the competitive influence is not as yet seriously felt. This is due to the fact that its numbers are comparatively small, and the field for extra-mural teaching is limited. Moreover, provided as the Medical Faculty is with a body of professors, whose efficiency and energy as teachers and workers will challenge comparison with any school in the United Kingdom, this University is producing work of the highest order. That this is due in great measure to the fact that the limited number of students permits an amount of individual teaching which is impossible elsewhere is undoubtedly true, and this consideration should not fail to point a moral.

There is no doubt that in Scotland the question of medical education is approaching a crisis, when many time-honoured methods will be put on their trial.

In Scotland, as in England, the chief mode of teaching is by means of systematic lectures. Courses of 50 or 100 lectures are the rule in all the subjects, and the chief duty of the teacher is the daily delivery of these discourses. No doubt during recent years the development of teaching by demonstration, and by other practical methods, has been receiving more attention than formerly, but its importance is far from being adequately recognised in the Scottish system. To fully appreciate the time-wasting absurdity of that relic of barbarism, the systematic lecture, in so far as many of the branches of medical education are concerned, one has but to visit some of the larger classes in the Medical Faculty of Edinburgh University. What could be more grotesque, were it not so serious in its consequences, than to see a Professor of Anatomy addressing a class of 500 or 600 students, describing with painful minuteness each carpal bone, pointing to each facet, demonstrating all its relations, and employing language in his description, the counterpart of which is to be found in "Quain" or "Gray"? That a class of such dimensions should maintain a respectful silence during such an operation says much for human forbearance. What benefit can follow such a performance passes comprehension. No doubt there are some subjects which may be conveniently handled in a systematic lecture, but they are comparatively few. It cannot be claimed for the method that it is a more vivid way of imparting knowledge. As matters now stand, the lectures have in most cases developed into mere dictation exercises, which the student leaves exhausted in mind and body with the effort of reducing the discourse to verbatim notes. If the lecturer feels that no existing text-book adequately represents his views on the subject he professes, let him by all means put his lectures into print, but why should he demand that 100 hours per session should be wasted by every student in committing them to writing, when the printing press once for all could do it in an incomparably better fashion? Would not the time thus spent be better employed at the dissecting table, the microscope, or the bedside?

It is generally admitted that the present efficiency of medical education in Scotland is due to the manner in which year by year the Universities have raised the standard for their degrees. To Edinburgh especially does the credit of this belong. But she, no less than the other schools, must take care that her teaching machinery

is kept in proper repair, thoroughly watched and rendered more effective as experience and circumstances demand.

The weak point all along has been the want of a due appreciation of the importance of practical teaching. That honest efforts at improvement in this direction have been recently made we gladly admit, but that they still fall far short of what the case demands no one can honestly deny. So long as there continues the outrageous waste of time which persistence in the indiscriminate use of the formal lecture system involves, together with the entire disproportion between the teaching strength and the multitude to be taught, the retention of the high standard of qualification can only be effected at the cost of "cram" and over-pressure. If Edinburgh is to hold its own as a great training school with its 1,700 students of Medicine, it must demand without delay an entire re-organisation of its modes of teaching, a liberal increase of its teaching power, and the most careful development and fostering of its means and material for practical training. Equipped as it now is with superb laboratories and a magnificent hospital, the maintenance of its present unique position depends on the wisdom and liberality of its teachers, and there is no reason why it should not continue to produce results worthy of its great history. That it is a great school at present we all admit, that it might make more of its opportunities we do not doubt.

And with Glasgow the case is similar. With the immense wealth of clinical material which its teeming population must provide, it might readily become, in the hands of able and energetic teachers, a practical school worthy to rival the great centres of Berlin and Vienna. But to effect this, all narrowness and jealousy must be laid aside, and a healthy competition encouraged between the academical and extra-academical schools. With Aberdeen the case is somewhat different. The limits of its hospital prevent its becoming a great clinical school in the sense in which it is possible to Edinburgh or Glasgow, yet its present efficiency might be widely extended in all directions under wise guidance. Nor is its growth as a scientific school necessarily limited by any such consideration.

There has been evidence of late that those concerned in the question of medical education in Scotland are turning their attention to its honest reform. If the Scottish schools are to retain the honourable position which their past achievements in teaching and discovery have given them, this question of teaching reform must be faced with courage, circumspection, and without loss of time. Effete methods which have served their day must be boldly discarded, and those which experience has proved to be more in harmony with the modern spirit must be established. Under such conditions it is not presumption to look for a future worthy of the great past.

UNIVERSITY OF EDINBURGH.—FACULTY OF MEDICINE.

Session. 1884–5.

Winter Session.

The session will be opened on Tuesday, October 28, 1884.

**Anatomy*—Professor Turner.
**Anatomical Demonstrations*—Professor Turner.
**Chemistry*—Professor Crum Brown.
Clinical Medicine—Professors Maclagan, Grainger Stewart, T. R. Fraser, and Greenfield (Professor Simpson on *Diseases of Women*).
Clinical Surgery—Professor Annandale.
**General Pathology*—Professor Greenfield.
**Institutes of Medicine or Physiology*—Professor Rutherford.
**Materia Medica*—Professor T. R. Fraser.
**Midwifery and Diseases of Women and Children*—Professor Simpson.
Practical Natural History—Professor Ewart.
**Practice of Physic.*—Professor Grainger Stewart.
**Surgery*—Professor Chiene.

Winter and Summer Session.

**Anatomical Demonstrations*—Professor Turner,
**Bandaging and Surgical Appliances*—Professor Chiene.
**Operative Surgery*—Professor Chiene.
**Obstetrical and Gynæcological Operations*—Professor Simpson.
**Practical Physiology, including Histology, Chemical Physiology, and Experimental Physiology*—Professor Rutherford.
**Practical Anatomy*—Professor Turner.
**Practical Chemistry*—Professor Crum Brown.

* In University New Buildings.

Summer Session.

Practical Instruction in Mental Diseases at an Asylum—Dr. Clouston, Lecturer.
Practical Natural History—Professor Ewart.
Practical Morbid Anatomy and Pathology—Professor Greenfield.
Practical Materia Medica (including Pharmacy)—Professor T. R. Fraser.
Practical Botany—Professor Dickson.
Vegetable Histology—Professor Dickson.
Tutorial Classes of Clinical Medicine and Clinical Surgery in the Wards of the Royal Infirmary by the Clinical Tutors, Dr. James Murdoch Brown, and Dr. James Bennet.

During the Summer Session lectures will be given on the following subjects :—

Anatomical Demonstrations—Professor Turner.
Botany—Professor Dickson.
Chemistry—Professor Crum Brown.
Clinical Medicine—Professors Maclagan, Grainger Stewart, T. R. Fraser, and Greenfield. (Professor Simpson on *Diseases of Women*).
Clinical Surgery—Professor C. Annandale.
Mental Diseases, with Practical Instruction at the Morningside Asylum—Dr. Clouston, Lecturer.
Medical Jurisprudence—Professor Maclagan.
Natural History—Professor Ewart.
Obstetrical and Gynæcological Operations—Professor Simpson.
Diseases of the Eye—Dr. Argyll Robertson, M.D.

Information relative to matriculation and the curricula of study for degrees, examinations, &c., will be found in the University Calendar, and may be obtained on application to the Secretary at the College.

During the session the following means are afforded for practical instruction :—

The *Dissecting Rooms* are open daily, under the superintendence of the Professor, assisted by Arthur Thomson, M.B., David Hepburn, M.B., C.M., and other assistants. The *Royal Edinburgh Asylum* is open in summer to members of the class of Medical Psychology exclusively for practical investigation in Mental Diseases, by the Physician-Superintendent, Dr. Clouston. *Chemical Laboratories.*—The laboratory for instruction in Analytical Chemistry and for chemical instruction, under the superintendence of the Professor, assisted by R. M. Morrison, D.Sc., John Gibson, Ph.D., and Leonard Dobbin, Ph.D., is open from 10 to 4. The laboratory for instruction in Practical Chemistry, under the superintendence of the Professor, assisted by R. M. Morrison, D.Sc. The *Physiological Laboratory* is open daily for physiological investigation, under the superintendence of the Professor, assisted by John Lockhart Gibson, M.B., C.M., and G. F. Alexander, M.B., C.M. The *Physical Laboratory* is open daily from 10 to 3, under the superintendence of Professor Tait. The *Medical Jurisprudence Laboratory* is also open daily during the Summer Session from 10 to 3, under the superintendence of the Professor, assisted by James Allan Gray, M.D. The practice of Obstetrical and Gynæcological Operations is carried out in the Obstetrical Museum, under the superintendence of the Professor, assisted by A. H. F. Barbour, M.A., M.D. The *Natural History Laboratory* is open daily, under the superintendence of Professor Ewart, assisted by J. Duncan Matthews, and C. Prince. The *Natural History Museum*, in the Museum of Science and Art, Chambers Street, is accessible to the students attending the Natural History class. The *Royal Botanic Garden, Herbarium*, and *Museum* are open daily during summer.

There are numerous fellowships, scholarships, bursaries and prizes open to graduates and undergraduates of the University, and others, particulars of which will be found in the University Calendar.

Minimum Cost of attending the Medical Classes, with the Order of Study.—Whilst there is no authorised order of study, the usual course is given below :—Preliminary Examination in Arts to be taken in the month of March or October, before entering medical classes. By order of the General Medical Council, all medical students require to be registered as such within fifteen days after the commencement of the session. Students are recommended to commence their medical studies by attending the summer session.

First Summer Session.—Preliminary examination fee, 10*s.*; matriculation fee, 10*s.*: Botany (garden fee, 5*s.*), 4*l.* 4*s.*; Natural History, 4*l.* 4*s.*; total, 9*l.* 8*s.*

First Winter Session.—Matriculation (for whole year), 1*l.*; Anatomy, 4*l.* 4*s.*; Practical Anatomy, 3*l.* 3*s.*; Chemis-

try, 4*l.* 4*s.*; hospital, 6*l.* 6*s.* (perpetual ticket, 12*l.*); total, 18*l.* 17*s.*

Second Summer Session.—Botany or Natural History, if not attended previously; Practical Chemistry, 3*l.* 3*s.*; examination in Botany, Natural History, and Chemistry, in October following, 5*l.* 5*s.*; total, 8*l.* 8*s.*

Second Winter Session.—Matriculation, 1*l.*: Institutes of Medicine, 4*l.* 4*s.*; Surgery, 4*l.* 4*s*,; hospital, 6*l.* 6*s.*; examination in Botany, Natural History, and Chemistry, in April, if not previously passed; total, 15*l.* 14*s.*

Third Summer Session.—Practical Pharmacy, 3*l.* 3*s.*; hospital; total, 3*l.* 3*s.*

Third Winter Session.—Matriculation, 1*l.*; Materia Medica, 4*l.* 4*s.*; Pathology, 4*l.* 4*s.*; Clinical Surgery, 4*l.* 4*s.*; hospital; examination in Anatomy, Physiology, Materia Medica, Pathology, in April or July, 5*l.* 5*s.*; total, 18*l.* 17*s.*

Fourth Summer Session.—Medical Jurisprudence, 4*l.* 4*s.*; outdoor dispensary, 2*l.* 2*s.*; hospital and clinical lectures; total, 6*l.* 6*s.*

Fourth Winter Session.—Matriculation, 1*l.*; Practice of Medicine, 4*l.* 4*s.*; Midwifery, 4*l.* 4*s.*; Practical Midwifery, 1*l.* 1*s.*; Clinical Medicine, 4*l.* 4*s.*; Vaccination, 1*l.* 1*s.*; outdoor dispensary, 1*l.* 1*s.*; hospital; total, 16*l.* 15*s.*

Fifth Summer Session.—Hospital; final examination for M.B. and C.M., 10*l.* 10*s.*; total minimum expenses for M.B. and C.M., 107*l.* 18*s.* (This total is irrespective of any additional classes which may voluntarily be attended.

Only one course of instruction on each subject is here stated, that being the minimum.

Fees for Degrees.—Examination in Botany, Chemistry, Chemical Testing, and Natural History, 5*l.* 5*s.*; examination in Anatomy, Institutes of Medicine, Materia Medica, Pathology, 5*l.* 5*s.*; final examination in Surgery, Midwifery, Practice of Physic, Clinical Medicine, Clinical Surgery, Medical Jurisprudence, and prescriptions, during last Summer Session, 10*l.* 10*s.*; registration fee, 1*l.*; total fees for M.B. diploma, 22*l.* Additional fee for M.D. diploma, 5*l.* 5*s.*; Government stamp duty (for M.D. only), 10*l.*

Note.—Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, 25*l.*; registration, 1*l.*

N.B.—The above fees include all charges for the diplomas.

Further information as to the classes, courses of lectures, &c., may be obtained on application to Thomas R. Fraser, M.D., Dean of the Faculty of Medicine; or from the University Calendar, published by James Thin, Edinburgh.

SCHOOL OF MEDICINE, EDINBURGH.

The Practical Anatomy Rooms and Chemical Laboratories will be opened on October 1st. The courses of lectures will be commenced—Winter Session, October 28th; Summer Session, May 1st.

Winter Session.

Anatomy: Practical Anatomy — Mr. J. Symington and Mr. Macdonald Brown.
Chemistry—Dr. Stevenson Macadam, Mr. J. Falconer King, Mr. Ivison Macadam, Dr. Drinkwater, and Mr. Ivison Macadam.
Practice of Physic—Dr. John Wyllie, Dr. J. O Affleck, and Dr. Byrom Bramwell.
General Pathology—Dr. Alexander Bruce.
Surgery—Mr. Duncan, Mr. A. G. Miller, Dr. C. W. MacGillivray, and Mr. C. W. Cathcart.
Midwifery and Diseases of Women and Children—Dr. Charles Bell and Dr. Peter Young.
Clinical Medicine (Royal Infirmary)—Drs. Claud Muirhead, Brakenridge, and Wyllie, Dr. Angus Macdonald (*Diseases of Women*).
Clinical Surgery (Royal Infirmary)—Mr. Joseph Bell.
Institutes of Medicine and Practical Physiology—Dr. James and Mr. James Hunter.
Medical Jurisprudence and Public Health—Dr. Littlejohn.
Materia Medica and Therapeutics—Dr. William Craig.
Diseases of the Ear—Dr. Kirk Duncanson.
Diseases of the Eye—Dr. John Robertson.
Vaccination (Royal Dispensary)—Dr. Husband.
Diseases of Children—Dr. James Andrew and Dr. Jas. Carmichael.
Practical Midwifery—Dr. Angus Macdonald and Dr. Charles Bell.
Practical Midwifery and Clinical Gynæcology—Dr. Peter Young.
Practical Gynæcology—Dr. Halliday Croom and Dr. David Berry Hart.

Summer Session.

Practical Anatomy—Mr. J. Symington and Mr. Macdonald Brown.
Practical Chemistry—Dr. Stevenson Macadam, Mr. J. Falconer King, Mr. Ivison Macadam, and Dr. Drinkwater.
Materia Medica and Therapeutics—Dr. Francis W. Moinet and Dr. William Craig, and Dr. G. A. Gibson.
Midwifery and Diseases of Women and Children—Dr. Angus Macdonald, Dr. Halliday Croom, Dr. Charles Bell, and Dr. David Berry Hart.
Medical Jurisprudence and Public Health—Dr. Littlejohn.
Practical Physiology—Mr. James Hunter.
Practical Pathology—Dr. Alex. Bruce.
Natural History, Zoology, and Comparative Anatomy—Dr. Andrew Wilson.
Clinical Medicine (Royal Infirmary)—Drs. Claud Muirhead, Brakenridge, and Wyllie, Dr. Angus Macdonald (*Diseases of Women*).
Clinical Surgery (Royal Infirmary)—Mr. Joseph Bell.
Practical Medicine and Diagnosis—Dr. Byrom Bramwell.
Diseases of the Eye—Dr. J. Robertson and Mr. George Berry.
Diseases of the Ear—Dr. Kirk Duncanson and Dr. P. McBride.
Vaccination—Dr. Husband.
Diseases of Children—Dr. James Andrew and Dr. Jas. Carmichael.
Insanity—Dr. J. Batty Tuke.
Diseases of the Skin—Dr. Allen Jamieson.
Practical Surgery—Mr. Duncan.
Operative Surgery and Surgical Anatomy—Mr. A. G. Miller, Dr. C. W. MacGillivray, and Mr. C. W. Cathcart.
Practical Midwifery—Dr. Charles Bell.
Clinical Midwifery—Dr. Halliday Croom.
Practical Midwifery and Clinical Gynæcology—Dr, Peter Young and Dr. Charles Bell.

The lectures qualify for the University of Edinburgh and the other Universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin; and the other medical and public Boards.

Fees—For a first course of lectures, 3*l.* 5*s.*; for a second, 2*l.* 4*s.*; perpetual, 5*l.* 5*s.* To those who have already attended a first course in Edinburgh the perpetual fee is 2*l.* 4*s.* Practical Anatomy (six months' course), 3*l.* 3*s.*; course of demonstrations, 2*l.* 2*s.*; perpetual, 4*l.* 4*s.* Practical Anatomy, with course of demonstrations, 4*l.* 4*s.* Practical Chemistry, 3*l.* 3*s.*; Analytical Chemistry, 2*l.* a month, 5*l.* for three months, or 10*l.* for six months. Practical Materia Medica (including Practical Pharmacy), Diseases of the Ear, Diseases of the Skin, and Diseases of Children, each 2*l.* 2*s.* Vaccination, 1*l.* 1*s.* For summer courses of Clinical Surgery and Clinical Medicine, each 2*l.* 4*s.*; Practical Anatomy (including anatomical demonstrations), Operative Surgery, and Practical Medicine and Medical Diagnosis, each 2*l.* 2*s.*; Insanity, 1*l.* 1s.

The minimum cost of the education in this School of Medicine for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, is 95*l.*, which is payable by yearly instalments during the period of study.

UNIVERSITY OF GLASGOW—FACULTY OF MEDICINE.

Lectures and Classes.—Winter Session.

Anatomy, Junior; Anatomy, Senior; Practical Anatomy—Professor Cleland and Demonstrators.
Chemistry, Chemical Laboratory—Professor Ferguson.
Clinical Medicine—Professor McCall Anderson, and Professor Gairdner.
Clinical Surgery — Professor George Buchanan, and Professor Macleod.
Materia Medica—Professor Charteris.
Midwifery—Professor Leishman.
Pathology—The Pathologists of the Infirmaries.
Physiology—Physiological Laboratory: Professor McKendrick.
Practice of Physic—Professor Gairdner.
Surgery—Professor Macleod.
Zoology—Professor Young.

Summer Session.

Botany, Botanical Demonstrations—Professor Bayley Balfour.
Clinical Medicine—Professor McCall Anderson, and Professor Gairdner.
Clinical Surgery—Professor Buchanan and Professor Macleod.
Embryology, and Demonstrations on Anatomy, Elementary Anatomy, Practical Anatomy—Professor Cleland and Demonstrators.
Forensic Medicine—Professor Simpson.
Lectures on the Eye—Dr. T. Reid.
Operative Surgery—Professor Macleod.
Practice of Medicine—Professor Gairdner.
Practical Chemistry, Organic Chemistry, Chemical Laboratory—Professor Ferguson.
Practical Materia Medica—Professor Charteris.
Practical Physiology—Professor McKendrick.
Zoology and Zoological Laboratory—Professor Young.
Diseases of Women—Professor Leishman.
Insanity—Dr. Yellowlees.

Class Fees.—Fee for each course, 3*l.* 3*s.*, except lectures on the Eye, 1*l.* 1*s.*; lectures on Insanity 2*l.* 2*s.*

In addition to the University courses, the Hospitals and Dispensaries afford ample means for practical instruction in the various departments of Medicine and Surgery.

Glasgow Western Infirmary.—This Hospital contains 400 beds for medical and surgical patients, with wards for skin diseases and for diseases of women.

Fees.—The fees for admission to the practice of the Infirmary are:—First year, 10*l.* 10*s.*; second year, 10*l.* 10*s.*; afterwards free. The fees for clinical lectures are included in the foregoing.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.[1]

Lectures are delivered on the subjects necessary for qualifying, and extra courses are given on practical subjects now required by examining boards. During summer, lectures on Insanity will be given by Dr. A. Robertson, Physician-Superintendent of the City Parochial Asylum.

Lectures.

Anatomy—Mr. H. F. Clark.
Chemistry—Mr. John Clark, Ph.D.
Clinical Medicine and Clinical Surgery—The Physicians and Surgeons of the Hospital.
Dental Surgery—Dr. J. C. Woodburn.
Diseases of the Ear—Dr. Macfie.
Diseases of the Eye—Mr. H. E. Clark.
Forensic Medicine—Mr. Glaister.
Materia Medica—Dr. John Dougall.
Medicine—Dr. J. W. Anderson.
Mental Diseases—Dr. A. Robertson.
Midwifery—Dr. J. Stirton.
Pathology—Dr. D. Newman.
Physiology—Dr. Barlow.
Practical Physiology and Op. Surgery—Dr. Barlow and Dr. Macewen.
Surgery—Dr. W. Macewen.

The Royal Infirmary contains 532 beds. Of these 214 are for medical, and 318 for surgical cases, with special wards for the treatment of venereal disease in males and diseases of women. Diseases of the ear and throat and skin are specially treated at the out-door department.

Appointments.—There are five physicians' and five surgeons' assistants, who are boarded and lodged in the Hospital free of charge, and who perform all the duties of house-physicians and house-surgeons. These appointments are held for twelve months—six in the medical, and six in the surgical wards—and are open to those students of the Infirmary who have completed their curriculum and passed all their examinations except the last, or who have a qualification in Medicine or Surgery, the latter being preferred. Clinical clerks, dressers, and dispensary clerks are selected from the students without any additional fee; and from the large number of accident cases, and cases of acute disease received into the wards, these appointments are numerous and invaluable to the student. Attendance at the dispensary for the treatment of out-patients, and admission to the Pathological Museum, also free.

Fees.—For each course of lectures, first session, 2*l.* 2*s.*; second ditto, and perpetuali 1*l.* 1*s.* The Anatomy Class fees are—first session, 4*l.* 4*s.*; second ditto, 4*l.* 4*s.*; afterwards 1*l.* 11*s.* 6*d.* per annum for Practical Anatomy; Practical and Systematic Pathology, 3*l.* 3*s.*

Hospital Fee.—The fee for perpetual attendance on the practice of the Infirmary and on the courses of clinical instruction and lectures is 21*l.*; six months, 6*l.* 6*s.*; three months, 4*l.* 4*s.* Prospectus can be obtained from Dr. Thomas, the Superintendent of the Hospital.

ANDERSON'S COLLEGE, GLASGOW.—FACULTY OF MEDICINE.

The Winter Session begins on Tuesday, October 28th, 1884, and closes on Tuesday, 31st March, 1885; and the Summer Session begins on the first Tuesday of May, and closes about the middle of July.

Winter Session.

Chemistry—Professor Dittmar.
Surgery—Professor Dunlop.
Junior Anatomy, Senior Anatomy, Practical Anatomy—Professor A. M. Buchanan and Demonstrator.
Institutes of Medicine (Physiology) and Practical Physiology—Professor Christie.
Materia Medica—Professor Morton.
Practice of Medicine—Professor Gemmell.
Ophthalmic Medicine and Surgery and Clinical Instruction at Ophthalmic Institution—Dr. J. R. Wolfe.
Dental Mechanics and Metallurgy—Mr. W. S. Woodburn, L.D.S.

Summer Session.

Operative Surgery—Professor Dunlop.
Surgical Anatomy, Dissection, Osteology—Professor A. M. Buchanan and Demonstrator.
Midwifery—Professor A. Wallace.
Ophthalmic Medicine and Surgery and Clinical Instruction at Ophthalmic Institution—Dr. J. R. Wolfe.
Aural Surgery—Dr. Thomas Barr.
Dental Anatomy—Dr. David Taylor, L.D.S.
Dental Surgery—Mr. J. R. Brownlie, L.D.S.
Medical Jurisprudence—Professor Alex. Lindsay.
Public Health—Dr. James Christie.
Practical Medical Chemistry—Professor Dittmar.
Botany—Professor Wilson.

Class Fees.—For each of the above courses of lectures (Anatomy excepted), first session, 2*l.* 2*s.*; second session, 1*l.* 1*s.*; afterwards free. *Anatomy Class Fees.*—First session (including Practical Anatomy), 4*l.* 4*s.*; second session (including Practical Anatomy), 4*l.* 4*s.*; third session, and perpetual, 1*l.* 1*s.*; summer fee (including Practical Anatomy), 1*l.* 11*s.* 6*d.*; Practical Anatomy only, 1*l.* 1*s.*; Osteology, 1*l.* 1*s.* Students who have attended classes at other schools, but who desire to pursue their studies at Anderson's College, will be admitted to such classes as they may have attended elsewhere at the reduced fees. Vaccination fee, 1*l.* 1*s.* *Clinical Instruction* may be obtained at the Royal Infirmary (*v.* above); also at the Ophthalmic Institution; students of Anderson's College being admitted to the practice of this Institution on paying a matriculation fee of 5*s.*

The fees for all the lectures and hospital practice required of candidates for the Diplomas of Physician and Surgeon amount to 48*l.* This is not payable in one sum, but students simply pay the fees for their classes as they take them out.

UNIVERSITY OF ST. ANDREWS.

There is no proper Faculty of Medicine in this University, but it is possible for the student to make an *annus medicus* by attendance on certain of the courses—as *Natural History*, Professor McIntosh, M.D.; *Chemistry*, Professor Heddle, M.D.; and *Anatomy and Medicine*, Professor Pettigrew, M.D.

UNIVERSITY OF ABERDEEN.—FACULTY OF MEDICINE.

Lectures.—Winter Session.

The Winter Session commences on Wednesday, October 22nd, and the Summer Session on Monday, April 27th.

Anatomy—Professor Struthers.
Practical Anatomy and Demonstrations—Professor Struthers and Assistant.
Chemistry—Professor Brazier.
Institutes of Medicine—Professor Stirling.
Surgery—Professor Alex. Ogston.
Practice of Medicine—Professor Smith-Shand.
Midwifery and Diseases of Women and Children—Professor Stephenson.
Medical Logic and Medical Jurisprudence—Professor Matthew Hay.
Materia Medica—Professor A. D. Davidson.
Pathological Anatomy—Professor D. J. Hamilton.
Practical Pathological Anatomy—Professor D. J. Hamilton.
Natural History—Professor Alleyne Nicholson.

Lectures.—Summer Session.

Botany—Professor Jas. W. H. Trail.
Practical Botany—Professor Trail.
Practical Anatomy and Demonstrations—Professor Struthers and Assistant.
Practical Chemistry—Professor Brazier and Assistant.
Natural History—Professor Alleyne Nicholson.
Practical Natural History—Professor Alleyne Nicholson.
Practical Physiology—Professor Stirling.
Practical Pathological Anatomy—Professor D. J. Hamilton.
Operative Surgery—Professor Alex. Ogston.
Practical Pharmacy—Professor A. D. Davidson and Assistant.
Practical Midwifery and Gynæcology and Clinical Diseases of Children—Professor Stephenson.
Practical Medical Jurisprudence and Hygiene—Prof. Mathew Hay.

[1] No Return.

The Anatomical Course in Summer includes instruction in Histology and in the use of the Microscope; and instruction in Osteology for beginners.

The following additional Courses of Practical Instruction are delivered in the University, or at the Institutions mentioned: *Practical Ophthalmology*—Prof. A. D. Davidson. *Dental Surgery*—Dr. Williamson. *Insanity*—Dr. Reid, Royal Lunatic Asylum. *Public Health*—Dr. Simpson. *Diseases of the Ear and Larynx*—Dr. McKenzie Booth, Dispensary. *Diseases of the Skin*—Dr. Garden, Royal Infirmary and Sick Children's Hospital.

The Aberdeen Royal Infirmary contains about 200 beds, and is visited by the members of the staff daily, at noon. Perpetual Fee to Hospital Practice, 6*l.*; or, first year, 3*l.* 10*s.*; second year, 3*l.* *Clinical Medicine*—Drs. Smith-Shand, Beveridge, and A. Fraser, 3*l.* 3*s.* *Clinical Surgery*—Drs. A. Ogston, Will, and Garden, 3*l.* 3*s.* *Pathological Demonstrations*—Dr. Rodger.

Sick Children's Hospital. Daily at 11 a.m.

General Dispensary, and *Lying-in and Vaccine Institution.* Daily, 10 a.m.

Eye Institution. Daily, 2.30 p.m.

Royal Lunatic Asylum. Physicians—Drs. Jamieson and Reid.

The Regulations relative to the Registration of Students of Medicine, and the Granting of Degrees in Medicine and Surgery, may be had of Professor Brazier, Dean of the Faculty of Medicine.

MEDICAL EDUCATION AND EXAMINATIONS IN IRELAND.

INTRODUCTORY ARTICLE.

(By our Dubliu Correspondent.)

In Ireland there are five Licensing Bodies, namely:—(1) The University of Dublin. (2) The King and Queen's College of Physicians. (3) The Royal College of Surgeons. (4) The Royal University. (5) The Apothecaries' Hall of Ireland.

I.—The University of Dublin, founded by Queen Elizabeth in the year 1591, is the most ancient of the educational institutions in Ireland. On the 3rd of March in the year named, a College was incorporated by Charter, or Letters Patent, as "the mother of an university," under the style and title of "The College of the Holy and Undivided Trinity, near Dublin, founded by Queen Elizabeth." Since that date, several Royal Charters have been granted by succeeding Sovereigns, extending the privileges of the University, and making such alterations in the statutes and constitution of Trinity College as were from time to time deemed necessary. The Degrees in Medicine, Surgery, and Midwifery granted by the University are as follows:—(1) Bachelor of Medicine; (2) Doctor of Medicine; (3) Bachelor in Surgery; (4) Master in Surgery; (5) Master in Obstetric Science. The last-named Degree (M.A.O., or "Magister Artis Obstetriciæ,") was instituted in June, 1876, when also a Licence in Obstetric Science was established. A candidate for the Degree of Bachelor of Medicine *must be a Graduate in Arts*, but may obtain the Degree of Bachelor of Medicine at the same Commencements as those at which he receives his Degree of B.A., provided the requisite medical curriculum shall have been completed, and the requisite Examinations passed. A Bachelor in Surgery must also be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must further have passed the M.B. Examination before presenting himself at that for the B.Ch. Degree, having previously completed the prescribed curriculum of study. A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations and produce certificates of having attended—(1) One winter course in Midwifery; (2) six months' practice in a recognised Lying-in Hospital, or Maternity; (3) a summer course in Obstetric Medicine and Surgery; and (4) two months' practice in the Cow-pock Institution of the Local Government Board for Ireland. The higher Degrees in Medicine (M.D.) and Surgery (M.Ch.) are conferred on graduates in Medicine and Surgery of three years' standing on complying with certain regulations, such as the reading of a thesis publicly before the Regius Professors of Physic and Surgery respectively. The University also grants Licences to Practise Medicine, Surgery, and Midwifery—or Obstetric Science—to candidates who have matriculated in Medicine, and who have *completed two years in Arts*, and four years in Medical Studies. The curriculum and examination required for these Licences are identical with those for the Degrees in Medicine, Surgery, and Obstetric Science respectively. From the antiquity and fame of the University of Dublin, and from the fact that their possession implies a full curriculum in Arts, the degrees in the Medical Faculty of the University are in great repute, and deservedly so. A qualification in State Medicine also is granted, after a searching and practical Examination, to candidates who are Graduates in Medicine of the University.

II.—The King and Queen's College of Physicians in Ireland was incorporated by Charter in 1667, and was re-incorporated by Charter of William and Mary in 1692, since which year it has been known under its present name. The College of Physicians grants the following qualifications:—(1) Licence to Practise Medicine; (2) Licence to Practise Midwifery; (3) Licence to Practise as a Midwife and Nurse-tender. Of these the first two are registrable qualifications, and are in much request. In the year 1883 as many as 154 candidates presented themselves for the Licence in Medicine, of whom 124 were successful; and 133 for the Licence in Midwifery, of whom 120 passed. Stated Examinations for the Licences in Medicine and Midwifery are held in the week following the first Friday in each month, except August or September. Among other requirements for the Licence in Medicine is an attendance during twenty-seven months at a recognised Medico-Chirurgical Hospital, six winter or three summer months in each of three years being the period allotted for clinical instruction. A three months' clinical study of fever, with notes of five fever cases is also required of candidates. The Professional Examination is divided into two parts, namely,—First: Anatomy, Physiology, Practical Histology, Chemistry, and Materia Medica. Second: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. The Licence in Midwifery is open to qualified candidates, who are not Licentiates in Medicine of the College, on certain specified conditions, a privilege which is largely availed of. The College also grants a Certificate in Sanitary Science to Licentiates in Medicine, as well as to Registered Medical Practitioners of the United Kingdom generally. In the case of the latter class of candidates the fee is raised from five to ten guineas. The examination for this certificate is held quarterly, in January, April, July, and October, and embraces the following subjects:—(1) Engineering; (2) Law; (3) Ætiology and Prevention of Disease; (4) Chemistry; (5) Meteorology, Climatology, and Vital Statistics. The candidates are further examined in analytical chemistry of air, water, and food. The higher qualifications are the Membership and the Fellowship. Only Licentiates in Medicine of the College are eligible for the Membership, and Members alone are eligible for the Fellowship. An examination for the Membership is held quarterly in January, April, July, and October, except in the case of candidates who were already Licentiates in Medicine on December 12th, 1878, the date upon which the Supplemental Charter of the College, constituting the order of Members, was granted. The Fellows are elected by ballot on fixed days in April and October. It is necessary to observe that the College of Physicians admits women to its Licences and the Membership. They are, however, debarred from the Fellowship under the terms of Russell Gurney's Act of 1876 (39 & 40 Vict. cap. 41.).

III.—The Royal College of Surgeons in Ireland was founded exactly one hundred years ago, in 1784. In 1882 the Regulations relating to the Education and Examination of Candidates for the Licence to Practise Surgery were completely re-modelled. Every candidate for the diploma, or "Letters Testimonial," is required to pass a Preliminary Examination, and Four Professional Exami-

nations in successive years. The Letters Testimonial will not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student, or to any one who has not attained the age of 21 years. The First, Second, and Third Professional Examinations are held in the July and October of each year. Should a student fail to pass in July, he may present himself at the Examination held in October. As a rule, the Examination of each year must be passed before a new session can be entered on. The Fourth and Final Professional Examination is also held in July and October, and in the following April. The College grants, in addition to the Letters Testimonial, a Diploma in Midwifery. Every candidate must be a Fellow or Licentiate of the College. Candidates for the Fellowship are admitted to Examination under five grades:—(1) As candidates possessing no qualification; (2) as Licentiates of the College of less than ten years' standing; (3) as candidates of less than ten years' standing, possessing qualifications in Surgery of other bodies; (4) as Licentiates of the College of more than ten years' standing; and (5) as candidates of more than ten years' standing, possessing qualifications in Surgery of other bodies.

IV.—The Royal University of Ireland. On the 15th of August, 1879, an Act "to promote the advancement of learning, and to extend the benefits connected with University Education in Ireland" received the Royal Assent, and on April 27th, 1880, Letters Patent were issued founding an University in accordance with the provisions of the University Education (Ireland) Act, 1879, just referred to, under the style and title of "The Royal University of Ireland." This, the youngest but one of the Universities of the United Kingdom, may be said literally to have been built upon the ruins of the Queen's University in Ireland. In the Medical Faculty three degrees, those of Bachelor of Medicine, Doctor of Medicine, and Master in Surgery, and two Diplomas, those in Obstetrics and Sanitary Science, are conferred. The degree of M.Ch., and the two diplomas are granted only to graduates in Medicine of the University. The course for the degree of M.B. is of at least four years' duration. Besides fulfilling the specified curriculum all candidates are required to pass the following examinations:—The Matriculation Examination; the First University Examination; the First and Second Examinations in Medicine; and the Degree Examination. The last three are to be passed at intervals of one year from each other. The Matriculation and First University Examinations, which must be passed by candidates for Medical Degrees, embrace the following subjects:—(1) Latin; (2) Any one of these languages, viz., Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic; (3) English Language and Literature; (4) Mathematics; (5) Experimental Physics. One Academical year must intervene between these two Examinations. It will thus be observed that one year in Arts only is required of candidates for medical degrees in this University. Furthermore, the fees are low, namely:—Matriculation Examination, 10*s.*; First University Examination, 1*l.*; First and Second Examinations in Medicine, 1*l.* each; M.B. Degree Examination, 3*l.*; M.D. Degree Examination, 5*l.*; M.Ch. Examination, 5*l.*; Dipoma in Obstetrics Examination, 2*l.*—18*l.* 10*s.* in all, compared with 43*l.* 1*s.* payable by a candidate for the Licences of the Colleges of Physicians and Surgeons.

V.—The Apothecaries' Hall of Ireland was incorporated in 1791 (31 Geo. III., cap. 34, "An Act for the more effectually preserving the Health of His Majesty's Subjects, for erecting an Apothecaries' Hall in the City of Dublin, and regulating the Profession of an Apothecary throughout the Kingdom of Ireland"). The Hall grants one Licence which entitles its possessor to practise Medicine and Pharmacy, and is recognised as a full qualification in Medicine for appointments in the Army Medical Department, the Naval Medical Department, and the Poor Law Medical Service in both England and Ireland. Candidates for the Licence must undergo a preliminary examination and a professional examination, of which the latter is divided into two parts. The fee for the Preliminary is 10*s.*, and that for the Professional, 16*s.*; so that the total cost of this qualification is only 1*l.* 6*s.* The Hospital attendance required of candidates is apparently only eighteen months, namely, Practice of Medicine and Clinical Lectures on Medicine, during two Winter and two Summer Sessions, and Practice of Surgery and Clinical Lectures on Surgery, during one Winter and one Summer Session; there being no proviso that the surgical attendance shall not be synchronous with the Medical.

For the Examinations of the above Licensing Bodies, students are prepared in five Metropolitan and three Provincial Medical Schools, in all of which the Course of Study is adapted, with more or less variations, to the requirements of the Licensing Bodies.

The Metropolitan Schools are—(1) The School of Physic in Ireland; (2) The School of Surgery of the Royal College of Surgeons; (3) The Carmichael College of Medicine; (4) The Ledwich (Original) School of Anatomy, Medicine, and Surgery; (5) The School of Medicine of the Catholic University. The Provincial Schools are those connected with the Queen's Colleges at Belfast, Cork, and Galway. A few explanatory remarks touching each of these institutions may prove of interest:—

1. *The School of Physic in Ireland* is a Medical School formed by an amalgamation of the Schools of the College of Physicians, and of Trinity College, Dublin, in conformity with the "School of Physic Act" (40 Geo. III., cap. 84), and subsequent Acts of Parliament, particularly the Statute of 30 Viet, cap. 9. The School is governed jointly by the Provost and Senior Fellows of Trinity College, and by the President and Fellows of the College of Physicians. The Teaching Staff of the School consists of five Professors appointed by the College, and four Professors and one Lecturer appointed by Trinity College. Of the five Professors appointed by the College of Physicians, four King's Professors are, by virtue of their office, Clinical Teachers in Sir Patrick Dun's Hospital, Dublin, of which the President and the four Censors of the College are *ex-officio* Governors, and have a voice in all matters connected therewith. And in this connection it is necessary to observe that this is the only instance now in Ireland of a School of Medicine being intimately bound up with, or attached to, a hospital. A few years ago the Medical School attached to Dr. Steevens' Hospital became extinct, although clinical work is still effectually carried on in that Hospital. In this respect the Irish Hospitals and Schools present a remarkable contrast to those in London and the larger provincial towns of England. The Irish arrangement no doubt arises from the comparatively short distances between the hospitals and schools in Dublin, and it possesses the advantage of securing for both hospitals and schools a variety of talent from different quarters. The School of Physic stands at the east end of the park of Trinity College, and includes a splendid chemical laboratory, a physiological laboratory, extensive dissecting rooms, and lecture theatres and museums.

2. *The School of Surgery of the Royal College of Surgeons* is attached by charter and has existed as a department of the College for nearly a century. It is carried on within the College buildings and is specially subject to the supervision and control of the Collegiate Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued in the School. Within the past two years the School has been considerably enlarged, indeed reconstructed, and fitted with the most modern and improved appliances. The Anatomical Department has been entirely remodelled, and a new laboratory has been constructed for the special accommodation of students in practical physiology.

3. *The Carmichael School of Medicine* was founded in the year 1826, by Ephraim MacDowel, Richard Carmichael, and Robert Adams, Surgeons to the Richmond Hospital, under the title of the Richmond Hospital School of Medicine. Subsequently, Mr. Carmichael endowed it with a valuable Prize Fund amounting to about 100*l.* a year, and bequeathed a large sum of money to the School for building purposes. In consideration of this munificent bequest the school has since been called the Carmichael School. In 1878 it was determined to transfer the School to the south side of the city. Accordingly a site was obtained at the corner of Aungier Street and Whitefriar Place, facing York Street, in immediate proximity to the

Meath, Adelaide, and Mercer's Hospitals, and but a short distance from the City of Dublin Hospital. On this ground the present buildings, entirely new from the foundation, were erected; and in their construction and arrangements the directors have rendered every department fully adequate to the requirements of the most advanced modern teaching of Medicine and Surgery. In consequence of these changes the title was altered to that of the Carmichael College of Medicine. The buildings include a Dissecting Room of large size, a "Bone Room," a Chemical Lecture Theatre, and Laboratory, a Histology Room, capable of accommodating 250 pupils, and separate rooms for Physiological Chemistry and Physiological Instruments. Prizes to the value of over 100*l.* are awarded annually.

4. *The Ledwich School of Medicine* was founded in 1810, by Dr. Kirby, and since then has been successively under the management of the Messrs. Ledwich and Mason, after the former of whom it is named. It is situated in Peter Street, Dublin, close to the Adelaide Hospital, with which institution however it has no direct connection. Its governing body have gone with the spirit of the times, and have introduced many modern improvements, including the lighting of the Dissecting Room at night with electricity.

5. *The School of Medicine of the Catholic University* is situated in Cecilia Street, Dublin. It is conducted under the authority and supervision of the Catholic University of Ireland, of which institution it practically forms the Medical Faculty. Its students are sent up for Degrees in Medicine to the Royal University, of which several of its Professors and Lecturers are Fellows.

The Provincial Schools of Medicine are the Medical Faculties of the Queen's Colleges, which were established by Charter in 1849. These Colleges are three in number and are called Queen's College, Belfast; Queen's College, Cork; Queen's College, Galway. Before the dissolution of the Queen's University in Ireland, these Colleges were its feeders; and in order to graduate in the University not only was it necessary to undergo the two University Examinations, but three sessions at one of the Colleges should also be kept. Now, the place of the Queen's University has been taken by the Royal University, but no such intimate connection exists between the Colleges and the new University, to which the Colleges are in no way affiliated.

The Clinical Hospitals of Dublin are ten in number, exclusive of the Rotunda Lying-in Hospital, the Coombe Lying-in Hospital, Cork Street Fever Hospital and House of Recovery, the Children's Hospital, Eye and Ear Infirmaries, Orthopædic Hospitals, Westminster Lock Hospital, etc.

We can but name them here in chronological order.

1720.—Dr. Steevens' Hospital.
1721.—The Charitable Infirmary, Inn's Quay (afterwards Jervis Street Hospital).
1734.—Mercer's Hospital.
1770.—Meath Hospital (constituted the County Dublin Infirmary in 1773).
1791.—House of Industry Hospitals (Richmond, Surgical, Whitworth, Medical, and Hardwicke Fever).
1798.—Sir Patrick Dun's Hospital (opened in 1808).
1832.—City of Dublin Hospital.
1834.—St. Vincent's Hospital.
1861.—Mater Misericordiæ Hospital.
1861.—Adelaide Hospital.

Among the principal Provincial Hospitals are the Belfast Royal Hospital; the North Charitable Infirmary, Cork; the South Charitable Infirmary and County Hospital, Cork; the County Infirmary, Galway; and Barringtons' Hospital and City of Limerick Infirmary.

Ophthalmic Hospitals.—At the Royal London Ophthalmic Hospital, Moorfields, the Surgeons attend daily at 9 a.m. Fee for clinical instruction, six months, 3*l.* 3*s.*, perpetual, 5*l.* 5*s.* At the Royal Westminster Ophthalmic Hospital, which contains 13 wards, with 50 beds, the patients are seen daily at 1 p.m., and operations take place at 2. The fees for students are the same as at Moorfields.

THE CLINICAL HOSPITALS OF DUBLIN.

DR. STEEVENS' HOSPITAL.

Medical and Surgical Staff.—*Physicians:* Dr. H. J. Tweedy; Dr. R. A. Hayes. *Obstetric Physician:* Dr. A. Duke. *Surgeons:* Mr. W. Colles; Mr. E. Hamilton; Mr. R. M'Donnell. *Resident Surgeon:* Mr. T. Myles.

Fees.—Hospital Practice, nine months, 12*l.* 12*s.*; ditto, six months, 8*l.* 8*s.* Further particulars may be learned from the Resident Surgeon at the Hospital; or from Dr. R. A. Hayes, Hon. Sec., 32, Merrion Square South.

JERVIS STREET HOSPITAL, DUBLIN.

Medical and Surgical Staff.—*Physicians:* Dr. Stephen M. MacSwiney; Dr. William Martin. *Surgeons:* Mr. Austin Meldon; Dr. W. Stoker; Dr. J. J. Cranny; Dr. Robert MacDonnell; Mr. J. V. Lentaigne; Dr. C. Gunn; Mr. A. G. Chance.

This Hospital, which is now rebuilt upon an extensive scale, is most central in situation. From its proximity to the quays and principal factories it presents unrivalled opportunities to the students of seeing every form of surgical injury. An extensive Dispensary for out-door patients is attached to the Hospital, at which the students are allowed to perform minor operations, under the guidance of the Surgeon on duty, and are rendered familiar with the details of dispensary practice. Instruction is given by the Physician and Surgeon on duty on alternate mornings, between 9 and 11 o'clock, at the bedside, when the nature, progress, and treatment of each case are explained. Two clinical lectures are delivered each week on the most important cases under treatment, when pathological specimens are exhibited. Surgical instruments and appliances of all kinds are constantly made the subject of special instruction. Surgical operations are performed on Tuesday mornings, at 10 o'clock, except in cases of emergency, when due notice is given if possible. Practical Pharmacy is taught under the superintendence of the Apothecary.

Resident pupils and dressers are selected from among the most attentive of the advanced students, without payment of any additional fee. Two interns are appointed each half year, and are provided with apartments, &c., free of expense. Special certificates are given to the resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. Certificates of attendance are recognised by all the licensing bodies and examining boards in the United Kingdom.

MERCER'S HOSPITAL, WILLIAM STREET, DUBLIN.

Medical and Surgical Staff.—*Physicians:* Dr. T. P. Mason; Dr. Charles Frederick Knight. *Surgeons:* Mr. E. S. O'Grady; Mr. F. Alcock Nixon; Mr. M. A. Ward.

This Hospital is situated in a central position, and is in close proximity to the School of the Royal College of Surgeons, to the Carmichael College of Medicine and Surgery, to the Catholic University, and the Ledwich School of Medicine.

Fees for the winter and summer session (nine months) 12*l.* 12*s.*; for the six winter months, 8*l.* 8*s.*; for the three summer months, 5*l.* 5*s.* Further information can be obtained from any of the medical officers of the Hospital, or from Dr. James Shaw, Registrar to the medical staff.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

Medical and Surgical Staff.—*Physicians:* Dr. Arthur Wynne Foot and Dr. John William Moore. *Surgeons:* Sir George H. Porter, Mr. James H. Wharton, Mr. Philip Crampton Smyly, Mr. Rawdon Macnamara, Mr. Lambert H. Ormsby, Mr. William J. Hepburn.

The session will commence on October 1st, and the course of clinical lectures on the first Monday in November. Clinical lectures, of which four will be delivered weekly, and instructions in Medicine and Surgery will be given on alternate days. The physicians and surgeons on duty will visit the Hospital at 9 a.m., so as to allow the members of the class to be in attendance at their respective Schools of Medicine at 11 a.m. The Hospital, which contains 120 beds for the reception of medical and surgical cases, and to which an extensive dispensary (open daily), lending library, and physical laboratory are attached; is within a few minutes' walk of the University, the Royal College of Surgeons, the Carmichael College of Medicine and Surgery, and the Ledwich School of Medicine. An additional ward has been erected for the reception of children, in which the pupils will have an opportunity of studying that highly important subject—infantile disease. Certificates of attendance at this Hospital are recognised by all the universities, colleges, and licensing bodies in the United Kingdom. Prizes will be given at the termination of the winter course to the best students in their respective classes. The office of Resident Pupil is open to pupils as well as apprentices. Further information may be obtained on application to Mr. W. J. Hepburn, Hon. Sec., 31, Upper Merrion Street, Dublin; or at the Hospital.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Medical and Surgical Staff.—*Physicians*: Dr. J. T. Banks; Dr. B. G. M'Dowel; Dr. S. Gordon; Dr. R. D. Lyons. *Surgeons*: Mr. William Stokes; Mr. William Thomson; Mr. W. Thornley Stoker; Mr. A. H. Corley. *Consulting Obstetric Surgeon*: Dr. Kidd. *Assistant Physician*: Vacant. *Ophthalmic Surgeon*: Dr. A. Jacob.

Clinical instruction will commence on October 1. These Hospitals contain 312 beds—110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases. Premiums will be awarded in Clinical Medicine and Surgery. The Richmond Institution for the Insane, containing over 1,200 patients, adjoins these Hospitals. Eight resident clinical clerks are appointed each half year.

Fees.—For the winter and summer session (nine months), 12*l.* 12*s.*; for the six winter months, 8*l.* 8*s.*; for the three summer months, 5*l.* 5*s.* Resident clinical clerks, 21*l.* for the winter session, 15*l.* 15*s.* for the summer session, including certificate of attendance.

SIR PATRICK DUN'S HOSPITAL.

Medical and Surgical Staff.—*Physicians*: Dr. John Malet Purser; Dr. W. G. Smith; Dr. J. Magee Finny. *Midwifery Physician*: Dr. J. R. Kirkpatrick. *Surgeons*: Dr. Thomas E. Little; Dr. Edward H. Bennett; Dr. Charles B. Ball.

Fees.—*Clinical Lectures and Hospital Attendance.*—The payment of 12*l.* 12*s.* entitles a student to the benefits of hospital attendance and clinical teaching for the winter and summer sessions, commencing October 1. Fee for winter session only, 8*l.* 8*s.*; fee for summer session only 5*l.* 5*s.* *Practical Midwifery.*—Students desirous of entering for twelve months' instruction in Practical Midwifery are required to pay a maternity fee of 3*l.* 3*s.* each. Students of Trinity College are not liable to any other payment for instruction in Practical Midwifery. Other students are required to pay 3*l.* 3*s.* each to the King's Professor for twelve months' practical instruction, in addition to the hospital maternity fee. Students who have paid the hospital maternity fee are entitled to attend the demonstrations in Obstetric Surgery given by the King's Professor.

Prizes.—The governors of the Hospital award a silver clinical medal in Medicine to the student who shall pass the best examination on the medical cases treated in the Hospital during the year; and a silver clinical medal in Surgery to the student who shall pass the best examination on the surgical cases treated in the Hospital during the year.

CITY OF DUBLIN HOSPITAL, UPPER BAGGOT-STREET.

Physicians: Dr. Hawtrey Benson and Dr. George F. Duffey. *Surgeons*: Mr. Henry Gray Croly, Mr. William I. Wheeler, and Dr. Henry Fitzgibbon. *Ophthalmic and Aural Surgeon*: Mr. Arthur H. Benson. *Gynæcologist*: Dr. William J. Smyly.

Fees—Nine months' hospital attendance, 12*l.* 12*s.*; six months, 8*l.* 8s.; three months, 5*l.* 5*s.* For further particulars apply to Mr. Wheeler, 27, Lower Fitzwilliam Street.

ST. VINCENT'S HOSPITAL, DUBLIN.

Medical and Surgical Staff.—*Physicians*: Dr. Francis J. B. Quinlan, Dr. M. F. Cox. *Surgeons*: Mr. Edward D. Mapother, Mr. J. S. McArdle. *Gynæcologist*: Dr. J. A. Byrne. *Ophthalmic Surgeon*: Mr. Redmond.

Fees.—Winter and summer session, 12*l.* 12*s.*; separately, 8*l.* 8*s.* and 5*l.* 5*s.* Further particulars may be learned on application to the Secretary of the Medical Board, Dr. McArdle, 7, Upper Merrion Street, Dublin, or at the Hospital during the hours of attendance.

MATER MISERICORDIÆ HOSPITAL, ECCLES STREET, DUBLIN.[1]

Medical and Surgical Staff.—*Physicians*: Dr. Christopher J. Nixon, Dr. Joseph Redmond, Dr. Michael Boyd. *Assistant-Physician*: Dr. John Murphy. *Surgeons*: Mr. Patrick J. Hayes, Mr. Charles Coppinger, Mr. Malachy Kilgarriff. *Assistant-Surgeon*: Mr. Kennedy. *Obstetric Physician*: Dr. T. M. Madden.

Certificates of attendance upon this Hospital, which contains 250 beds, including 50 beds for fever and other contagious diseases, are recognised by all the licensing bodies in the United Kingdom.

Prizes.—Two clinical prizes (the "Leonard Prizes") of 15*l.* each, one medical and one surgical, will be given at the end of the winter session.

Fees.—For nine months, 12*l.* 12*s.*; six winter months, 8*l.* 8*s.*; three summer months, 5*l.* 5*s.*

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, PETER STREET, DUBLIN.[1]

Physicians: Dr. Henry H. Head and Dr. James Little; *Obstetric Physician*: Dr. R. D. Purefoy; *Assistant Physician*: Dr. Wallace Beatty; *Surgeons*: Mr. J. K. Barton and Mr. Kendal Franks; *Ophthalmic Surgeon*: Dr. Rosborough Swanzy.

Further particulars can be obtained from any member of the staff.

ROTUNDA HOSPITALS, RUTLAND SQUARE, DUBLIN.

Master: Arthur V. Macan, M.B., B.Ch., M.A.O., F.K.Q.C.P.: *Consulting Physician*: James Little, M.D., F.K.Q.C.P.; *Consulting Surgeon*: William Colles, M.D., *Assistant Physician*: Richard Henry, M.D., and John Lilly Lane, F.R.C.S.I.; B.A., L.K.Q.C.P., L.R.C.S.I.; *Pathologist*: G. F. Duffey, M.D., F.K.C.P.

This Institution consists of two distinct Hospitals, namely, the lying-in-hospital, into which 1,200 labour cases are on an average admitted annually, and the auxiliary hospital, set apart for the reception and treatment of patients suffering from the various forms of uterine and ovarian disease; about 500 patients are received into this hospital during each year. There is also in connection with the Hospital a large extern maternity (1,500 patients were in the past year attended at their own homes), and a dispensary for diseases peculiar to women, which is open daily. Pupils

[1] No Return.

are admitted to the practice of all these departments. Clinical instruction in Midwifery and the Diseases of Women is given daily, and lectures are delivered regularly during the session on these subjects. The diploma from this Hospital is granted to pupils on their passing an examination before the Master and Assistants, after a period of six months' attendance on the practice of the Hospital. It is recognised by the Local Government Board as a qualification in Midwifery for all hospitals and dispensaries under their control. Accommodation is provided for a limited number of intern pupils. Pupils can enter at any time.

Terms of Attendance.—Intern pupils, for six months, 21*l.*; three months, 12*l.* 12*s.*; two months, 9*l.* 9*s.*; one month, 6*l.* 6*s.* Extern pupils, for six months, 10*l.* 10*s.*; three months, 6*l.* 6*s.* Application to be made to the Master or Assistant-Physicians, at the Hospitals, Rutland Square, Dublin.

PROVINCIAL MEDICAL SCHOOLS IN IRELAND.

QUEEN'S COLLEGE, BELFAST. — FACULTY OF MEDICINE.[1]

Professors and Lecturers.

Anatomy and Physiology—Dr. P. Redfern.
Chemistry—Dr. E. A. Letts.
Materia Medica—Dr. J. S. Reid.
Medical Jurisprudence—Dr. J. F. Hodges.
Midwifery—Dr. R. F. Dill.
Natural Philosophy—Dr. J. D. Everett.
Practice of Medicine—Dr. James Cuming.
Practice of Surgery—Dr. A. Gordon.
Zoology and Botany—Dr. R. O. Cunningham.

The demonstrations in Anatomy are delivered by Dr. Anderson. The lectures in Midwifery, six months' course, will commence on February 1, and the lectures in Medical Jurisprudence and the courses of Botany and Practical Chemistry will commence in May.

Fees.—Anatomy and Physiology—First course, 3*l.*; each subsequent course, 2*l.* Anatomical Demonstrations and Practical Anatomy—each course, 3*l.* Practical Chemistry, 3*l.* Other medical lectures—first course, 2*l.*; each subsequent course, 1*l.*

Two Medical Scholarships are awarded to the students of each year of the medical course. The examinations commence on October 23.

Clinical Instruction is given at the following Hospitals :—

Belfast General Hospital.—A winter session, 5*l.* 5*s.* A summer session, 2*l.* 2*s.* Perpetual fee, payable in one sum of 10*l.* 10*s.*, or two instalments of 5*l.* 5*s.* each on entering for the first and second years. Hospital fee, 10*s.* 6*d.* each winter or summer session.

The Ulster Hospital for Diseases of Women and Children and Midwifery Dispensary, 11, Fisherwick Place—Fee for winter six months, 3*l.* 3*s.*

The Belfast Lying-in Hospital—Fee for the session, 2*l.* 2*s.*

The Belfast District Lunatic Asylum — Fee for course, 3*l.*

QUEEN'S COLLEGE, CORK. — FACULTY OF MEDICINE.

Professors.

Anatomy and Physiology—Dr. J. J. Charles.
Chemistry and Practical Chemistry—Dr. Maxwell Simpson.
Materia Medica—(vacant).
Midwifery—Henry Corby, B.A., M.D., M.Ch.
Natural Philosophy—Prof. John England.
Practical Anatomy—The Professor, assisted by Demonstrators.
Practice of Medicine—Dr. D. C. O'Connor.
Practice of Surgery—Dr. Stephen O'Sullivan.
Zoology and Botany—Professor M. Hartog.

[1] No Return.

All the lectures are recognised by the Royal University of Ireland, by the Universities of London, Glasgow, Aberdeen, and St. Andrew's; the Colleges of Surgeons of Dublin, Edinburgh, and London; by the Apothecaries' Companies; by the Army, Navy, and East Indian Medical Board, &c.

Hospital Attendance.—Clinical lectures on Medicine and Surgery are delivered at the North and South Infirmaries, by the Physicians and Surgeons of those Institutions.—Fee for twelve months, 8*l.* 8*s.*; fee for six months, 5*l.* 5*s.* Practical Pharmacy at the same Infirmaries.—Fee for three months, 3*l.* 3*s.* Clinical Midwifery at the Lying-in Hospital, with Practical Attendance upon thirty Midwifery cases.—Fee for six months, 3*l.* 3*s.*

Clinical instruction is also given at the Mercy Hospital, the District Lunatic Asylum (Fee, 3*l.* 3*s.*), the Children's Hospital, the Fever Hospital, and the Ophthalmic and Aural Hospital.

Scholarships. — Eight Scholarships are awarded to students in Medicine, if qualified, viz., two Scholarships of 25*l.* each to students commencing their first, second, third, and fourth years. Clinical Medicine and Surgery at the North and South Infirmaries, and Clinical Midwifery at the Lying-in Hospital.

QUEEN'S COLLEGE, GALWAY.—FACULTY OF MEDICINE.

Professors and Lecturers.

Anatomy and Physiology, and Practical Anatomy—Dr. J. P. Pye.
Botany and Zoology—Dr. R. J. Anderson.
Chemistry—Dr. T. H. Rowney.
Logic and Mental Philosophy—Dr. T. W. Moffett.
Materia Medica—Dr. N. W. Colahan.
Medical Jurisprudence—Dr. R. J. Kinkead.
Midwifery and Diseases of Women and Children—Dr. R. J. Kinkead.
Natural Philosophy—Dr. Joseph Larmor.
Practice of Medicine—Dr. John I. Lynham.
Practice of Surgery—Dr. J. V. Browne.

Clinical instruction is given at the County Galway Infirmary, Town, and Fever Hospitals which are in the immediate vicinity of the Queen's College.

Eight Scholarships of the value of 25*l.* each, and Exhibitions varying in value from 12*l.* to 16*l.* are appropriated to students pursuing the course for the degree of M.D.

Fees.—Anatomy and Physiology, 3*l.* first session; afterwards 2*l.* Practical Anatomy, 3*l.*; Practical Chemistry, 3*l.*; Operative Surgery, 3*l.*; other classes, 1*l.* for each course extending over one term only, 2*l.* for each course extending over more than one term, and 1*l.* for each re-attendance on the same. Hospitals, 4*l.* 4*s.*

For further information, application may be made to Professor Townsend, M.A., D.Sc., Registrar.

The West London Preparatory School of Medicine. —The West London Hospital, having been recently enlarged, now contains 101 beds. The extensive and populous surrounding district, the railways which converge almost to its very doors, and the neighbouring river-traffic fill its wards with every variety of accident and disease. The Staff, naturally desiring to utilize this material for the work of medical education, determined on the establishment of a Preparatory School of Medicine, where a definite course of practical instruction might be within the reach of all those students who wish to prepare themselves for one of the medical schools of the metropolis. The objects aimed at are:—(1) To give in a more complete and systematic manner than has heretofore ever been attempted, all the advantages of a year's pupilage at a first-class provincial infirmary or county hospital. (2) To give instruction in natural science. (3) To give commencing medical students an early insight into medical work, so that they may, without needless loss of time or money, be able to judge whether or not they have chosen the right profession. Arrangements have been made, by which lectures on Elementary Surgery, Elementary Physiology and Histology, Osteology and Chemistry, and Physics will be given in the winter session; and courses on Elementary Medicine, Materia Medica and Botany in the summer session. It is intended that the student shall be efficiently prepared, if he desires it, for the first examination for the L.R.C.P. Lond.

SYNOPSIS OF THE REGULATIONS OF THE EXAMINING BODIES.

EXPLANATION OF LETTERS USED IN TABLES.

(*a*) A first or second class gained in the Natural Science School, enables the student to dispense with these two years of study.
(*b*) In each examination, subjects (1) and (2) may be taken separately.
(*c*) Four years, if B.A. has been passed with honours.
(*d*) The examination in Physiology and Histology may be postponed to a subsequent year.
(*e*) Graduates who have passed the B.S. or M.B. respectively in the First Division are excused one year of hospital or two years of private practice.
(*f*) The University of Durham also grants Licences in Medicine and Surgery. The subjects of examination and other conditions are the same as those for the corresponding degrees, but no extra examination in Arts is required.
(*g*) The October examination is intended only for students who have failed in the previous July, or who have received special permission to present themselves.
(*h*) The first part may be passed at any time subsequent to completion of third year from registration as a medical student.
(*i*) Candidates who have passed the examinations of various recognised examining bodies will in certain cases be exempt from re-examination in the subjects in which they have passed.
(*j*) Graduates in Arts of a recognised university are exempt from this examination; and candidates who have passed a recognised Arts examination are not re-examined in the subjects in which they have passed.
(*k*) The first two parts may be taken together at the end of the third year, or all four parts together at the end of the fourth year.
(*l*) Graduates in Arts of a recognised university are exempt from examination in Logic and Moral Philosophy.
(*m*) The curriculum and fees for the degrees of the University of Glasgow are the same as in the case of the University of Edinburgh.
(*n*) The University also grants Licences in Medicine, Surgery, and Obstetrics respectively to candidates who have completed two years in Arts but have not taken the B.A. degree; also a degree in Obstetrics.
(*o*) Candidates who have passed the previous professional examination of a recognised corporation are excused from passing this examination.
(*p*) The College also grants a Licence in Midwifery. Fee £3 3*s*. Fee for double Licence in Medicine and Midwifery £16 16*s*.

CORRESPONDENCE.

MEDICAL EDUCATION IN VIENNA.

(By Our Vienna Correspondent.)

I HOPE that a short account of the educational arrangements at the Medical Faculty of Vienna, which has long been a favourite place of resort for foreign medical students and practitioners, may prove of some use to the English readers of your valuable Journal. Those who cherish the intention of some day visiting the school at which Hyrtl, Rokitansky, and Skoda received their education and carried on their important work, and which is now represented by such distinguished men as Brücke, Billroth, Bamberger, Nothnagel, Braun, Stellwag, Kaposi, and others, will find perhaps in these lines a special interest.

Before giving you a view of the educational facilities at the Vienna Medical Faculty in general, I must devote a few words to the arrangements which especially concern the students who wish to pass their examinations here. Every student of an Austrian Medical Faculty has to attend lectures during a period of five years, and he cannot be admitted to the final examinations for the degree of Doctor of Medicine until he has fulfilled the so-called "quinquennium." Foreigners who possess the right of attending the Universities of their own country are also received at the Universities in question, and are subjected to the same laws as native students. If they have already taken the degree of doctor at a foreign faculty, they are received as "extraordinary students," and are not obliged to complete the five years if they wish to take the degree at one of the Medical Faculties of Austria, but may pass their examinations when they please.

All public lectures, most of which are delivered by ordinary professors, are open to foreigners for the same fee as is required of the ordinary student. The fee for each course of lectures is in proportion to the number of hours which they occupy during one week, each hour a week being charged at the rate of 1fl. and 5kr. (about 1*s.* 10*d.*) for the whole semester. Thus for the course of lectures on Internal Medicine, which occupies ten hours a week, the fee is 10fl. 50kr. per semester. Payment is made each semester at the commencement of the course.

The lectures in the different departments of Medicine are so arranged that the student has an opportunity of attending all his subjects in the course of five years. To elucidate this point it will be necessary to give the hours of the different lectures. The lectures on Anatomy are delivered, every day, except Sunday, from 9 to 10 a.m. The dissecting rooms are open on the same days from 8.30 a.m. till dusk, the respective professors giving demonstrations from 3 to 5 p.m. The fee for dissections and demonstrations for the whole semester is the same as that for a course of six hours a week, namely, 6fl. 30kr. From the beginning of the next semester, the lectures on Anatomy and the demonstrations in the dissecting rooms will be in the hands of two professors, Professor Charles Langer and Professor Charles Toldt (the latter having been appointed to the Second Chair of Anatomy, recently created). The hours of instruction coincide, as in all cases where there are two professors for the same subject, so that the students may follow whichever of the teachers they please. The lectures on Physiology and Histology, by Professor v. Brücke, take place from 11 to 12 o'clock five times a week. The physiological laboratory, also under the direction of Professor Brücke, is open on every week day, and the fee for the whole semester is the same as that for a course of six hours (6fl. 30kr.). Besides these lectures there are many others in the same departments which serve as "repetitoria," and in which students have the opportunity of perfecting their knowledge, as for instance, two so-called "private courses," by Professor Schenck, on Histology and Embryology, and courses on some selected subject in Physiology by the Extraordinary Professors Exner and v. Fleischl, assistants to Professor Brücke. The fees for these lectures, however, differ from those I have mentioned above, the extraordinary professors, privat-docents, &c., being allowed to fix whatever fees they please; hence the name "privat-Curse," or briefly "Curse," the name of the official lectures being "Vorlesungen," or "Collegia." The students of the Vienna Medical Faculty are occupied during their first two years with the various branches of Natural History (Zoology, Botany, Mineralogy) and with the above-mentioned subjects, and in the second year with Pharmacology five times a week, from 10 to 11 a.m. (delivered only in winter), by Professor Vogl.

At the beginning of the third year they commence their clinical studies and the subjects connected with them, as Pathological Anatomy and so on. The hours for Internal Medicine are from 8 to 10 a.m. in winter (in summer from 7 to 9 a.m.), those for Surgery from 10 to 12 in winter (from 9 to 11 in summer.) In each case the lectures are delivered by two professors at the same hour five times a week. Bamberger and Nothnagel being Professors for Internal Medicine, Billroth and Albert for Surgery. Pathological Anatomy is taught from 12 to 1 in winter (from 11 to 12 in summer), by Professor Kundrat. The class of Practical Pathology is held three times a week from 3 to 4 p.m., also under the direction of Professor Kundrat. Besides this there are also, as in other subjects, private courses by the assistants of the professors and others, by extraordinary professors and privat-docents, as for instance by the Extraordinary Professors Benedikt, Stern, Drasche, Schrötter, Rosenthal, Stoffella, and by the Privat-docents Rollett, Bettelheim, Breuer, Heitler, Drozda, Taksch, Bixch, Langer and Abeles in Internal Medicine; in Surgery by the Extraordinary Professors Mosetig-Moorhof, Dittel, Salzer and Böhm, and the Privat-docents Englisch, Wölfler, Hofmokl, Fieber, Ultzmann, Jurié, Frisch and Maydl. The lectures on General and Experimental Pathology, by Professor Stricker, are delivered from 1 to 2 p.m. on five days a week in winter (in summer the hours are not fixed); Forensic Medicine from 2 to 3 p.m. (five times a week), by Prof. Edward Hofmann; lectures on Mental Diseases from 5 to 6 p.m., by Professor Meynert, five times a week, and by Professor Leidesdorf, from 5 to 6½, three times a week. A student has therefore the opportunity of attending the lectures on Internal Medicine, Surgery, Pathological Anatomy, General and Experimental Pathology, Forensic Medicine and Psychiatry, or some of them in the same semester. The lectures on Dermatology, by Professor Kaposi, are delivered from 8 to 10 a.m. in winter (7 to 9 in summer); Ophthalmology from 10 to 12 in winter (in summer 9 to 11), by Professor v. Stellwag and Dr. v. Reuss (the Second Chair of Ophthalmology being vacant); Gynæcology and Obstetrics from 12 to 2 in winter and summer, by Professors Charles v. Braun and Spaeth. All these lectures are delivered five times a week, and they are fixed at such hours they can all be attended in the same semester. The lectures on Syphilis, by Professor Neumann, are delivered from 3 to 4 in winter (in summer from 9 to 10) and the lectures on the same subject, by Professor Auspitz, from 9 to 10 a.m., in both cases five times a week. Professor Auspitz will lecture for the first time in the next semester in the newly-created second clinic for Syphilis; the hour for the summer lectures in his clinic is not yet published. Lectures on Children's Diseases are delivered four times a week by Professor Widerhofer and on Surgical Pædiatrics once a week by Professor Weinlechner, both in the St. Anna Children's Hospital, from 11 to 12 in winter and summer.

Besides these official lectures, the fees for which are fixed on the scale already mentioned, there are some important courses which deserve to be noticed. The lectures on Laryngoscopy and Rhinoscopy, by Professor Schrotter, take place five times a week from 10 to 11 a.m. The course lasts six weeks, and the fee for each course is 20 florins. Professor Stoerk holds a course on the same subjects from 11 to 12 a.m. also five times a week, the length of the course and the fee being the same. Professor Schnitzler's course on the same subjects occupies from 8 to 10 five times a week, the course lasting four weeks; the fee for this too is 20 florins. There is also a course on the same subjects by Privat-docent Dr. Chiari, occupying five hours a week (the time of meeting is fixed according to the wishes of the class); the fee for each course of six weeks is 20 florins. Courses on Diseases of the Ear are delivered by the Extraordinary Professors Dr. Adam

Politzer, five times a week from 12 to 1, and Dr. Gruber, five times a week from 11 to 12; each of these courses lasts six weeks, and the fee is, for practitioners 15 florins, for students 10 florins. A further class on Diseases of the Ear meets six times a week, from 4 to 5 p.m., under the direction of Privat-docent Dr. Urbantschitsch, the duration of the course being six weeks, and the fee being for practitioners 15 florins, for students 10 florins. Privat-docent Dr. Albertus Binz also holds a class on Ear-Diseases twice a week, Saturday and Sunday, 10 to 11.30 a.m.; duration of course three months; fee for practitioners 10 florins, for students 10 florins.

It would take too much space to enumerate all the other "courses" in the different departments of medical science, and I will content myself with remarking that in the approaching semester, lectures will be delivered by 18 ordinary professors, 36 extraordinary professors, 61 privat-docents, and 31 assistants; the number of the courses being 201.

The study of Medicine at Vienna is greatly facilitated by the fact that almost all the lectures are delivered in the General Hospital, and in adjoining establishments, as the Institution for Anatomy and Physiology, the St. Anna Children's Hospital and the polyclinics. The new building of the University (a master-piece of architecture) is also in the neighbourhood of the General Hospital, so that medical students and practitioners have a good opportunity of attending the lectures delivered in the other faculties if they care to.

English students and practitioners who are not acquainted with the German language, will find that almost all the teachers in Vienna are more or less acquainted with English, and can give the necessary explanations; the only difficulty is in understanding the official lectures delivered by the ordinary professors, but they may be looked upon as providing a good opportunity of learning German. Last, but not least, in any description of the educational facilities at the Vienna Medical Faculty, the conveniences for residence and the intellectual distractions of the Austrian capital ought not to be disregarded. The Josefstadt and especially the Alsergrund, our Quartier Latin, supply students and practitioners with lodgings which are very near the General Hospital; nay, there is room for a certain number of residents in the interior of the General Hospital itself. Need I say anything about Vienna as a beautiful and pleasant city, or speak of its art institutions, its theatres, its lovely environs, or of the "kindliness" of its inhabitants? These I fancy are too well known to need mention, for many an English student in leaving us has said that here he had spent the happiest days of his life.

Medical Times and Gazette.

SATURDAY, SEPTEMBER 13, 1884.

METHOD IN MEDICINE.

A "Students' Number" would not go forth in orthodox completeness without some words specially addressed to those about to enter on the study of a profession of whose members it has been aptly said that, while few can hope to amass a fortune in its exercise, all may expect to realise a competence. Not as novices, however, but as *confrères* and in the spirit of elder brotherhood would we welcome those whose names annually go to swell the first-year lists; who bring fresh faces to the lecture-room, and fresh intellects to train for the mastery of those great problems of life and of death which are ever present to perplex and baffle us. For no false step at the outset will more completely dwarf the object of a noble calling, and nothing is more certain to distort the relative value of its methods, than the mistaken notion that a student is no longer a student when he has passed the examinations prescribed by his curriculum, or that the possession of a diploma will suffice to shut up the term of study "in measureless content." He who would really practise his profession must be ever learning of and by it—so true is it that the wisest scholars are the most humble, and the greatest the most teachable. Moreover, starting with such a view as this—realising that life is only one great studentship—one is better enabled to appreciate the relative importance of its several stages. Examinations, for instance, lose much of their sinister significance when we come to regard them as a convenient means of reckoning the amount of progress gained; they are no longer the appalling obstacles in an intellectual steeplechase, but rather occasions of mental stock-taking, opportunities for testing how far we still retain a discriminating yet comprehensive grasp of the various threads of knowledge which we should be picking up and weaving into the pattern of our lives. Primarily, an examination is a test of the (presumed) fact that certain knowledge has been acquired by the candidates. The element of competition is quite a secondary matter, and it is one which can be hopefully attempted only by those who have so worked as honestly to satisfy the first requirement of the test. He who starts and works consistently with the idea that the thorough acquisition of knowledge is the first object, and the passing of examinations a quite subsidiary but incidentally useful diversion, will be able to face these ordeals as calmly as the ordinary diner does his cheese, and to digest them with at least equally satisfactory results. Like turnpikes on the high-road, examinations demand toll of every traveller who has elected to travel by that particular route; an idle, clever, and miscalled "lucky" vagabond may now and then contrive to beg, borrow, or steal enough to pass some or even all the gates, but this will not secure him an honourable or an honoured position in the crowd beyond. It is only those who have worked and who have earned throughout the journey who can lightly pay the toll which marks the distance traversed, and yet leave intact the self-acquired intellectual capital which they have learnt not only how to gain but how to use.

There is, of course, an "art" of examinations as there is of all other unnatural things, but its culture cannot be profitably undertaken by those whose knowledge is inadequate to the test; and for the honest and well digesting worker it may be explained in a few words. In the first place, the real meaning of each question must be fully understood before its answer is attempted; otherwise there will occur much "ink-shed" of knowledge misapplied, and therefore sure to be discredited. Such a caution may to some seem almost needless. But mistakes of this sort are so common in the examination room, and they indicate so often that habit of un-thorough haste which makes the apparent acquisition of information so easy, and its genuine possession so doubtful, that we cannot let it pass unnoticed. Speaking with a somewhat extensive knowledge of the different species of his genus, we should be inclined to say that it is the most common and conspicuous fault of the unsuccessful examinee. Secondly, give only the information of which you are

sure; or one lucky "shot" which is successful, half a hundred fail; and the "bad shot" is double-edged, revealing not only the positive ignorance displayed in a misstatement, but also the negative ignorance implied by the absence of information asked for but not forthcoming. The answer should be as full as is necessary for clearness, but no more; and so framed as to be free from all needless repetition and tautology; in other words, excellence should be aimed at in the order of its being to the point, clear, and terse. It is wonderful how much time is gained in the hardest and most keenly competitive examination by the careful reading and selection of questions, and by a brief *schema* of the stages by which each shall be answered. Method such as all this implies is not a special inspiration gained at the time of examination; it can only be obtained by practice in the methodical selection and acquisition of knowledge. There is no better means to this end than the practice of carefully reading and extracting the pith from a standard authority on each subject which is to be "got up." The very labour involved in such a process aids most powerfully in impressing its important details on the mind; the separate acts of reading the passage in the original, of marking it, of condensing its meaning into a few brief but connected sentences, and of entering these in the notebook, are as so many separate and successive blows driving the facts home into our consciousness; while, at the same time that these kernels of truths are thus safely garnered, we are fixing the habits by which they are spied out and winnowed from amongst less valuable surroundings.

The student must never forget that his work is done, not in order that he may pass examinations and gain prizes or scholarships, but that he may be fitted—or, rather, that he may learn to fit himself—to occupy in life a position to which attach the gravest responsibilities. To this end his aim must be to know and seek out and gain the truth for the truth's sake; to gather facts and to store them as far as possible in their due order, to descry the relationship between them, and to perceive their application. Theories he must meet with and be grateful for, using them thankfully, yet warily, and regarding them only as the scaffolding which enables facts to be arranged definitely in accordance with natural laws, but which can be dispensed with, and which must be taken down when at length the building of Truth's temple is complete; remembering that while theories shift and crumble, facts are immutable—naked truths which no lapse of time may alter, and which no amount of usage can wear away. It is the first aim of every student to discover and to recognise the truth; but it is the high privilege of the physician and the surgeon to learn to apply it for the benefit of others—to abolish pain, to mitigate suffering, to sustain and to prolong life, to prevent and to destroy disease, to arrest the hand of death itself. And for this the great field of human nature must be subjected to the same keen and searching observation. The cultivation of tact, patience, gentleness and sympathy must go hand in hand with that of truth and honour in the practice of professional no less than of private life. No more difficult problem, for instance, can well be set to any man than that which so often confronts the medical attendant—the question of deciding in what form and at what time the truth of which he may be the sole human repository, the only possible exponent, shall be revealed. One of the most distinguished leaders of the profession sometimes tells the story of how, as a young man, he was called upon to make a diagnosis which, involving the imputation of an inherent mortality distasteful to family pride, was received with almost scornful derision. A few years later, when time had only too fatally corroborated his forecast, the physician was consulted by a relative of his former patient, and a similar expression of opinion was met with equal incredulity. Afterwards, yet another member of the same family sought advice from the doctor whose diagnosis had been scouted years before: "You see, in spite of themselves, they could not help coming back to *the man who had told them the truth.*"

Lastly, it may be pointed out that the acquisition of knowledge by the methods which have been briefly sketched results in the formation of a confidence proportionate to the depth and breadth of its foundation. The examination-table equivalent for "stage-fright" does not exist for the man who "knows his work," or, more truly, knows his knowledge,—who is conscious that what he does know is honestly and thoroughly his own, so clearly and methodically arranged that it can be expressed without effort, and applied intelligently. Strong in the value of the information which he does possess, and can produce when asked for, such a candidate is not likely to be worried or flurried by a question here and there to which he may not, perhaps, be able to furnish a complete reply. And what is true in this respect of the examination-room is even more true of those ordeals which, in actual practice, test so keenly the thoroughness of a medical man's training. The self-confidence begotten of thoroughly-acquired practical knowledge is the parent of that calmness and resource by which victory may oftentimes be won in the face of imminent disaster. No men are perfect, and the best are liable to errors and misfortune; but the best men use their errors and learn by them. To the honest worker, even failures and mistakes become the material of future successes, and are made the stepping-stones to a more worthy self-reliance. In the practice of no other profession may it be said more truly or less boastfully that—

> . . . . thoroughly to believe in one's own self,
> So one's own self be thorough, were to do
> Great things.

SOME LETTERS OF ADVICE.

From the Dean of a London Medical School to a Widow who proposes that her son shall enter the medical profession.

Dear Madam,—I will do my best to answer your questions, but it is at all times difficult to give such advice as you require and ten times more difficult when the young man whom it concerns is a stranger to one. Your son, you say, is quick and intelligent, but not fond of books; he is high spirited, but without much self control—which, I fear, when a mother confesses it, means a good deal—and you are anxious not to expose him to the temptations of a

medical student's life without placing him under the direct supervision of someone who will advise him, control him, and in some measure take the place of a parent. In a word, you do not yet think him fit for that emblem of liberty—a latch-key. The first question then is, whether he should enter the medical profession; the second, it being decided that he shall enter it, where, when, and how he shall commence his studies.

I do not think that the fact of a boy's not being fond of books is necessarily a bar to his becoming a doctor. Ours is indeed called a learned profession, but I do not fancy that the bulk of medical men, and certainly not the bulk of medical students, are learned, in the sense of being bookish men. Some reading of books is, indeed, obligatory, but our aim nowadays is to teach much more by laboratory and ward work than by work in the study. Two or three hours a day, steadily continued, are ample to give to separate reading, and if your son has moderate application and the good sense to know on which side his bread is buttered—to use a vulgar expression—he ought not to find it difficult to devote so much of his spare time to his books. The impetus given by the novelty of his work ought to carry him through the most tedious part of it, and if he has, as you say, an observant eye and some natural quickness, he should, under competent teachers, find the remainder of it a pleasure rather than a toil. If he succeeds in qualifying, the prospect open to him is materially better than in most other professions. There are naturally always difficulties in starting, but I find that the majority of our students are making a fair income in one part of the world or another within a few years of passing their final examination.

As to *when* he should join us I think there ought to be no longer delay than is absolutely necessary. He will be eighteen next July, you say; keep him at school till then, let him read up for his preliminary examination, and if he passes it, join in the October following. *Where?* Well, of course, I have a preference for my own school, but all the London and most of the Provincial schools now give an excellent education and keep a sharp watch over their students. For one with your son's proclivities I should say a moderately small school such as ours would expose him to less danger of temptation than a larger one. *How?* By all means send him straight from school to the hospital you choose. Do not, pray, be persuaded to place him for a year or two first with a country practitioner. Such a course has been the ruin of scores of young men, who have thereby lost the habits of work impressed on them at school, and come to us puffed up with a little smattering of knowledge and disinclined to enter upon the hard drudgery which is necessary before the really interesting part of their work is reached. Your idea of placing him in the house of one of the lecturers of the school to which you send him is a good one. There are many such who would be glad to take him, and would do their very utmost to keep him out of folly. Many students, I believe, are better left to themselves; but if you distrust your son's power of self control, by all means keep him for a year or two longer in some sort of leading string. I hope that these few lines will be of some material assistance to you in making your decision.

To the Same, from a Country Apothecary.

* * * Remember, dear Madam, that the profession of Medicine is an art no less than a science, and as such should be learnt by apprenticeship as well as by studentship. In the case of other arts—say painting or engineering, for example—it would be deemed ridiculous simply to teach the sciences on which they depend, and then to turn the student adrift to practise his art as best he might. The custom is rather to let the pupil practice at first under the eye of a master, until he has shown that he can with safety take the whole responsibility upon himself. This was the rationale of the apprenticeship system which used to prevail in Medicine; and though I am willing to admit that it erred in its neglect of scientific teaching, I cannot help feeling that the present authorities are pushing matters to the other extreme, and sacrificing everything to this teaching of science. I think it would be hardly too much to say, that of the young men who yearly join the profession, only the very small number who have held responsible offices, house-surgeoncies, &c., are really competent to enter at once into the field of practice. The rest have to learn their art upon their patients. I have seen the results of the system in the young men who come to me from time to time as assistants. Many of them are entirely unable to treat a common bronchial cold, or to draw up a diet sheet, or, indeed, to deal efficiently with any of the petty ailments which form the bulk of private practice. Such cases seldom appear at the hospitals, or if they do are treated lightly, small importance being attached to any but grave and rare complaints. And even if the student should see them properly treated, the facts fail to impress him, for he has no responsibility in connection with the case, and nothing to make him remember it. Under the old system, on the other hand, the apprentice was allowed after a time to treat patients under the eye of his master, and he was thus in a position to readily grasp and retain those methods of treatment, and those nice points in diagnosis by which he saw his master succeeding after he had failed; for nothing teaches like failure. There are a thousand and one little points of treatment that made the reputation of many a country practitioner, which have never found their way into books, and which are either unknown to or ignored by the London teacher. These, under the old system, were handed down in successive generations from master to pupil, and the pupil began his art at the point where his master left off. Now, the pupil, though incalculably better grounded in science, does not, so far as his art is concerned, begin even with knowledge that his father or his father's generation possessed.

I wish we could combine the two systems—the new and the old. I have given up thinking that it would be advisable for the student to commence by apprenticeship, for I see how necessary it is to begin scientific education in the school-room, and to carry it on without a break until the time for its practical application is reached. But I strongly hold that no man should be allowed to call himself qualified and permitted as such on his own responsibility to deal with any case that comes to him, unless he can show that he has actually learnt to *treat* patients, and not merely to describe their maladies on paper. The resident appointments in the London and provincial hospitals, invaluable as they are, are not nearly numerous enough to give every student the opportunity of holding one, and the only alternative seems to be that all who have not had that advantage shall pass a certain time after their curriculum, or during the later portion of it, with some general practitioner who has public appointments which will allow him to give his pupils charge of patients with a limited responsibility. If your son is lucky enough to get a resident post at his hospital, well and good. If not, pray think over this matter—on which I have unfolded my views at such length only because I feel so strongly on it—and when the time comes, seek out some reliable practitioner who may confer on your

son some measure of the benefits that the master of old conferred on his apprentice. Be assured that by so doing you will spare him many a mortification, and his future patients, possibly, some risk.

From a Successful Surgeon to a Young Genius who has decided to study Medicine.

My Dear Boy,—I am rejoiced to hear of your decision, and you may count on my doing everything in my power to help you, both now and hereafter. I make this promise with a light heart, for I am sure that a brilliant and clever fellow like you will turn out a credit to everyone who has had anything to do with him. You must not forget, however, that genius has its special dangers and defects as well as its special facilities and advantages. And the study of Medicine is a field in which the former are often more prominent than the latter. Name and fortune are not to be made with us by a *coup*, as they may be in literature or commerce. I never remember to have heard of anyone in our profession awaking to find himself famous, and if you have ever dreamt of such fortune pray dismiss it from your mind at once. Imagination and invention such as yours may have their full play in Medicine—nowhere more so. Most of our great discoveries—Hunter's, of tying arteries for aneurysm, for instance—have been, so to speak, strokes of genius, but with us such strokes only come to those who have spent long years in observation and thought. They are like the blooming of the aloe. So my advice to you and to every other student of Medicine is, "observe, observe." Do not let yourself be discouraged by the idea that everything that is worth observing has been observed already. A fresh mind coming to a problem may see things that everyone before has missed. I have the less hesitation in impressing this advice upon you, because I know you to be, possibly by original constitution and certainly by your education, more inclined to introspection—which, if it is observation at all, is certainly of the most fruitless kind—than to the observation of external phenomena. Let me ask you, did they ever teach you at school or at college to observe a single thing but the meaning of a Greek particle or the value of a cosine. Your life has hitherto been spent amongst books, the study of which you have been taught to look upon as your end and aim. Henceforth you will have to regard books not as an end but as a means, and often a very inefficient means, towards the study of facts. What you read in them you will in nine cases out of ten be able, sooner or later, to observe and verify for yourself, and let me tell you that a fact personally observed is worth a hundred observed only vicariously. Do you remember our walk along the North Devon Coast last summer? Possibly you forget though how I pointed out to you a hundred little sights and sounds of nature while you were dreaming how to crystallize into a sonnet the vague impressions on you of the many-sounding sea. My boy, vague impressions and the conjury of sonnets and triolets have no place in Medicine, and if you do not throw them aside or grow out of them, no success will come to you in your chosen path. The truest success in Medicine, the admiration of your contemporaries and of posterity, can only be gained by faithful observation of nature, and if you desire those things that is the faculty which you must cultivate and employ. I have spoken plainly, because with your splendid abilities you will be expected to do great things with us, but if you trust only to genius and not to hard and energetic labour, you will find yourself at forty in a Bloomsbury garret, instead of in those Elysian fields of the doctors—Brook Street and Cavendish Square.

From a London Physician to an old Schoolfellow, who has asked advice about his son.

My Dear Friend,—You have put to me the problem of the day, "What to do with our boys?" I doubt not that there are at this moment, thousands of parents throughout the country in the self-same quandary as yourself. I cannot give them all the advice that I am going to give you, because if they all took it, it would defeat its own object, and would turn out very bad advice indeed. But between you and me, as old and dear friends and schoolfellows, I will say this, that for a young man of good abilities, application, and above all good manners, there is no profession which offers so certain a prospect of moderate success as that to which I have the honour of belonging. I do not speak of the so-called higher walks of it, which are indeed overcrowded, though even here for men of talent and tact, sense and sensibility, the outlook is not nearly so hopeless as it has been painted. But what I had more in my mind was the prospect open to the young general practitioner in our large cities and populous country districts. People have not now the same prejudice against young doctors as they used to have—in town the young general practitioners are having it all their own way—and where a man is thoroughly efficient, and a gentleman in every sense of the word, and not only in the conventional sense, he will not be long before making such an income as will allow him to see the piccaninnies growing up around him without despair and bitterness. You know your son better than I do, though I remember him as a singularly bright child, and may distrust his power of succeeding. But if you think well of my advice, you should without long delay let him try his chance for a scholarship at one of our old universities, mine or yours, it matters not which. At either he will learn that *savoir faire* which no one needs more than the doctor, and he will above all have an opportunity of making friends who may prove simply invaluable to him in after life. A colleague of mine used to say, that youth was the time for gaining friends and knowledge, and manhood the time for using them. But without being so cynical I may confess that I can hardly remember a friend made in my youth who, besides the pleasure of his friendship, has not been to me the source of some tangible advantage. Therefore send your son to a university where he will meet with men who are destined for other professions than his own. Make up your mind to let him enter the profession of Medicine by that channel, and your decision on his later course—for I know you hate deciding—may be for a while deferred.

From a Country Practitioner to his Son, who has just entered at a London Hospital.

* * * I hope you are comfortable in your lodgings. I daresay you will be rather lonely at first, after the merry life you have been having down here. There is no place so lonely as a large city when one is without friends. I remember when I went, as a young man, to Paris, to walk the French hospitals, I was for a time abjectly miserable until I found friends. After that the whole aspect of things underwent a change, and I had a time which I look back upon as the happiest of my life. But do not make friendships prematurely. The acquaintances that are most ready to hand are just those which are least desirable, and which you may find it most difficult to shake off if they prove uncongenial. Be sure of this, that the friendships that are best worth making are, like most other good things in this world, only gained through merit and patience. The best of your fellow-students, and especially those of

older standing than yourself, will wait to see what kind of a man you are and how you demean yourself, before proffering you their acquaintanceship. If they see you about with rowdies and idlers, they will conclude that you are a bird of the same feather—a conclusion which I am sure you do not wish them to form—and you will find that you have acquired a reputation that it may take months to break down. Therefore beware of these "old man of the sea" acquaintanceships.

As to your studies, you will get better advice from your lecturers than I can give you, for the whole plan of medical education has undergone a complete change since I was a student. We had to shift for ourselves and to help ourselves much more than the modern medical student. But do not rely too much on your teachers, and do not be satisfied with the minimum that they require of you. That is necessarily regulated according to the average, or even the less than average, mind; and I think I may say, without making you conceited, that you will find your abilities as superior to those of the ordinary run of your fellow-students, as you will find them inferior to those of the few picked men amongst them. After your long vegetation down here you will probably discover that your powers of memory and concentration are out of training, and that prolonged reading is a weariness to the flesh. Do not be disheartened at this, and do not above all things imitate those inexperienced Swiss tourists, who on the day after their arrival start off on expeditions which are only within the powers of trained muscles; otherwise you may find yourself laid up, metaphorically, with blistered feet and aching muscles. Have patience rather; mind and memory will soon get into training if you begin with short spells of study and lengthen them gradually. A few words as to the art of reading. Never read in an easy chair; if you find your thoughts persistently wandering after making honest efforts to chain them to your book, give up reading for the time; after you have finished your chapter or your subject, shut the book and see how much of it you remember, turning again to the book to repair all gaps in your memory. After each lecture read up the subject in your text-book with the help of your notes. Never let your reading be slovenly, with the notion of first getting a general idea, and filling in the details on a second reading. That is a thriftless mode of work. Try also to ask in respect to everything you read *Cui bono?* Remember that whatever you learn has a practical application. The proximate object of course is the satisfaction of your future examiners, but there is a remote object too, and by ferreting this out as well as you can in your present ignorance of later studies, you will increase those links of association which the memory needs, if it is not to be overburdened. Let your memory concern itself with facts, and not words and tables. Each fact that you read is linked to others by innumerable hidden ties, the discovery and appreciation of which make study fruitful and easy. I could find much more to say to you, but this is I think sufficient pabulum for your mind for the present.

From a prosperous young Specialist to his Brother, who desires to follow in his footsteps.

* * * I will say nothing to discourage you. It is fruitless to fight against destiny, when, as usual, it takes the form of inherited warp of nerve-cell. Strange that we should both throw back to the first baronet after two generations of soldiers, barristers, and other idlers. But while I myself say nothing to divert you from your purpose, pray let not my prosperity too much encourage you. Act as far as you can as though I and my doings had no existence. It may seem arrogant in me to warn you not to expect my good fortune, but I will do more, I will counsel and urge you to turn away from it should it offer. Sometimes I can find it in me to envy those of my contemporaries who, as the saying goes, are eating out their hearts waiting for practice that never comes. In my better moments it seems to me that eating out one's heart like that is a hundred times better than eating out one's brains as I am doing. I wonder whether anyone but the successful specialist himself ever realises the utter weariness that he often feels at spending his life in a small and monotonous field, too worn by the dull round of work to have either the time or the energy to wander into that open campaign of pure research, which is so much more varied and pleasant, if so much less remunerative. Some men can do both, but they are blessed with exceptional physique and power of work. I for my part cannot even find the inclination to work out the scientific result of my personal observations. Ten years ago, as you know, I looked forward to a long period of idle time in which I would follow my bent and give myself up to the study of science without being disturbed by the importunities of private patients. But in what I am often tempted to regard as an evil hour I took another path, and ever since have had to neglect that higher calling no less than my own scientific culture. Let this picture, written though it be perhaps in a dark moment, deter you from following that acquisitive bent which is common to all, and stifling that special, rare, and precious bent towards research which I once had, and which I am glad to think is germinating also in you. Mind, all this is no argument against specialism—it only tells against specialism over-driven. And do not think that we specialists are alone, or indeed in chief, to blame. No, it is the public who make specialism and specialists what they are. Do you think it does not gall me when men in our profession write bitter things about specialism? It galls me all the more because I know them to be partly true. But we cannot help ourselves, we are the slaves of the public, and must do their bidding. From such slavery I beg you to keep free.

From a Second-year's Student to his Friend, a Freshman.

I MEANT to have been up in town on the 1st to do the honours of the hospital to you, but a wretched sprained ankle has laid me by the heels, and I shall not be able to put in an appearance for another week. I was going to give you no end of good advice. First-year's men, fresh from the country, as a rule do heaps of silly things, simply because they have no one by their side to say "Don't." They come up brim full of enthusiasm and the best intentions, and put on a pace which it is utterly impossible to keep up. They do everything to excess. They not only read too much, but they eat too much, smoke too much, and some of them drink too much. Before they came up they were probably out from morning to night playing cricket and tennis, and the consequence of the sudden change is, that before a month is over they knock up, with a spotty face, a brain that refuses to work, and a mouth that can neither smoke nor eat. Don't you do any of these stupid things. Mind and get a run for an hour every day, if only to keep in training till the football fairly begins. And don't read too much. You will find that three-quarters of the men who begin with a spurt drop off before a month is over. It is the steady dogged two or three hours a day, week after week, that breaks the back of the first year's subjects.

Don't rush off at once and buy a new set of bones, and a spick and span dissecting box, and a surgical pocket-case, and all the books that the lecturers advise you to read. I can tell you where to pick them up cheap by the time you want them; and besides, I have always found that the men who start by investing in these fineries are the first to get rid of them and the last to use them. Then don't take elaborate notes of the lectures, and waste half your day in copying them out. There are not more than two or three of our men who are worth that amount of trouble. I can't imagine why they make us sit hour after hour in a stuffy lecture-room, when one can read the whole thing through in half the time at home. The use of a lecture, I take it, lies in what a man shows, not in what he says, and if you are scribbling for your life you miss half of it. Then don't waste your time in making pretty diagrams with coloured chalks, as you will find many of your fellow students doing. It is a babyish make-believe of work. A rough ten minutes' drawing will serve your purpose quite as well as an elaborate work of art. I can't think of any more advice at present, for it is not quite in my line, and I daresay you would not take it if I gave it. Remember, if you want to be liked by the men, you must not get set down as being either a baby or a rough.

MISCELLANEOUS INFORMATION.

CHANGES IN THE STAFFS OF THE LONDON HOSPITALS AND SCHOOLS.

St. Bartholomew's Hospital.—Dr. Norman Moore has been appointed to the Assistant Physicianship which had not been filled up at the date of issue of our last Students' Number. Mr. W. Bruce Clark has become one of the Assistant Surgeons in place of the late Mr. James Shuter. Dr. Haig has succeeded Dr. King as Casualty Physician. Dr. Hensley now lectures on Forensic Medicine in place of Dr. Southey.

Charing Cross Hospital.—Sir W. Guyer Hunter has been elected Consulting Physician. There is still a vacancy for an Assistant Physician. Dr. Mott has been appointed lecturer on Physiology in place of Dr. Wolfenden. The office of Demonstrator of Morbid Anatomy is vacant.

St. George's Hospital.—Two of the Consulting Staff have died since last year, Mr. Cæsar Hawkins and Dr. A. W. Barclay. There have been no changes of importance in the school.

Guy's Hospital.—The School and Hospital have lost the invaluable services of Dr. Hilton Fagge. Dr. Pye-Smith has become Physician. In the School, Dr. Pye-Smith lectures on Medicine with Dr. Moxon, in place of Dr. Pavy. Mr. Golding Bird has succeeded Dr. Pye-Smith as lecturer on Physiology, and Dr. Wooldridge takes the class in practical Physiology. Dr. Goodhart lectures on Pathology, in place of the late Dr. Fagge. Mr. Poland has become one of the Demonstrators of Anatomy, and Mr. L. A. Dunn has succeeded him as Surgical Registrar.

King's College Hospital.—There have been no changes of importance.

The London Hospital.—There have been no changes in the Hospital Staff. In the School, Mr. Rivington has succeeded Mr. James Adams as lecturer on Surgery, and teacher of Operative Surgery; Mr. Treves lectures on Anatomy, and Mr. Mansell Moullin teaches Practical Anatomy; Mr. F. J. M. Page takes the class in Chemical Physics.

St. Mary's Hospital.—There have been no changes in the Staff of the Hospital. Dr. Waller has succeeded Mr. Pye as lecturer on Physiology. Dr. Crichton Browne, F.R.S., has been appointed lecturer on Psychological Medicine, and Mr. Silcock has succeeded Mr. Pepper as Medical Tutor.

Middlesex Hospital.—Dr. Edis has become Obstetric Physician in succession to the late Dr. Hall Davis, and Dr. W. A. Duncan has been elected Assistant Obstetric Physician.

St. Thomas's Hospital.—The office of Curator is vacant by the resignation of Mr. Stewart, on his election at the College of Surgeons in succession to Professor Flower. The post has not yet been filled up. Dr. George Gulliver lectures on Comparative Anatomy in place of Mr. Stewart.

University College Hospital.—The office of Surgical Registrar is vacant by the resignation of Mr. Victor Horsley, who has been appointed Professor at the Brown Institute.

Westminster Hospital.—Mr. Boyce Barrow has taken charge of the Aural Department in place of the late Mr. Keene. In the School, Mr. Hebbert has been appointed Demonstrator of Anatomy, and a new chair has been created of Morbid Histology, to which Dr. Heneage Gibbes has been elected.

EDUCATIONAL VACCINATION STATIONS.—In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, the following arrangements are made:—

1. The Vaccination Stations enumerated in the subjoined list are open, under certain specified conditions, for the purpose of teaching and examination.

2. The Public Vaccinators officiating at these stations are authorised to give the required certificates of proficiency in vaccination, to persons whom they have sufficiently instructed therein; and

3. The Public Vaccinators whose names in the subjoined list are printed in italic letters, are also authorised to give such certificates, after satisfactory examination, to persons whom they have not themselves instructed:—

LONDON.—Principal Station—Surrey Chapel, Blackfriars-road: *Dr. Robert Cory*, who attends on Tuesday and Thursday, at 2 p.m. North-west Stations—Marylebone General Dispensary, 77, Welbeck-street: Mr. William A. Sumner, on Tuesday, at 2 p.m.; Hall of the Working Men's Christian Association, Omega-place, Alpha-road: Mr. William A. Sumner, on Wednesday, at 10 a.m. West Station—9, St. George's-road, Pimlico, S.W.: Mr. Edward Lowe Webb, on Thursday, at 10 a.m. East Station—Eastern Dispensary, Leman-street: Mr. Charles T. Blackman, on Wednesday, at 11 a.m. North Station — Tottenham-court Chapel, Tottenham-court-road: Mr. William Edwin Grindley Pearse, on Monday and Wednesday, at 1 p.m. South-west Station—2, Regent-place, Horseferry-road: Mr. William Edwin Grindley Pearse, on Tuesday, at 2 p.m. Strand Station—14, Russell-street, Covent-garden: Mr. Robert William Dunn, on Thursday, at 11 a.m. South-east Station—Vestry Hall, St. John's, Horselydown: Mr. John Gittins, on Monday, at 2 p.m. St. Thomas's Hospital: Dr. Robert Cory, on Wednesday, at 11.30 a.m.

BIRMINGHAM.—St. Jude's School-room, Hill-street, near Small-bank-street, on Monday, at 11 a.m.; the Assembly Rooms, 103, Constitution-hill, opposite Bond-street, on Tuesday, at 11 a.m.; the Wesleyan Methodist Infant School-room, Monument-road, on Wednesday, at 11 a.m.; the Wesleyan School-room, Peel-street, Winson-green-road, on Wednesday, at 2 p.m.; and "The British Workman" Reading Rooms, Sherborne-street, near Grosvenor-street, on Thursday, at 11 a.m.: *Dr. Edmund Robinson.*

BRISTOL.—The Public Vacciuation Station, Peter-street; *Mr. Henry Lawrence*, on Wednesday, at 10 a.m.

EXETER.—The Dispensary, Castle-street: *Mr. William A. Budd*, on Thursday, at 3 p.m.

LEEDS.—Heed-street: *Mr. Frederick Holmes*, on Tuesday, at 2.30 p.m.

LIVERPOOL.—St. Mary's School-room, Edgehill, West Derby, *Mr. Roger Parker*, on Thursday, at 2.30 p.m.

MANCHESTER.—72, Rochdale-road: *Mr. Ellis Southern Guest*, on Monday, at 2 p.m.

NEWCASTLE-UPON-TYNE.—The Central Vaccination Station, 21, Nun-street: *Mr. John Hawthorn*, on Wednesday, at 3 p.m.

SHEFFIELD.—The Public Vaccination Station, Townhead-street: *Mr. William Skinner*, on Tuesday, at 3 p.m.

EDINBURGH.—Royal Dispensary: *Dr. William Husband*, on Wednesday and Saturday, at 12. The New Town Dispensary: Dr. James O. Affleck, on Wednesday and Saturday, at 1.

GLASGOW.—The Hall of the Faculty of Physicians and Surgeons: *Dr. Hugh Thomson*, on Monday, at 12. The Royal Infirmary: Dr. Robert Dunlop Tannahill, on Monday and Thursday, at 12. The Western Infirmary: Dr. David Caldwell McVail, on Monday, at 1 p.m.

Candidates for the certificate by examination are recommended to communicate some days beforehand with the Examiner at whose station they propose to attend.

The Apothecaries' Society of London.—Prizes are annually offered by the Society for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most in the examination; and a silver medal and a book or books to the candidate who does so in the next degree. Also two prizes for proficiency in the knowledge of Botany, consisting of a gold medal to the candidate who distinguishes himself the most in the examination; and a silver medal and a book or books to the candidate who does so in the next degree. *Medical and Surgical Scholarships.*—Each Scholarship is of the annual value of 100*l.*, and is tenable for two years on certain conditions. It is open to all students of the medical profession whose standing at the time of the examination is not less than four and not more than five years from the date of their registration, and who have obtained and possess an English medical qualification.

Pharmaceutical Society of Great Britain: School of Pharmacy.—The session will commence on October 1st, 1884, and extend to July 31st, 1885. Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood and Mr. Dunstan, on Monday, Tuesday, and Wednesday mornings, at 9 o'clock, commencing on Wednesday, October 1st. There will be two coursss of sixty lectures during the session—the course which commences in October and ends in February being repeated, with additions, in the following five months. Each course will be complete in itself. Additional lectures in Physics and Chemistry will also be delivered by Mr. Dunstan during the course. Lectures on Botany and Materia Medica, by Professor Bentley, on Thursday, Friday, and Saturday mornings, at 9 o'clock, commencing Friday, October 3rd. During the session, two courses of lectures will be delivered, each consisting of 60 lectures. The first course, extending from October to the end of February, will comprise Botany and Materia Medica with especial reference to Structural Botany, and the use of the microscope in distinguishing the various drugs; and the second course, which commences in March and extends to the end of July, will also comprise Botany and Materia Medica, with especial reference to Systematic and Practical Botany. Each course will be complete in itself, although each will have a definite object in view. The portion of the second course on Systematic and Practical Botany, consisting of 20 lectures, commences in May and ends in July. Separate entries may be made for this portion. The laboratories for the study of Practical Chemistry will be opened on Wednesday, October 1st, at 10 a.m., under the direction of Professor Attfield, assisted by the Demonstrator of Practical Chemistry, Mr. F. W. Short, and an Assistant-Demonstrator, Mr. E. J. Eastes. Pupils can enter for any period at any date. A complete course of instruction, including the higher branches of Quantitative Analysis, occupies ten full months, and dates from the day of entry to that day twelvemonth. The laboratories are open daily. Vacation months, August and September. Prospectuses and further particulars may be had of the professors or their assistants, 17, Bloomsbury Square, W.C.

The London School of Medicine for Women.—Three of the licensing bodies now admit women for their diplomas and degrees, viz., the University of London, the Royal University of Ireland, and the King and Queen's College of Physicians in Ireland, All the courses of lectures required by these bodies are given at 30, Henrietta Street, Brunswick Square, W.C., the sessions corresponding with those of other medical schools. Clinical instruction and lectures are given at the Royal Free Hospital, which contains 150 beds; attendance on confinements is obtained in connection with one of the lying-in hospitals, and practical experience of fever cases, a certificate of which is required by the Irish College of Physicians, may be acquired at the London Fever Hospital. The composition fee for the ordinary curriculum and clinical instruction at the Royal Free Hospital amounts to 125*l.* An entrance scholarship of 30*l.* is offered for competition at the end of September in each year.

Mr. Thomas Cooke's School of Anatomy, Physiology, and Surgery.—This school is intended to meet the requirements of two distinct classes of students—*i.e.*, (1) advanced students and qualified practitioners, who may wish either to extend their knowledge of the foregoing subjects, or to recall to mind what they once knew and have since forgotten. (2) Beginners entering upon their medical studies by a short term of apprenticeship. For the former, rapid advanced classes, complete in three months, but still thoroughly practical, are provided; and for the latter, when required, more elementary classes of six months' duration. For prospectus of particulars and terms, apply to Mr. Thomas Cooke's private address, 16, Woburn Place, Russell Square, W.

Brompton Consumption Hospital.—The clinical practice of this Hospital, which has over 300 beds, is open to students of Medicine and practitioners. Fee for three months, 3*l.* 3*s.*; six months, 5*l.* 5*s.*; perpetual, 10*l.* 10*s.* A course of clinical instruction in Auscultation will be given by the medical officers. Certificates of attendance on the medical practice of this Hospital are recognised by the University of London, the Apothecaries' Society, and by the Army, Navy, and Indian Boards.

London Fever Hospital, Islington.—This Hospital is recognised by the Royal University of Ireland, and certificates of attendance on fever cases given by the Resident Medical Officer are accepted. These certificates are also accepted by the King and Queen's College of Physicians, Ireland.

Special Hospitals in London.—Besides those special hospitals already mentioned, the practice of the following may also be attended:—The Hospital for Sick Children, Great Ormond Street, W.C. (9 a.m. every day). The Evelina and East London Hospitals for Children. The Hospital for Diseases of the Throat, Golden Square, W. The Central Throat and Ear Hospital, Gray's Inn Lane, W.C. The Hospital for Women (clinical lectures during the Session). St. Peter's Hospital for Stone. St. Luke's Hospital for the Insane (two Clinical Assistants appointed half-yearly). The National Hospital for the Paralysed and Epileptic, &c.

Bath Royal United Hospital.—The Hospital contains 120 beds, is recognised by the General Medical Council, and licensed for dissection. It has a good library, and an excellent museum, containing a large number of interesting specimens both in Pathology and Comparative Anatomy. A year spent at the Hospital counts as one out of the four required before qualifying for practice. The number of patients admitted during the year was 1,053; out-patients, 8,914. Fees for attending the Hospital practice—Six months, 5*l.* 5*s.*; twelve months, 10*l.* 10*s.* Instruction in Pharmacy, 5*l.* 5*s.* Pupils entering in October can, if desired, be instructed in the subjects required for the First Professional Examination of the Royal College of Physicians, which can be passed during the year spent at the Hospital. The subjects are—Chemistry and Chemical Physics, Materia Medica and Pharmacy, Medical Botany, and Osteology. For further particulars, apply to the Registrar and Curator.

Norfolk and Norwich Hospital.—This Hospital contains 150 beds. Resident pupils are taken upon application to the House Surgeon, Mr. D. D. Day.

The Examination for Certificates in Sanitary Science by the University of Cambridge will begin on Tuesday, October 7th. The names of candidates, who must be on the *Medical Register* of the United Kingdom, should be sent to Dr. Anniugson, Cambridge, on or before September 28th.

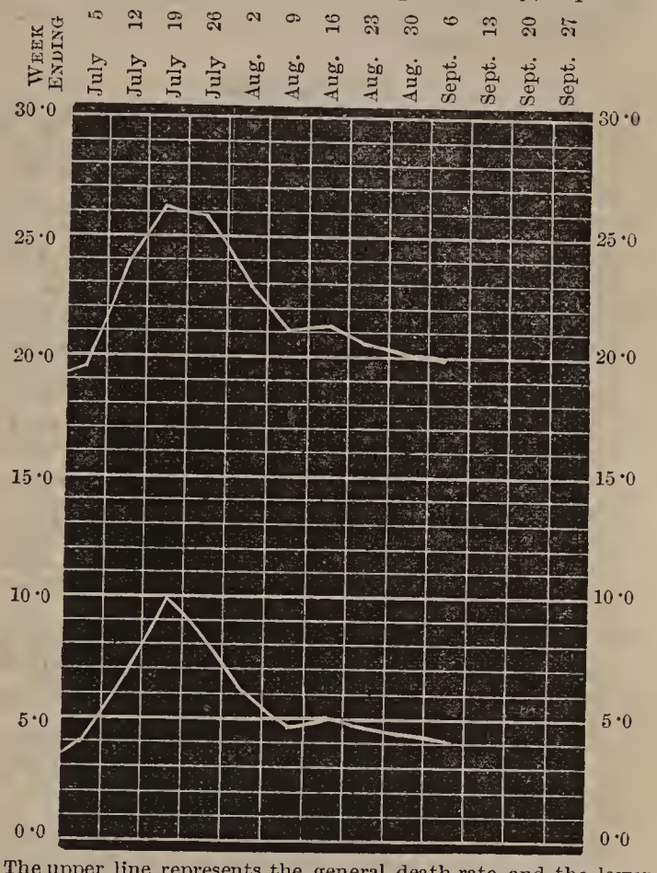
Army Medical Department.—Deputy Surgeon-General Thomas John Murphy, M.D., is granted retired pay, with the honorary rank of Surgeon-General; Brigade-Surgeon FitzGerald Edward Scanlan is granted retired pay, with the honorary rank of Deputy Surgeon-General.

EDITORIAL NOTES.

The serious character of the outbreak of cholera at Naples has shown itself in the most unmistakable manner in the rapidly-increasing daily death-roll in that city. In a few days after its first appearance the daily number of fatal cases had reached 100, and for many days now it has very considerably exceeded that figure, the latest intelligence at our disposal putting the figure at 493. During the past few days there would appear to have been many most painful exhibitions of superstitious beliefs amongst the poorer classes, to which, together with the setting at defiance of every known sanitary law, the virulence of the present epidemic may be attributed. If, however, the authorities can only profit by their experience and learn to appreciate the merits of cleanliness as compared with quarantine, the lives that are now being sacrificed in so wholesale a manner will not have been lost in vain. There has been no serious spread of the cholera in Spain since our last note on the subject, though a few cases are still reported from Alicante. The French do not seem to have quite shaken off the cholera yet, though the daily number of victims is now comparatively small.

In spite of the inclement weather last Saturday, the collection made on that day on behalf of the Hospitals has exceeded that of previous years, being already more than 2,300*l.* the amount taken last year, and there are yet some outlying districts to be accounted for. The amount obtained in the streets, however, forms only a small portion of the total Hospital Saturday Fund, the main bulk being collected in the workshops and amongst the *employés* of large business houses. This year no less than 20,000 establishments have received its collecting sheets, so that it may be confidently expected that, when these have all been returned, the sum total collected will be very considerably in excess of anything collected in this way in former years. The fund is supposed to be subscribed by the working classes, and it is evident that the main bulk of it is so collected, but the amount taken in the streets cannot of course be said to be given by any one class in particular. This being so, and the only object of the street collection being to obtain money, it seems a great pity that the suggestion, which has often been made, that the collection should be made in the season, should not be adopted.

As will be seen by a reference to our chart, the curve of the death-rate is still continuing its downward career, though the fall in each instance is but slight since last week. A considerable fall is yet necessary before the end of this quarter, if it is not to have a black mark against it as owning a death-rate much above that of the corresponding quarter of the last three years. The deaths from zymotic diseases numbered 314 during the week, just 10 per cent. above the corrected average. Of these, diphtheria accounts for 31, "and *exceeded those returned in any week on record*" (the *italics* are our own), and whooping cough for 36, as against 16 and 4 from these diseases in the previous week. Surely here is some work for the Local Government Board to do. If there is one disease more than another which is amenable to sanitation and hygiene it is diphtheria. The 31 deaths already mentioned do not, in all probability, represent



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the first ten weeks of the current quarter.

the total mortality from this eminently preventable disease, for we notice that five children under the age of five years are said to have succumbed to croup, and we shall probably not be far wrong if we assume that three out of those five died of diphtheria. Diphtheria used to be reckoned amongst the epidemic diseases; it has, however, for a long time past earned the right to be named amongst the endemic diseases of London. When are we going to banish it from our doors?

MEDICAL NEWS.

APPOINTMENTS.

Beresford, Charles William, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Markyate Street District, *vice* Dr. S. W. Mackey, resigned.

Campbell, Jas. J., M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Corner, M. C., L.S.A. Lond.—Resident Medical Officer to the Tower Hamlets Dispensary, *vice* Samuel E. Pritchard, L.R.C.P., M.R.C.S., deceased.

Dalzeil, J. Kennedy, M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Howard, Thomas, M.B., C.M.—House Physician to the Royal Infirmary, Glasgow.

Hunter, R. R., M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Marshall, William, M.B., C.M.—House Physician to the Royal Infirmary, Glagow.

Mason, Henry, M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Muirhead, Islay Burns, M.B. and C.M. Glas.—Medical Officer to the Second Aylesford District, Malling Union, *vice* Mr. Thomas Holyoake, resigned.

Peacock, Alex., M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Russell, Frank, M.B., C.M.—House Physician to the Royal Infirmary, Glasgow.

Scott, Robert, M.B., C.M.—House Surgeon to the Royal Infirmary, Glasgow.

Smith, William Harvey, M.B. Durham, and M.R.C.S. Eng.—Medical Officer to the Workhouse and Meriden District, of the Meriden Union, *vice* M. W. C. Partridge, deceased.

Stark, J. Boyd, M.B., C.M.—House Physician to the Royal Infirmary, Glasgow.

White, Barrington Syer, M.R.C.S. Eng., L.M. and L.S.A. Lond.—Medical Officer to the Seventh District, Tonbridge Union, *vice* Mr. W. Fear, resigned.

VACANCIES.

County Asylum, Lancaster.—Assistant Medical Officer. Salary £100 per annum, increasing £10 annually, with board, &c. Candidates must be duly qualified and registered, unmarried and under 30 years of age. Applications with testimonials to be sent to the Medical Superintendent, before September 27th.

Gloucester County Asylum.—Assistant Medical Officer. Salary, 100 guineas per annum, with board, lodging, and washing. Candidates must be duly qualified, registered, unmarried, and not over 30 years of age. Applications and testimonials to be sent to the Medical Superintendent, on or before September 15th.

Hulme Dispensary, Manchester.—House Surgeon. Salary, £130 per annum, with furnished apartments and attendance at Dispensary. Candidates must possess registered qualifications in Medicine and Surgery. Applications with testimonials to be sent to the Honorary Secretary, Medical Committee, at the Dispensary, on or before September 17th.

Saint George in the East Parish.—Medical Officer to the South District, *vice* Dr. S. E. Pritchard, deceased. Salary, £250 per annum.

St. Peter's Hospital for Stone and Urinary Diseases, etc., Henrietta Street, Covent Garden.—House Surgeon. The Appointment will be for six months. Honorarium, 25 guineas, with board, lodging, and washing. Candidates must be M.R.C.S., and have held the position of House Surgeon at a Public Institution. Applications with testimonials to be sent to the Secretary, on or before September 30th.

Swansea Hospital.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28.

The Hospital for Women, Soho Square, London, W.—House Physician. (*For particulars see Advertisement.*)

University College, London.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

West Bromwich District Hospital.—House Surgeon. Salary, £80 per annum, with board, residence, and washing. Candidates must be surgically qualified, registered, and unmarried. Applications, stating age, &c., with not more than three recent testimonials, and accompanied by candidates' degree or diploma, and certificate of registration, to be sent to the Honorary Secretary W. Bache, Esq., Churchill House, West Bromwich, on or before September 20th.

DEATHS.

Evans, E., M.R.C.S., at 72, Clapham Road, S.W., on September 1st, in his 97th year.

King, D. A., M.B., M.R.C.P., late of 26, Harley Street, at Torquay, on September 4th, in his 28th year.

NOTES, QUERIES, AND REPLIES.

BRITISH MEDICAL BENEVOLENT FUND.

[TO THE EDITOR OF THE MEDICAL TIMES.]

Sir,—The late Sir Erasmus Wilson has munificently left the British Medical Benevolent Fund £5,000, but as Lady Wilson takes a life interest in the whole of his property, this legacy is, of course, not payable until after her death.

I take this opportunity of bringing before the profession our urgent need of funds, for we are totally unable at the present time to help many of the deserving cases that come before us.

Subscriptions may be paid to the Treasurer, Dr. Broadbent, 34, Seymour Street, Portman Square, or to

Your obedient servant,
George P. Field,
Hon. Financial Secretary.

31, *Lower Seymour Street, Portman Square,*
September 10th, 1884.

A Constant Reader.—The questions you put are points for a legal and not a medical authority.

A Guardian, Plymouth.—You will obtain the desired information in the present number. We never recommend particular hospitals

A Provincial Teacher.—The next Examinations at the College o- Surgeons will be in October. The dates will be duly advertised in the *Medical Times.*

Bibliopole.—The Library and Museum of the Royal College of Sur geons, both of which are at present closed, will be re-opened on Wednesday, October 1st.

Dr. Campbell.—Registration and Preliminary Examinations have been discontinued at the Royal College of Surgeons. Write to the Registrar of the General Medical Council, Oxford Street, who will give you information on the subject.

E. Williams.—Best made by warming together and well-mixing equal parts of olive oil and lead plaister.

J. S. P.—The article has already appeared.

CLINICAL REMARKS ON PERITONITIS.[1]

II.—PERITONITIS OF THE LOWER ABDOMEN—PERITYPHLITIS.

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

(*Continued from page* 6.)

I HAVE in the preceding observations treated first of peritonitis having a pelvic origin, because that variety is above all others important and instructive, not only in respect of its frequent occurrence in the female after parturition, but in respect of the lessons which it reads to us about peritonæal affections in general. You have learned accordingly, from the case of M. T., that even the most general, diffuse, and rapidly fatal form of peritonitis may have its origin in a disease set up in the pelvis perhaps years before, local, circumscribed by adhesions, and not even at the *post-mortem* examination revealing distinctly the mode of its extension from the organs first affected to the general peritonæal cavity. This form of fatal accident is much more likely to escape a thorough diagnosis, or to be erroneously judged, during life, in a virgin than in a married woman, because the former is more ignorant of the symptoms of intra-pelvic disease, and more likely to be reticent about them than the latter. But the interesting case of Mrs. McM. further discloses the fact that a married woman, having ample experience of the usual incidents of pregnancy and child-bearing, and with no possible motive for undue reticence, intelligent, moreover, and apparently giving a clear account of her own case, may suffer for several weeks from rather acute and widely diffused peritonitis without once adverting to its probably pelvic origin, although the uterus is then found firmly fixed in the pelvis by some form of morbid material impacted in Douglas's space; perhaps a hæmatocele, or other form of disease that might equally have happened in the case of an unmarried woman. Taken in connection with the case of M. T., therefore, this experience is surely very valuable and remarkable, and what it teaches us is, that in no case of peritonitis in the female, if otherwise unexplained, are we justified in omitting to explore this possible source of its origin; no, not even if it should appear that some other disease, say of kidney, liver, or lung, remote from the pelvis, has actually been present; for even then we may be entirely misled as to the cause of the peritonitis. I remember a case long ago which was under the care of more than one experienced gynæcologist, and as the parties are now all dead, there can be no injury done to any one by referring to it for your instruction. The patient, a lady in a very good social position, was supposed to have had pneumonia, and died, according to repute, of the pul-

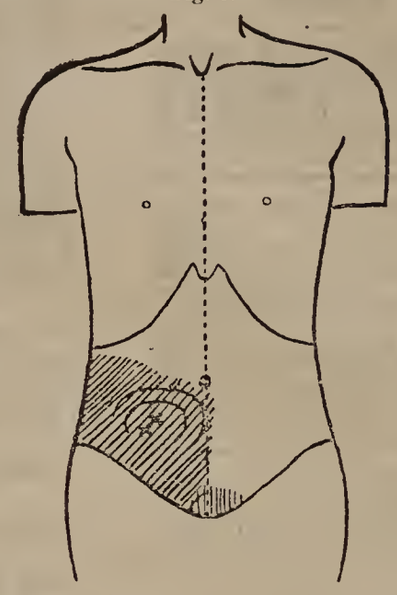
[1] Summer Clinical Course in the Western Infirmary, Glasgow, May to July, 1884.

monary affection ; but she also had what proved to be a tubercular and adhesive peritonitis. At the *post-mortem* examination the latter disease attracted fully more attention than that of the lung, inasmuch as it had been very partially, if at all, recognised during life. The peritonitis was general and diffuse, although perhaps with more matting of the intestines in the lower part of the abdomen than elsewhere. Under these circumstances I thought it worth while to pass my finger into the vagina, and felt something hard and abnormal, which presently proved to be a stem pessary, completely imbedded in the vaginal and uterine tissues, and encrusted all over with metallic rust and salts, thus showing that its very existence had been forgotten, probably for years, both by the patient herself, and by one of the gentlemen then present, who had, in the first instance, directed the wearing of it ! The stem of the pessary had nearly perforated the fundus of the womb, and the whole aspect of the parts made it only too probable that the long-continued pelvic irritation, proceeding from this very tangible cause, had broken up the general health of this woman, and had led both to the peritonæal and the pulmonary disease.[2] This, and the cases of M. T., and of Mrs. McM., further show, I think, that you cannot absolutely infer from the wide diffusion and absence of localisation of the physical signs of peritonitis, that it is *not*, in a particular case under observation, of pelvic origin ; although, as other and more frequent instances show, there is usually a distinct enough suggestion derived from the physical signs in the abdomen, of the pelvic origin of pelvic peritonitis ; the abdominal changes being more or less similar to those shown in our second figure. These things being premised, we may now proceed to study some other kinds of peritonæal inflammation in the light that is thrown upon them by the preceding remarks.

The experience of the last few days has brought under our notice, in the male ward, a case that may very well become the text for a few clinical observations in this connection. Pelvic peritonitis, or even peritonitis originating in connection with disease of the pelvic organs in the male, is rare ; arising, as a rule, only from deep and widely diffused septic inflammations in the neighbourhood of the genito-urinary tract ; or from cancerous or other ulcerations in the rectum or bladder, causing widespread destruction of tissue. But peritonitis of the lower abdomen in the male is by no means rare ; and it arises under conditions which cannot always be exactly defined by clinical observation, but which connect it, more or less closely, with one or other iliac fossa ; more frequently with the right than the left. In the present instance it is the right iliac region which is chiefly affected ; and on this account I have provisionally called the case one of *perityphlitis* ; although it must be admitted at once that the evidence of direct connection of the lesion with the *caput cæcum*, which would be necessary to entitle the disease very strictly to this denomination, is not conclusive. In this respect, however, the case resembles many others which you must expect to meet with in practice.

H. F., aged 16, a clerk, was admitted to the Western Infirmary on June 30th, 1884, with symptoms very evidently of an acute abdominal affection, originating about three weeks before admission. He began to suffer from pain just before retiring to bed ; which became much worse during the night, and soon afterwards vomiting set in, and continued pretty severe and constant during the earlier part of his illness, being scarcely, if at all, relieved at the time of his admission. Constipation had existed, more or less, throughout, but moderate in degree, and always easily relieved by mild laxative medicine, which, when administered to him on several occasions before admission, acted without any perceptible increase of pain. His statements as to the original seat of the pain correspond, in general, with the area indicated by the shading in this diagram (Fig. 3), which defines the full extent of the relatively

Fig. 3.



dull percussion, and also of a certain increased resistance and sense of something abnormal to palpation, as mapped out in your presence on 4th July. It seems probable, indeed, that the pain and tenderness may have been greater, if anything, within the area marked out by the ‡ than even in the iliac fossa, inasmuch as we found a rather more distinctly definable prominence there than elsewhere ; and there, also, two leeches had been applied before admission, but not until June 25th. The very detailed record we have of the case permits me to state, in brief, that no trace of any blow, hurt, or strain, and no history of any chronic disease, or of any ulceration of the bowels, in particular, no suspicion of enteric fever, or of tubercular disease, could be made out as having immediately preceded the acute symptoms just described ; nor was the patient aware of having swallowed anything likely to prove obstructive or indigestible. There was a degree of slowness in micturition, but otherwise no evidence of implication of the pelvis or pelvic organs in the inflammatory exudation, which, on the whole, seemed to have attained its height either before, or about the period of, admission ; although the vomiting, even several days thereafter, could scarcely be said to have at all yielded to the treatment employed. The persistence of this one symptom, however, and of moderate constipation along with it, was less alarming than it might otherwise have been, because the vomited matters were always merely watery and bilious, and the stools, whether spontaneously voided, or procured by injections (for we purposely avoided giving laxatives by the mouth) were perfectly devoid of any abnormal character. It was clear, therefore, that, whatever the local cause of the peritonitis, it was not of the nature of a mechanical obstruction or internal strangulation. I should add that there had been no rigors at any time, either before or after admission, and that the temperatures, just reaching 101° Fahr. on July 5th, rapidly subsided, and became normal, or even subnormal; the pulse, however, keeping up a rate of 112–16, even after the subsidence of the temperatures. It was reasonable to infer from these facts the absence of any considerable deep suppuration, or source of septic infection. As re-

[2] I had a drawing made of the more obvious facts at the time, and perhaps it may be still in some one's gynæcological collection ; for I have it not, having parted with it to the eminent gynæcologist here referred to.

gards this last point, however, I told you that my mind was by no means quite at ease; for although the tongue was evidently cleaning, there was a peculiar odour of the breath, almost indescribable, but still suggestive of possible blood-poisoning; and even while the local signs and the fever were evidently yielding, the emaciation and the vomiting appeared to me rather worse than at first, on July 11th, after twelve days of careful watching and treatment, both local and general.

These slight presentiments of evil were more than verified on July 15th. It was then noted that "notwithstanding the normal and subnormal temperatures from July 6th onwards, and the absence of any new physical signs, vomiting has been persistent, and he has been quite unable to take nourishment, emaciation also making rapid progress, so much so as to give rise to the *facies Hippocratica* in a considerable degree. The bowels, so far from being confined, have been for the last three days very loose, with watery evacuations. Thirst considerable; pulse quite regular, not very small, 120 or more. Tongue, with the exception of a few aphthous patches, is perfectly clean. There is just a possible suggestion of superficial fluctuation over what was the most prominent part of the swelling, but it is not so well-defined as to lead to any practical conclusion." From this time it was evident to me that this man was dying, and he succumbed, in fact, within twenty-four hours from the date of this report, with vomiting and purging continued up to the last, in spite of all the usual remedies diligently employed. A *post-mortem* examination was refused, to our great disappointment.

Now here is a case which is incomplete, pathologically speaking, because we are necessarily debarred from knowing exactly what was the state of the peritonæum and the viscera affected; and yet it will stand for a type of not a few others, and all the more so on this account. For it is simply a matter of fact that cases of this kind are not uncommon, and that the majority, I think the great majority, of them end not, as in this case, fatally, but in recovery. When they end in recovery we are, of course, often in the same difficulty as in this case, of exactly defining the pathological conditious under which the lesion has arisen. From my previous experience I do not hesitate to say that I had good hopes (although with misgivings freely expressed) of the recovery of this man up to a fortnight after his admission. But when the case was obviously tending to the worse, and especially when diarrhœa set in, and the vomiting persisted with a rising rate of pulse-frequency (though with a falling or normal temperature) and a haggard expression of countenance, I knew that the end could be not far off; and yet the man was not dying strictly of the peritonitis, nor of any obvious extension of the local lesion, but of something else. I believe it was septic poisoning; but, of course, I cannot prove this. And, speculating as to the probable cause of the septic poisoning, I believe there was ulceration somewhere of, or into, the intestinal canal, and that the peritonitis was, accordingly, a secondary phenomenon in this case, just as it is in the cases of pelvic origin to which we have already adverted.

When we turn now to the records of other fatal cases for instruction, we are obliged to go outside my own personal experience, so far as the Western Infirmary is concerned; for, although during the ten years it has been open I have had a number of cases more or less resembling this one, and yet ending in recovery, this is the only fatal case of perityphlitis, or of anything resembling it, that I have had during the above period.[3] There have been, however, four cases recorded in Dr. Coats's Pathological Register, of which two were specimens sent in from without, and derived from private practice. There remain only two cases, therefore, as representing the mortality of this hospital of more than 300 beds, from this kind of localised peritonitis, in ten years; of course there may have been one or two others not submitted to *post-mortem* examination. But taking the whole of these four recorded cases as the basis of our instruction, I find that in three of them there was ulceration of the vermiform appendix of the cæcum, and in each one of these three there was a small concretion of impacted fæcal matter at the distal end, which in one case was partially separated by ulceration from the main body of the appendix. In this case (No. 920) there were adhesions, with thick creamy pus confined in them, involving so many coils of intestines as to form almost a general peritonitis, but with much greater firmness of adhesion in the pelvis and right iliac regions than elsewhere. The whole duration of the illness had been six weeks; and the symptoms, speaking generally, were very like those of our patient as just described. In another case (No. 329) there was also general peritonitis; the intestines being glued together with soft lymph, especially in the lower part; but the source of the whole inflammation was a concretion the size of a date-stone, composed of impacted fæcal matter, and of the consistence of firm clay, at the distal end of the appendix vermiformis. In the third case (No. 415) there was a somewhat fungating ulcer of the appendix, with a concretion the size of an orange-pip, the appendix being (as in the last case) doubled and curved round upon itself and adherent to the cæcum; and from this a large collection of matter extended as far as the spleen. The abscess, however, had been circumscribed, and instead of proving fatal through general acute peritonitis, the pus had made its way back into the cæcum by several large abnormal openings clearly from without inwards, and with considerable sloughing of the wall of the bowel. In the fourth case (No. 85), in which alone there was no indication of disease originating from the appendix vermiformis, there was a large sac, communicating with the cæcum, and lying posterior to it; also attached to the pelvic organs. The exact connections of this sac were difficult to make out; but the ovaries (and I presume also the uterus) were found to be intact.

These four cases exemplify very fairly the general experience of pathological authorities, showing that in a very considerable proportion of *fatal* cases of inflammatory lesions in the ilio-cæcal region the *processus vermiformis* is in some way or other the source of the inflammation. In a minority there is inflammation of the cellular tissue lying chiefly behind the cæcum and ascending colon; and in such cases the peritonæum may escape implication, the abscess opening directly into the cæcum. And as in the case of the uterine organs the names *perimetritis* and *parametritis* have been devised to indicate the two modes of spreading of the inflammatory action referred to, so here the words *perityphlitis* and *paratyphlitis* have been employed; the former, however, embracing by far the greater number of cases, and being accordingly much the more familiar term in works on the subject. There is, moreover, a certain number of cases in which, though the inflammatory processes extend to the neighbourhood of the cæcum, they do not originate there; as where a pelvic abscess (parametritis) burrows upwards along the sheath of the psoas and iliacus muscles, or where a spinal or perinephric abscess burrows downwards along the same sheath, and may end in forming a communication with the bowel, or by opening in the groin. In these cases the peritonæum usually remains exempt.

Now, in the cases which recover (and these, as I have said, are the large majority) it is often not possible to make an exact diagnosis of the seat of the primary

[3] One other fatal case occurred in private practice. I was in attendance, along with Dr. Fergus, on a well-known shipbuilder, a powerful and very healthy man, who had never known serious illness before, but who died in a few weeks from gangrenous perityphlitis, in the early part of the present year.

lesion, and therefore it is vain to attempt to classify them as above ; but in many or most of them the local peritonitis, extending from the right iliac fossa upwards and inwards, is the most prominent fact, and the name *perityphlitis* is applied without a too curious inquiry into the unknown origin of the lesion. The evidences of the inflammation are the pain, superficial or deep ; tenderness on pressure, increased resistance, swelling, and dulness on percussion in the right iliac fossa ; fever, often with repeated shiverings and usually of a remittent type, which may go on, in protracted cases, into a kind of hectic ; the bowels being more often than not constipated, but occasionally with intervals of diarrhœa. Vomiting is by no means a constant feature of such cases, but is sometimes pretty obstinate. Indeed, I have known the vomiting and constipation together such as to raise serious questions as to the existence of a mechanical obstruction or invagination of the bowel ; but usually it is not so. In well marked cases, the dense semi-solid feeling of impaction extends quite down to the pelvis, in others towards the middle line and sometimes even above the umbilicus ; and, in the female sex, it may be only after careful examination of the pelvic organs that such cases can be distinguished from peritonitis of pelvic origin. Occasionally, and especially when it is inexpedient to make such examination owing to the patient being unmarried, or to the rapid recovery, it remains a doubtful question to the last. I have seen several such cases in female children who all made good recoveries ; and although these cases passed for perityphlitis, I am by no means sure of the pathology of them even now.

The most important clinical fact, however, to keep in view in dealing with such cases, is that a large proportion of them do, in fact, recover more or less completely, and after a longer or shorter period of careful management. This favourable prognosis is not commonly set forth, at all events so as to have impressed my own mind, in the various monographs on typhlitis and perityphlitis ; perhaps owing to the fatal cases, and those submitted to *post-mortem* examination, being chiefly accumulated in medical literature, and thus becoming unduly prominent. In one very admirable memoir, however, I find the view now presented fully more strongly asserted than I should have been disposed to put it, even apart from the evidence in the cases above noticed. "I believe," writes the late Dr. Hilton Fagge, "that even when acute peritonitis is set up by ulceration of the cæcal appendix, the disease, if properly treated, is infinitely less dangerous than is supposed. I have never myself seen a case of this kind terminate in death when its nature was correctly diagnosed, and when no purgatives nor enemata were allowed to be given. Nor of late years have any fatal cases occurred in the hospital (Guy's) except a few cases in which death occurred very shortly after admission. I have, therefore, been accustomed to give a favourable, though a guarded, prognosis in cases of typhlitis, even when symptoms of diffused peritonitis are present. It may, of course, be said that the very fact that one can make an exact diagnosis proves that the disease is not running on to a fatal termination within the first few hours, and that the signs of the general inflammation do not preponderate very greatly over those of the local mischief, and I am ready to admit that there may be cases of sloughing of the appendix which are necessarily fatal. But, as I have shown, the differences in cases of typhlitis appear to be differences of degree, and not at all of kind ; and I believe I am justified in saying that when this disease is skilfully treated it scarcely ever terminates otherwise than in the recovery of the patient."[4]

Dr. Fagge further argues that there is no good reason to suppose (as has been supposed) that such cases, when they end in recovery, "differ essentially from cases of perforation of the appendix," which he regards as "really always the starting-point of the inflammation" (p. 214). He alludes to three cases in which it was pathologically determined that perforation was the cause of an attack which had virtually ended in recovery, when either a new attack of perityphlitis, or an intercurrent disease, attacked and carried off the patient. The most important of these cases is the following :—"A patient suffering from chronic pleurisy was attacked with pain in the right iliac fossa and the other symptoms which I have just mentioned ; a firm tumour, dull on percussion, could be felt in the right iliac fossa. Under careful management the abdominal disease subsided, but pneumothorax occurred, and of this he died a few days afterwards. The cæcum was closely adherent, a small collection of purulent matter surrounded the vermiform appendix. This was perforated at its extremity, and outside it lay a small mass of hardened fæces."

I have already conceded that it is often impossible, clinically (in cases which end in recovery), to be sure of the exact seat and nature of the original lesion ; and to this extent I am disposed to think that the weighty and striking sentences above quoted from a great master of clinical and pathological investigation recently removed from us, may require some qualification. But the words of a man like Hilton Fagge must be taken as implying not only strong conviction, but conviction founded on an amount of closely observed fact which is perhaps not fully brought out in the details of the memoir itself. There are many circumstances tending to the belief that peritonitis even from perforation of the small intestine is not so absolutely desperate a case as it has been frequently represented ; and we have already seen that peritonitis of considerable severity and diffusion, arising from pelvic causes, admits of resolution, in many instances, with a completeness and rapidity that it is not easy, pathologically, to explain. The vermiform appendix is placed so as to offer the most favourable conditions possible for the isolation and limitation of the results of an ulcerative lesion, or even of a perforation ; but it is not necessary to suppose that in most, or all, of these cases actual perforation occurs, if we only accept the idea that an ulcerative or other lesion *tending* to perforation is usually forestalled, as it were, by reparative processes which may often tend to prevent the threatened fatal rupture. In such processes adhesive peritonitis, I believe, plays a principal part, and it is only a question of degree whether the extension and the character of the peritonitis are such as accurately to fulfil this, its conservative work in the organism, or such as to become more or less of a disease and a danger *per se*. At all events, there seems no escape from the conclusion that in some cases, at least (such as the one above quoted), even perforation of the vermiform appendix may be followed, or accompanied, by what *nearly* amounts to a complete recovery, through adhesion of it to the surrounding parts.

Dr. Fagge further points out that "typhlitis often recurs again and again at intervals of a few weeks. It is also exceedingly apt to relapse during convalescence if the patient is allowed to commit any indiscretion." This statement I can fully confirm, and the importance

[4] "Guy's Hospital Reports," 3rd series, vol. xx., 1875, p. 216. "Observations on some points connected with the Diseases of the Liver and of the Peritonæum." By C. Hilton Fagge, M.D. It will be observed that Dr. Fagge employs the term "typhlitis" as the more generic one, in preference to peri-typhlitis, which, he says, "ought to be reserved for cases in which the inflammation extends especially to the connective tissue, outside the back of the cæcum. But it is commonly used rather vaguely, perhaps with the unacknowledged feeling that it has a wider signification than typhlitis, meaning that the seat of the disease is about, or in the neighbourhood of, the cæcum." But this is not in accordance with analogy of peri- and para- metritis.

of it, from a practical point of view, in connection with the preceding observations, need not be more particularly pointed out. The treatment of all such cases should be conducted on the same principles (*mutatis mutandis*) as in peritonitis of pelvic origin. Rest of the parts, absolute if possible, is the main indication of treatment, and this, in the case of the cæcum or vermiform appendix, implies, of course, abstinence from the use of purgatives, and not unfrequently, also, the administration of opium, and the limitation of the diet. Enemata, if employed at all, should be only such as to empty the rectum; but, on the principle that a lower bowel loaded with fæces is more open to strain than one cleared out by warm water in moderate quantity, I am not sure that I am prepared to accept without some qualification Dr. Fagge's conclusion that enemata, as well as purgatives, are to be entirely proscribed as a first condition of safety. It is perhaps necessary, however, to protest against Eichhorst's special recommendation of *Abführmittel*, *e.g.*, large cold water enemata three or four times a day in what may chance to be regarded as *typhlitis stercoralis*.[5] I cannot say that I have had such experience as would induce me to pronounce this an entirely distinct form of disease, and if, on the other hand, the constipation, which often attends a case of inflammatory swelling in the iliac fossa, is not to be taken as the cause, but as the result of the inflammation, usually, if not always, associated with ulceration of the vermiform appendix, a treatment founded on mere emptying the lower bowel, mechanically or otherwise, cannot be expected to be successful. A liquid diet, at first exclusively employed, and afterwards only a very gradual introduction of the most completely digestible solid foods, will be rightly held to be imperative, owing to the same very obvious and paramount necessity of securing rest, as far as possible, to the whole intestinal tract, and especially to the cæcum. In cases where vomiting is obstinate and long-continued, I should not be restrained from clearing the rectum of its contents so far as to allow of nourishment and stimulants being given *per anum;* and morphia might in such case be used in considerable doses hypodermically. The patient should be rigidly kept in bed and absolutely in the recumbent posture, till the tenderness and swelling are nearly if not quite gone; and, holding in view the risk of relapses, it is hardly possible to insist too much upon great care in this respect. The only local treatment I am disposed to recommend is the use of fomentations (medicated or not), poultices (if not too heavy); sometimes, if there is much distension, or if the fever is very high, the local application of cold for short periods by iced cloths; and in more chronic cases the painting of iodine tincture, or liniament. Eichhorst mentions in addition the mercurial ointment, and the vaseline of iodoform; of these I have no experience.

(*To be continued.*)

ABERDEEN—DEATH OF DR. JOHN WOOD.—Dr. John Wood, who for fifty years was a medical practitioner in Aberdeen, died in Aberdeen on Thursday, September 4th, in his 85th year. The deceased, who was a native of Fetteresso, studied at Aberdeen University in Arts. Subsequently he went to Edinburgh, and completed his medical education there, being admitted a member of the Royal College of Surgeons, London, in 1828.

MEMORANDUM ON THE "COMMA-SHAPED BACILLUS," ALLEGED TO BE THE CAUSE OF CHOLERA.[1]

By Surgeon-Major TIMOTHY RICHARDS LEWIS, M.B.
Assistant Professor of Pathology, Army Medical School.

WITH a view of studying the phase which the cholera question has now entered upon, in consequence of the publication of the results of the investigations of the German Cholera Commission in Egypt and India, I availed myself of the opportunity which the present vacation at the Army Medical School afforded of proceeding to Marseilles, where the disease has been prevalent since the end of June. Sir Joseph Fayrer was so kind as to enlist for me the valuable assistance of Dr. Le Roy de Méricourt, Médicin en Chef of the French Navy, who, in various ways, did his utmost to further my wishes. Dr. Marroin, the Chief of the Sanitary Department in Marseilles, was so good as to introduce me to the authorities of the Pharo Hospital, where the cholera cases are treated, and where, with the permission of the Principal Medical Officer, Dr. Trastour, I was able to renew my acquaintance with the disease, and to collect material for studying afresh the microscopy of the intestinal discharges.

Before, however, referring to the results of my own observations, it will be convenient to epitomise the published history of the German Commission; to point out the salient features of the results of their investigations in Egypt and in India; and to make a few brief comments on such of the circumstances and conclusions as appear to call for notice. Shortly after the arrival of the Commission in Egypt, Dr. Robert Koch reported, on behalf of himself and his colleagues, that no special micro-parasites had been discovered in the blood, the lungs, the spleen, the kidneys, or in the liver in cholera, but that the intestinal mucous membrane was permeated by certain bacilli which nearly resembled in size and form the bacilli found in glanders. As is well known these bacilli are straight, and are, in fact, uncommonly like the ordinary microphytes associated with decay. Dr. Koch also states in connection with this subject that he had, previous to proceeding to Egypt, found similar bacilli in the intestinal mucous membrane of four natives of India, but that he had then looked upon them as due to merely *post-mortem* changes. When he came to Egypt, however, and found these same bacilli in the intestines of perfectly fresh cases, he felt that an important link was furnished towards establishing the identity of the disease in Egypt with Indian cholera.

It is highly probable that the specimens from India which Dr. Koch had examined were those which were sent, at the request of the Imperial Health Department in Berlin, by the Sanitary Commissioner with the Government of India. These consisted of numerous dry cover-glass specimens of blood which I had collected from several cholera patients, and of portions of the viscera of four natives who had died of the disease. All these were examined by me before they were despatched, and portions of each were reserved for further study. I had heard nothing further of them, but the publication of the remarks above referred to in Dr. Koch's Report of September the 17th, 1883, from Alexandria, recalled them to my mind, and I was glad to infer that my own negative results had been confirmed in Berlin. As already observed, no importance had been originally attached to the organisms which were present in the intestinal mucosa. During the last six months I have examined hundreds of

[1] Report to the Director General of the Army Medical Department.

stained microtome-sections of these four, and of other specimens of cholera intestines in my possession, and have found that when the mucosa is infiltrated with microphytes at all they are either micrococci, bacteria, or long-oval, and straight bacilli.

In the report of the Commission, dated Calcutta, February the 2nd, 1884, Dr. Koch, however, announces for the first time that the specific bacillus of cholera is curved or comma-shaped, and not straight, so that apparently it had become necessary to abandon the microbe first fixed upon. Assuming that the four specimens from natives of India which had been examined by Dr. Koch were those which passed through my hands, the evidence they furnish seems to be in accordance with this view, as in not one of them have I been able to detect any invasion by unmistakable "commas," though at least one of the specimens may fairly be characterised as abundantly infiltrated (in the manner described by Dr. Koch) by straight (and as I prefer to call them) putrefactive bacilli. Judging from my own experience, therefore, any extensive infiltration of the intestinal mucous membrane in cholera by comma-shaped bacilli must be exceedingly rare ; and this, I believe, is likewise the experience of the members of the late French Cholera Commission, MM. Straus, Roux, and Nocard, whose acquaintance I had the pleasure of making at M. Pasteur's laboratory on my return through Paris.

Whilst at Marseilles I had, as already stated, opportunities of observing numerous specimens of choleraic excreta, and found that comma-shaped bacilli were, more or less conspicuously, present in all of them, though in some instances more than one slide had to be examined before any could be satisfactorily detected. It may also be mentioned that some of the discharges in which these organisms were present manifested an acid reaction when tested with litmus paper. As Dr. Koch himself remarks, the proportion which the comma-shaped bacilli bear to other organisms in the dejecta varies greatly. In some instances only one or two specimens are to be found in the field of the microscope, while in others they are very numerous, and Drs. Nicati and Rietsch (who are at present engaged in the study of the disease at Marseilles) were so kind as to show me a specimen of choleraic material they had obtained from the small intestine, in which the "commas" existed almost to the exclusion of all other organisms. This is a condition, however, which, I understand, is exceedingly rare. On the other hand, I have seen samples of choleraic dejecta in which totally different organisms prevailed to a like exclusion of others ; and in one instance at Marseilles spirilla of various sizes and forms were the most conspicuous of the micro-organisms present. So far, therefore, the selection of the comma-shaped bacilli as the *materies morbi* of cholera appears to be entirely arbitrary.

Dr. Koch and his colleagues have adduced no evidence to show that they are more pernicious than any other microbe ; indeed, as a matter of fact, the sole argument of any weight which has been brought forward in favour of the comma-shaped bacillus being the cause of cholera, is the circumstance that it is more or less prevalent in every case of the disease, and that the German Commission had not succeeded in finding it in any other. With regard to the suggestion that the cholera process may in some way favour the growth of these bacilli, and that these are not necessarily the cause of the disease, Dr. Koch remarks, in the report from Calcutta above cited, that such a view is untenable, inasmuch as it would have to be assumed "that the alimentary canal of a person stricken with cholera must have already contained these particular bacteria ; and seeing that they have invariably been found in a comparatively large number of cases of the disease both in Egypt and India—two wholly separate countries—it would be necessary to assume, further, that every individual must harbour them in his system, This, however, cannot be the case, because, as already stated, the comma-like bacilli are never found except in cases of cholera."

Had Dr. Koch and his colleagues submitted the secretions of the mouth and fauces—the very commencement of the alimentary canal—to a careful microscopic examination of the same kind as that to which they have submitted the alvine discharges, I feel persuaded that such a sentence as the foregoing would not have been written seeing that comma-like bacilli, identical in size, form, and in their reaction with aniline dyes, with those found in choleraic dejecta, are ordinarily present in the mouth of perfectly healthy persons.

[Since this memorandum was submitted, I have observed that Dr. Koch states, in his recent Address on the subject, that after his return to Berlin he had examined, amongst other things, the secretions of the mouth for comma-shaped bacilli, but had found none ; and, further, that he had consulted persons of much experience in bacterial researches as to whether they had ever seen such organisms and was told that they had not. It may be of assistance to future observers if I give the dimensions of half-a-dozen comma-shaped bacilli as found in each of the following : (*a*) In the alvine discharges of three cholera-affected persons ; (*b*) in the small intestine of a person who had died of the disease and in whom they existed almost to the exclusion of other organisms ; (*c*) in a cultivation of them in agar-agar jelly ; and (*d*) in the secretions of the mouth of three healthy persons, ranging from four to fifty years of age. The measurements were made (with the valuable assistance of Mr. Arthur E. Brown, B.Sc., Lond.) under a magnifying power of 1,000 diameters—a Powell and Lealand's $\frac{1}{16}$th of an inch oil-immersion lens, with a wide angle condenser, being used.]

† S-shaped Comma-bacilli.

There is no difficulty in putting this statement to the test; and to any one acquainted with the methods ordinarily adopted for staining and mounting fungal organisms of this character, no special directions need be given. The procedure followed by me to demonstrate these "commas" in the saliva is precisely that adopted for finding them in the dejections. A little saliva should be placed on a cover-glass (preferably in the morning before the teeth are brushed) and allowed to dry thoroughly, either spontaneously or aided by a gentle heat. The dry film thus obtained should be floated for a minute or two with one or other of the ordinary solutions of aniline dyes adopted for such purposes, such, for example, as fuchsine, gentian-violet, or methylene blue. The cover should then be gently rinsed with distilled water, and the film re-dried thoroughly. The preparation may now be mounted in dammar varnish or Canada balsam dissolved in benzol, and should be examined under a $\frac{1}{12}$-th or $\frac{1}{16}$-th of an inch oil-immersion lens.

As in choleraic discharges so in the saliva the number of comma-shaped bacilli will be found to vary greatly in different persons, and at different times in the same person. Sometimes only one or two "commas" will be seen in the field, at others a dozen may be counted, and, occasionally, little colony-groups of them may be found scattered here and there throughout the slide.

It may be remarked in passing, and as bearing upon what has been already said regarding the general absence of comma-shaped bacteria from the intestinal mucosa itself, that they do not appear to manifest any special tendency for attacking the decaying epithelial scales of the mouth, but that, on the contrary, they are for the most part found free in the fluid, the epithelium being studded with other bacterial forms.

Persons who have not been in the habit of examining dried saliva-films will probably be surprised at the number and variety of the organisms which are, more or less, constantly to be found in the mouth; and especially at the number of spirilla with which the fluid is generally crowded. The alvine discharges in cholera sometimes swarm with precisely similar spiral organisms, and, indeed, as has long been known, the fluid exuded into the intestines in this disease is peculiarly suitable for the growth of these and allied microbes. But so far as my own experience—dating from 1869—of the microscopic examination of such a fluid goes, all the microphytes ordinarily found in it are likewise to be found, to a greater or less extent, in the secretions of the mouth and fauces of unaffected persons. And with reference to the comma-like bacilli found in cholera, to which such virulent properties have been ascribed, I shall continue to regard them as identical in their nature with those ordinarily present in the saliva until it has been clearly demonstrated that they are physiologically different.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Epidemiological Society of London.

(Continued from page 285.)

Cancer.

Forty years ago, Mr. Thomas Wilkinson King drew the following results from some 1,000 *post-mortem* examinations performed at Guy's Hospital.[14] "Of all females who die about 44 years of age, nearly one-half have cancers; of males one-eighth. Of males above 65, one-fifth of all who die are cancerous."

[14] *London Medical Gazette*, for 1845, p. 597.

Only too many cases of malignant disease present themselves in India, especially in the large city hospitals; but, starting with the above facts, we must, I think, consider that the diseases of this class are by no means remarkably prevalent in India.

It is true that the great majority of soldiers' wives in India have not reached the cancer age. Still there are many middle-aged women among them. In 1881 there was only one case of cancer in a strength of 3,741.

Although I have known it occur in several cases, true *Scirrhus* is undoubtedly rare in Lower Bengal. It is not, in India, the scourge of Englishwomen as it is at home.

Preps. 263 to 274 in the Calcutta M. C. Museum, well illustrate scirrhus. There is a great deal of *Medullary Cancer*, especially among the young of the native poor. I have seen enormous growths, chiefly of the hæmatoid form, repeatedly.

Epithelial Cancer is, I believe, the form of malignant disease most prevalent in India, and is probably quite as common there as it is in England, attacking the conjunctiva, skin, lip, tongue, os uteri, penis, &c., in Europeans, Eurasians and natives. Two of my medical brother officers died from epithelioma of the tongue, a third and an officer's wife died from this disease attacking the glottis. I saw a very marked case of epithelioma of the penis in a pariah dog. The surgical report shows that, in the Madras General Hospital, there were fourteen operations for cancerous disease in 1882. Eight were cases of amputation of the penis for epithelial cancer. Five were for the removal of epitheliomata of the lower jaw, lower lip, tongue and submaxillary gland. In one case the cancer of the penis was encephaloid.

Dr. Elmslie gave[15] a very remarkable account of epithelioma as it occurs among the native Kashmiri poor at Sirinagar. Out of 5,080 dispensary patients no fewer than 30, or one in every 254 patients were found to have unmistakable epithelioma.[16]

The disease, as it occurs in that locality, shows a remarkable preference for the abdomen and inner aspects of the thighs. It invariably occupied these sites in the 30 patients. Dr. Elmslie attributed the disease to the universal employment, in cold weather, of the *kangri*, an earthenware pot usually covered with fine wicker-work, containing ignited charcoal, which is worn under a loose woollen gown in close proximity to the skin. Indoors or in the sitting posture, the *kangri* is placed between the thighs. He suggested that the heat of this earthen vessel might act as that of a short-stalked tobacco pipe does in causing epithelioma of the lower lip.

Surgeon-Major G. C. Ross has confirmed the above observations as regards the cause and prevalence of epithelioma in Kashmir.[17]

At pp. 558 and 566 of his "Clinical and Pathological Observations in India," Sir Joseph Fayrer has some valuable remarks upon epitheliomata as occurring in old burn cicatrices exposed to irritation.

[15] *Indian Medical Gazette*, vol. i, p. 325.

[16] Without questioning the fact that epithelioma is very prevalent in Sirinagar, I may allude to a point which has often come practically to my notice,—that in India, as elsewhere, a fair amount of success in even a few cases of operative surgery often gains us a local reputation which leads a majority of those similarly afflicted to come to us even from a considerable distance. Hence, we may fall into the error of supposing that the disease in question is more prevalent, especially in our locality, than it really is. Thus, in the time of Esdaile and his successors, the dispensary at Hooghly had, beyond all others in Lower Bengal, a reputation for the safe removal of scrotal tumours. I often said, when a passed student told me that he had been appointed to a dispensary, "Do not lose a month in attracting, by every practicable honest means, those who are known to all the town as having ugly but benign wens and fatty tumours. The successful removal of a few of these will establish your reputation more securely than years of undemonstrative medical practice will do."

[17] *Indian Medical Gazette*, October, 1878.

Preps. 251 to 252 in the C. M. well illustrate epithelioma in Europeans and natives.

As in England, *Melanotic Cancer* is an ordinary cause of death in Bengal among grey and white horses.

We can scarcely drive through Calcutta without seeing animals having the characteristic globular tumours beneath the skin.

We are told, in the account of Bangalore in the "Madras Medical Topographical Reports" (p. 70), that horses at that station are liable to "enlargement of the tail which becomes covered with large black tubercles constantly increasing in size and number; the tail becomes enormously enlarged, and, as the disease extends, the animal pines and dies. It appears to be of a melanotic character and, on dissection, a black secretion has been found in the lungs, liver, kidneys, and in other viscera; and, in one case, a melanotic spot was discovered in the heart." In India, as in England, this form of cancer is rare in human subjects. I saw what appeared to be the commencement of such deposit on the foot of a well-to-do East Indian. It has occurred in the eyeball,[18] and on the hand.[19]

Dr. Shortt removed one or two melanotic tumours from patients in Orissa.

Dr. D. Wilkie has recorded a case of carnification of the lung from the pressure of a melanotic cancerous liver. It occurred in a jockey, probably English, æt. 46. It is not said how long he had been in India.

Preparations 318 to 326 in the C. M. represent this form of cancer as occurring in man, and in the horse and cow.

Webb gives, at p. 1 of his "Pathologia Indica," the case of a native in whom there was melanosis of the lungs and heart. Here, as in the case of a woman whom I saw a few years ago in London, there was cough with expectoration of broken-down melanotic cancerous matter.

Colloid Cancer is represented in Ewart's Catalogue, Preparation 327. The growth affected the mesentery. Having seen a very marked case of colloid of the stomach at Guy's, I was on the look-out for this form of malignant disease in India, but never met with it in my own practice.

Fibrous Tumours (*vide* Diseases of the Uterus), and most other non-malignant growths are not rare in India, and are fairly illustrated in the Calcutta Medical College Museum.

I only saw two genuine cases of *Hodgkin's Disease* in a respectable European woman, in whom the progress of the malady was not at all active while she was under my care; and in a native gentleman of high rank, in whom it proved rapidly fatal. In August, 1880, Assistant-Surgeon Koilas Chandra Banerjea brought before the Calcutta Medical Society an elaborately but very imperfectly detailed case of a Mahomedan, æt 30, who died with an enormous amount of glandular disease (lymphadenoma) after about twenty-two months' suffering. It appears, although the report is very indefinite on this point, that a large aggregation of diseased mesenteric and other glands, matting together most of the upper abdominal viscera, had "caused erosion of the vertebræ."

Three preparations in the C. M., 242 to 244, illustrate *Vascular Tumours*.

Nævus.—Speaking of *Injuries to the Skull*, I have mentioned a case in which most extensive vascular nævi occupied nearly the whole of the scalp and the thickness of the calvarium in a Cookie girl. (See Diseases of the Skin.)

Molluscum fibrosum occasionally produces extreme deformity in natives. A by no means very unhealthy oldish man living near my college, had his body thickly covered by the characteristic pendulous tumours of all sizes up to that of a goose egg, and the growths on his head had produced such an extraordinary cowl-like elongation of the skin that it was widely pendulous, resembling in form the hanging portion of a cock's comb.

Dr. John Adam described and figured[20] the case of a Hindoo, of Jessore, the subject of molluscum. His face and limbs and body generally were studded over with small berry-like sessile elevations, and a tumour, in colour and texture not unlike the skin of a toad's back, arose from the integument surrounding the ear and, becoming very bulky, hung down over the neck in longitudinal folds to the middle of the pectoral muscle. The paper, which includes a report from a Hukeem, upon the native opinions regarding molluscum, should be consulted by those who are interested in this disease.

Mr. Brett reported and figured[21] the case of a native of Delhi whose body and limbs were covered with tumours of molluscum from the size of a pumpkin to that of a pea. Nine hundred and ten were counted. Mr. Brett removed one weighing about three pounds from the back. In June, 1880, Mr. O'Connell Raye exhibited at the Calcutta Medical Society a native woman, æt. 22, who was born with a small nodule on the inner and upper aspect of her left armpit. Gradually increasing and becoming pendulous, it weighed seven pounds when Dr. Raye removed it. The whole of her body was covered with small nodular growths. Her mother had similar growths all over her body. Dr. Raye observed that the condition was hereditary and congenital. He had seen a similar case operated on by Dr. Farrell, in Dublin. Dr. McLeod drew attention to several cases of a similar kind described by Dr. James Wise, late of Dacca, published in a compilation by Drs. Fox and Farquhar on certain skin and other diseases of India, &c. Several of Dr. Wise's cases, and one contributed by Dr. Bainbridge, of Dhalia, resembled very closely Dr. Raye's case. In three of Dr. Wise's nine cases the disease was hereditary.

Dr. Chatham Gray[22] had under his care a native boy of 12, covered with molluscum, in whom the eyelids were especially affected. One eye was lost, the other was almost disorganised.

Cheloid—Preparation 200 in our C. M. is "A keloid outgrowth about four inches long, two inches broad, and one inch thick, formed in the cicatrix of a burn. The contrast between the whole surface of the growth, and the small portion of integument which has been removed with it is very striking. It consists of fibro-cellular structure." At Chittagong a boy of 12 had the forearm drawn up by a burn cicatrix, the thick web of which was nearly a foot long and five inches deep. An extensive cheloid growth occupied the web midway, and was inclined to ulcerate. I removed a large triangular mass and straightened the limb.

A chapter, p. 552, of Fayrer's "Clinical and Pathological Observations in India," is devoted to a series of important cases of "cicatrices after burns treated by surgical operation."

I never saw a case of *Rodent Ulcer* in India. My colleague, Dr. William Palmer, tells me that, after I left, he treated three very well marked cases of this disease in the Medical College Hospital. The patients were native men, all over 40 years of age. The nose was principally involved, and, the disease not being extremely advanced, cicatrization was obtained by the use (under chloroform) of chloride of zinc.

In a report on the diseases of Kashmir,[23] Surgeon-

[23] *Indian Medical Gazette*, for October, 1878.

Major Ross says that *Lupus* is common there. One desperate operation was performed for its cure—dissecting off the whole cheek and integument over the malar bone of a boy—successfully. Some cases were treated by nitric acid.

I never happened to meet with a case of lupus, not of syphilitic origin, in that country either in the European or in the native. Among 7,125 dispensary cases treated in Calcutta, Dr. Chuckerbutty met with only one example of lupus, which may have been syphilitic. Among 1,920 cases of skin disease in natives which he treated in Calcutta, my friend Dr. William Palmer met with eight cases of lupus.[24] He draws a very clear distinction between the non-specific and syphilitic forms of lupus. He does not expressly define the character of these eight cases; but, in a recent communication, he tells me that, in his experience, the non-specific is by far the more frequent type of this disease in Bengal. If it be true that the non-specific disease is a form of struma, its rarity may be due to the great immunity from the external forms of scrofula of the vast majority of the natives of the plains of India.

A NEW INHALER: WITH REMARKS ON ANTISEPTIC INHALATION.

By J. WARD COUSINS, M.D. Lond., F.R.C.S.,
Surgeon to the Royal Portsmouth Hospital.

The discovery of Koch's bacilli amid the morbid processes, which are now grouped together under the term of pulmonary phthisis, and the new theory grafted upon it—that micro-organisms are the essential elements in the development of tubercular disease—have certainly stimulated the revival of the old treatment by inhalation, and have stamped it with fresh value and importance. It is, however, a matter for pathological investigation to decipher what is the exact relation between these specific bacilli and the pneumonic changes which pass on to softening and excavation, and whether the organisms are to be regarded as the cause or the mere outcome of these necrotic processes. At present we are not warranted in assuming that phthisis is the product of a distinctive bacillus imbedded in the tissue of the lung, and we must wait for the results of future investigation and experiment. Still, the progress of research clearly points to the conclusion that phthisis, with its many variations, will soon be recognised as a specific disease, characterised by the formation of a new growth containing specific micro-organisms, which can be detected in the sputum during life, and in the structures invaded by the disease after death.

Now there is some subtle association between this modern theory and the fashionable treatment of inhalation, which appears almost to be anticipating its final demonstration. But it must be stripped of all speculative value, and the test of experience must be the real guide for its adoption. The notion that antiseptic vapours are weapons of destruction upon these mysterious organic forms may seem a hopeful creation of the imagination, but, certainly, there is not a fragment of evidence even to suggest the assumption that volatile antiseptics are killers of bacterial growth hidden in the substance of the lung. Moreover, it is not possible to conceive how either dry or moist vapours, in any form, possessing a low degree of volatility, whether administered by the aid of respirators or by immersion in the atmosphere of a chamber charged with the most powerful medicinal substances, can ever be sufficient in potentiality to arrest within the pulmonary tissue the development of the specific organisms which are found to be intimately associated with the existence of tubercle.

The recent revival of the old question as to the contagiousness of phthisis has also exercised an important influence in promoting the treatment by inhalation and has even succeeded in giving it a new direction. The possible communication of the disease by contagion of some sort has long been a matter of controversy, and many men of distinction have taken part in this ancient disputation, but at the present moment it is still surrounded by many difficulties, and it appears almost as far off as ever from a final settlement. The discovery of micro-organisms has produced a complete resuscitation of the old dispute, and has surrounded it with new and impressive issues.

Some regard the results obtained by the inoculation and artificial cultivation of the specific bacillus as strong evidence in favour of the doctrine, and their convictions on the matter induce them to advocate a special method of applying topical remedies to the air passages. The speculations concerning the existence of the bacillus in the phthisical breath, and the dissemination of its germs in the air mingled with the germs of universal distribution are far beyond the limits hitherto reached by scientific research. Yet, the mere conjecture that germs may find an entrance from without has certainly roused the ingenuity of some inventive minds, and suggested to them the grave necessity of intercepting them by a mechanical device at the very threshold. It is in this way too often that enthusiasm developes theory, and theory wields a directing force in the construction of methods of treatment which are utterly inconsistent with scientific truth, and even common experience.

Surely it is a fact beyond dispute that no kind of inhaling contrivance can defy the entrance of germs with the air of inspiration; at the same time no form of respirator can be persistently employed by the patient. In reality it is a mere fad to attempt to filter and sterilise the air, for there is not a particle of evidence to support the notion that such filtration can be essential to the successful application of inhalations in those individuals who are actually labouring under tubercular disease; and it is extremely improbable that any laborious endeavour to sterilise the air can help to check the growth of organisms which have already found a lodgment in the lung. Even admitting that it is possible by the intermittent application of a complex cover over the mouth and nose to reduce the number of infective particles which enter the body, and to isolate, in a measure, the patient from the invisible hosts around him; then, it clearly follows that this sort of device ought to be considered in the light of a protecting instrument for any individual threatened with pulmonary disease, who is unfortunately exposed by social circumstances to the danger of a polluted atmosphere by contact with others actually labouring under phthisis, and, therefore, the disseminators of an infective material, which is capable of impregnating the organs of any susceptible of its invasion.

On the other hand, I am not singular in holding the opinion that all efforts to filter the inspired air are theoretically unsound, and practically useless, and that the cumbrous instruments constructed with this intention often indirectly exercise a baneful influence on the surroundings of many who are daily endeavouring to protect their lungs with antiseptic inhalations. The constant use of a close inhaler fosters the common prejudice against fresh air and sufficient ventilation, and the treatment degenerates into a struggle between germs within and germs without, hopefully carried on by breathing through an uncomely mask, and by con-

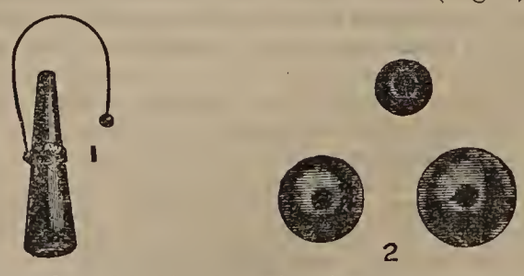
[24] "Rough Notes on the Common Forms of Skin Disease met with in Calcutta."

finement in a close and stuffy atmosphere. Depend upon it, every remedial agent employed in the management of chest disorders must be positively injurious to the patient whenever it distracts the attention from the common and hygienic measures which are so essential to the general improvement of the system, and the increase of the vital resistance of the whole organisation.

Now, in whatever light the speculations are regarded concerning the action of inhalations as destroyers of bacilli or as protectors against floating germs, it must be admitted that this treatment has made remarkable progress, and has also been practised with very great success. What, then, is the *modus operandi* of antiseptic inhalations in pulmonary affections? Surely the action of these remedies admits of a very simple explanation? They are valuable not only in the treatment of phthisis in all its forms, but they are fortunately equally applicable for many other chronic disorders of the chest, and their judicious administration is certainly followed by very considerable relief. Dr. Solomon Smith rightly observes (See *British Medical Journal*, February 23rd, 1884): "We are forced to believe that the benefits derived from the use of antiseptic inhalations are due to the infiltration of the lungs with antiseptic material, rather than to any action upon the floating germs." The vapours which are mingled with the inspired air penetrate deeply into the passages, and are there absorbed by the moisture of the respiratory surface, and thus, by direct application, they purify the air in the remote portions of the lungs, and cleanse the mucous membrane generally by preventing decomposition in the fluids, and stimulating more healthy secretion. In chronic bronchitis, bronchorrhœa, with dilated bronchi, and emphysematous affections the efficacy of the treatment is beyond dispute; for by assisting the discharge of the expectoration, and by delaying the septic changes which occur within it, they remarkably modify the disorder at the very seat of its activity. In phthisis these topical remedies have proved also powerful auxiliaries to general treatment. They check decomposition in the secretions, and aid in the evacuation of the infectious materials, which are the direct products of the disintegration of the pulmonary tissues, and which by the processes of absorption and diffusion often establish new centres of disease.

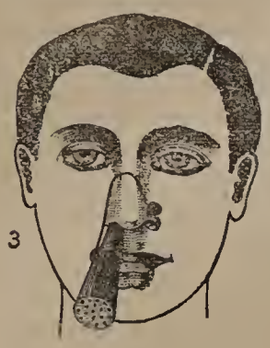
But apart altogether from any specific effect of the antiseptic vapours, it must be admitted that the act of continuous inhalation exerts a very salutary influence by stimulating full and repeated expansion of the lungs, and the forced activity of these organs is in itself an important factor of the treatment. The value of free inspiration, and the part it plays in the successful application of antiseptic inhalation has scarcely received the general recognition to which it is justly entitled. Many years ago the late Dr. Ramadge warmly advocated the use of an inflating tube for the simple purpose of expanding the lungs, and stimulating their functional activity by voluntary effort. In phthisis these organs are very imperfectly expanded. The sputa collecting in the passages obstructs the aërial movements, and some portion of the air only partially changed becomes imprisoned in the remote parts of the pulmonary tissue, and thus the healthy balance between inspiration and expiration is disturbed, the breathing becomes shallow, at the same time the gradual contraction and emaciation of the thoracic parietes are seriously accelerated. Now it appears to me that much of the success which has followed the introduction of antiseptic inhalation is due to persistent expansion of the lungs by forced inspiration; and certainly this novel and fashionable system corroborates the value of the mechanical method practised by Dr. Ramadge. His notions respecting the antagonism between emphysema and phthisis have now almost passed into oblivion, but his special treatment of utilising functional activity as an instrument for arresting the progress of tubercular disease is surely now receiving a remarkable acknowledgment in the revival of respirators and local medication. The new treatment is, in fact, a close repetition of the old mode of inflation with the addition of an antiseptic vapour to the inspired air, and the beneficial effect produced by its persistent employment can in a great part at least be fairly attributed to the expansion of the chest in full and forced inspiration; for this not only assists in maintaining the volume of the lungs, and in stimulating the activity of those portions of their structure still free from the elements of tubercle, but it also favours the circulation itself, and helps on the processes of local and general nutrition by which a vital resistance is developed, restraining the progress of the disorder and powerfully contributing towards its final arrest through the contraction and limitation of the local disease. The advocates of antiseptic inhalation are quite unanimous as to the necessity of employing it with great regularity and perseverance over a long period; but there is much diversity of opinion as to the method of application, and the form of instrument best adapted for the treatment. In a recent number (June 12th, 1883) of the *British Medical Journal*, Dr. Arthur Hassall refers to "the comparative inefficiency in diseases of the lungs of the methods of inhalation now in use by means of oral and oro-nasal inhalers," and he advocates the revival of the old method of treatment by means of a chamber charged with antiseptic vapours, and he is now engaged in perfecting an apparatus which he hopes will render this system more generally practicable. The experience of most practitioners at the present time is, however, clearly in favour of the direct inhalation of dry vapours, and a great variety of instruments have been constructed for the purpose, for the most part modifications of the original respirator inhaler suggested by Dr. Sinclair Coghill in 1876. The simplest forms of apparatus are now almost universally preferred as they are more comfortable to the patient, and more readily tolerated during prolonged application. Some inhalers are too heavy, and cause a feeling of oppression, and sometimes even difficulty of breathing. Others are objectionable by pressing on the face, and causing irritation of the skin. It is my opinion that all close oro-nasal respirators and complex instruments present no real advantages, and that they must soon fall into disuse, as their employment is seriously irksome to many patients. An inhaler ought to be a very light mechanical contrivance, especially designed to permit the voluntary introduction of medicated vapour by full inspiration, at the same time securing the freest possible access of air, so that the continuous and daily practice may be rendered both endurable and pleasant.

The small instrument represented in the engraving appears to me to possess all these essential qualifications. It consists of a vulcanite receptacle (Fig. 1) for holding the little pledget of cotton wool upon which the inhalant is dropped. The wire suspends the inhaler, and serves also as a compressor of the nose. When used for nasal inhalation one of the balls (Fig. 2) must

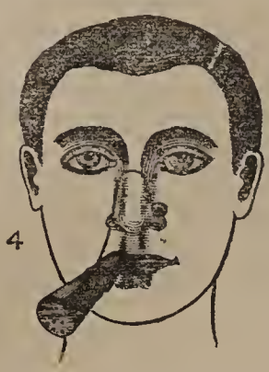


be selected, and half only of its circumference ought to enter the nostril. During oral inhalation another ball

is used, or the neck of the inhaler can rest against the upper teeth. The Figs. 3 and 4 explain the methods of



3



4

adjusting the instrument. By merely opening and closing the mouth the patient can regulate the entrance of the antiseptic vapour into the lungs. It is extremely light, and causes no fatigue or oppression, and it does not require to be taken off during coughing, and expulsion of the sputa. I am much indebted to Messrs. S. Maw Son & Thompson for the care they have bestowed upon the manufacture of my inhaler, and I am glad to add that it can be obtained from that firm at a very moderate price.

The following table exhibits the respective weights of some of the best known inhalers now in general use :—

	Drs.	Grs.
Coghill's Metal Inhaler	8	45
„ Nickelled Inhaler	7	19
„ Celluloid Inhaler	3	27
M'Kenzie's Metal Inhaler	15	40
„ Nickelled Inhaler	18	52
„ Celluloid Inhaler	8	29
Robert's Nickelled Inhaler	9	3
„ Metal Inhaler	7	2
Burney Yeo's Perforated Zinc Inhaler	3	40
Ward Cousins' new Antiseptic Inhaler	1	12

In conclusion, it has been my endeavour to confine this paper strictly to the consideration of open inhalation ; and I have ventured to suggest that it is not merely a convenient mode of employing the breath as a medium for the introduction of antiseptic vapour, but that it is also a simple and mechanical method of sustaining forced inspiration, and thus utilising the antagonism which fortunately exists between pathological change and healthy activity. Any reference to the value of different inhalants, and antiseptic combinations has been intentionally avoided, and for information on these important matters, I must especially mention the paper of Dr. Sinclair Coghill (*British Medical Journal*, May, 1881), and also many recent contributions by Dr. Burney Yeo, and other eminent physicians. To Dr. Sinclair Coghill we are undoubtedly indebted for the revival of inhalation as a regular part of the treatment of pulmonary disease, and a perusal of his published experiences will be extremely serviceable to any who have not yet given it the attention which it merits.

The French Association for the Advancement of Science.—On the occasion of this learned body holding its thirteenth session at Blois this year, M. Masson, the treasurer, announced that its prosperity continued progressive, not only by reason of the number of members which had increased every year, but of the legacies which had been bequeathed to it. At the present time it numbers nearly 4,000 members and possesses a capital which exceeds 400,000 francs.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

COMPOUND FRACTURE OF FOREARM—RECOVERY, WITH GOOD USE OF HAND—REMARKS.

(Under the care of Mr. RICKMAN GODLEE.)

(For the notes of this case we are indebted to Mr. Montague Williams, Registrar and Pathologist.)

J. D., aged 10, was admitted on February 11, 1884 Just before admission was riding on the back of a brewer's dray ; he fell off and was knocked down and run over by a passing tramcar.

On Admission.—Boy is of good muscular development, healthy looking, with brown hair. Is very much frightened and somewhat collapsed. On examination there is a large wound across the back of wrist; the wrist joint is widely opened, the lower end of ulna with the epiphysis is broken off and projects in the middle of the wound. Several small vessels are wounded, but no artery of importance. The wound is full of dirt. The soft parts on the back of joint are mostly divided, with the exception of the thumb muscles and extensors of the little finger. The skin was undermined for the distance of an inch or more above the wound, and also to some less extent below. Hæmorrhage stayed by the application of a tourniquet to the brachial artery. The wound was washed with carbolic acid (1 in 20) but the mud was not cleared out of it, the limb put up on a back splint and the patient removed to the ward. About three or four hours later, chloroform was administered. The pulse under the anæsthetic became irregular, and the breathing feeble ; towards the end of the operation the pulse was almost imperceptible. Mr. Godlee first slit up the skin where it was undermined. He then washed the wound thoroughly with carbolic acid (1 in 20). The dirt was removed by scrubbing with a nail brush, and scraping with a Volkmann's sharp spoon. The nails were carefully pared and all dirt removed. The crushed tissues were then dissected away, and the epiphysis of the ulna removed by bone forceps. The wound was then powdered with iodoform, which was well rubbed in, and chloride of zinc (gr. xl ad ℥i) was thoroughly applied. The tendons of the extensor indicis and part of the extensor communis were stitched together as well as possible. Several small arteries were tied and one large superficial vein. The extensor tendons of the thumb were not injured. The wound was again repowdered with iodoform ; no stitches were introduced and no drainage used. The parts were dressed with protective and wet gauze, and the whole enveloped in an antiseptic dressing, a single anterior splint adjusted and packed with salicylic wool. The spray was not used during the operation. The patient was put to bed, and an opiate given. It was also found necessary to administer an enema of brandy. He was allowed iced-milk in small quantities to drink. Boy passed a restless night, tossing about continually. Temperature the next morning was 100·6.° Pulse 104, much improved in volume and almost regular. The wound was dressed. The parts were looking well and clean. Is in no pain. The carbolic spray was used during the dressing. Sensation over all parts of the hand is perfect. Passed a comfortable day ; has taken his nourishment well throughout. On the 13th the wound was again

redressed with antiseptic precautions; the discharge quite aseptic; temperature 99·2°. On the 14th the edges of part of the outer flap were sloughy looking; the discharge profuse and the odour sweet. Sensation not impaired except over sloughing points. On the 16th it was dressed. On the 18th the extent of the sloughing surface was more increased; temperature 98·8°. The dressing is slightly offensive. The hand is in an exaggerated position of abduction. The fractured ends of the ulna are protruding from the wound. On the 20th it was more healthy looking; fresh granulations are covering the wound. Mr. Godlee, on the 24th, found the wrist still unnaturally abducted. He applied a poro-plastic splint, the hand part of which was bent backwards to the flexor surface of the fore-arm, in order to hyper-extend the wrist. On the 12th of March the note states that the wrist is in a good position and the patient able to flex fingers to a slight degree. The wound is very small and everywhere covered with healthy granulating tissue. On the 17th he was discharged with instructions to attend the out-patient department for dressing, which he did, until the wound was soundly healed. When the patient left the hospital, he only possessed such power of extension as was given by the interossei and lumbricales. He was able to contract extensors of fingers, but their action was confined to dragging on the scar. Flexion was unimpaired. The scar appeared to be firmly fixed to the subjacent parts. After a time, however, when the splint was removed and the patient was allowed to exercise his hand at will, the scar became more movable, and he was able to extend his fingers almost, if not entirely, to the full extent. There was a considerable amount of movement in the wrist-joint, also pronation and supination.

Remarks by Mr. Godlee.—The extensive wound when I first saw it was full of caked London mud, presented a most unpromising appearance, but as the vessels were uninjured and the soft parts on the anterior aspect entire, I thought it right to try to save it. The success appears to be a good illustration of the advantages to be gained from the thorough employment of antiseptics. I believe great good is gained by applying more than one of the antiseptics which we are in the habit of using, and by applying them very thoroughly. The use of the sharp spoon and of the nail brush was found of great service in clearing away the particles of mud which had penetrated into the deepest recesses of the wound. The wound was left completely open, in fact all the undermined portions of skin were slit up. The stitches uniting the tendons gave way in the course of the first week, but the ends which had been united by them remained in contact with each other. After the wound had been healed, when it was found that the common extensor appeared to act only upon the scar, it was not anticipated that it would ever gain command over the fingers; and it is not a little remarkable that after some time the scar softened and the power of extension returned to the fingers, which at first could only be brought into such a degree of extension as can be effected by the action of the lumbricales and interossei; when I last saw him the hand could be easily extended almost to the straight position.

VESICAL CALCULUS—CONGENITAL MORBUS CORDIS—LITHOTOMY—RECOVERY.

(Under the care of Mr. RICKMAN GODLEE.)

Charles L., aged 8 years, was admitted into Barclay Ward on the 3rd of March last. His parents tell us that he has constant and painful micturition, a condition of things which have persisted since his birth. The urine voided has never been blood-stained, but often thick and muddy-looking. He is constantly wetting his bed at night. Has been cyanosed from birth, and unlike children has shown no inclination to play, but prefers to sit quiet. He often complains of palpitation and præcordial pains. Has had no past illnesses of particular note. Three sisters at home in good health, parents enjoy good health likewise. On admission, the boy is of spare muscular development, of lethargic temperament and apathetic. Cyanosis is evident in face and finger-tips. These latter are also clubbed to a marked degree. There is a decided præcordial thrill of an undulating character. Cardiac dulness is much exaggerated; commencing at the lower border of the second costal cartilage, it extends downwards to sixth intercostal space; laterally it extends a finger's breadth to the left of the nipple line, and likewise to the right border of the sternum. The intensity of the heart's impulse is one inch below and one inch internal to nipple. A loud, harsh, bellows murmur is audible at heart's apex, loudest at pulmonary cartilage, and systolic in time; it is traceable into the axilla, and round to the inferior angle of the scapula. The second sound is faintly audible at the heart's apex, elsewhere it is absent, the normal cardiac sounds being irrecognisable. The heart's action is occasionally very irregular, intermitting frequently with the radial pulse. Pulmonary resonance normal. Breathing vesicular. Liver and splenic areas not increased. Pulse 80, fairly full, compressible, intermittent at times. Urine sp. gr. 1015, acid. Traces of albumen, pus in large quantities, no blood. Dr. Sansom considers the bruit systolic in time and of pulmonary origin, the right side of the heart hypertrophied and dilated; thinks also that attempts might be made to administer an anæsthetic with due caution.

On March the 16th an anæsthetic was administered of pure chloroform. The patient had scarcely inhaled a drachm before cyanosis became more marked, the lips were livid as also were the fingers and finger-nails. The pulse was full, bounding, irregular and very slow. The cutaneous and superficial veins of the body were much dilated and their various courses readily traceable. The sound was passed and a calculus felt. Slight syncope now ensued. This was relieved by chafing the extremities and administering brandy by the rectum and the mouth. Patient was removed to his bed.

The following morning the pulse was 70, more regular, and the patient comfortable.

On the 22nd chloroform was again administered with great caution, it being inhaled with frequent admixtures of pure air. Cyanosis as before was increased and the pulse slowed (50); the pupils were contracted, respiration being feeble and shallow. In the lithotomy position Mr. Godlee performed the usual lateral operation. The stone was quickly found and readily removed. Very little hæmorrhage followed; the legs were tied together. The patient quickly rallied and was removed to bed. The stone weighed 110 grains, was smooth, oval, fawn coloured, and consisted of uric acid.

On the following morning the patient was comfortable after a quiet night. Temperature 98·2°, pulse 70. Passes plenty of urine through the wound. There is no hypogastric pain. On April 5th, the note states that he now voids his urine *per vias naturales*, a little escaping still through the wound. On the 11th the wound had quite healed and he gets up daily. On the 21st he was discharged quite cured and greatly improved in general health.

Remarks by Mr. Godlee.—One very interesting point in this case was the question whether or no it would be safe to administer an anæsthetic, and if so, which should be selected. It was judged best to employ chloroform rather than ether, because it was thought that the secretion of mucus from the bronchial tubes

might, by seriously interfering with the respiration, prove dangerous to him considering the very marked degree of cyanosis depending on his congenital heart disease. The use of chloroform placed the patient in a highly critical condition. His appearance was remarkable; all the superficial veins standing out as large blue lines throughout the body, and his respiration and heart's action being very seriously impaired. At the time of operation he was never brought deeply under the influence of the anæsthetic, and the result was that, owing to his struggling, there was no very serious increase in the cyanosis. The case after the operation exhibited no unfavourable symptoms; but it should be added that he returned to the hospital some time after the last recorded note and was still complaining of considerable frequency of micturition.

Medical Times and Gazette.

SATURDAY, SEPTEMBER 20, 1884.

The Medical event of the week has been the publication of Dr. Crichton Browne's report on educational over-pressure in elementary schools. Mr. Mundella has supplied a corrective—in whose interests it is not quite obvious—to Dr. Browne's glowing periods, in the form of a memorandum by Mr. Fitch, a well-known official of the Education Department, and a member of the Senate of the London University, the publication of both being considerately deferred until there was a clear board and plenty of time for their consideration. We have abstracted and commented on both papers elsewhere, but may here observe that all the actors in this little comedy appear to have entered upon their parts with perhaps too much enjoyment. Dr. Crichton Browne evidently wrote his report *con amore*, as who would not if he could write like him? Mr. Fitch clearly performed his part of dispassionate critic with a gusto, which appears, according to Dr. Crichton Browne's letter in Thursday's *Times*, to have led him into certain inaccuracies of statement; Mr. Mundella characterized Dr. Browne's report in words that were evidently put together with some amount of glee, and even the children in the Board Schools, we are told, co-operated with manifest enthusiasm. But the highest amount of literary pleasure evidently fell to the share of the *Times* leader-writer, who would appear to have spent his ink not like the cuttlefish in a spasm of fear, but in a spasm of delight. Meanwhile, amidst all this display of forensic talent, the interests of the poor clients, the over-driven dullards, seem likely to be forgotten.

On the same day, Tuesday last, that the above-mentioned leader appeared, the *Times* also published an admirable signed article by Mr. Brudenell Carter, on the effect of civilization on the eyesight, in which the effect of unphysiological schooling on one of the most important of human functions was described in clear, incisive language, devoid of all suspicion of rhetoric. Whether the *Times* took a leaf out of Mr. Mundella's book and thought it well to insert a corrective to its own leader, or whatever other motive may have led to the happily-timed insertion of Mr. Carter's letter, it is beyond our power to guess. It is sufficient for us to note the appearance of the article as an important fact, and to impress on every reader who has not yet read it to do so without delay.

The 28th Congress of the Social Science Association was opened at Birmingham on Wednesday under the presidency of Mr. Shaw-Lefevre. The Health Section will be presided over by our valued contributor Dr. Norman Chevers, but his address it is understood will not be delivered until next Tuesday. Dr. Chevers will thus have a certain advantage over his fellow presidents whose addresses are to precede his, in that he will be able to comment on some of the subjects previously discussed, an advantage of which, we understand he intends to avail himself. The address will also deal with our sanitary shortcomings, and will advocate the establishment of a Ministry of Public Health, and—another favourite scheme of the author's—the publication of medico-topographical reports of towns and districts. Many papers of great interest will be read in the Health Section, cholera, vaccination, hospital ships, and the eyesight of school children being amongst the subjects that will be presented for discussion.

The cholera is still raging at Naples, though with so much less fury than a week ago, that King Humbert has felt himself justified in leaving the city, after a visit which has raised him at one leap to the top of the regal class. The epidemic appears to have reached its height on Wednesday week, the 10th instant, when 966 new cases were reported, 328 of which proved fatal, while there were 146 deaths amongst cases previously under treatment. On the 11th these figures were respectively 809, 332, and 98; on the 12th they were 872, 288 and 107; on the 13th 642, 239 and 109; on the 14th 643, 231 and 140; on the 15th 470, 167 and 116; on the 16th, the last day for which we have statistics, 463, 158 and 107. Thus in the week the new cases and the rapidly fatal cases have diminished by one-half, while the number of deaths among cases previously under treatment has shown a less marked falling off. On Tuesday week 50 per cent. of the new cases were dying within 24 hours (viz., 398 out of 794); last Tuesday only 34 per cent. of the cases proved thus rapidly fatal. The epidemic is prevalent in other parts of Italy, especially at Spezzia, and it appears to be spreading in Spain, while in France it is slowly dying out.

The cholera has made its appearance in Paris, at the Hôpital Bichat, which has been set apart by the Administration for the reception of such cases. Two deaths have occurred, with the symptoms and *post-mortem* appearances of the classical form of the disease. The first patient came from Perpignan, where the cholera still rages. The subject was suffering from diarrhœa when he started, and had endeavoured to check it by copious libations. The second patient also came from the South, and had been unwell for several days previously to his fatal attack. Isolation, disinfection, and immediate burial after death were of course ordered. No other cases having occurred since last week, it may fairly be assumed that the two above-mentioned cases

were "importations from abroad." The sanitary condition of Paris happens to be remarkably good at the present moment, and the death-rate remarkably low, being 985 last week, and 932 the week before. The average rate is about 1,200.

The cholera, writes our Paris correspondent, is still the prevailing topic in all medical circles, and the great subject of discussion at the Academy of Medicine. It might indeed be said that the subject has now been worn thread-bare, and that not one single notion of scientific value or practical utility has been evolved from the discussions of our medical senate, or, in fact, from the labours of congresses and learned bodies. Neither the *comma* of Koch, nor the germ theory; neither the doctrine of contagion, nor that of spontaneous evolution, has been able to stand the test of searching investigation and impartial criticism. Our faith in the efficacy of quarantine has been sadly shaken, but we have not received in return any new revelation as to the means of preservation which the progress of science might recommend as more efficacious; nothing has been ascertained as to the best methods of treatment, and we do not even know why an epidemic, after doing its worst, is found at last to die out spontaneously. In short, the *résumé* of all the discussions that have taken place since the outbreak might be summed up in the poet's words — "All that we know is, nothing can be known."

The Academy has, however, ordered a (statistical) enquiry to be set up as to the circumstances which have accompanied or apparently favoured the various outbreaks of cholera which have taken place in France. This gigantic effort will no doubt do much good to those who undertake it, and a vision of crosses, stars, decorations and more substantial rewards is dimly perceptible in the distant future; but, for our part, we should have greatly preferred the creation of a chair of epidemiology, proposed by the Government but set aside by the Academy. We possess, at the Faculty, a chair of "Histoire de la Médecine," which, in spite of the talent and learning of the three professors who have successively filled it, is manifestly a superfluity and painfully collects a scanty audience round the official representative of medical history and doctrines, as they flourished in times long past.

The history of epidemics is, on the contrary, one of the most interesting and important subjects in the whole field of science. Teeming as it does with information of daily importance and practical utility, it would attract at once the attention of the public; and the creation of an official chair, with all its surroundings, would speedily collect an army of investigators round an intelligent chieftain, and might perhaps lead to unexpected "finds" in the diggings of science. Personal motives are said to have played a part in the decision of the Academy. In this case, as in some others, a little "*mild despotism*" might have led to better results.

It is stated that at last success has attended the efforts to convey cholera to the lower animals. Drs. Nicati and Rietsch, inspired by Dr. Koch's example and advice, collected masses of the cholera microbe from the intestines of patients, who had just died of the disease, and inoculated some dogs and guinea-pigs with them. All the animals operated on were seized with the symptoms of cholera, and died, the guinea-pigs within 48 hours, the dogs within four days. Other experiments were made with regard to the influence of the gastric juice and the bile on the growth of the microbes, which it was found were destroyed by both these secretions. It is suggested that a certain means of diagnosing a suspected case of cholera is provided by the injection of the stools of such a case into the duodenum of a guinea-pig, which will forthwith, if the case is one of true cholera, succumb to the disease. We are not told, however, whether the injection of a simple diarrhœa stool, under the same circumstances, may not be attended by a like result. The experiments as well as the conclusions of Drs. Nicati and Rietsch will, no doubt, be subjected to the sharpest scrutiny.

The "comma" bacillus is turning out to be a common bacillus after all. In another column we publish a memorandum on this notorious microbe by Dr. T. R. Lewis, of Netley, which has been kindly forwarded to us by the Director General of the Army Medical Department. The two most important facts pointed out by Dr. Lewis are, first, that the bacillus found by Dr. Koch in Egypt was not the same as that found by him in India; and, secondly, that comma-like bacilli, indistinguishable from those found in cholera, are ordinarily present in the saliva of perfectly healthy persons. The moral is clear. First, it is impossible to attach much importance to conclusions dependent upon the discovery of organisms, with regard to the distribution of which experts express such very different opinions; and, secondly, it is unwise—and was unwise in Dr. Koch—to publish reports in the middle of an investigation. Science is becoming too theatrical—its popularity with the public exerting a baleful influence on it, and tempting men to achieve a cheap fame by publishing premature and immature results. Of course Dr. Koch may be able to dispose successfully of his critics, and to show that his results are not so crude as they are alleged to be. But men will be tempted to follow Dr. Koch's example, who have less ability to hold their own.

The meeting of the French Scientific Association, at Blois, has been largely attended, and has been graced with many interesting medical and surgical communications, which, thank Heaven! were not exclusively devoted to the topic of cholera. The irrepressible microbe, however, made its appearance in the lecture delivered by Professor Bouley upon "the latest discoveries of M. Pasteur." Not contented with sounding the praise of his hero, the celebrated veterinarian made a savage onslaught upon Professor Jaccoud for having dared to question, in his clinical lectures, the practical bearing of the germ theory upon medicine. Professor Jaccoud's strictures were couched in the most cautious language, and preceded by a well-deserved tribute of praise to the leaders of modern science. But nothing short of "*prostration of the whole body*," as before Eastern monarchs, will satisfy

the disciples of the great man whose triumph has been sufficiently glorious to suggest the propriety of leaving a small corner in the vast empire of human knowledge, for freedom of speech and liberty of conscience.

Several questions of interest were discussed in the Medical Section. M. Chaumier read a paper in support of the doctrine of the epidemic and contagious nature of acute pneumonia, regarding it as a constitutional affection, of which the pulmonary signs were but the local expression. He stated that in his experience pneumonia always occurred in epidemics, and he had found that those who suffered first in an epidemic were often those who had had previous attacks of pneumonia, a fact which he explained by suggesting that their dwelling-places perhaps preserved the pneumonic germ a long time. He had further noticed that epidemics attacked by preference certain classes of persons, for instance the young and old people, only attacking those of the other category later. He also read a paper deprecating the drug treatment of cases of pneumonia, and advocating the use of cold baths. At the same meeting M. Verneuil read a paper for M. Bessette, on the use of the thermo-cautery in the treatment of spontaneous gangrene. It was based on the case of a man, aged 54, who being the subject of diabetes, and having also albuminuria, had nevertheless recovered after the amputation of his foot, for spontaneous gangrene, by means of the thermo-cautery. Several of the speakers who took part in the debate were able to testify, from personal experience, to the efficacy of the method recommended in the paper. An interesting point in reference to these cases was mentioned by M. Verneuil, who observed that it was only in diabetics who were intemperate that these spontaneous gangrenes made their appearance.

At the last meeting of the Paris Academy of Sciences, the President publicly congratulated M. Chevreul, the illustrious chemist, on the occasion of his *ninety-ninth* birthday. The celebrated professor, who is in the enjoyment of admirably good health, has lectured at the Museum of Natural History for the last fifty-seven years; and if, as we all hope and wish, he is spared for a few years more, he will be an authentic and splendid instance of a centenarian.

Some interesting examples of the Metaplasia from medullary tissue to bone, were recently shown to the Lyons Society of Medicine by M. Vincent. This observer has conducted a prolonged series of experiments in connection with this subject, the most striking of which have consisted in the transplantation of discs of medullary tissue, taken from the radius of young cockerels, into their rapidly growing combs. Bone-formation followed the transposition of tissue, and M. Vincent was able to show several specimens of bone produced in this way.

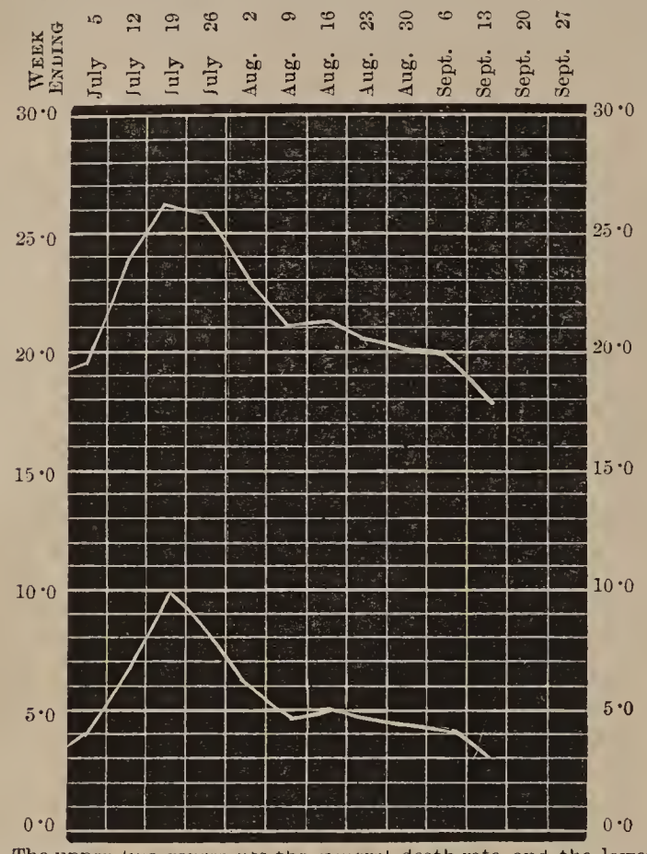
The *Gazette Médicale* has the reputation of being a well informed journal, and it is somewhat strange to find it stating in a recent *feuilleton* that Sir Erasmus Wilson, "the most illustrious representative of English dermatology since the death of Dr. Tilbury Fox," has bequeathed a large sum of money to the Medical Society of which he was the president. Probably, however, French readers would find quite as startling errors in English Medical journals, if they took the trouble to look for them.

The labours of the Red Cross Conference at Geneva terminated on Saturday week in a grand banquet given by the town. Amongst the many questions brought under discussion was one relating to the desirability of the adoption of the antiseptic treatment of wounds by armies in the field, which, strange to say, was supported by only two-thirds of those present, there being a large number of abstentions when the division was taken. Several resolutions were not discussed from want of time, but a proposal by the Greek delegates that in time of peace the aid societies should take part in other humane works, such as the care of the sick, and affording aid in time of great public disasters, was carried without opposition. The subject for the prize of 5,000 francs, offered by the Empress Augusta, has been announced. It is as follows: "The best form of barrack hospital, including rapidity of construction, economy of cost, hygienic qualities, together with the greatest adaptation to the necessities of sick and wounded patients in war." The Empress has further expressed her intention of presenting a gold medal with a likeness of herself, as a part of the prize. The final act of the Conference was the determination to erect a monument at Geneva to commemorate the foundation of the society there twenty years ago.

Our societies will soon be at work again now, as the following list of their dates of commencement will show. The Obstetrical Society will meet on October 8th and not on the 1st as stated in their printed card, and on the same day the Dermatologists will commence their operations. On the following day the Ophthalmological Society will resume, and the day after that will see the Clinical Society at work. The Pathological Society will hold their first meeting on October 21st, and will be followed by the Medical Officers of Health on the 24th. The Medical Society meet on Monday, October 27th, and on the day following the session of the Royal Medical and Chirurgical Society will be opened. The Epidemiologists will meet on the day sacred to the memory of Guy Fawkes.

The report of the Registrar-General for last week must be regarded as satisfactory. The total number of deaths was 1,373, or one below the corrected average for the previous ten years, and the death-rate has fallen 2·1 per 1,000 during the past week. Amongst the zymotic diseases small-pox accounts for 9 deaths, and measles for 11, or 6 below the corrected average, whilst scarlet fever is credited with 23 deaths, no less than 33 below the corrected average. The deaths from whooping cough too, 27 in number, were 6 below the average, diphtheria alone of this class of disease being above the average in mortality, the total number of deaths 22, or 9 less than last week, being still 10 above the corrected average. The deaths from diarrhœa, dysentery, and enteric fever showed a considerable diminution in numbers, but deaths from diseases

of the respiratory organs displayed a slight tendency to rise. The deaths of children under one year were



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the first eleven weeks of the current quarter.

398, a total which contrasts very favourably with the 936 deaths in the same column for the third week in July.

On the 15th instant, the temporary Hospital for Infectious Diseases at Liverpool was declared ready for the reception of small-pox cases, and during the closing days of the previous week it was visited by numerous persons who then paid, it is to be hoped, their first and last visit. The building stands half way up the declivity of a hill that slopes downwards to the estuary of the Mersey, and is so exposed to sea breezes, that a palisade has been erected to break the force of the wind. On the top of the hill is Parkfield House, and beyond this, but out of sight of the hospital, are the densely populated districts of Toxteth Park. The site is a most desirable one, both on account of its healthy situation and its secluded position. Unfortunately it is intended for a dock, belongs to the Dock Board, and is now let to the Corporation, who are only monthly tenants. The hospital is partly composed of canvas tents and partly of iron huts. These are arranged in two rows parallel with the river. The rows are connected at numerous points by beautiful covered walks that divide the intervening space into grass plots, abundantly planted with evergreens and shrubs. Rustic boxes filled with plants are placed outside the windows, and the general appearance of the hospital is rather that of a winter garden than of a lazaretto. Nor are the internal arrangements of the hospital neglected for outside appearance. There artistic effects are also studied, but there also we find the newest and most approved appliances combined with beauty. A foundation of concrete supports a boarded floor. The closet arrangements are of different kinds and of the newest patterns, whilst the drainage of the hospital is isolated from all pre-existing drains and complete in itself. An ingenious contrivance mixes carbolic acid and water, and when the vessel is full its contents are automatically discharged into the drains. The mortuary and *post-mortem* rooms are in a picturesque hut that looks like a summer-house amongst the trees. The kitchens, the central administrative blocks and the disinfecting rooms are situated at separate points and are the best of the kind. Telephonic communication is established with everyone, and the telephone to the house surgeon's bedroom keeps a bell ringing at his ear until he gets up, and he cannot stop it until he comes downstairs.

The estimated cost of the building is 12,000*l*., and it provides accommodation for 150 patients. There is room on the grounds for as many more. It is generally felt already that the tents are a mistake in this country, and these will probably be displaced gradually by the huts, which are more convenient. The epidemic for which it was built (small-pox), is now over, only about four new cases having been reported last week, but it will be available for typhus, of which disease Liverpool has generally plenty of cases. Dr. R. Robertson, visiting physician to the Liverpool Workhouse, has been appointed physician to the new hospital, on account of his large experience of infectious disease at the former place. Dr. Moore is resident medical officer. There is also a matron, and six nurses are ready for work. The hospital is entirely the work of the city engineer, and reflects great credit upon his taste, experience, and evident desire, irrespective of cost, to afford the medical officers every facility for the successful treatment of their patients. If the permanent infectious hospitals are constructed with the same skill, foresight, and liberality, Liverpool will possess models of what such hospitals should be.

By the death of David Alexander King at the early age of 28, a life full of promise has been cut short, and St. Bartholomew's Hospital has to mourn the loss of one of her most brilliant pupils. Dr. King crowned a long list of school triumphs and successes by taking the Gold Medal at the University of London in the examination for M.D., a result which did not surprise those who had best opportunities of judging of his ability. It is but little more than a year ago since he was elected to the Casualty Physicianship at his old hospital, following that up almost immediately by his appointment on the staff of the Brompton Hospital for Consumption. These posts, however, he was not destined to hold long, for an attack of pleurisy, about this time last year, was but the precursor of the serious pulmonary tuberculosis which, later on in the autumn, compelled him to give up all thoughts of continuing the practice of his profession in London. His death has severed many a friendship, but his memory will long be cherished by those who knew him best.

The return of public favour to English spas and watering places is leading to the re-opening of old and forgotten mineral springs and the opening of new ones.

At Canterbury two mineral springs, which were first discovered nearly two centuries ago by Dr. des Moulins, but which have been unused for fifty years, are about to be re-opened; while at Hastings a chalybeate spa was formally opened last week in connection with a new hydropathic establishment. The latter is said to be of the same character as though somewhat weaker than the waters at Tunbridge Wells. Considering that a gallon of the Tunbridge spring contains no more than an ordinary dose of iron, there must evidently be some occult qualities in these waters or a vast amount of credulity in their consumers if they are ever to come into general repute again.

Our readers will learn with satisfaction that the Prince of Wales has been able to send 4,000*l.* to the Lord Mayor as a result of the hospital *fête* recently held at the International Exhibition. The amount will form a tangible addition to sums raised by means of the Hospital Sunday and Hospital Saturday Funds; but is it not a matter for some reproach that charity, pure and simple, is not of itself a sufficient stimulus to unloose the purse-strings of the well-to-do?

PHYSICIAN AND PEDAGOGUE.

Those who are seriously anxious for the solution of the important question as to whether a harmful amount of pressure exists as the result of our system of elementary education, will not read without some regret the report and accompanying memorandum on this subject which have just appeared as Parliamentary papers. Valuable as both these papers are from different points of view, it cannot be denied that the object for which the enquiry was instituted seems less likely to be furthered now than before their publication. It will be remembered that Dr. Crichton Browne was asked some months ago by Mr. Mundella to report to him his impressions of the effect of work on the health of children attending elementary schools. The present report, published after some little Parliamentary pressure and departmental delay, contains an account of Dr. Browne's investigations, together with his conclusions on the subject, which are in accord with the opinion he had previously formed and expressed, that a considerable amount of physical and mental harm may justly be traced to the educational over-pressure which is encouraged by our present system. The memorandum which accompanies this report is written by Mr. J. G. Fitch, one of the chief inspectors of schools, who accompanied Dr. Browne on some of his visits of enquiry. The opinion of Mr. Fitch evidently is that there is practically no over-pressure in the school system, while he directly traverses almost every conclusion of Dr. Browne's and emphatically impugns his data and his reasoning. We may at once say that, while believing with Dr. Browne that a great deal of the alleged over-pressure does exist, and is calculated to engender considerable evils, he has, in our opinion, by the style and method he has adopted in support of his conclusions, given a great occasion to his opponent for a considerable dialectic victory. Were the *facts* indeed cited by Dr. Browne the only foundation for the inferences he has drawn, Mr. Fitch might be credited with a still more important success. The great matter for regret with regard to Dr. Browne's report is, that it is apparently based on observations, as he himself states, made in the brief intervals of leisure which he was able to obtain from his official duties. That Dr. Browne had previously formed an opinion as to the existence of some degree of over-pressure in our schools, and that he is well known as an able exponent of the evils resulting from such over-pressure, should increase rather than diminish the weight of his teaching; nor would it perhaps be going too far to hold that any widely-expressed opinion of medical men conversant with the ailments of the young, and engaged in hospital practice which brings them into contact with many School-board children, would alone be sufficient to decide whether or no there was any necessity for enquiry into the existence of over-pressure. We may certainly give Dr. Browne the credit of having ably emphasized his contention—and he really claims no more than this—that his conclusions possess "some general value and significance, and justify perhaps a further and more complete investigation of the question to which they refer." But in the controversy which will arise on the matter this modest claim will be forgotten, as it already apparently has been by Mr. Fitch; and we can hardly wonder if Dr. Browne's incomplete though eloquent essay is criticised by the same canons which would be applicable to a more laboured and business-like Parliamentary report. The contention which Dr. Browne, now that his paper has been placed before the public in this official form, will be said to have undertaken to support by fresh evidence, involves an enquiry far too vast and complex to rest upon such a very limited number of observations as he was able to make; and were there not a well grounded conviction in the medical mind—the aggregation as it were of many scattered experiences—that much that he says is true, and that a startling disregard of obvious and incontrovertible physiological laws does still obtain in our schools of all grades, we should have to admit that Mr. Fitch partially makes out his own case when he says that Dr. Browne's paper contains not a line which seems to deserve the name of "*proof*" that youthful sickness, weakness, or any other evil is directly traceable to over-work at school. All is fair, we suppose, in war and controversy; and it would have been too much to hope that Mr. Fitch, eager and critical as he has shown himself to be, would be sufficiently free from all taint of official bias to lose this freely given opportunity of regarding Dr. Browne's paper as a serious attempt at exhaustive demonstration of an important thesis. The quasi-accidental garb this report has assumed of a Parliamentary paper is as prejudicial to its real merits and the good it ought to do, as it is conducive to the triumph of those who see no blot in an educational system which is unchecked by medical inspection, and delivers over the developing brains of thousands of children to teachers devoid of physiological knowledge.

There are several points in Dr. Browne's report which on the face of them deserve serious consideration, and to which Mr. Fitch has done but scant justice. That over-pressure in some sense does exist, has been already officially admitted, and, as Dr. Browne insists, has been affirmed by school inspectors, and by

large bodies of teachers. It is certainly to be deplored that in the heat of dialectic dispute Mr. Fitch has passed so lightly over these undoubted facts. Whether Dr. Browne has clearly made out his case that detention and "home lessons" are sufficiently common to constitute a great evil, may at present be somewhat open to doubt, but his allegation that the testimony of teachers is overwhelming as to the existence of harmful over-pressure, is far too weighty and important to be almost ignored, as it has been by Mr. Fitch. Dr. Browne states that he has conversed personally with upwards of sixty teachers, only two of whom denied the existence of over-pressure. All the others deplored it, and many expressed forcibly the pain they felt in having to apply it to the helpless children they are called on to teach. We are convinced that a large number of unprejudiced medical men would from their own observations endorse the opinion of these teachers.

A great deal of the matter contained in Dr. Browne's report is doubtless somewhat hypothetical, and difficult of proof, though much of it is of great interest and importance; and we could wish that he had omitted for the present all reference to the possible remote consequences of over-pressure with regard to the alleged increase of insanity and nervous disease. But when he comes to the consideration of what he calls the connecting links between over-pressure and the increase of nervous disease, he gives some facts of undoubted value, whether we regard them in the light of "links," or only as ultimate results. Among the evils which he refers to—headache, sleeplessness, chorea, stammering, and short-sightedness we would especially notice that Dr. Browne makes out a good *primâ facie* reason to believe that there is quite an undue proportion of headaches among elementary-school children; and the facts and evidence that he adduces on this point are far more weighty and better substantiated than the somewhat captious and strained criticism of Mr. Fitch would lead us to believe. Here at all events Dr. Browne's method of enquiry will not appear so slipshod to the experienced medical man, or to the logician, as Mr Fitch says it did to him; though even here we must freely admit that Dr. Browne's argument, as it stands, is *per se* insufficient to demonstrate his conclusion. With respect to the harm accruing to the eyesight from overwork, Dr. Browne gives some valuable evidence that short-sightedness increases rapidly amongst our school-children during their educational course. This subject is enlarged upon in an instructive manner by Mr. Brudenell Carter, in a letter to the *Times* this week; and both authorities agree that there is evidence in England, and still more in Germany, that over-use of the eyes in book work, and badly lighted rooms, are productive of great and permanent injury to the sight, with many indirect evil consequences. The necessity for further enquiry into the whole matter seems to be gravely emphasized by many parts of Dr. Browne's report; and we can but again express our regret that an excess of zeal and rhetoric, and an absence of demonstrative argument have caused so many joints to be left open in the harness of such an able man as Dr. Browne for the entry of the barbed shafts of such an acute debater as Mr. Fitch. We can but hope that those who are really interested in this very important matter will not be blinded by the immediate and superficial result of the controversy; and that, while allowing to the Government Inspector the glory of having made a palpable though somewhat unfair hit, they will read between the lines of the practical physician's report, and confess that, at the least, the truth lies between them. The existence of over-pressure and the nature of its resulting evils can only be established and assessed by medical men of good physiological and practical knowledge. There is ample reason, as almost all unbiassed people, whether medical or lay, who have any knowledge of school-work would admit, to more than suspect the existence of over-pressure in a very appreciable degree; and we would urge the Government to appoint a small but carefully-selected commission, of which at least half should be composed of medical men who have had experience of practice among children, and especially at children's hospitals, to earnestly and thoroughly investigate the subject. And if each of these medical men were accompanied by a lay commissioner possessing the critical talent of Mr. Fitch, without his obvious professional bias, we should have reason to hope that out of our present darkness on this matter a fruitful light would at last arise.

MEDICAL TEACHING IN THE PROVINCES.

Mr. Shandy, it will be remembered, held very strong opinions, which he expressed with his usual vigour, as to the evils threatened by the excessive growth of London. He deplored the current of men towards town upon one frivolous errand or another, and if he had been an absolute prince would have taken care that his metropolis "tottered not through its own weight, that the head should be no longer too big for the body, that the extremes, now wasted and pinned in, should be restored to their due share of nourishment, and regain with it their natural strength and beauty." If Mr. Shandy had lived in this last quarter of the nineteenth century he would have seen—especially in connection with that medical errand, the memory of which gave such intensity to his language—not one metropolis, but many. There would have been no need now for Mrs. Shandy to have travelled to London; she could have been equally well attended at any one of those nearer northern cities, which are now rising, medically and in every other respect, into such prominence. As was pointed out by the writer of the interesting article on the Liverpool Medical Faculty in our Students' Number, the growth of our provincial towns in wealth and population has entirely changed the character of medical practice therein. "Pure physicians, surgeons, oculists, aurists, gynæcologists, and dermatologists can now make good livings, and give time for teaching also, where formerly there were none but general practitioners so immersed in practice that teaching as we now understand it was an impossibility with them." As a result of these improved opportunities, the leading practitioners in some of our so-called provincial towns are rivalling, and now and then outdistancing, their metropolitan brethren in the

public esteem. It is not uncommon, we are repeatedly informed, for patients who have sought relief in vain in London to succeed in finding it at Birmingham, and certainly in one branch of surgery, the radical treatment of hernia, the surgeons of Liverpool have acted as pioneers to the whole profession. It is true that there have always been distinguished physicians and surgeons in the provinces who by the mere force of their talent and character, and in spite of all disadvantages, have won for themselves a reputation throughout England. But these have been isolated examples, and they have never been able to found a school, for their pupils, if they had any, have been invariably sucked into the great vortex of London life. We do not go to Edinburgh to find the best of Simpson's pupils, for instance. But the conditions have undergone a change. What we are now witnessing, or hoping that we witness, is something very different from the occasional appearance of a provincial comet. It is nothing less than the gradual growth in the provinces of self-contained and self-dependent schools of medical thought and practice, differing in local colour from the great London school, in the same manner though not to the same degree that that school differs from the schools of Paris, Vienna, and Berlin.

This new activity is especially marked in the progressive organisation of the provincial medical schools. No one who has studied the articles on these schools which we published in our last number, or the statistics of the students entering at them, which we gave some weeks ago, can fail to be struck with the growing importance of the provincial centres of medical education. Thirty years ago the medical critic would have been justified in deploring with Mr. Shandy the current of men and money—or in other words of students and fees—to the metropolis. At that time London seemed to enjoy a monopoly of medical education south of the Border. The foundation and successful career of King's and University Colleges had stimulated the older hospitals to import greater method into their educational arrangements, and though the schools were far less completely organised than they are now, there was then no country hospital which could compete with them, and none which professed to give more than a preliminary training in preparation for the final walking of the London hospitals. Some fifteen years ago, however, the provincial authorities began to bestir themselves, and since then the progress of the country schools in organisation and in the favour of students has been so remarkable, that their competition is beginning to be apprehended even by London teachers. The establishment of the Victoria University, and the association of several of the schools, viz., those of Birmingham, Liverpool, Leeds, and Bristol, with Science Colleges has given them another advantage over many of the London schools, where the teaching of the preliminary sciences can only now be carried on at considerable tension. From this and other causes the proportion of provincial to London entries has increased in the last five years from less than one half to nearly two-thirds. In 1883 the eleven London hospitals scored 377 entries, while the eight provincial schools obtained 241, whereas, in 1879, the numbers were respectively, 461 and 225.

There are some who would deplore this result, and no doubt it is one which cannot be regarded with entire equanimity by metropolitan teachers. But the movement is a healthy one and deserves to be regarded with a favourable eye. It may be quite true that such subjects as anatomy, physiology, chemistry, and the other foundation sciences cannot be taught so economically in small schools as in large ones, and that is a strong argument, as we have often pointed out, for the amalgamation of the London schools in respect of such teaching. If it should be found possible it might also, no doubt, be advantageous to the provincial schools to unite their forces for this purpose, and to teach the primary subjects at two or three instead of at eight different centres. Such an arrangement, however, would seriously interfere with one of the main advantages of provincial schools, viz., the possibility of the students residing at or near their homes. But whatever be the advantage of centralising primary medical instruction, no one has yet been found to advocate the centralisation of clinical teaching. The greater the number of hospitals at which clinical medicine and surgery are systematically taught, the greater the advantage to the students, to the physicians and surgeons, to the patients, and to the profession. The growth of working clinical schools in all our large centres of population ought to be regarded by us here in London with sympathy and approval, and encouraged by every means in our power. He is not a true servant of science who looks askance on such progress, because it keeps fees out of his pocket.

ARMY MEDICAL REPORT FOR 1882.

[Third Article.]

The health of the troops abroad during 1882 was of course less satisfactory than that of the men at home. To the usual causes of disease among soldiers must be added, increased intemperance, the depressing effects of climate, and the hardships of war. Before we refer to the reports of different stations we must notice some observations recorded on the subject of intemperance in the Army serving in the East Indies. We are told that "year after year the extension of teetotalism (See Bengal) in the Army is a fact, and it becomes a perplexing one when found in conjunction with a greater number of the particular illnesses due to drink. It is of interest to ascertain whether on the whole there is an increase of sobriety in the force of late years or not." The writer of the report would, if he could, take crime in the Army as a test of the increase or decrease of habits of drinking, but does not consider the evidence within the scope of medical enquiry; so he takes "the relative prevalence of 'dyspepsia' to be a fair index of drinking habits among soldiers." But surely dyspepsia is not frequently the cause of military crime? We know that it is hard for a man with a bad stomach to be a good Christian; but it is not to be supposed that indigestion culminates in crime. The grossest effects of drinking are shown in the prevalence of

alcoholic poisoning, and of delirium tremens; and to these diseases no doubt military crime could be traced. Comparing 1881 with 1882, we find that in the former year the admission rate for dyspepsia was 38·0 per 1,000 while in 1882, when teetotalism was spreading, it was 42·1 per 1,000; showing an increase in the latter year of 4·1. With regard to the admission rate from alcoholic poisoning and delirium tremens in 1881, it was 3·5 per 1,000; and in 1882 it was 4·8, being an increase of 1·3 in the latter year. And yet in 1881 the proportion of abstainers was only about 1 to every $10\frac{1}{2}$ men, while in 1882 it was 1 in every $8\frac{3}{4}$ men. The author notices the admissions from accidents as affording a possible gauge of intemperance, but here again we find that the admission rate for 1881 was 99·1 per 1,000, while in 1882, the year of the spread of teetotalism, it was 107·6, being an increase of 8·7 per 1,000. Medical opinion seems divided as to whether the open canteen system tends to foster or decrease habits of intoxication? Here again we are met by the puzzle that the restrictions of limited hours of purchase were of less efficacy than the open system, as it is believed a smaller sale of canteen drinks takes place under the latter regulation. A possible solution of the conflicting theories might be found in the investigation of the drink purchase in the native bazaar.

Teetotalers may possibly hold some intoxicants as not forbidden; and beer drinkers may be induced to supplement their potations on unlicensed native premises. In the bazaar too, doubtless, there are various intoxicants to be procured not usually supplied in European liquor houses, and we have heard of cases of delirious intoxication which owed their origin to Indian hemp.

The depressing effects of climate must be taken into consideration when we compare the sick rate abroad with that which prevails at home. Sanitation can do much for soldiers' in the East, but it has to struggle against weary odds. Everything that can be done in cantonments affects but a small portion of the enormous country, which is a hot-bed of filth. The fluctuations of the great meteorological phenomena overmaster the best directed attempts of science to control disease; and the high temperature, while it lowers the spirits of the men, leaves their bodies less capable of resisting sickness. We are told that "the interest taken in athletic sports is languid and fitful," and that soldiers look on "games" as merely so many calls upon their labour. During war, the fatigues and exhaustion inseparable from a campaign are superadded to the effects of heat, and no doubt the lowered and uncertain diet tends largely to increase disease. Of course these causes do not affect all foreign stations alike, and the disease and death-rates vary accordingly. Thus at Gibraltar the deaths were 10·31 per 1,000, and of constantly sick 50·35. There was an increase of mortality, as compared with the previous year, of 5·81 per 1,000, and this was partly due to the number of fatal cases of "enteric fever." The *youth* of the soldiers is given as the probable cause. We are informed that "the four infantry regiments composed of comparatively seasoned soldiers, being required for service in Egypt, were replaced in the middle of summer by four unacclimatised regiments from England, consisting chiefly of *very young soldiers*. It is remarked that this undoubtedly increased the sick rate of the garrison."

At Malta we find the greater prevalence of enteric fever was also noticed. The Principal Medical Officer remarks: "The increase is difficult to explain, but since the year 1875 it has gradually increased, and the type of the disease shows it to be more severe. This certainly is my opinion, since Malta has been garrisoned by regiments composed of young soldiers, who are well known to be more liable to the disease than men of mature age." It was not possible, we find, to attribute the disease to any insanitary condition of the barracks or the water supply The grog shops are mentioned as not being in good sanitary condition there, but after all the heaviest drinkers do not reside in grog shops, nor are they likely to be injured by the water they consume there. In Cyprus, again, we find that while in 1881 there were but two cases of enteric fever, in 1882 there was an increase in the admission rate from this disease of 35·3 per 1,000. Only one case was clearly due to local causes, and all the others were imported. "They all occurred in the West Kent Regiment, and though the dates of their admission to hospital were some time after the arrival of the regiment in Cyprus, there can be no doubt that all these attacks were the result of service during the campaign in Egypt."

We suppose the *germ* theory must account for this; but we must notice that "the preponderance during the greater part of the year of very young soldiers in the Royal Sussex Regiment is also given as a cause of the general increase of disease." In Canada we observe that intemperance is returned as the cause of numerous admissions from accidents, wounds, contusions, and fractures. This can scarcely be wondered at, since "proportionately there are more drinking shops in Halifax than in London." At Bermuda, venereal disease was dreadfully prevalent. The admission rate for all forms, was 78·8 per 1,000. The Principal Medical Officer states: "This enormous increase is due to the entire want of supervision and restriction; the need for active and timely interference has been very forcibly represented to the Government of the island." So much for what *legislation* can do or leave undone in combating or fostering disease. In the West Indies, we see a great improvement in the health of the troops. There was a lucky immunity from yellow fever, which had been epidemic in Barbadoes in 1881. At "the Cape" we again have to notice enteric fever. The disease caused 240 admissions and 47 deaths, all the cases occurring in Natal. Here the disease may be attributed *to filth*. The Principal Medical Officer remarks: "This fever has always occurred amongst troops in camp at Natal in the hot season, when the annual rains wash all the filth and refuse down into the water courses; and on the subsidence of the flooded state of the rivers and streams, dirty muddy banks, and refuse not carried away, are left exposed to the sun's rays with an almost tropical heat."

We notice the prevalence of malarial fever at the Mauritius, the percentage of which among the troops is attributed to the faulty position of the barracks. Sanitation might do something here, but we fear the

money difficulty will silence science. In China we find venereal disease triumphant. The admission rate for all forms was 147·4 per 1,000.

The report from Bengal treats largely of enteric fever, and here we must notice the rather remarkable fact, that it is not so very long ago since authorities asserted *that enteric fever was never seen in India.* The truth probably is, that the disease was there, but not diagnosed. On looking back at the Blue-book for 1879, we find some remarks upon this subject in an excellent paper by Dr. Crawford. He said, "In Army life, accuracy of diagnosis is sacrificed to promptitude in classification, and a most undeserved reflection is apt to be cast upon the medical officer for unavoidable errors on his part by his being compelled to do that which, in a disease like enteric fever in this country, is often most difficult and sometimes impossible, in the absence of pathognomonic symptoms." If we turn to the appendix of the Report for 1881 we find in the remarks made by Dr. Maclean, Professor of Military Medicine, that it was at one time imagined that there were two types of enteric fever in India, but the theory is now abandoned. The outbreak in Bengal in 1882 occurred at different stations, and the causes can hardly be determined. The opinion, however, seems to be that the theory of the action of heat, as exciting enteric fever in young men newly arrived in India, is not supported by the evidence. Passing on to Madras, we find an outbreak of enteric fever, which occurred mostly at two seasons, and the deduction is "that some peculiarity of climate or some insanitary condition existed at or previous to these periods which did not exist at other times." We notice particularly that the state of the drainage after the first fall of rain was suspected as a cause of the disease although no insanitary condition about the barracks or their water supply was detected. At Bombay, again, enteric fever was not traced to insanitary causes, but cases are noticed *among the men recently arrived from Egypt,* and the attacks among *young soldiers* are also commented upon.

The report on the health of the troops serving in Egypt is interesting. It gives the medical history of the Army of Occupation, and supplements the story of the campaign, so ably told by Deputy Surgeons-General Hanbury and Marston, in the Blue-book for 1881. The whole period of the residence of British troops, to the end of 1882, must be divided into two parts, as the Expedition lasted from the 17th July to the 9th of October, and the Occupation from the 10th of October to the 31st December. The death-rate of the war period was 76·57 per 1,000, and that of invaliding 766·01 per 1,000.

During Occupation when the fighting was over, the death-rate increased to 100·69, and invaliding decreased to 286·61 per 1,000. With regard to the invaliding we must bear in mind that there was no use in retaining sick men in Egypt when the war was over; for there was no necessity to patch them up for a little more fighting. We notice that during the period of Occupation "the sickness from fevers was largely increased by, and the mortality from them mainly due to, the great prevalence of enteric fever." The report remarks that it would be impossible to enter into the causes that have been assigned by pathologists for the disease, but as far as Egypt was concerned, *all the conditions* were present for the operation of any or all of them. Filthy barracks, foul water, bad food, hard work, fatigue, and reaction after the excitement of the campaign all played their part; but be the causes one or many, it is curious to notice the long period of incubation exhibited by many patients who suffered. For instance, the Brigade of Guards left Alexandria between the 10th of October and the 2nd November, and cases continued to be admitted for nearly nine weeks after that date. It is remarked that "the disease was of Egyptian origin, and that it was not due to infection from one to another (in England) seems highly probable, because the spread of it was confined to those who had been in Egypt." The difficulties of diagnosis are again recognised, and we see that medical authors are blamed for dogmatic assertions in their text-books, since "this fever does not invariably conform to the temperature ranges which have been *far too arbitrarily laid down.*" (The italics are our own.) There is a notice also of the typhoid fever of the French Army of Occupation of Tunis, which deserves perusal. We have only space to remark that the immunity of the hospital attendants is given by the French authorities as an argument of incontestable value against the opinion that *contagion* alone is the cause of the development and the extension of this epidemic. With regard to diseases of the eye, which were so prevalent in Egypt, and which in many cases assumed a purulent character of great severity, we hail with pleasure the pride and delight exhibited in the remark: "By the vigilant and unremitting attention of the medical officers the disease may be said to have been literally *stamped out* in a comparatively short period and *in no instance has there been loss of sight.*" And here we close our notice of the report itself. It is a record of honest work, done in the attempt to investigate, control, and cure the diseases and the suffering to which our soldiers are exposed.

REVIEWS AND NOTICES OF BOOKS.

HEITZMANN'S HISTOLOGY.[1]

(Second Article).

The more one studies the various chapters of this work, whether written by Dr. Heitzmann or by one of his many pupils, the more will one be inclined to admit that a Histological school of great value exists in America. As Dr. Heitzmann says in his preface: "A doctrine which is accepted by good observers in America cannot be lost, but will develop independently of European microscopists, who to a great extent are prejudiced by the teachings of the older masters." And this is true. Scientific teaching has made great strides in America within recent years. Heitzmann is the histological chief of America, and

[1] "Microscopical Morphology of the Animal Body in Health and Disease." By C. Heitzmann, M.D. Trübner and Co.

his school of followers is large. They bring a freshness to bear upon debateable matters which is very agreeable, and we are sure that our readers will derive pleasure and instruction from reading their essays.

To resume our review. The author devotes a chapter to the elucidation of muscle, and adopts Brücke's view that sarcous elements do not exist as solid and unchangeable masses in the living muscle, but are groups of molecules arranged in columns of a varying configuration, at the moment of death. "I am unable to see in the living striated muscle anything else than in the living protoplasm in general, namely, granules and heaps of granules of living matter, the sarcous elements, and between these a noncontractile interstitial substance . . . . All the sarcous elements, whatever may be their size and arrangement, are uninterruptedly connected in both longitudinal and transverse directions . . . . The smaller the sarcous elements, the more rapid and continuous the action of the muscle, and *vice versâ*. Heart, the most active of muscle, has the smallest sarcous elements. Contractility is increased, in bioplasm in general with the smallness of the points of intersection of the reticulum. The theories of Krause's 'muscle caskets' and Schäfer's 'connecting lines' (in the water beetle) 'between the two narrow distal rows, have arisen from the erroneous idea that the filaments run *between* the sarcous elements, while in reality they directly connect them, often at their edges." It is evident that the writer has very decided opinions, leaning to older views modified by his own researches, but we are afraid that we are not any nearer a correct understanding of the structure of muscle, so apparently simple and at the same time so unintelligible.

In Chapter X., writing of the lymphatic system, Dr. Heitzmann says: "During the last fifteen years many erroneous views concerning the lymphatic system have arisen, due to the method of studying, viz., by 'parenchymatous injection' of coloured liquids. Perforations were made at random in the tissues of the body, and liquids were then forced in from without. The results and views obtained by this means are only worthy of being forgotten . . . . . Throughout the lymph ganglia, the spleen, and the lymph tissues in general, erroneously termed 'adenoid tissue,' lymph vessels probably do not exist. . . . . Lymph vessels are like blood-vessels, found only in connective tissue formations . . . . The assertion of Von Recklinghausen that connective tissue is pervaded by spaces and canals, destitute of walls of their own, and thought to be the roots of the lymphatic system, is erroneous, as proved by the chapter on connective tissues . . . . We are not justified by any facts in connecting the spaces round connective tissue corpuscles with the lymphatic system."

Many of the author's pathological views are peculiar and original. They are the outcome of his convictions of opposition to the cell theory. We have not space to refer to these in detail. We will, therefore, only quote Dr. Heitzmann's ideas of the pathology of inflammation. His views on this subject lead him "to the conclusion that a *cellular* pathology, according to the theory of Virchow, cannot be maintained, for in the tissues of the animal body there are no 'individuals,' no 'cells,' and consequently can be no isolated 'cellular foci of disease.' Inflammatory change consists in, first, a dissolution, a liquefaction of the basis substance; and secondly, an increased production by the living matter of its own kind. It is the living matter as distinguished from the interstitial liquid, a solid basis substance, that alone can reproduce its kind, and therefore originate the extensive new formations pseudo-membranes, callosities, vegetations, &c. . . . . The designation 'granulation tissue' is scarcely tenable for the earliest stages of the inflammation, inasmuch as there is no new tissue produced, but only a formation analogous to that from which the inflamed tissue sprang . . . . The general designation of 'inflammatory new formations applied to 'suppuration' or 'formation of pus corpuscles,' is decidedly incorrect." Heitzmann claims that newly appearing as well as newly-formed elements are interruptedly connected by filaments of living matter, with each other, and with non-inflamed neighbouring tissue. Wandering cells are single corpuscles separated from their neighbours. Newly-formed blood corpuscles, lying within newly-formed blood-vessels are really separated from the parent soil. Pus corpuscles are isolated elements separated from one another by liquid.

At first is an excess of nutriment, the youngest portions of the tissue unit (nucleus and nucleolus) are first affected and return to the juvenile condition; the basis is subsequently dissolved out, and a number of centres (such a nucleus or nucleolus) return to the juvenile condition. If the connection between the corpuscles remain, a medullary tissue is produced; if not, hæmato-blasts, and eventually red corpuscles.

Tumours and tuberculosis have long chapters devoted to them. Heitzmann concludes that tubercle is an inflammatory new formation, rising from an inflammation with a scanty neoformation of living matter and without any new formation of blood-vessels.

We cannot follow the author through the remaining pages of his book. It will have been seen from the numerous quotations we have made, what an independent thinker he is. Indeed the book is strikingly original. We venture to think that the earlier portions, however, are the best. The work contains many papers written by the author's own pupils, some of which are important. The list of contributors includes Abbott, Beyer, Bödecker, Davis, Elsberg, Emerson, Franke, Greene, Hasslock, Heitzmann, Hoeber, Holbrook, Hurlbutt, Johnstone, Meyer, Millard, Müller, Ripley, Rockwell, Schöney, Tanszky. Many of these writers contribute papers of great value and originality. That all this work should have been done during the last ten years, speaks well for the energy of Heitzmann and his pupils.

The style of the book is good, and we cannot close our remarks without calling attention to the excellence of the engravings, of which there are nearly four hundred. These are all original, and taken from the author's own drawings. We congratulate the publishers upon having produced an admirable volume, well printed with clear type, upon good paper, and well bound. Some of our English publishers would do well to take example by this.

THE INTERNATIONAL MEDICAL CONGRESS.

XI.—Section of Laryngology.

President:—Dr. Morell Mackenzie.

The laryngoscopists have this year for the first time obtained the franchise in the great International Medical Parliament. At Amsterdam they were not represented at all, in London they were only admitted as a sub-section, but at Copenhagen they were allowed the full honours of a Section. The meetings were well attended during the entire week. Drs. Bayer (Brussels), Beschorner (Dresden), Bosworth (New York), Bresgen (Frankfort), Catti (Fiume), Daly (Pittsburg), Delavan (New York), B. Fränkel (Berlin), E. Fränkel (Hamburg), French (Brooklyn), Gottstein (Breslau), Hooper, Hedley, Hering (Warsaw), Krause (Berlin), Michael (Hamburg), Morell Mackenzie, Moure (Bordeaux), Roe (Rochester, U.S.A.), Schmiegelow (Copenhagen), Schnitzler (Vienna), Schäffer (Bremen), Semon (London), Welmer (Frankfort), and many other well-known representatives of laryngoscopy from Europe and America being present. Dr. Morell Mackenzie was unanimously elected President.

The Structure and Diseases of the Tonsils.

At one of the first meetings, Dr. Bosworth, of New York, presented a communication on "The Structure of the Tonsils and their Diseases, from a practical point of view." His views represented a "new departure," for in opposition to Luschka, Sharpey, and other anatomists, who have described the tonsil as an almond-shaped organ possessing a fibrous investing sheath, he maintained that the tonsil is in fact "a group of glands." His pathological views were also somewhat curious, for he argued that quinsy is not tonsillitis, but "a phlegmonous inflammation of the areolar tissue of the soft palate or pharynx." It cannot be said, however, that Dr. Bosworth's new views were received with any favour by the members of the Section.

Motor Impairments of the Larynx.

On the following day Dr. Felix Semon read a paper in which he proposed "an ætiological classification of the motor impairments of the larynx," and after dealing with this subject in considerable detail, he proceeded to make some remarks on abductor paralysis. He stated that from examinations made both on living and on dead subjects, he had come to the conclusion that when the vocal cords are at rest, the glottis is more widely open than in the so-called "cadaveric position" which has hitherto been supposed to represent the intermediate condition of the vocal cords, *i.e.*, their position midway between inspiration and vocalization. Allowing, however, for this, the glottis is still the narrowest part of the air tube, and Dr. Semon expressed the opinion that "within the nucleus of the spinal accessory nerve there is a strict differentiation of the ganglia according to their functions, and that the one ganglion on each side which presides over the abduction of the vocal cord on that side, constantly receives impulses from the neighbouring respiratory centre. These impulses, however, are not generated within the respiratory centre itself, but are brought into action by stimulation transmitted to the respiratory centre through the afferent nerves contained in the trunk of the pneumogastric."

Dr. Hermann Krause, of Berlin, then read a very interesting communication, giving an account of experiments performed by him on animals, which went to show that the voluntary muscles of the larynx have a cortical centre. On exposing a dog's larynx, and irritating a certain section of the cortex by electrical currents of moderate intensity, he invariably noticed rising of the larynx, movement of the vocal cords to a position midway between expiration and phonation, raising of the palate, contraction of the constrictor pharyngis, and movements at the base of the tongue. By applying stronger currents, the adductor muscles were thrown into a state of spasm. That the part of the cortex in question is the centre of the laryngeal movements was further confirmed by experiments of extirpation, which were successfully performed on both sides in ten dogs. The cortex was experimented upon, first on one side and then on the other, and after all inflammatory symptoms had subsided, and the cerebral wounds had cicatrised, or were in course of cicatrisation, it was found that eight of the dogs had entirely lost the power of barking, and on attempting to do so uttered either no sound at all or only a hoarse whine. In the case of the two dogs which were still able to bark after the operation, it was shown that the excision had not been properly performed. From these experiments, Dr. Krause had come to the conclusion that the so-called paralysis of the *ab*ductor muscles of the vocal cords is in reality tonic spasm of the *ad*ductors, and that the wasting of the abductors is a secondary degenerative change resulting from non-use. The reading of this paper was followed by a somewhat warm controversy, in which Drs. Semon, B. Fränkel, Krause, and others took part, but no decision was arrived at.

The President, in closing the discussion, expressed regret that more attention had not been bestowed on the important subject of classification, and that the burning topic of the abductors had monopolised the debate. He called attention to spasm of the vocal cords, one of the items in the proposed ætiological basis of arrangement. He (Dr. Morell Mackenzie) considered that the affection might be called "vocal cramp," and might be looked upon as analogous to "writer's cramp." It affected only those who had to use their vocal organs to excess, and he had met with it principally among clergymen. In the only cases in which he had found it in women, the patients had deaf relations to whom they were constantly speaking in a loud voice. An example of the affection occurring in a huntsman was shown at the International Medical Congress in London by Dr. Semon, on behalf of the speaker.

Dr. Bryson Delavan, of New York, next gave a report of two cases, which tended to show by clinical evidence that there is a cortical centre of motion for the larynx in the vicinity of Broca's convolution, and supplied by the anterior branch of the middle cerebral artery. One of the cases which supported this view was that of a man, aged 69 years, who suffered from hemiplegia on the left side, and paralysis of the left side of the face and tongue. His voice, from having been full, deep, and sonorous, became cracked, piping, and uncertainin tone. The left vocal cord was seen both by Dr. Delavan and Dr. Clinton Wagner, to whom the case was referred, to be fixed in the median line, that is, in the position of adduction. In the second case (which was originally reported by Dr. Seguin), there was also at first left hemiplegia with impaired power of articulation, from inability to control the muscles of the pharynx and larynx. No laryngoscopic examination was made. Subsequently the patient had an attack of right hemiplegia with aphasia, from which he died. The autopsy showed that the surface of the third frontal convolution on the right side, and the grey matter beneath it was yellow in colour, and had a tough elastic feel. The lesion was about an inch square in superficies, and a quarter of an inch in thickness. A similar change, but less in degree, was found on the left side. The left middle cerebral artery was plugged by an embolus, at a point half an inch from its origin. A portion of brain, about half an inch in diameter, supplied by this artery, was in a softened state.

(*To be continued.*)

ABSTRACTS AND EXTRACTS.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

Abstract of Dr. Crichton Browne's Report, and Mr. Fitch's Memorandum.

Dr. Crichton Browne commenced his investigation with the opinion that educational over-pressure did exist to some extent in elementary schools, an opinion, he tells us, founded upon three things; first, statements made to him by medical men; secondly, the fact that certain well-known physiological laws were disregarded in the elementary,

schools, which laws could not be disregarded with impunity; and thirdly, the assumption that the indiscriminate brain-forcing which he had seen in middle and high class schools extended into the lower schools also. He then proceeded to mention the evidences of over-pressure which he had met with in the course of his investigation.

(1) The first point was the *detention* in school after hours, which the teachers assured him was necessary, in order that the requirements of the inspector might be satisfied, and a sufficient number of passes be obtained.

(2) *Home lessons* came next, but as these were not approved of by most of the London teachers, not much was said upon this head.

(3) *The testimony of the teachers themselves*, as expressed in their associations and conferences, showed that in London at any rate they believed firmly in the existence of over-pressure. Of upwards of 60 teachers with whom he conversed on this subject, only two denied the existence of over-pressure.

(4) *The condition of the children* would settle the question of over-pressure in itself. In the elementary schools the backward children were the ones who suffered from the effects of over-pressure, as one teacher had forcibly observed to him, "Not only do these dull children break down in health under our manipulations, but they grow more stupid, seeming to lose in general intelligence what they gain in mere technical knowledge of reading, writing and arithmetic." Examinations he pointed out were in this direction producing a rich crop in the future of nervousness. Backward children he divided into three classes, the dull, the starved, and the delicate. *Dulness* shaded off gradually into imbecility, a condition which might supervene at any point in the mental evolution. The *starved* constituted a more important section of the backward children. A not inconsiderable number of children were found to have come to school without any breakfast at all, besides a much larger number who were quite insufficiently fed. Then there were the *delicate* children, labouring from a great variety of ailments, but all were expected to get through the same amount of work, and make the same progress as those who were healthy.

Over-pressure had its origin in great measure in the *examination* system, and this arose from the system of *payment by results*, results proximate and partial, not the real final results, which could not be known under many years. When asked as to the effects of over-pressure, the steady increase in insanity might be pointed out as an evidence of high pressure, though at present sufficient time had not yet elapsed to demonstrate its relation to education. The great increase in suicide too, was instanced as coinciding in time with the modern extension of education, and as being most prevalent in regions where education was most widely diffused. But it was in other diseases of the brain and nervous system that the evils of over-pressure were more clearly manifested, hydrocephalus and cephalitis being instanced as diseases which had become relatively more common at the school age during the last twenty years. Diabetes mellitus was specially singled out as an instance of the greater tendency to diseases of the nervous system in modern days.

The next step was to ascertain if any connecting links between these grave disorders of the nervous system and educational over-pressure existed, and for this purpose he had enquired into the history of *headache* amongst some of the children. The result of this investigation was that 46·1 per cent. of the children professed to suffer from them habitually. These results were obtained after considerable cross-examination in every case where there seemed any reason to doubt the answer of the child. It was further found that in a considerable majority of cases the headache occurred in the afternoon, but that in the higher standards evening headache predominated, whilst the morning headache occurred, as might have been anticipated, amongst the half-starved. The headache was frontal in a very large proportion of the cases. Next the question of *sleeplessness* was enquired into, a subject beset with many difficulties, as various causes might intervene to produce sleeplessness besides school troubles, but *somnambulism* and *somniloquency* could be more easily proved to exist, and were found to exist in considerable proportion and to be more or less directly associated with the school work. Of *chorea*, contrary to expectation, he met with no examples, though choreiform movements were occasionally seen.

A brief allusion was made to the relation of *neuralgia* and allied disorders and *shortsightedness* to education.

The report concludes by contrasting the condition of the children in some schools in the south of Scotland with those in London, much to the disadvantage of the latter in a physical point of view.

Mr. Fitch commences his memorandum by expressing his regret that he had not been told the object of Dr. Browne's investigations, as he would have been able to introduce him to typical schools, and in other ways to aid him in obtaining reliable information as to the working of the Education Acts. He also calls attention to the fact that Dr. Browne was not an unprejudiced observer, having denounced the system before he had any personal knowledge whatever of its working.

The schools which Dr. Browne visited happened to be situated in some of the poorest districts in London, and Mr. Fitch considers that before attributing any ailments found amongst these children to the school work, a similar enumeration ought to be made of children not at school at all, of children under instruction in the higher schools or at home, and of an equal number of human beings, children or adults, collected at random.

He objects to the method adopted by Dr. Browne of questioning the children in a body, asking them to hold up their hands if they had a headache and so forth, and considers that the children regarded the whole thing as a joke, and the results so obtained to be unreliable.

Mr. Fitch quotes long extracts from the Registrar-General's Reports, which show a continuous and satisfactory improvement in his opinion in the death-rate of children of school age during the last few years, but they also show the very fact for which Dr. Browne contended, viz., an increase in the death-rate from diseases of the brain during that period.

As to the health of children in the schools Mr. Fitch gives it as the result of his experience that wherever the school work is best done, there the signs of health and cheerful activity are most manifest.

Over-pressure, he says, is a new word, and public discussion of it is new, and, so far as he is aware, every case in which scholars have been alleged to have suffered or died in consequence of the strain of school work has broken down upon close investigation, and been shown to be attributable to other causes.

Mr. Fitch denies that the requirements of the Education Department have been increased of late years, or that more time is devoted to instruction now than formerly; and as regards the detention of the children in schools after hours, Mr. Fitch complains that Dr. Browne does not mention the names of the schools where he found this to be the case, or the names of the teachers who said that they were obliged to keep the children in in order to satisfy the requirements of the inspectors and obtain a sufficient number of passes. The schools in which the best results are obtained are those in which detention for the purpose of preparing lessons is wholly unknown.

Mr. Fitch absolutely disbelieves Dr. Browne's statements about the effect on the children's minds of the examination and says that on the contrary the children look forward to them with great eagerness.

As regards the work that is expected of backward children, Mr. Fitch points out that the same is not expected of them as of other children of their own age, for the simple reason that the more clever children get promoted, leaving them behind. Home lessons seldom require more than half an hour to prepare, and are in less general use at the present time than at any period during the last twenty years.

He objects that Dr. Browne states that teachers have at their conferences and associations expressed their disapproval of over-pressure, without taking the trouble to verify or correct the anecdotes, rumours, and resolutions of local meetings, on which such statements are based.

As regards the payment by results, he contends that Dr. Browne is entirely under a misapprehension in his remarks,

as it is the managers of the school and not the teachers who are paid by the results, and the results do not refer to the examinations alone, but to the general discipline and conduct of the school. In conclusion he does not hesitate to say that every one of Dr. Browne's judgments appear to be hasty and inaccurate and arrived at by a loose and partial method of enquiry. "There is," he says, "in Dr. Browne's paper much strong assertion, but there is not a line which seems to me to deserve the name of 'proof.'"

THE PRESS ON DR. CRICHTON BROWNE'S REPORT.

The *Times* says:—"The report of Dr. Crichton Browne is undoubtedly full of interest, and it is written with much literary ability. But it asserts a foregone conclusion in almost every page, its reasoning is so deplorably loose and inconsequent, it contains so much irrelevant matter, and its style is so rhetorical, not to say florid, as to deprive its conclusions of much of their weight and authority. This judgment is strengthened by the perusal of Mr. Fitch's temperate and able memorandum, in which Dr. Crichton Browne's qualifications for his task are examined, his methods of inquiry criticised, and his alleged results subjected to a searching but fair examination. A comparison of the two in tone, temper, sobriety of language, and cogency of reasoning will lead inevitably to the conclusion that the Education Department may far more safely be trusted in the matter of over-pressure than Dr. Crichton Browne."

The *Daily News* says:—"Dr. Crichton Browne has indicated very forcibly and very vividly what the dangers are against which educationists should be scrupulously on their guard; but he has invested these imaginary dangers with the character of reality. There may occur a few cases of over-pressure; it would be strange if among four million children this were not the case. But we are convinced that such instances are extremely few and far between. The elementary curriculum is certainly adapted, even to the capacity of slow and dull children, and the hours are not by any means too long."

The *Daily Telegraph* is "not surprised that the report has been kept back so long, for it certainly gives a very startling account of the injury to health caused by the excessive education of weak, stunted, sickly, and ill-fed children in our great cities and towns. Though the report may be 'sensational,' the result is due not only to Dr. Browne's style, which is fervid, but to the facts. We are forcing upon children physically unfit an education suitable only for well-fed scholars. That is a cruelty which no official apologies can explain away."

The *Globe* says that it is notorious that in all schools of all classes there is over-pressure, and that if Dr. Crichton Browne had seen no signs of it, he must have been dishonest or blind. This is a medical question, and the right course for the Government would be to institute a medical inquiry, to decide the issue between themselves and Dr. Browne. It will be deplorable if the controversy is allowed to end with an appeal from the Education Department to its own officials, who, acting no doubt in entire good faith, cannot help seeing with official eyes.

The *Pall Mall Gazette* affirms that no one can read the report without being painfully impressed with a new sense of the grim realities of life in London. Dr. Browne may be as mad as any of his patients, as the *Times* almost suggests, but he has done good service in startling the public by so lurid a picture of what in some easily conceivable circumstances must be the inevitable result of the working of our educational machinery; his contrast between the starved, rickety children of our slums and the hardy bairns of the Scotch peasantry, is painfully suggestive of a great flaw in our social organisation.

The *Echo*, claiming to speak with full knowledge of the inner working of Board Schools in more than one locality, does not hesitate to say that everywhere teachers could pick out children who in their judgment ought not to be forced up to examination, and that in such cases the teachers do not feel free to act in accordance with their judgment. The *Echo* thinks it would be advantageous to obtain the appointment of a medical man, if possible, on each Board of Managers. The powers of managers have been somewhat increased of late; and perhaps Dr. Crichton Browne's report may stimulate them to greater activity. If managers, however, take action, they must take care to do so long before the annual examination. It is of no avail to withdraw a child on the eve of the visit of the inspector; where over-pressure exists it is in the preparation for that visit.

The *Leeds Mercury* says:—"We fear that Dr. Crichton Browne's report on over-pressure in schools is conclusive as to the need of relaxation of the present system of cramming information into children of tender age. The difficulty, however, is to draw the line between what should and what can be done, and possibly it will be found that the ultimate responsibility must rest with the parents and not with the teachers. The latter might easily be discouraged into a listless indifference, which would be more fatal than the present stimulation. But parents, when they take the trouble of giving attention to the matter, may easily see that the demands upon their children are not beyond their capacity."

PHARMACOLOGY AND THERAPEUTICS.

Treatment of Diphtheria.—Recent numbers of the *New York Medical Journal*, and of the *Boston Medical Journal*, have contained several communications on this subject, chiefly with reference to the use of large doses of mercuric chloride, a method which appears to have originated with Dr. G. A. Linn, and which was afterwards so warmly endorsed by Dr. Wm. Pepper, of Philadelphia, as to have become known as Pepper's treatment. Dr. Thallon points out that the drug has hitherto been used in two ways. (1) As a local application (spray or wash). (2) As a constitutional remedy. He is sceptical as to the value of local treatment, except that of a soothing character. As regards the second method, he points to Koch and Sternberg's experiments which prove that the addition of one thirty-thousandth part of corrosive sublimate will arrest decomposition in bacterial fluid outside the body, while one twenty-thousandth will effectually sterilize it; and, having regard to the relative proportions of blood and body-weight in the individual, to the natural disease-resisting power of living tissue, to the fact that the elimination of the drug is slower than its absorption (Mayençon), and that it therefore possesses a cumulative action, and its value as an "aplastic antiphlogistic" (Robt. Hamilton), he asks whether it is entirely out of the way to suppose that during some period of the treatment by large doses of the perchloride, there may be enough of the salt circulating in the blood—either free or in combination—to arrest, or at least to modify, the septic process? The doses should be large, frequently repeated, and *freely* diluted. He usually employs one or other of the following formulæ:—(1) ℞ Hydrarg. Bichlor, gr. ss; Tinct. Ferr. Chlor., fl. ʒ iij; Glycerin. fl. ʒ ss., Aq. ad. ʒ iij. M. Sig. fl. ʒ j, as directed, in water. (2) ℞ Hydrag. Bichlor. gr. ss., Vin. Pepsin., Elixir Bismuthi, aa., ʒ jss., M. Sig. fl. ʒ j, as directed, in water. Each teaspoonful thus contains gr. $\frac{1}{40}$. The condition of the false membrane is the best guide as to increasing, continuing, diminishing or stopping the remedy. Several cases are given in which this treatment proved valuable; no toxic effects were observed. In the sloughing sore-throat of scarlatina a similar beneficial action was noted. Dr. A. Jacobi objects to the use of pilocarpine, believing that it sometimes hastens the fatal termination by inducing cardiac failure. In certain cases steam-inhalations are of great value, but care must be taken that the patient is allowed abundance of fresh air at the same time; he is also convinced of the utility of turpentine vapour (a tablespoonful of the rectified spirit or oil may be poured into water heated over a lamp or stove, every hour or oftener). The treatment by bichloride of mercury he has found very satisfactory as a rule; to infants half-a-grain (sometimes more) may be given in the 24 hours, and this quantity may be kept up for a considerable number of

days; free dilution (one grain to a quart of water) serves to obviate salivation, stomatitis, and gastro-intestinal disturbance, but should these occur, inunction of the oleate of mercury may be substituted for the internal administration of the bichloride. Dr. J. L. Smith is impressed with the importance of alcohol in the treatment of certain cases; he had often known a child one year old take with advantage as much as a teaspoonful of brandy or whisky every hour. Mercuric cyanide, favourably reported of by Dr. Erichsen, of St. Petersburg, some years since, in doses of gr. $\frac{1}{96}$ to gr. $\frac{1}{48}$, has recently been again advocated by Seledén of Stockholm, who gives, every hour or half hour, one teaspoonful of a solution containing gr. $\frac{1}{10}$ to the ounce, which is also to be used as a gargle. Dr. G. A. Linn states that suffocation from obstruction of the air-way—of which there is danger when the diphtheritic membrane invades the larynx, causing croup—is mainly due to a spasmodic condition of the glottis, and can be relieved by giving chloride of gold, which is a specific in simple croup. It acts like a charm, is tasteless, and causes no nausea. It should be given dissolved in distilled water, the medicine being dropped into a glass, and the use of a spoon avoided. The dose for a child 2 years old is from one-fiftieth to one-thirtieth of a grain every hour until relieved. In diphtheritic croup it should be given in conjunction with bichloride of mercury. Of the latter salt, Dr. Linn gives one-twentieth to one-twelfth of a grain every three hours to a child 2 or 3 years old, and one-eighth of a grain to an adult. In mild cases it should be given thus to the end of the third day; in malignant cases for two or three days longer.

The Treatment of Pulmonary Affections.—In a paper on the local treatment of the respiratory organs in the *Liverpool Medico-Chirurgical Journal* for July, Dr. F. T. Roberts points out the importance of getting a patient to pay voluntary attention to the acts of breathing and coughing. In many acute pulmonary affections, it was better that the patient should be left at rest, and not be frequently made to breathe deeply for the purposes of clinical examination. On the other hand, there were cases in which it was important to recognise the necessity for energetic respiratory action, so as to open up and prevent the collapse of the smaller air-tubes and air-vesicles. The placing the patient in a suitable posture would materially aid in this matter, and sternutatories and emetics acted in the same way. This line of treatment was indicated where there was a tendency to hypostatic congestion, also in some cases of phthisis, to prevent the possible risk of further infection.

The Hydrobromate of Homatropine.—In a paper on inflammation of the iris, read by Professor Reynolds at the Kentucky Medical Society (*Philadelphia Medical Times*, June 28th), he expresses the opinion that sulphate of atropia will have to be abandoned as a mydriatic in consequence of the violent inflammation and the increase of tension of the eyeball which it frequently gives rise to. Fortunately, he adds, the hydrobromate of homatropine produced by synthesis, by "that prodigy in science, Marck," well supplies its place and is unattended by its dangers. It is, indeed, more promptly and powerfully efficient in dilating the pupil and suspending the accommodation of the eye, and more readily relieves the pain of ciliary neuralgia. "I have gradually come to rely upon the anodyne properties of this drug, because, in my experience, its soothing effect is more persistent than that of atropia, while the therapeutical indications are the same." Its expensiveness is the only objection, as it is now retailed at 75 cents a grain, which is dissolved in a dram of water; but a single drop of the solution is enough for one application. It may be applied in severe cases of pain from acute iritis every five minutes until the pain abates, and that for an indefinite time without producing any constitutional disturbance. In the healthy eye the effects on the pupil disappear in from 24 to 30 hours, while those of the sulphate persist from 8 to 14 days.

Iodoform in Diabetes.—In Seguin's *Archives of Medicine* for April, Dr. Sara Post reports in considerable detail two cases of diabetes in which she tried Moleschott's iodoform treatment, with the result of "showing coincident diminution of sugar and urea, together with an increase of weight; also and more especially showing that toxic doses of the drug are unnecessary, and, further, that they are prejudicial to its therapeutic action." After noticing also what has been done by other observers Dr. Post thus terminates her paper, "(1) Iodine in doses of from 1 to 2 grammes per day, has diminished the sugar and urea, and has increased the weight in two moderately severe cases; (2) The therapeutic influence of the drug was limited to the first few weeks of its use; (3) Increase of sugar and of urea with diminution of weight accompanied the iodoform toxæmia in both cases; (4) The toxic symptoms were anæmia, salivation, diarrhœa, agitation, trembling, choreiform movements, sleepiness, and paresia. To conclude: It is proposed that in iodoform treatment of diabetes, systematic interruption to the medication should be made. With a dose of one gramme in the twenty-four hours, the interruption may be made at the end of from one to two weeks; the intermissions may consist of from one to two weeks, and the entire quantity may be given in a single dose, securely sealed and taken at night."

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XV.

Appliances for Minimising the Dangers to Health and Life Incident to Certain Trades.

The enormous power exerted by the circular saw, the steadiness of its movement and the ease with which its action can be guided and controlled, has led to the extension of its application to nearly every cutting operation from sawing timber to ivory carving, the saws themselves or "drums" ranging in diameter, according to circumstances, from a couple of yards to the third of an inch. As might have been expected accidents have increased in proportion, and the loss of one or more fingers is of frequent occurrence. Men thus mutilated may be seen in any workshops, but amputations of arms or hands are by no means uncommon, and occasionally a man, stumbling over the heaps of sawdust, has fallen on a saw revolving 1,200 times in a minute and been literally cut in two.

Other accidents, sometimes of a fatal character, are caused by the jumping or the recoil of the timber, by knots or other hard bodies flying out and striking the heads of the men, and, especially where metals are the materials operated on, by dust or filings entering the eyes with some force.

To prevent such accidents is not difficult, and two models of circular saw benches are here exhibited, provided with guards constructed on very different principles. That shown by Mr. J. B. Lakeman, H.M. Inspector of Factories (1316), is in the form of a roof protecting the upper half or more of the segment of the saw exposed above the bench. It consists of a sheet of iron of suitable width following the curve of the saw, and then bent off horizontally at either end, and is capable of lateral, horizontal and vertical adjustment.

The other (1319), by Messrs. Clayton and Shuttleworth, of Lincoln, consists of a narrow strip of sheet iron in the same plane as the saw which it encircles, through about two-thirds of its circumference. It is connected by a double crank to the axis of the saw, and to a weight which somewhat more than counterpoises it. It is thus capable of revolving around the saw so far as to cover the whole of the exposed semi-circumference or to uncover the working quadrant. It is adjusted by a clamp to any desired position, but when released from the clamp the weight of the counterpoise carries it backwards and uncovers that part of the saw.

Each, no doubt, will be preferred under certain circumstances; Mr. Lakeman's effectually shelters the workman from accidents of every kind, but the other, while guarding the cutting edge of the saw, does not conceal it from view, an obvious advantage in carving, cutting out the teeth of

wheels for watches, and other complicated and delicate operations.

Mr. W. Clark, of Plumstead, exhibits a model of an apparatus for drawing dust and foul air from grinding machines, which has already been adopted in the laboratory of the Royal Arsenal at Woolwich, but would seem calculated to effect a hygienic revolution in every department of grindery. Beneath each grinder's lathe is a hopper communicating with a horizontal pipe; these pipes enter a long rectangular chamber placed transversely, with doors or sliding flaps at each end; here the heavier particles are arrested, and from it they are removed as often as may be necessary. The finer and lighter dust passes from this chamber through large tubes to a vertical exhaust shaft in which a powerful fan maintains a strong draught throughout the entire apparatus. This shaft is kept full of spray to intercept the dust, the escape of which is further guarded against by a series of shelves fixed on either side of the shaft and slanting downwards towards the centre. The mixed dust and water runs down there in a semi-fluid form to a tank at the bottom of the shaft, whence it is drawn off from time to time.

It is much to be desired that the use of this apparatus could be made compulsory in all knife, needle, button, glass and other dry grindery works until some equally or more efficient contrivance be devised.

Professor E. V. Gardner exhibits a partial model, though unfortunately without any explanations, of his patent apparatus for making white lead, and samples of the product in the crude and prepared states. We have on several occasions commented on the manufacture as at present conducted, the failure of the most elaborate and stringent regulations and precautions to appreciably lessen its terribly fatal effects on the women employed in taking down the stacks and in carrying the pans to and from the stoves, as well as to the want of success that has attended all attempts to substitute precipitation processes, the products of which are harsh, crystalline, and unfit for finer work. Professor Gardner's process has, however, been before the world for over two years, and while the result is a soft amorphous genuine white lead, it is entirely free from danger to health, being conducted by electrolysis in closed chambers, and moreover, occupies but as many weeks as the older one does months. Should its practical success realise the hopes of the patentee, the stack process ought certainly to be made illegal after a period of a few years, since the professor would, no doubt, be willing to permit its general adoption on payment of a royalty.

Messrs. Harrison, of Hatton Garden (1327), Davis, of Kennington (1328), and Squire, of 413, Oxford Street (1329), exhibit a variety of eye, nose and mouth protectors, but however effectually these may answer the purposes for which they are designed, we believe that the real or imagined inconveniences attending their use will always stand in the way of their general adoption, and for this reason, among others, we attach more importance to means such as the exhaust system of Mr. W. Clark, which we have just described.

The interference with the respiratory and digestive functions from the faulty attitudes assumed by shoemakers in their work and their habit of pressing the last against the chest or steadying it between the feet and knees are matters of common observation. To obviate these, Mr. C. Hare, of Norwich, shows a simple but ingenious last (1336), mounted on a stand provided with a ball and socket-joint, which can be fixed in a moment in any desired position; and Mr. Sparkes Hall, of Regent Street, an upright shoemaker's bench (1337).

The Rettie Patent Seat Co., Limited, appear to have solved the problem of providing seats for shop assistants which shall not present any impediment to movement behind the counter. They exhibit (1334) a number of these attached in different positions around a dummy table and desk. The seat is hinged to the leg and this to the foot, which is fixed to the floor *beneath* the counter, and by means of a strong spiral spring the two hinges so work together that a single movement of the hand serves to bring the seat into use or to replace it completely out of the way. Of course these seats will be found convenient wherever space is limited, but to female attendants in shops their adoption would be a blessing. The address of the Company is 10, Bush Lane, Cannon Street.

Mr. Robert Adams, of 17, Blackman Street, Boro', exhibits a number of improvements in window fastenings, cord-holders, &c. (1320), among which we may mention the Toby cord-holder, which, originally intended for venetian blinds, has been adapted to fastening ropes of any size. By its use, as the inventors state, any person in workshops or warehouses can remove goods from the ground floor to upper floors without assistance, thus avoiding to a great extent accidents which occur through carelessness in leaving hold of the rope before the person at the top receives the goods. The catch is simplicity itself, but the grip is remarkably firm, and the more so the heavier the weight attached. He exhibits also a patent window, which can be instantly reversed for cleaning without removing the sashes from the frame, and a method of making sliding windows reversible to avoid the danger of external cleaning, which can be applied to existing sashes at a trifling cost.

Still better are the window-frames and sashes shown by Mr. W. W. Nichols, of 42, Luard Street, Caledonian Road, N., in Class 25 (703), which require no weights, one frame balancing the other; and his method of rendering ordinary sashes reversible, for cleaning, without removal of the beading, at a cost of 7*s.* 6*d.* per window. There are in this section a large number of appliances for minimising the dangers incident to slipping belts, and other operations connected with machinery; also, safety-lamps, steam pressure-gauges, safety-valves and plugs, governors, indicators, apparatus for use in mines, &c., too numerous, and of a too purely technical character for description in our pages.

But we cannot conclude without calling attention to the Silicate cotton, or slag-wool, spun, under C. Wood's patent, from blast furnace slag, by Fred. Jones & Co., of Perren Street, Ryland Road, N.W. It is an asbestos-like fibre, having the appearance of ordinary white wadding, perfectly incombustible, very light (one ton covering an area of 1,800 square feet, one inch thick), and inexpensive. Perfectly dry and non-absorbent, and absolutely free from organic matter, it is as the manufacturers describe it, "fire proof, frost proof, sound proof, and vermin proof," as well as a bad conductor of heat. It seems likely to supersede nearly everyother material for fireproofing and pugging walls, floors, roofs, &c.; for lining iron buildings, and covering steam-boilers, pipes, refrigerating chambers, &c. They have also, though not exhibited here, a slag felt, made from the cotton, the adhesive medium being also inorganic, a silicate of potash, and a cement of which the slag silicate is the basis.

OBITUARY.

JULIUS COHNHEIM.[1]

Born at Demmire, in Pomerania, in July, 1839, Julius Cohnheim pursued his University studies at Berlin, Würzburg and Greifswald, and received his diploma in 1861. Even during his studentship he engaged in the study of pathological questions, which were afterwards to occupy so much of his attention, and a translation of his inaugural dissertation on Inflammation of the Serous Membranes appeared in the 22nd volume of Virchow's *Archiv*. Chosen, in 1864, as assistant in the Pathological Institute of Berlin, by Virchow (who had the melancholy duty of announcing the news of his death at the Copenhagen Medical Congress), he laboured hard at minute and pathological anatomy, and had already acquired a high reputation when in 1867, on the appearance of his celebrated treatise "Ueber Entzündung und Eiterung," his name became known to the whole scientific world. This produced a true revolution in the study of pathological anatomy, and years hence, when the history of the doctrine of inflammation comes to be written, must be regarded as an "epoch-making" work. At this scientific epoch, its

[1] By Prof. Wittich, in the *Berliner Klinische Wochenschrift*, Sept. 3.

author devoted himself almost exclusively to experimental enquiry with results unsurpassed by those of any of his contemporaries. Receiving a summons to Kiel, in 1868, he there held the Chair of Pathological Anatomy and General Pathology until 1872, when he repaired to Breslau, as successor to Waldeyer. There, during the winter of 1872–73, he was obliged to suspend his teaching and resort to the South, on account of an attack of aphonia accompanied by great debility. Restored for a time to health, he resumed his labours with all his former energy, and this is to be regarded as the most fruitful period of his too short career. Although tormented at times by severe attacks of gout, his capability and love of work were something wonderful; and now students assembled around him in crowds from all parts of Germany. Now appeared his important essay on the medulla of bones in pernicious anæmia, and other works on the pathology of the circulation. He enlarged and corrected his former work on embolism, and in collaboration with other enquirers produced new essays on the subject; and it was at Breslau that he brought out, in 1877, the first volume of his great work on General Pathology. The appearance of the second volume was delayed until 1880, owing to his having entered upon a wider sphere of action at Leipzig, in 1878. This book will long remain an object of the most industrious study by all those who earnestly occupy themselves with the questions of general pathology. It is a work most fertile in ideas, written in a highly attractive style, rich in material facts, and distinguished above all by the abundance of the suggestions which it contains. Although in the great progressive march of pathological enquiry this or that view may have to be modified, it will in the distant future still constitute the starting-point in medical enquiries. Although the preparation of such a book occupied much of his time, other remarkable work was published, and especially in collaboration with Schulthess-Rechburg and Charles Roy. In his Institute there was always a series of pupils engaged in experimental research, and Cohnheim himself produced two somewhat more popular essays on the Problems of Pathological Anatomy, and on the Contagiousness of Tuberculosis. This last essay presented the subject with great precision, and his views were soon afterwards confirmed by Koch's discovery.

Cohnheim's strength now began to give way. The attacks of gout became more frequent and more severe, and nutrition failing him he visibly wasted away, and he was obliged to withdraw more and more frequently from his beloved teaching and suspend his work at the Institute. His mental vigour, too, gradually slackened, especially since he had become subject to severe uremic attacks and asthma. On the 15th August he quietly sank, and the autopsy disclosed granular kidney with deposit of urates, and a "colossal" hypertrophy of the heart. Those of his joints which were more frequently the seat of severe attacks of gout, were found in an entirely normal condition, and quite free from any gouty deposit. As regards Cohnheim's scientific disposition, it always led him to go to the bottom of things, and seek out the traces of pathological processes, and he had no taste for the investigation of what are called "rare cases." He thought that the most frequently occurring morbid processes possessed the highest interest, and he pursued with eagerness the study of such subjects as inflammation, venous stasis, embolism, &c., hence the doctrine of tubercle, the commonest of diseases, always possessed a powerful attraction for him. He preferred the experimental mode of investigation, under the idea that the complicated conditions of pure observation may be simplified by becoming separable in their elements, and so rendered more accessible to investigation. In this way the physiologists have reaped such splendid results, and he felt himself strongly attracted to their methods, owing, in some measure, to his intimate friendship with some of these enquirers. But he was no mere imitator of known physiological methods, but multiplied and improved these independently, according to the requirements of pathology. His earlier important histological and his numerous communications on pathological anatomy, show his intimate acquaintance with anatomical methods, to which he may have later attached less importance. The new ætiological direction of pathology attracted also his strong sympathies; and his views as stated in his Pathology show that long since he was on the side of those who attribute to micro-organisms an essential part in the production of diseased processes. At first he ridiculed the exaggerated expectations entertained; but as facts became more pressing he did not attempt to withstand their influence. It was one of the honourable characteristics of Cohnheim's methods of investigation that he never hesitated to acknowledge and rectify former errors. It would be an entire mistake if we sought to limit his significance in medical science to his published works. That influence was much more prominently exhibited in the work which he caused to be done under his superintendence in his Institute, in this way stimulating and animating his whole surroundings. This is borne witness to by the very number of the important works which were published under his direction. To his academical teaching he was fondly attached; and at the commencement of the summer session of this year, when he was unable to ascend the steps, he caused himself to be carried into the theatre in order that he might for at least a few more times discharge the duty that was so dear to him. Personally, Cohnheim was eminently a lovable, true and genial man, strongly desirous of aiding those who stood in need of his services. Professor Wittich declares that during the ten years which he had the pleasure of acting as his assistant, never did a shadow of a difference arise between them; and he believes that all his other assistants would testify in the same way.

FLEETWOOD CHURCHILL, F.K.Q.C.P.

We deeply regret to announce the unexpected death of this estimable member of the profession, which took place on Saturday morning, September 6th, at his residence, from heart disease. At the time of his death Dr. Churchill was 51 years of age. He was the eldest son of the late Dr. Fleetwood Churchill, of the last edition of whose well-known work, on "Diseases of Women," he was the editor and joint author. After entering Trinity College, Dublin, at an early age, he forsook University studies before he graduated in either arts or medicine. Having become a Licentiate of the Royal College of Surgeons in Ireland in 1853, he served for some time in the Royal Navy, finally settling down as District Surgeon and Health Officer at Simon's Town, Cape of Good Hope. After several years Dr. Churchill returned home to his native city, Dublin. In 1862 he joined the King and Queen's College of Physicians as a Licentiate in Medicine; in 1868 he became a Fellow of the College and also a Licentiate in Midwifery. As time went on he was chosen to fill such important and responsible posts as those of Physician to the Pitt Street Institution for Diseases of Children, Physician to the Clergy Daughters' School, and to the Magdalen Asylum for Penitent Females, and Assistant Secretary to the Vaccine Department of the Local Government Board for Ireland (formerly the Cow-Pock Institution, Dublin.)

In his own College also he filled various posts of dignity and responsibility. He served as Examiner in Midwifery from 1874 to 1878, and again from 1880 to 1882. He was chosen Censor of the College in 1878, acting in this capacity for two years, during the second of which he was nominated to and filled the post of Vice-President of the College. In 1882 he was once more elected Censor, and his two years' term of office had not expired when he died.

Honest, upright, modest and retiring, Dr. Churchill made for himself many friends. His kindness to poor patients was proverbial, and by them especially, as well as by a large circle of acquaintances, his premature and unexpected death will be much deplored.

Small-Pox in Glasgow.—It is satisfactory to report that for the past fortnight no fresh cases of small-pox have been registered. A full month has now elapsed since the discovery of the last case, and as the last patient was dismissed from the Small-pox Hospital on the 23rd August, the city is now entirely free from this disease, and should it reappear it must be by importation from without.

GENERAL CORRESPONDENCE.

PHARMACISTS AND THE PHARMACOPŒIA.

[To the Editor of the Medical Times.]

SIR,—Looking over the *Times* of last month, on returning to town, I noticed in its impression of the 18th, a letter from Mr. Thomas Hughes, chemist, of Llandilo, which would appear to minimize the labours of the Royal College of Physicians, and of the General Medical Council, anent the pharmacopœia, as compared with the pharmacists. "It is not," he says, "to the compilers of our pharmacopœias that we are indebted for our modern remedies, or their preparation, but to individual efforts of practical men engaged in the business," instancing amongst others, to use his own words—"Bullock's splendid preparation of Pepsine." But Mr. Hughes does not seem to be aware that it is not to a pharmacist the medical profession is indebted for the discovery of that "splendid preparation," but to a Fellow of the Royal Society, and of the Royal College of Physicians, viz.—Dr. Beale, of Grosvenor Street.

I am, Sir, Yours, &c.,
T. M. SUNTER, M.D., Oxon.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a Certificate to Practise, on Thursday, September 4th, 1884:—

Frank Edward Mathews, 4, York Place, Hill Rise, Richmond.

The following gentlemen passed on Thursday, September 11th:—

Sidney Barwise, The Oaks, St. Paul's Road, Birmingham.
Frederick Martindale Blackwood, 9, Park Place, W., Sunderland.
Milton Romaine Callender, 15, St. Thomas's Crescent, Newcastle-on-Tyne.
John Lynes, 6, Argyll Road, Kensington.
William Frederick Pedler, 1, Albert Villas, Serpentine Road, Regent's Park, N.W.
Edward Williams, 37, Great Coram Street, W.C.

The following gentleman also, on September 4th, passed the Primary Professional Examination:—

Percy Dean Bray, Middlesex Hospital

THE SOCIETY OF APOTHECARIES.—At the Preliminary Examination in Arts, held at the Hall of the Society on the 11th, 12th and 13th of September, 1884, the following candidates received certificates of proficiency in General Education, viz.:—

In the Second Division in alphabetical order—

Alfred Alexander, *Jno. Hampden Barker, Frederick Wells Beville, Edward Walter Brunton, *G. M. Robertson Bryant, *Aubrey Conway, *Basil Wiseman Conway, Frank Gillett Cory, *Sydney Robert Cross, *Horatio Nelson Crossley, Ernest Buxton Cutting, *Jno. Halliwell, William Hindle, Wm. Robert Howard, Arthur Talman Ilott, David Owen Jones, Jno. Howard Jones, Arthur Edwin Joscelyne, Percy Jno. Kingston, Charles Robert Maitland, *Fras. R. Septimus Milton, Eustace Ayton Payne, Jno. W. George Prince, Ernest James Reynolds, Reginald G. W. St. Cedd, *Eleanor Sophia Warner, Richard Milbourn West.

The following Candidate passed in Greek alone:—

Herbert Wm. Tolner Crow.

The following Candidates passed in Elementary Mechanics alone:—

Stuart A. Charles Dallas, Charles Stanger Bowker, Charles Edwin Cornwall, Jno. Edward F. Hosking, Richard J. O'Hajloran, Robert E. Franklyn Pearse, Nigel Alan Alison Trenow, Leslie Herbert Walsh.

Those marked * passed also in Elementary Mechanics.

THE NURSING STAFF OF THE ARMY.—A Royal warrant has been issued amending the provisions of the warrant of the 10th of June, 1884, relating to the nursing staff of the Army. The new warrant directs that Art. 298, as regards the pay of lady superintendent of nurses, shall stand amended as follows:—Lady superintendent of nurses, 150*l.*, increasing by 10*l.* yearly to 200*l.* a year, with an additional allowance of 50*l.* a year to the lady superintendent of the Royal Victoria Hospital, Netley, for training the nursing staffs and carrying out such duties as the Director General of the Army Medical Department may from time to time direct. The following is to be added after Art. 776:—A senior nurse acting as superintendent shall receive pay at the rate of 20*l.* a year, in addition to her wages. The pay of the woman servant appointed to attend on the nurses at each hospital shall be at such rate (not exceeding 25*l.* annually) as the Secretary of State shall determine. The following is to be added to Art. 982:—The lady superintendents at the Royal Victoria Hospital, Netley, and at the Herbert Hospital, Woolwich, retired pay at the rate of 20 per cent. of their salaries, after ten years' service, rising by 2 per cent. for each additional year of service up to a *maximum* of 50 per cent. An acting superintendent or nurse retiring without having previously obtained permission to do so shall forfeit all claim to pension.

NAVAL MEDICAL DEPARTMENT.—In accordance with the provisions of Her Majesty's Order in Council of the 1st of April, 1881, Fleet-Surgeon A. M'Donald, M.D., has been placed on the retired list of his rank. The following appointments were made at the Admiralty on September 6th:—E. J. Sharood, Fleet Surgeon to the *Agamemnon;* H. M. Nash, Staff Surgeon to the *Rapid;* J. L. Bagnall Oakeley, Surgeon to the *Lion;* Edward Ferguson, Surgeon to the *Agamemnon;* J. B. Clibborn, Surgeon to the Plymouth Division, Royal Marines; and J. E. H. Williams, Surgeon to Plymouth Hospital.

EGYPT.—Surgeon-Major F. A. Churchill, of the Army Medical Department, has arrived at Wady Halfa from Cairo, and assumes the duties of Principal Medical Officer to the British troops there. Several medical officers are now *en route* to that place in view of the concentration of troops there.

CHOLERA RELIEF.—The Mayor of Marseilles has written to Mr. Stuart Cumberland accepting his offer to give special thought-reading demonstrations for the benefit of the widows and orphans of the cholera victims in Marseilles, Toulon, and the neighbourhood.

RICHMOND SANITARY IMPROVEMENTS.—A new departure was recently inaugurated, by the opening of a dust destructor for the disposal of the dust and refuse of the parish, which, as usual, has proved a most burdensome material to get rid of. The destructor, which is erected on a piece of waste ground on the north side of the railway, is the invention of Mr. Stafford, the borough engineer of Burnley, where the system has been in operation for some little time past with great success. The buildings consist of a central shaft, 90 feet in height, with two furnaces at the sides in the shape of a beehive, the flues from which carry off the smoke and gaseous matter to the chimney and create a thorough draught. Both the first cost and the subsequent working of the destructor seem to be on eminently economic principles, the expense of erection being about 70*l.* without the shaft, while it is calculated that one is sufficient to consume the refuse of a town of 20,000 inhabitants. To effectually destroy all the objectionable matter produced by a town of 70,000 inhabitants, three destroyers would be necessary, costing a total of 210*l.*, or about 3*l.* per 1,000 of the inhabitants, or at the rate of 30*l.* per 1,000 loads of refuse. The Richmond surveyor calculates that the 3,920 houses in the town will henceforth, be cleared weekly with a saving of 374*l.* per annum upon the present system of collecting every fortnight without the destructor. The experiment of Saturday last certainly showed that the furnaces dealt with the refuse in a most complete and satisfactory manner, not even objecting to consuming a heterogeneous mass of unconsidered trifles, such as preserved meat tins, bottles, an iron shovel, and the like. Moreover, the consumption of coal is small, and the little smoke issuing from the shaft appears to be unobjectionable. The residue of the burnt rubbish should be a set-off to the cost from a commercial point of view, consisting as it does of a hard metallic-ringing clinker, which will be admirably adapted for road foundations, as well as furnishing excellent material for builders' mortar. An important experiment has been tried at Burnley of

consuming a mixture of a ton of ashes to half a ton of excreta, both of which were destroyed in an hour and a quarter with no unpleasant remainder. In addition to the destructors now at work at Burnley and Richmond, others will shortly be in operation at Leicester, Birkenhead, and Batley, while Bradford, Worcester, Cambridge, and Bournemouth will probably adopt the system. A vast improvement to the public health can hardly fail to be realised, when we think not only of the unsavoury areas of parish waste grounds, but of the still more dangerous, because concealed, habit of erecting rows of houses upon a *ci-devant* kitchen midden, or filling up the foundations with the contents of the dust-bin. It is not too much to say that builders, by so doing, have caused the death of many thousand occupiers.

Recent Legacies.—Charlotte Baroness de Rothschild, the widow of the late Baron Lionel Nathan de Rothschild, has left the following legacies:—To the London Hospital and the Evelina Hospital, 10,000*l.* each; to St. George's Hospital and to the Jewish Ladies' Lying-in Charity, 5,000*l.* each; to the West London Hospital, Hammersmith, the Jews' Hospital and Orphan Asylum, Norwood, and the Clementina Hospital at Frankfort, 3,000*l.* each; to the Jewish Convalescent Home, Norwood, the German Hospital, Dalston, and the Metropolitan Free Hospital, 2,000*l.* each; to the Buckinghamshire Infirmary at Aylesbury, the Royal Sea-Bathing Infirmary, Margate, the Hospital for Incurables at Putney, and the Earlswood Asylum, 1,000*l.* each. The late Mr. Edwin Cox, of 11, Rochester Terrace, Kentish Town, has bequeathed 500*l.* each to the Royal Free Hospital, Earlswood Idiot Asylum, the City of London Truss Society, the Hospital for Consumption and Diseases of the Chest at Brompton, the Cancer Hospital, Middlesex Hospital, Westminster Hospital, Charing Cross Hospital, and St. Mary's Hospital.

Church Parade.—In support of the funds of the Great Northern Central Hospital, Caledonian Road, on Sunday, the 7th inst., "a grand demonstration and church parade" was held under the auspices of the amalgamated, friendly, temperance, and trade societies. A procession was started, at 2 o'clock, at the Manor House, to proceed to Holy Trinity Church, Cloudesley Square, marshalled by Messrs. Godden, Clarke, and Marchant. In the procession were some 50 or 60 banners appertaining to temperance societies, whilst flags belonging to trade and other societies were profusely displayed. The members of the demonstration carried collecting boxes for the reception of donations towards the most deserving institution for whose benefit the day's proceedings had been inaugurated. Starting from the Manor House, the procession moved down the Seven Sisters Road into Holloway Road, and along the Camden and Caledonian Roads, and on to the church. The full order of procession was as follows:—Metropolitan Police, the 11th Middlesex Rifle Volunteers' brass band, Ancient Order of Shepherds, Manchester Unity of Oddfellows, Improved Order of Old Friends, Loyal Ancient Order of Shepherds, Ancient Independent Order of Oddfellows, United Order of Comical Fellows, Fraternal Brothers, Buffaloes, Druids, &c. After divine service, which was well attended, and at which an appropriate address was delivered, the processionists re-formed, and returned by various routes to a point at which they broke off for their respective homes.

Death of Dr. Joseph Janvier Woodward, U.S.A.—Although it was generally known that Surgeon Woodward had been on sick leave for several months past, the news of his death, which occurred on the 18th ult., will come as a shock to the profession, for he was little more than fifty years of age, and his brilliant career might well have been expected to have continued for many years to come. He graduated at Philadelphia and practised medicine in that city until he was appointed Assistant Surgeon in the Army in 1861. He served with distinction in the war and contributed much to the advancement of his profession. His observations on camp-dysentery and on typho-malarial fever, for instance, were of a nature to throw positive light on many difficult questions connected with these affections and their management in armies. His original work in microscopy, and more particularly in photo-micrography, after the termination of the war, was such as to give him a world-wide reputation; and, finally, the excellence of the literary work done by him in conjunction with the late Surgeon Otis, in preparing the early volume of the "Medical and Surgical History of the War of the Rebellion," helped not a little to give the work the character which was at once accorded to it wherever medical science was cultivated.—*New York Medical Journal*, August 23.

St. John Ambulance Association.—A report has been received at St. John's Gate stating that at the recent visit of the Prince and Princess of Wales to South Shields, to open the Coble Dene Dock, the St. John Ambulance Corps, connected with the local Volunteer Fire Brigade, were stationed at convenient places with appliances for rendering "first aid" in the event of accidents owing to the great crush of people. Fortunately their services were not required, except in a few cases of fainting, but the workmanlike appearance of the corps attracted the attention of their Royal Highnesses, and the Mayor of Gateshead and other leading officials expressed their satisfaction at its evident readiness for any emergency. It is much to be regretted that every large town does not follow so excellent an example.

The North West London Hospital.—As was recently announced, the Committee of Management of this hospital requested Sir T. Spencer Wells, Bart., Mr. John Marshall, F.R.S., and Mr. Ernest Hart to act as a committee of reference, with a view to the remodelling of the laws and regulations of the hospital. These gentlemen have now, in conference with the Committee of Governors of the hospital, approved a revised constitution, which they have declared satisfactory, and which they commend to the public and the profession. Applications for the vacant positions on the staff should be made to the Secretary at the Hospital, Kentish Town Road, on or before Thursday, September 25th.

Kidderminster.—The outbreak of typhoid fever at Kidderminster is of a more widespread character than has been stated. There are about 150 cases, and the majority of these appear to have broken out within a period of three days, just at the time of the high temperature three weeks ago. Though the higher parts of the town are most affected, there are cases about the low-lying parts as well, and, in fact, the general distribution of the fever is one of the significant circumstances connected with the outbreak. It evidently points to some common origin, such as sewer gases or a tainted water supply. The borough went to a great expenditure some years ago for sanitary works, and was supposed to be well provided in regard both to sewage and water. A system of flushing the sewers is carried out, and all analyses of the water which have hitherto been made have shown the quality to be unimpeachable. A further analysis is now ordered. The Medical Officer of Health has suggested to the Sanitary Authority the free opening of the Infectious Hospital to non-pauper cases of fever, but so far the Authority has demurred to do so. It is understood, however, that if all the medical men in the town recommend such a step, it is left to the Mayor to decide finally whether it shall be done.

Health of Glasgow.—During the fortnight ending 30th August, there were registered 512 deaths against 500 in the previous fortnight. The deaths from diarrhœa have been 80, almost double the number in the preceding fortnight; in fact, since the same period of the year 1878, there have not been so many deaths from diarrhœa. The temperature experienced then was similar to the recent sultry weather in Glasgow. The death-rate alone from this cause was four per cent. For many years past the fatal effect of this malady has not been so great. At present there are 187 cases of scarlet fever, 68 of measles, 43 of enteric fever, 37 of whooping cough, and 12 of typhus fever, making a total of 347 cases in the hospitals of the Council, as compared with 338 in the preceding fortnight.

Glasgow—Great Destruction to Fish in the River Allan.—A tank of creosote oil, belonging to the Caledonian Railway Company, weighing about ten tons, on its

way north, on Saturday last, was shunted to a siding at Blackford, close to the River Allan. No precautions seemingly were taken to prevent the liquid from finding its way into the river, and the result is that all the fish in the Allan, south of Blackford, as far as the Forth, have been killed.

Unsound Meat at Glasgow. — A female provision dealer was fined in the sum of three guineas, with the alternative of 30 days' imprisonment, on Saturday last, at the Eastern Police Court, Glasgow, for exposing for sale 2 cwt. of unsound pork on the 9th instant. A police sergeant and inspector stated that while proceeding along the street, they "felt," a strong smell coming from the meat which was spread out on a board in front of the shop. It was ticketed as "fresh in." Medical evidence was adduced showing that it was quite unsound. The magistrate ordered the pork to be destroyed.

Galashiels Water Supply.—At a recent meeting of the Corporation, a communication was read from Dr. Hardesty, medical officer, giving it as his opinion, in view of the possible outbreak of cholera, that all the wells in the town should be closed as being dangerous to health if used for dietetic purposes. The Inspector of Works had been previously instructed to procure samples of water from a number of wells, and test them by the permanganate process. Nine of these samples were placed on the table for inspection, all, or nearly all, presenting a beautiful purple hue, giving little or no indication of contamination from sewage matter. It was stated that although a most abundant supply of excellent water has been introduced for a number of years, many of the wells are still in common use. After some consideration, it was resolved to take immediate action on Dr. Hardesty's report, and order the closing of every well in the town, to the number of about a hundred.

Montrose.—On September 2, at the monthly meeting of the Montrose Asylum and Infirmary Board, the convener of the House Committee of the Infirmary reported that the trustees of the late Dr. Joseph Glen, London, a native of Montrose, had paid to the Institution 200*l.* bequeathed by that gentleman.

Retirement of M. Fauvel.—Ushered in without any explanation or comment, among the paragraphs of the daily journals is the statement that, by a ministerial order, Dr. Proust, *agrégé* of the Paris Faculty, and Assistant-Inspector of the Sanitary Service, has been appointed Inspector-General of this service, in place of Dr. Fauvel, who has retired on his pension with the title of Honorary General Inspector. The *Revue de Thérapeutique* (Sept. 1), commenting upon this announcement, observes that when the circumstances in the midst of which this resignation has been made are remembered, it is to be regretted that not a word concerning the motives of its being made is uttered. It cannot be regarded in the light of a disgrace, for the greater number of what Dr. Fauvel calls his "prophecies" concerning the cholera have been verified with tolerable exactness. It is therefore satisfactory to learn that his shattered health, or some other personal motive, obliged the inspector to give in his resignation during the full course of the epidemic.

Cremation Societies in the United States.—There are a number of cremation societies in this country, but only one crematory, that at Washington, Pennsylvania, and the difficulty and expense of sending bodies to that place will prevent, for some time at least, any extensive adoption of this mode of disposing of the bodies of the dead. There is but little doubt, however, that the number of those who favour cremation is steadily increasing, and it will not be long before other furnaces are built. A few days since, a meeting was held in New York, and plans were suggested of a public subscription to secure money to build a crematory near New York. Boston and Philadelphia have each cremation societies, and before another year has elapsed will probably have crematories.—*Philadelphia Medical Times*, August 23.

Death from Hydrophobia.—A woman died in University College Hospital last week of hydrophobia, appearing after an unusually long incubation period, viz., twelve months.

The Virus of Rabies.—In answer to a query addressed to M. Pasteur by Dr. Heath, of New York, Dr. Rouse, the assistant director of M. Pasteur's laboratory replies—"In an animal that has died of rabies there is nothing virulent but the saliva, the salivary glands, and the nervous system. The blood, the muscles, and the viscera do not appear to contain the rabies virus. I do not know of an instance of the inoculation of rabies in the performance of an autopsy. The attenuated virus which you ask for is still under investigation. Thus far, it has only been tried on dogs, and in the present state of our knowledge M. Pasteur would not dare as yet to make trials with it on man."—*New York Medical Journal*, 23.

Llandudno.—Lady Augusta Mostyn laid the corner stones of a Cottage Hospital which is in course of erection at Llandudno, on September 4th, as a public memorial to the late Mrs. Nicol. The Bishop of Bangor delivered the address. The cost of the building will be about 4,000*l.*

APPOINTMENTS.

Bonnar, Thos. A., L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Bishopton District, Sedgefield Union, *vice* Mr. T. Thompson, deceased.

Claremont, Louis Bennett, M.R.C.S. Eng., and L.R.C.P. Lond.—Medical Officer to the Second District, *vice* Dr. John Hall, deceased.

Sheraton, Geo. R., L.R.C.P. Edin., and M.R.C.S. Eng.—Medical Officer to the Sedgefield District, and to the Workhouse, Sedgefield Union, *vice* Mr. T. Thompson, deceased.

VACANCIES.

County Asylum, Lancaster.—Assistant Medical Officer. Salary, £100 per annum, increasing £10 annually, with board, &c. Candidates must be duly qualified and registered, unmarried and under 30 years of age. Applications with testimonials to be sent to the Medical Superintendent, before September 27th.

Kidderminster Infirmary.—House Surgeon. Salary, £140 (increasing £10 per annum to £170), with residence and attendance in the Infirmary. Candidates must be unmarried. The candidate appointed to enter into a bond not to practice within six miles of Kidderminster, until after the expiration of five years from the time of the termination of his engagement. Further information may be obtained from the Secretary, to whom applications should be sent before September 26th.

National Dental Hospital, 149, Great Portland Street, W.—House Surgeon. Salary, £50 per annum. Candidates must be Licentiates of Dental Surgery. Applications, with testimonials, to be sent in on or before September 29th.

North-West London Hospital, Kentish Town Road.—Senior Physician and Senior Surgeon. (*For particulars see Advertisement.*)

Settle Union.—Medical Officer to the Clapham District, *vice* Mr. J. H. Knox. Area, 25,345 acres. Population, 1,450. Salary, £21 per annum. Also, Medical Officer to the Arncliffe District, *vice* Mr. J. Anthony, resigned. Area, 17,998 acres. Population, 362. Salary, £5 per annum.

St. Peter's Hospital for Stone and Urinary Diseases, etc., Henrietta Street, Covent Garden. — House Surgeon. The Appointment will be for six months. Honorarium, 25 guineas, with board, lodging, and washing. Candidates must be M.R.C.S., and have held the position of House Surgeon at a Public Institution. Applications with testimonials to be sent to the Secretary, on or before September 30th.

Swansea Hospital.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28.

University College, London.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

West Bromwich District Hospital.—House Surgeon. Salary, £80 per annum, with board, residence, and washing. Candidates must be surgically qualified, registered, and unmarried. Applications, stating age, &c., with not more than three recent testimonials, and accompanied by candidates' degree or diploma, and certificate of registration, to be sent to the Honorary Secretary W. Bache, Esq., Churchill House, West Bromwich, on or before September 20th.

DEATHS.

Clark, Samuel, M.D., late of Folkestone, at Tunbridge Wells, on September 14th, aged 69.

Goodall, W. P., F.R.C.S., formerly of Birmingham, at Southborough, Kent, on September 10th, aged 50.

Macarthur, T. A. C., L.R.C.S., late Army Medical Department, at Walton, Liverpool, on September 10th

Marsh, John, M.R.C.S., at Woodbridge Road, Ipswich, on September 11th, aged 63 years.

Paterson, R. H., M.R.C.S., L.R.C.P., at Gainsborough, on September 7th, aged 34.

Sharp, G. W., F.R.C.S., on September 7th.

NOTES, QUERIES, AND REPLIES.

An Old Barts. Man.—The authorities of St. Bartholomew's Hospital have discontinued the Introductory Lecture for some years past.

Dr. Nicholson.—The second preparation you mention is prescribed very largely to our knowledge, and with good results, but it would be inconvenient, if not risky, for a medical journal to give the results of comparative trials of proprietary articles. Proprietors are very grateful for favourable reports, but they are apt to show an unbecoming amount of resentment if other proprietors' articles are praised at the expense of theirs. On these grounds we regret that we cannot either ask for, or give, the information you require.

M., St. George's.—Mr. Charles Hawkins, Principal Serjeant-Surgeon to the King, was the first Master of the College of Surgeons in 1800. The late Mr. Cæsar H. Hawkins was elected a Trustee of the Hunterian Collection in 1871, with Sir John Lubbock, Bart. It was the great Duke of Wellington who was also a Trustee. Mr. Lombardi, of Pall Mall, has published an excellent photograph of the late Duke of Wellington. You can obtain most of the medical celebrities from Messrs. Barraud, of Oxford Circus, including the three you mention.

COMMUNICATIONS RECEIVED—

Prof. Gairdner, Glasgow; Mr. Henry Morris, London; Dr. Norman Chevers, London; Dr. James Oliver, London; Mr. H. A. Knutsen, London; Dr. Sunter, Hounslow; Capt. Hobson, London; The Secretary of the International Health Exhibition, London; Messrs. G. Putnam & Sons, London; The Secretary of the Apothecaries' Society, London; Dr. Willoughby, London; Dr. Guillemard, Cambridge; Our Liverpool Correspondent; Mr. Straehl-Siebenmann, London; Mr. Wynter Blyth, London; The Director-General of the Army Medical Department, London; The Registrar-General for Scotland, Edinburgh; Our Vienna Correspondent; Mr. A. APPOINTMENTS FOR THE WEEK.

Friday, September 19 (this day).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday, September 20.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, September 22.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, September 23.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

International Health Exhibition (Hygienic Laboratory), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Common Poisons."

Wednesday, September 24.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, September 25.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, September 26.

International Health Exhibition (Hygienic Laboratory), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Bad Food."

CLINICAL LECTURE
ON WINTER HÆMOGLOBINURIA.

By PROFESSOR NOTHNAGEL, Vienna.

GENTLEMEN—The patient I show you has a somewhat rare complaint. He says that when he goes out in the cold in winter, and his feet get chilled, he suffers from peculiar sensations; he is seized with a shivering throughout the whole of his body, and afterwards he feels hot and perspires profusely. These are febrile symptoms which remind one of malaria. The patient suffered from various acute infectious diseases during his childhood, and at the age of 18 he contracted syphilis. Three years ago he had the first of his present attacks following exposure to cold, and during the present winter the attacks have occurred so frequently that the patient is almost afraid of going out when it is cold. It is a very strange affection. He further states that during the attack he suffers from great thirst as long as the shivering lasts. We cannot conclude that this man's affection is of a malarious nature, for its occurrence is irregular and dependent upon the influence of cold. Moreover, he states that he has no attacks during the summer, but only in winter.

When one hears of such strange symptoms, one's first idea is to ask the patient what is the appearance of his urine, what is its colour. Now the patient says that on making water immediately after an attack the urine is black, but what he passes subsequently is clear. Here is a specimen of this black urine; it looks as if it contained blood. We will examine the urine, after the method of Heller, to see if this is so. We boil the urine with caustic potash, the phosphates fall to the bottom of the glass, and you see that the precipitate has a brownish red colour due to blood pigment being mixed with it. On microscopical examination we do not find any red blood-corpuscles. The urine contains albumen, for on heating it we obtain a flaky sediment. This sediment has a red colour, while the urine, when separated by filtration, is quite clear. This shows that the blood-pigment is entirely carried down by the precipitate. If we now boil the sediment with alcohol which has been rendered acid with dilute sulphuric acid, the alcohol absorbs the blood-pigment. The blood-pigment therefore exists free in the liquid and not in combination with red blood-corpuscles. In those cases in which we find blood in the urine we call the affection hæmaturia, and the blood may be derived from the bladder, from the ureters or the kidney. In all such cases we find red blood-corpuscles in the urine, and we have good reason to call the affection hæmaturia. But there exists another class of cases in which the urine is also coloured with blood, and in which you find blood-pigment too,

examination with the spectroscope showing the characteristic absorption lines of hæmoglobin. On examining a drop of the urine under the microscope, however, you do not find a sign of a red blood-corpuscle. You find instead of red blood-corpuscles a detritus which has a brown or blood red colour. We call such an affection hæmoglobinuria.

This affection occurs under different conditions, the number of which has very much augmented with the increase of our knowledge in the last fifteen years. First we observe hæmoglobinuria in cases of poisoning; for instance, with carbolic acid, or with other acids, as sulphuric and phosphoric acid; also in cases of poisoning by arseniuretted hydrogen; secondly, in burns of the skin; thirdly, in certain acute infectious diseases, as for instance, scarlet fever and typhoid. In all these conditions the affection is rare, they are *not* usually accompanied by hæmoglobinuria. But we had an opportunity of observing hæmoglobinuria in a large number of cases about ten years ago, when the treatment of consumption and carcinoma by the transfusion of lambs' blood was in vogue. It was shown that when the blood of an animal of one species is transfused into the system of one of another species, it is injurious to the latter, but when transfused into one of the same species it causes no harm. If one transfuses blood from a lamb into a dog, it may prove fatal to the latter, just as it might to a man treated in a similar way. The serious symptoms observed in such a case are to be considered as a direct consequence of the transfusion, the blood-corpuscles of one species having a pernicious influence on those of another. Landois has shown that marked hæmoglobinuria occurs in such cases, which he attributes to the fact that the red blood-corpuscles are dissolved; it is therefore an artificial hæmoglobinuria. Besides this there exists a form of hæmoglobinuria which is to be considered as a special affection, and which has been termed winter or paroxysmal hæmoglobinuria. In general, this disease is seldom met with. The majority of such cases have been recorded in English, American, and German literature; very few have been recorded in French literature, and still fewer in Russian. The disease presents the following symptoms: The patient is seized with it in paroxysms, hence the name paroxysmal. In the intervals he is perfectly well, though exhausted and weak owing to the loss of the blood-corpuscles which have been destroyed, but besides this general weakness he does not complain of anything. The attack is in most cases produced by cold, and for this reason the affection is chiefly observed in winter, whence the alternative name "winter" hæmoglobinuria. It is the effect of cold on hands and feet which especially produces the affection. Sometimes one is able to bring on an attack artificially. Rosenbach gave one of his patients a cold bath in summer and an attack resulted. The sensations of the patient in the attack are very unpleasant; he yawns constantly; he is then seized with shivering through the whole of the body which is followed by heat and perspiration (a temperature of 40° C. and upwards has been observed). The patient then passes urine which is of the colour of blood; the same colour may be noticed two or three times in the subsequent twenty-four hours and then it disappears. The albumen in the urine coagulates and forms a compact mass which rises to the surface and has a brown colour due to the blood-pigment which it contains. If you boil this sediment with alcohol rendered acid by dilute sulphuric acid, the pigment is absorbed by it, and the sediment remains uncoloured. Sometimes casts are to be found in the urine, but this is an exception; there may, indeed, be blood casts, for the hæmoglobin may coagulate while still in the urinary passages. We know by our experience in cases of transfusion that the coagulated hæmoglobin may even block the urinary passages. Sometimes hyaline casts are also to be found. When the attack has passed off the casts disappear together with the pigment, and the urine again becomes clear. The attacks may occur at different intervals, and they are very injurious to the patient, for they have the same influence as losses of blood.

How does hæmoglobinuria arise? Probably by the influence of cold. If we make blood freeze, the blood-corpuscles are destroyed, and we have then blood with a colour like lac dye. During the attack there circulates in the vessels ruby-coloured blood, that is to say, besides the red blood-corpuscles there is there free hæmoglobin; this fact was proved by the abstraction of blood by means of a cupping-glass during an attack. Clinical observation thus entitles us to suggest that it is the influence of cold which destroys the blood-cells. We believe that in these cases the red blood-corpuscles have less resistance to low temperatures than usual, and are destroyed; the hæmoglobin is said to have an influence on the vaso-motor centre, hence the shivering, followed by heat and perspiration. As to the prognosis, the disease lasts in some cases several years and then disappears suddenly. In some patients we obtain good results from anti-syphilitic treatment, even when the disease has not a syphilitic origin. Besides this the patient must have good nourishment; he must live on meat, milk, eggs, and wine, and iron must be given to him. If we do not succeed in curing the patient in this way, we must order him to a milder climate during the winter.

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Epidemiological Society of London.

(Continued from page 401.)

True Leprosy.

Such full accounts of this disease, as it occurs in India, have been given in works accessible to all English readers,[25] that I shall now do little more than state a few results of my own observation. I constantly saw cases of this disease throughout my long Indian service, and I was officially desired to make trial of (1) the cashew oil and (2) the gurjon oil upon cases in the Medical College Hospital.

The disease presents itself in natives of all ranks, seldom in the rich and well-to-do; but I have seen it in a sovereign prince and in a rich man. It is scarcely proved that it can attack Europeans. I saw, only for a moment, a boy of European appearance in whom I considered that the disease was commencing; and it was said that, many years ago, a Madras Medical Officer was leprous, and there was strong suspicion of another case; but, in India, many of the fairest "European" aristocrats are descended from native ancestors, and leprosy is not rare among half-castes.

[25] Among many others—Horace Hayman Wilson, on "Kushta," or "Leprosy," as known to the Hindus; "Transactions of the Medical and Physical Society of Calcutta," vol. i., p. 1; F. Brett, *Indian Journal of Medical and Physical Sciences*, vol. v., p. 96, N.S.; Erasmus Wilson, *Lancet*, April, 1856; Quain's Dictionary; Morehead, *op. cit.* 695; Carter, "Transactions of the Medical and Physiological Society of Bombay," No. 8, p. 5, N.S.; "Report of the College of Physicians," commented upon, from Indian experience, by N. C. Macnamara, in the *Indian Medical Gazette*, 1866—a highly valuable monograph, afterwards published in a separate form by Messrs. Wyman & Co., of Calcutta; "Anæsthetic Leprosy," by J. N., *Indian Medical Gazette*, vol. ii., p. 215, *et seq.*; Vincent Richards, "Indian Annals of Medical Science," No. xxxi., 1873, p. 303; Drs. Lewis and Cunningham, in the "Twelfth Report of the Sanitary Commissioner with the Government of India;" Mr. Peters, *Edinburgh Medical Journal*, for March, 1883.

The census report of the North Western Provinces, for 1881, gives nearly 18,000 lepers in a population of nearly 33,000,000.[26] Mr. Peters gives, upon the authority of Mr. McCorkell, C.S., a statement from the census of 1872 showing that, in the Collectorate of Belgaum, in Western India, the number of persons disabled by leprosy was 4,131 in a population of 938,750, or 0·44 per cent. Yet in the Belgaum Leper Asylum, and from its neighbourhood, Mr. Peters could only find 29 lepers to treat in 28 months. Mr. Vincent Richards states that the proportion of lepers in Balasore is said to be about one in 5,000; in the Sonthal Pergunnahs, 1 in 700; in Bancoorah, 1 in 350; in Beerbhoom, 1 in 250; and in Burdwan, 1 in 450.

The latest Bengal census returns give 8·15 per 10,000 as the proportion of cases of leprosy in that province.

The statistics given in these reports cannot be received with implicit confidence, as it is not to be supposed that returning officers can always differentiate cases. Clearly the prevalence of leprosy varies greatly in different localities. It is probably at least as prevalent in India as Sir J. Simpson has shown it to have been in the United Kingdom almost from the time of the Norman Conquest up to the reign of James the First.

The fact that most Indian leper asylums have few inmates is probably due to the almost painless character of the disease, even when it is causing the most ghastly mutilations, and, consequently, to its popularity as a qualification for professional beggary. I have not seen a very great deal of it in native bazars; but hosts of mendicants do not seek relief in the streets and by the road-sides, preferring to live upon food and alms bestowed by the wealthy with a large, if indiscriminating, bounty for which we have not always given the people of India sufficient credit.

The *Differentiation* of leprosy, especially of the anæsthetic and leucopathic form, from simple leucoderma often becomes a question of more than medical importance in India. A Hindu leper cannot inherit the estate of his next of kin, because, as one impure by reason of disease, he is debarred the sacred duty of firing the funereal pyre. Consequently, European physicians are consulted in questionable cases; here an incorrect opinion would be something worse than a clinical error. Having gained an idea of the physiognomy of leprosy from engravings and wax models, the young medical officer should, on landing in India, lose no time in visiting the leper asylum which is maintained at each of the Presidency towns. There, in an hour, he will master all that is best worth knowing with regard to the aspect and condition of the leprous.

It is especially needful to distinguish scars and simple leucoderma from the white spots of leprosy. In the dark races of India, the scar of a blister or a burn long remains white until, in course of time, pigmentation goes on so far as to leave the seat of injury darker than the surrounding skin. An old Hindu writer of mine brought me his son, a young lad, who stretched out a very suspicious looking claw upon which were large white scars. The father hastened to say that these were burns. Truly, but the cicatrices were anæsthetic. The leprous hand, wanting sensibility, had been used too freely in meddling with fire, and had been severely burnt. Surgeon-Major Peters notices this liability of the extremities of the leprous to burning while cooking, and to be gnawn by rats at night.

Dr. William Palmer justly observes[27] that cases of leucoderma are more frequently brought to notice in India than in London; first, because they attract more attention by contrast with the darker skin of the natives; and, secondly, because there is an uncomfortable feeling that the white patches may be mistaken for leper spots; but whether they are really of more frequent occurrence is, he considers, doubtful.[28] In examining cases, those of simple leucoderma may be at once set aside. There is no anæsthesia or hyperæsthesia of the white spots when we test their sensibility with a skewer-like point of wood,[29] and no second sign of leprosy, no elevation of the white patch, no enlargement of nerves, no leonine visage or conjunctival deposit or thickening of ear-lobes or of other integument, no claw-like contracted appearance of the hands nor loss of phalanges, no scleroderma, open, deeply-excavated ulcers or suspicious cicatrices. As Dr. Palmer points out, in leucoderma, both the epidermis and the true skin, with its glands, remain normal in every respect except colour. Dr. Palmer holds that, the anæsthetic being the early form of the disease, the very mildest cases of circumscribed anæsthesia of skin are to be regarded as examples of leprosy, although these milder cases often show but little tendency to assume the more severe form.[30]

When I first went to Calcutta, I saw a case in which my friend the late Dr. Allan Webb gave me some excellent hints on the diagnosis of obscure leprosy. A pilot in the decline of life appears to have become slightly disordered in mind, having sent an insolent message to his superior. I was upon a committee who had to examine him and to report upon his condition. His appearance was European, but we understood that he had a strain of dark blood. His right forearm was considerably wasted, and the fingers, especially the little and ring finger, much contracted and bunched, and hardened like birds' claws. His countenance appeared quite natural. Dr. Webb showed us that the ulnar nerve on the diseased side was thickened and nodular from the elbow downwards, and that *the ear-lobes were much enlarged, pendulous, hardened, and thickened.* Dr. Webb said that this condition of the ears is a crucial test in all cases of chronic leprosy, however obscure the other symptoms may be. I think that it is M. Marx who says that the French *cagots*, who are descended from lepers, are distinguished by not having the ear-lobes developed. Soon after I read this I noticed that one of the ear-lobes of a handsome English lady was entirely wanting, evidently by congenital defect. In my experience Webb's test has never failed, but the deposit may be slight. "Rotundity of the pulps of the ears" is one of the signs of leprosy given by Barnhard Gordon, in his early description of English leprosy, cited by Sir J. Simpson.

In June, 1883, Dr. Thin stated, at the Medico-Chirurgical Society,[31] that a bacillus had been found in Norwegian leprosy by Hansen, in the leprosy of Southern Europe by Cornil and Suchard, by Majocci and Pellizari, and in a leper from South America by Kœbner. Dr. Thin found it in three cases of Chinese leprosy, in material supplied him by Dr. Manson, of Amoy; in West Indian leprosy in tubercles sent him by Dr. Hillis, of Demarara, and in the epiglottis of a

[26] *Medical Times and Gazette*, January, 1883.

[27] "Rough Notes on the Common Forms of Skin Disease met with in Calcutta," p. 22.

[28] See Dr. A. Wood's case of "Leucoderma in a Pathan." *Indian Medical Gazette*, vol. vi., p. 178.

[29] In our own country, as late as the 17th century, a discerning public appear to have drawn a very indistinct line between those two ostracised wretches the witch and the leper. In Scotland, witch-finders were designated as "common prickers," and received a fee for each witch they discovered. At the trial of Janet Preston, in 1646, the magistrates of Dalkeith, "caused John Kincaid, of Tranent, the common pricker, to exercise his craft upon her. He found two marks of the devil's making; for she could not feel the pin when it was put into either of the said marks, nor did the marks bleed when the pin was taken out again. When she was asked where she thought the pins were put into her, she pointed to a part of her body distant from the real place."—Charles Mackay's "Memoirs of Popular Delusions."

[30] Dr. I. Newton has published, *Indian Medical Gazette*, for 1868, p. 251, some careful observations on the microscopical conditions of the structures affected in Leprosy. He found that "Leprosy is essentially an affection of the gelatine-yielding tissues."

[31] *Medical Times and Gazette*, vol. i., for 1883, p. 713.

leper patient who died in New South Wales. He also observed bacilli in the blood of a leper patient from Hindustan.

Popular opinion, in Europe and in India, has generally held leprosy to be contagious; but I am unacquainted with any indisputable facts in support of this idea. I knew a Calcutta leper, of European habits, who had been married for many years to a woman who appeared to be perfectly free from the disease. Mr. Vincent Richards mentions the case of a Mahomedan shopkeeper 70 years old, married fifty years, with two children, whose wife was not affected.

With regard to *Cause*, heredity has been frequently traced. In analysing 191 cases observed in Balasore, Mr. Richards found that, in over 44 per cent., the father was affected; in only 30 the mother; and in 13 per cent. both the father and mother: 53·40 per cent. had relatives affected by the disease. Bad food, damaged grain, and putrid fish in insufficient quantity—to use Mr. Vincent Richards' words, "any diet deficient or redundant in particular elements," are doubtless operative; but no medical man of Indian experience will agree with those who maintain that the disease is mainly due to a fish diet. Leprosy is rife in districts where fish is scarcely known; and, as Mr. Peters shows, natives whom caste prejudices deprive entirely the use of fish are victims of this disease.

Hoarseness, evidently due to laryngeal disease, has frequently been noticed in Indian lepers. In England a writ *de leproso amovendo*, Fitzherbert, Not. Brev. pp. 520–21, was made applicable to those lepers who appeared in the sight of all men that they were lepers "*by their voice*, and their sores, the putrefaction of their flesh and the smell of them." Barnhard Gordon mentions, among the infallible signs of English mediæval leprosy, "voice nasal," in the early stage of the disease, and, later on, "voice hard and barking."

Dr. James R. Jackson[32] relates the case of a leprous woman in whom ulceration, partly destroying the nasal and palate bones and removing the uvula, extended to the rima and laryux, producing œdema glottidis and necrosis of the thyroid cartilage. Laryngotomy gave relief, but she died in about a month from extension of the laryngeal mischief, and "rapid effusion into the lungs." She inherited the disease from her mother. Her brother was similarly diseased.

Until we become accustomed to treat them, we are surprised to find how readily leprous sores often heal. In 1876 Dr. Cayley successfully extracted an opaque lens in a leper.[33] Mr. Birch amputated the great toe of a leper, aged 35, and the foot of another, aged 22; both made good recoveries.

With regard to *Treatment*, I have no faith whatever in the *specific* efficacy of any lauded remedy—chaulmogra oil, the cashew, the gurjon oil treatment, in fact of any plan that had its trial and its day while I served in India.[34] Hitherto it has, I believe, been a law subject to no exception whatever, that, treat him and improve his condition to the utmost, *he who is once a confirmed leper continues to be a leper until he dies.* Some years ago the late Dr. Bhau Dhajee, of Bombay, an able physician of great experience in leprosy, brought out an atlas of very large and beautiful photographs displaying the appearance of lepers before and after treatment. To one unacquainted with this disease, nothing could well be more complete and apparently radical than the appearance of cure in most of these countenances; but one to whom the leper visage is familiar sees in these, as in many other cases of "recovery" which I have examined, that, whether the face of the leper be emaciated or fat, ugly, menacing and rugged, or smooth, pleasant and comely, it still bears the ineradicable stamp of leprosy. The fact is that, in a large proportion even of fully developed and advanced cases, cachexia may be so far removed, mainly by good feeding, as to give the patient a fat and healthy appearance. Under treatment, say by the gurjon, cashew, or chaulmogra oils, tonics, and good food, the ulcers often heal readily, and the patient's general condition is vastly improved. He was a cachectic leper, he becomes a robust leper; but he remains as essentially a leper by constitution as he ever was, and his good food, oleaginous frictions, and other comforts being taken away, he will assuredly fall back into a state of leprosy. Consequently, we cannot cure leprosy—we cannot touch the constitutional disease therapeutically—but we can make the leper fat and comfortable, and thus, doubtless, greatly prolong his life.

Unquestionably a generous diet and the free inunction of *ghee* (clarified butter) and oil after the native manner are among the leading indications in the treatment of leprosy. A poor dietary, such as is allowed in certain Indian asyla, is a great mistake and failure of charity. A half-starved, voracious dyspeptic, such as the leper generally is when we begin to treat him, requires the best food and, as his digestion improves, plenty of it. The management of English lepers in the middle ages appears to have been simple. They were strictly confined, in habits of religion, to lazar-houses, where they had a singularly liberal and varied diet.[35]

Dr. Crombie has made some interesting observations[36] on *Ainhum*, or spontaneous amputation of the fingers and toes, as occurring in Eastern Bengal.

He refers to the publication of Drs. Tilbury Fox and Farquhar, p. 20. Dr. Wise gave him his first information of two cases which occurred in his practice, and of which he made an official report in January, 1873.

Quoting Dr. da Silva Lima, of Bahia, Dr. Sangster states, in Quain's Dictionary, that ainhum "is peculiar to the African race," being found not only amongst the inhabitants of the West Coast of Africa, but also amongst the Hindoos of African descent, as well as amongst the slave population of South America. Assuredly there can be very little suspicion of an admixture of African blood among the Caucasian natives of Eastern Bengal.

Dr. Colles found these appearances in a finger which had separated. The specimen is in the Medical College Museum:—"Distal phalanx normal in shape; its cancellous structure opened out, and filled with yellowish oily fat (commencing fatty degeneration); distal interphalangeal joint intact; distal end of second phalanx bony, the remainder of the bones converted into fibrous tissue; no bone at point of spontaneous amputation; fatty and fibrous tissues increased in quantity; skin moderately hypertrophic.

In a case in which a little toe had been removed, Dr. G. C. Roy found that "the place of the first phalanx was supplanted by an indurated tissue surmounted by the shell of its cartilaginous articulating surface, so that,

[32] *Indian Medical Gazette*, November 1, 1866, p. 339.

[33] *Indian Medical Gazette*, April, 1876.

[34] I have no experience of Dr. J. M. Fleming's mode of "curing" leprosy by carbolic acid, *Indian Medical Gazette*, vol. vi., p. 14; or of Mr. Lawrie's practice of nerve stretching in anæsthetic leprosy. *Ibid.* September, 1878.

[35] SURTEES mentions that, at Sherburn Hospital, "the daily allowance of the lepers was a loaf weighing five marks, and a gallon of ale to each; and betwixt every two, one mess or commons of flesh three days in the week, and of fish, cheese or butter, on the remaining four. On high festivals, a double mess; on the feast of St. Cuthbert, in Lent, fresh salmon, if it could be had, if not, other fresh fish; and on Michaelmas-day, four messed on a goose. With fresh fish, flesh or eggs, a measure of salt was delivered, the twentieth part of a razer; when fresh fish could not be had, red herrings were served, three to a single mess, or cheese or butter by weight, or three eggs. During Lent each had a razer of wheat, to make furmenty (simulum), and two razers of beans to boil. Sometimes greens or onions, and every day, except Sunday, the seventh part of a razer of bean meal; but on Sunday a measure and a half of pulse to make gruel. Red herrings were prohibited from Pentecost to Michaelmas; and, at the latter, each received two razers of apples."

[36] *Indian Medical Gazette*, for August, 1873, and June, 1874.

during amputation, the knife passed smoothly through its structure. Under the microscope it was found to consist of white fibrous tissue, in which were sparsely interspersed fusiform nucleated cells and oil-globules."

This disease is not absolutely confined to Eastern Bengal. It has been observed by Mr. C. J. H. Warden at Bhaugulpore in a native cultivator who had always resided in that district.

Ainhum appears to be a form of leprosy corresponding with the "joint evil," or "Coco Bay," of the West Indies. Richard Towne clearly describes the joint evil as leprosy in his work on the "Diseases of the West Indies," published in 1726. He gives the following description of the local mischief —"The nails curl inwards, and the extremities of the fingers and toes begin to ulcerate. These ulcers which never digest, but generally look dry, without much foulness or fœtor, gradually creep from joint to joint, till they have eroded," *i.e.*, eaten away, "all the fingers and toes."

In India, this fatty degeneration of bone and other structures also occurs in larger joints, as in the ankles and wrists. This subject will be illustrated under the heading "Fatty Degeneration of Bone," in the Chapter on Diseases of the Bones.

Struma.—I have thought it best to consider this constitutional condition, as it is observed in India, under the heading of *Phthisis.*

I apprehend that, at present, the occurrence of *Rickets* among natives and Europeans born in India is not proved. Several of my brother officers of great experience in the Upper Provinces tell me that they have never seen it. Preparations 1,181, 1,249 and 1,250 in Ewart's Catalogue are specimens of bones deformed by rickets, but they are not stated to have been from native subjects. I do not find that any Indian observer has written on the occurrence of this disease in the country. Certainly the disease is not common in Indian hospitals. During my long experience as a clinical physician, I never said to my students—"Here is a typical case of rickets." But the cause of this rarity needs investigation. Thus—(1) Struma and phthisis occur among the natives of Bengal, but far less frequently than among the inhabitants of London. Does rickets follow a similar law? (2) Did not rickets frequently occur before Glisson wrote upon it late in the 17th century? Was not Homer's model for the picture of Thersites a victim of rickets? Was not Richard the Third, with his crooked back, unilateral atrophy and overhanging brow?

Did not this disease come to light only when national prosperity and the advance of medical science began to enable the puny and deformed children of the poor to live on, as no such children did in Sparta or in India when infanticide was lawful? What, in the middle ages, were "changelings," believed to be substituted by elves? The fact that extremely poor, semi-barbarous people, untaught in the means of securing the survival of the least fit, are not found to have rickety children in their huts is not proof that such children are not born to them. I have seen at Delhi a burial ground filled with hundreds of little white tombs placed over the infants of the Great Moguls. It is rather the exception than the rule that one of the polygamous rulers of India leaves an heir of his body. Hence the law of adoption. What do all these invaluable little lives succumb to? Many observers have noticed the rarity of congenital deformity in India; but this observation demands qualification. True, there are not many hunch-backed, bow-legged, or knock-kneed natives; but, in India, there is no scarcity, *first*, of those congenital deformities which do not impair bodily vigour. I could have collected scores of such cases, among others that of a good-looking servant of my own, endowed with six toes on each foot and six digits on each hand, who took away a cart-load of my best property. I regret that his extremities have not found place in our College Museum. Or, *second*, of those which qualify for a life of beggary, or which mark their possessor as lucky.[37]

Vide Dr. A. Garden's elaborate report upon nine cases of malformation of the hands and feet in natives, which he observed in six years.[38] There are not many known congenital malformations which have not been seen in natives, as these pages will show.

I trust that the discussion which took place at the Pathological Society in 1880-81 has led medical men in India to take up rickets as a special study. I used occasionally to see, in the native bazars, an object who was probably rickety. Search should be made among those professional mendicants who are cripples, always remembering that in India, as in this country, children are often crippled for begging purposes. Instances of pelvic deformity in native women are extremely rare; but a small collection of Indian cases of Cæsarian section which I have made gives countenance to the opinion that females in that country are not wholly exempt from rickety distortion impeding labour.

(*To be continued.*)

THE BRAIN OF THE SCHOOL-CHILD.[1]

By FRANCIS WARNER, M.D., F.R.C.P.,
Assistant Physician to the London Hospital.

Public education is presumably undertaken for two purposes, (1) the benefit of the child, (2) the benefit of the public. From both points of view it is very desirable that all the mental and moral faculties of the child should be cultivated. Inasmuch as the properties of mind depend to a very great extent upon the condition of the brain, it is highly desirable that the educationalist should have some knowledge as to what kind of a brain he has to educate, and that he should know something of its various properties and functions, not only its intellectual manifestations; such knowledge may enable him to preserve the balance of the powers of the brain as it developes.

It will be granted that the educational processes should be adapted to the children, and it must be admitted that the average educational processes must be adapted to the average child. Are the average methods of education adapted to all children? A while ago it was found out that the deaf and the blind could not be taught in ordinary school-rooms; these are now in part provided for by small special classes. I desire to draw attention to another class—the nervous, irritable children; children who are irregular in attendance on account of headaches, recurrent chorea, occasional fits; habitual truants whose brain defect can be proven; the child so dull that it remains among the infants and learns nothing, As a hospital physician I meet with many such children, though doubtless they are but a small percentage of the school population, and from what I see I think these are practically not educated.

Is this to the public advantage? Why are the deaf and the blind educated? A part of the reason is that they may not become paupers. Why are the children

[37] In the chapter on "Congenital Imperforation of the Lower Bowel," I have noted that a child born without an anus is designated by the Up-Country natives a "Pargumber," or "Messenger from God." Mr. W. Cockburn states, in "Panjab Notes and Queries," vol. i., p. 64, that people born with deformities, such as double thumbs, &c., are accounted very lucky, being furnished with a natural preventative against *nazar*, the evil eye.

[38] *Indian Medical Gazette*, May, 1875.

[1] A paper read at the meeting of the Social Science Congress at Birmingham, September 19th, 1884.

of slight brain defect uneducated—children tending to become passionate, to pick up bad habits and practise them, tending to criminality, or, if too feeble for that, to pauperism? They are not neglected intentionally, but because they are not known to the school managers, it is nobody's business to find them out; they are not classified, and take their chance with the rest. Now my argument is, we can discover such children, and pick them out by definite physical signs; we can pick out from a class the child not up to the average, the child tending to failure from want of brain-power.

To say that such children are few in every school is no reason for their neglect; we rejoice that but few have such inborn conditions as make them tend to social failure, pauperism, or crime, but we wish that none should thus fail. Let such tendencies be detected early, and pointed out to the educationalist, that he may tend such cases carefully, helping to correct the defects due to brain condition.

I do not propose here to describe the physiology, and pathology of the child's brain, but I think that some such knowledge should be acquired by those responsible for large schools. Having looked carefully through the books now being exhibited at the Health Exhibition, and having made enquiries of all the school publishing societies, I find works on physiology, but none on the study of the brain of the child. In the exhibition only one exhibit contains a health register, and that comes from Japan. The brain of the school-child should be undergoing rapid development; the school-managers cannot be responsible for its nutrition as far as that is dependent upon food, but they may in special cases regulate the teaching according to the brain condition.

Let it be known and remembered that every movement and every posture of the body is an index of the action of the nerve mechanism. Let the teacher and manager study the children, the way they stand, the manner in which they hold out their hands, the appearance of their faces; let them study the expression of each child's condition.

Particularly should observation be directed to note any bodily defect about ears, eyes, lips, &c., for when there is a visible defect, if only in an ear, the brain is often coincidently defective in its development.

In various published essays I have given these signs in detail, so refrain from giving them here. I believe that, roughly speaking, a layman may be taught the physical signs of brain conditions with sufficient accuracy to guess, with some degree of certainty, the children with slight brain defect, recurrent headaches, those who sleep badly, and are excitable; such teaching our profession can give to teachers.

Neglect in these matters does lead to unintentional cruelty to children, and to what I think more important, to the educational neglect of wrong-brained children. The teachers do not want to neglect them; such neglect is due to ignorance, for which the managers are responsible. Now, as to these wrong-brained children, they are worth helping; in most cases a genius is abnormal; the very faults and nervousness may be trained to become admirable qualities—sensitiveness of mind, mobility of mind; and the fidgety child may become an active man. Such children too often escape from an educational process unsuited to them, but still, better than no education. The nervous, excitable boy, always ill with sick headaches while at school, is excused from school attendance; at home he is idle; too often the parents are neglectful and unwise; and as he grows up, when drink or passion inflame him, he commits some act bringing him within the power of the police. I have seen the education of many such continued with success when removed from large schools, and placed at inferior, but small and quiet schools. Again, the weak-brained, feeble-minded child often gets so teased, that at last he cannot be induced to go to school; his attendance is excused on the ground of health. What becomes of him after that?

Two important questions arise, then: (A) How can wrong-brained children be picked out? (B) What can be done for them?

A. How can the wrong-brained be picked out?

This raises the question whether the ordinary school manager is able, unassisted, to discover the brain condition of the children. Should there be an occasional medical inspection to aid the managers to determine how they may help on the development of the children? This might be met by occasional medical inspection, say twenty times in the year. We are not speaking of questions of hygiene or cases of illness. At the inspection, an experienced doctor, looking over the school class by class, would soon select those probably requiring some special care; the teachers would present for examination any child they found specially troublesome, often complaining, short-sighted, very passionate, &c.; and the cases of children excused from attendance on grounds of health would be considered; advice might be given on all cases. At a school I recently visited, a child was presented by the teacher as "not dull but somehow wrong"; grave brain defect was obvious; the advice given was to keep the child, if possible, at school and out of the gutters.

A boy was brought to me who was frequently absent, and often punished when in school; he had harelip, a defect of the heart, and an ill-developed brain. He has a right to be educated, and ought not to be punished for dulness of brain.

In examining a child as to brain condition, general excitability may be expressed by general fidgetiness and finger twitching. The posture of the hand when held out by a healthy child is straight; it assumes a special posture in the nervous, excitable child, and a different position in simple fatigue. The teeth are usually ground in an ill-sleeping child. The parts around the eye are visibly relaxed in conditions of headache, making it unnecessary to take a child's word as to whether it suffers; we can see it for ourselves. As to training the brain to stand strains, I believe it is better for the nervous child to be educated. It must meet the shocks and strains of life, and if *properly* educated and exercised it will bear those shocks and strains better than if untrained to think and to exercise self-control.

B. What can be done for these children?

I am not a technical educator; a want is pointed out, and we are prepared to show how this special class of children may be classified, and in individual cases or a group of cases we can say what will aid brain development.

In classes for the dumb I have seen cases very defective in brain being educated. In the highest class at Darenth Schools I have seen feeble-minded children being educated and sent out into the world. Small classes and special teachers could well manage the dull, the excitable, the wrongly-made children.

As to the expense of teaching a few children in a small class-room, instead of in a large room, would not the money be well spent in an effort to lessen crime, pauperism, and social failure? Should the endeavour be made to educate and save the child, or to reform the drunkard and criminal, and redeem the pauper to society?

I should like to see a tentative effort made. Provide inspection for a few large schools and two small class rooms with suitable teachers, and the truth of these statements would, I think, be soon demonstrated, and the value of classifying the brain-power of the children

would be recognised. The school examiner classifies by intellectual functions only. Every weakly or troublesome child who now escapes from public education is a failure of the system, and every such child is likely to be a public harm.

CASE OF DETACHMENT OF THE RETINA, IN A PERSON AGED 70, INVOLVING TOTAL BLINDNESS, CURED BY WOLFE'S OPERATION.

By J. McGREGOR-ROBERTSON, M.A., M.B., C.M.,
Junior Surgeon, Glasgow Ophthalmic Institution, Demonstrator of Physiology in the University.

Hugh S., aged 70, storekeeper in a ship-building yard, applied on the 23rd of August, 1884, for admission to the Ophthalmic Institution, because of blindness of the right eye.

The man's history was unusually good. He had always enjoyed perfect health, was of regular habits, and looked a hearty, hale old man.

He began to be troubled with his eyes about 18 months ago. One evening while walking along Argyle Street, Glasgow, he noticed that each of the lamps on the opposite side of the street appeared to have two lights instead of one, one of which was white the other blue. He stopped and then walked across towards the lamp, and as he approached it the two lights came nearer to one another till at a certain distance they merged into one. On going away again the two lights re-appeared. He then tried shutting one eye, and found that the white light was perceived by the left eye, and the blue one by the right, but the lights were crossed so that the blue light, perceived by the right eye, was to his left side. He thus became aware that something was wrong with the right eye, which gradually grew worse until he could not discern shadows with it. Lately he began to see floating objects before his left eye.

In Dr. Wolfe's absence I examined the patient. The following was the condition of the right eye: Pupil imperfectly dilatable, tension normal, a large retinal detachment at the lower and outer portion of the fundus and some floating pigment. The detachment completely obscured the fundus when one looked straight into the eye. But when the eye was rotated strongly inwards a glimpse of the disc could be got. It appeared only moderately clouded. There were a few floating shreds in the part of the vitreous not implicated in the detachment. Vision was almost completely abolished. The patient could not see the lamp held before him, nor could he discern the shadow of a hand held in front of him. Away to one side, however, he could catch a glimpse of the white cuff on the wrist of the hand held up, though when trying to touch it he missed it. As he himself expressed it he was "perfectly blind but for a wee bit blink away to the one side." In the left eye no floating bodies could be discerned through the undilated pupil. I considered the detachment one suitable for operation and requested the man to return on the following Monday, August 25th, when Dr. Wolfe confirmed my diagnosis, and thought it a favourable case. For, although the blindness was altogether out of proportion to the extent of the detachment, and although the remaining clear portion of the retina failed to form images, the chances afforded by an operation should not be withheld in such a case, since, when a large retinal surface becomes detached, the rest becomes torpid and then loses sensibility. It is remarkable that after the withdrawal of the effused fluid, the retina not only regains its function but the detached portion applies itself to its old site. When the macula is not involved, normal vision becomes re-established; but when the macula loses perception of light by long detachment there is eccentric fixation; that is, a neighbouring portion of the retina is used for it. In this case the signs of commencing embarrassment in the other eye also indicate the desirability of the operation to remove the effused fluid.

The operation was performed on the 2nd September, Dr. Kirkwood, of Rutherglen, along with myself assisting. Having introduced the speculum, Dr. Wolfe made a vertical incision into the conjunctiva and fibrous capsule at the outer and lower angle of the cul-de-sac. The edges of the wound were separated by two small strabismus hooks, and the eyeball having been rotated upwards and inwards, Dr. Wolfe entered the sclerotome through the sclerotic into the sac of the detachment. A large quantity of brownish fluid followed the withdrawal of the instrument. The wound was brought together by two fine silk ligatures, and the patient was put to bed.

On the sixth day after the operation the ligatures were removed. There was not the slightest reaction in the eye, which looked healthy and clear. With the exception of a red mark where the conjunctival incision was made it bore no marks of operation. The left eye was blindfolded, and it was found that with the right he could see everything and every person in the room, and walk to any part of it without hesitation. He could see with perfect distinctness a ring on the little finger of a hand held up at six feet distance and could with very little trouble tell the time to a minute on a white faced watch. He could also read Snellen's CC at ten feet, C at five feet, XL at three feet, and XX at twelve inches.

In *The British Medical Journal* for 3rd May, 1884, I reported a case of detachment of the retina, cured by Wolfe's operation. That case and the present one are remarkable testimonies to the value of the operation. It was performed on a man of the age of 38, this on a man aged 70. The former case was complicated with irido-choroiditis and nebulous cornea, the latter was uncomplicated. After the lapse of seven months the regained sight of the former has not at all diminished in quality, the man at this date being able to tell the time, to a second, on a watch, and to pursue his occupation as a tailor, and that in spite of the worst possible hygienic surroundings. Is it too much to expect that the present patient, a man of still vigorous health and of strictly regular habits, will benefit still more by the operation, and to conclude that the operation whose simplicity is one of its great merits is destined to occupy an important position in eye surgery?

ACUTE VOMITING IN INFANCY TREATED BY NUTRIENT ENEMATA.

By A. WITHERS GREEN, M.R.C.S., L.R.C.P., Lond.

H. Edward H. is a rickety, bottle-fed child, 7 months old. On September 6th it had a bottle of milk which was somewhat sour, but went to rest as usual. During the night the child was seized with vomiting and diarrhœa. I was called to see it at 5 a.m. On the 7th I found the eyes sunken into their sockets, great pallor and listlessness. The infant was cutting its right upper central incisor. I lanced the gum and ordered one teaspoonful of castor oil. After the oil had acted the diarrhœa ceased, but the sickness was unabated. Milk, whether fresh cows', condensed, or

artificially prepared human milk, was not retained, neither was barley water, rice water, beef tea, nor raw beef juice, in fact everything was pumped up unaltered, sometimes seeming hardly to have got into the stomach. By the evening of the 8th the child had been some hours passively convulsed or else very restless, extremities at times cold and fontanelle very depressed. Lime-water, bismuth, Hyd. c creta, gr. $\frac{1}{4}$ every four hours, Tinct. Opii ℥ $\frac{1}{8}$, Tinct. Iodi ℥ $\frac{1}{4}$, Creosote ℥ $\frac{1}{12}$, Glycerinum boracis, all seemed useless. Nutrient enemata were now commenced, after my evening visit on the 8th, and were continued until the morning of the 12th, as nearly as possible every two hours. The enemata were in amount two tablespoonfuls with half a teaspoonful of brandy in each, and consisted sometimes of condensed, or fresh cows' or artificially prepared human milk, sometimes of beef tea of different kinds all slightly warm. After a few times the child kept quite quiet while the injections were being given, and seemed revived after them. None of them were returned. Since the nutrient enemata were commenced the bowels have acted twice daily, gradually getting less slimy, and more natural. For rather more than three days and three nights no nourishment was taken by the mouth, the lips being moistened with brandy and milk. On the 9th a warm vinegar and water compress was kept most of the day round the waist, and since the 9th one tablespoonful of cod-liver oil was rubbed into the chest after washing the child each morning. During the night of the 11th beef tea, made with Liebig's extract of meat, was kept on the stomach, one tablespoonful about every four hours. On the same day the child smiled and seemed hungry, but was sick if more than a small quantity was given at a time. From the time the stomach began to retain beef tea, Bismuthi subnit. gr. $\frac{1}{2}$, with Tinct. Opii ℥ $\frac{1}{8}$ was given when any sickness or retching occurred and seemed to do good. On the 13th half a teaspoonful of cod-liver oil began to be given three times a day by the mouth. On the 14th half a teaspoonful of steel wine began to be taken as well. Though the beef tea was the first thing retained by the stomach the child soon began to refuse it, preferring its bottle of cows' milk (boiled) and water. The parents consider the issue highly satisfactory as they thought their child was for some days a little better than a corpse while now it is daily gaining strength and vigour.

REPORTS OF
HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

UNIVERSITY COLLEGE HOSPITAL.

SUPPURATION IN ANTRUM—SUPERFICIAL NECROSIS OF MAXILLA—GOUGING—RECOVERY.

(Under the care of Mr. BERKELEY HILL.)

(For these notes we are indebted to Mr. VICTOR HORSLEY, Surgical Registrar.)

ARTHUR D., aged 4 years, was admitted into the hospital on May 11th, 1884.

Personal History.—He had measles in August of last year, and appeared to have made a good recovery. He was now strong and lively, and had not suffered from any other antecedent illness. Two years ago he fell, striking the left cheek sharply against the prominent edge of a fender, causing a deep lacerated wound just below the orbit. This wound healed very well, a doctor's assistance not being required or sought.

Family History.—The child's father, who had had several attacks of rheumatic fever, died of phthisis, at the age of 36. The mother belongs to a "consumptive" family. There have been two other children, one of whom died in this hospital of diphtheria a little while ago. There is no family history of tumours.

Present Illness.—The swelling on the face first appeared about Christmas last. It was bathed with warm water and gradually increased in size. The swelling was lanced at another hospital some two months later, and subsequently poultices were applied. Since this there has been a constant discharge of pus. This incision is about in the place of the original lacerated wound.

Admission.—The left cheek is found much swollen, the greatest prominence being over the canine tooth of the upper jaw; here the skin is stretched, but is freely movable. Just beneath the lower eyelid the skin is reddened and pus exuding. A hard lump is felt over the situation of the canine tooth, as large as a cobnut; the surface of the swelling is smooth, and it is rather tender when pressed.

May 15th.—On exploring the sinus on the cheek with a probe, bare bone is felt; but no opening into the antrum could be found, nor any loose bone; the amount of pus was small. Hot boracic fomentations were ordered.

May 21st.—Mr. Hill made a free opening into the antrum, over the left canine, and found some superficial necrosis of the superior maxilla and malar bones, which he scraped away. The antrum was plugged with boracic lint.

May 24th.—The cavity was syringed out with carbolic lotion, and iodoform applied to the sinus on the cheek.

May 27th.—Discharged, well.

Remarks.—In the great majority of cases, abscess of the antrum is produced by dental caries, or by alveolar abscess. But in the present instance we have a case which was apparently due to injury inflicted some two years previously. There was no difficulty in the diagnosis; while the success of the treatment was doubtless due to the free opening which was made.

SUPPURATION IN THE LEFT ANTRUM WITH SYMPTOMS INDICATING DISEASE OF FRONTAL SINUS.

(Under the care of Mr. GODLEE.)

THOMAS N., aged 47, a clerk, was admitted into the hospital under the care of Mr. Godlee. His personal and family history are good. He is of temperate habits and there is no cancer or tendency to tumours in his family.

Present Illness.—Just before Christmas last year, he received a blow from the leg of a couch over the left brow which made him feel silly for a time. A large lump formed at the seat of injury. This became discoloured and lasted about ten days. A week after the injury, while eating his breakfast one morning, he noticed an offensively smelling discharge from his left nostril. This has continued for some time and then goes away. He has had severe headache at times, lasting for several days and then going away. This pain begins over the spot where he received the blow, thence shoots up to his occiput. The discharge from the nose comes on after the headache. For three months past he has completely lost the sense of smell.

Present State.—Examined with a speculum, there is seen a yellowish discharge from the floor of the middle

fossa of the left side of the nose; the mucous membrane is red and congested.

He was ordered flying blisters over the position of the frontal sinuses, under which there was at first considerable improvement. He was then temporarily discharged.

September 3rd.—On re-admission he still complained of the pain over the left frontal sinus, which extended backwards in a defined manner for about the length and breadth of a forefinger. There was very offensive discharge from his nose.

He was chloroformed, and it was determined to explore the antrum before opening the frontal sinuses, where the mischief was however expected to exist. A trocar and canula were passed in above the first molar tooth, and a quantity of creamy offensive pus was evacuated. Mr. Godlee now gouged an aperture through the anterior wall of the antrum, after first separating the gum and mucous membrane from the alveolar border.

The cavity was scraped out with a sharp spoon, and it was plugged with wet boracic lint, dusted with iodoform, after being irrigated with chloride of zinc solution.

September 4th.—Patient passed a very good night; all pain from the frontal region had disappeared.

September 5th.—He was discharged greatly relieved.

Remarks by Mr. Godlee.—The interest of this case consisted in the fact that both the history and symptoms appeared clearly to indicate disease of the frontal sinus, whereas there was no swelling, tenderness or discomfort in the region of the antrum. The pain was referred to the inner part of the superciliary eminence and was thus clearly not due to supra-orbital neuralgia which not unfrequently accompanies suppuration in the antrum.

HÆMATURIA—MEDIAN CYSTOTOMY—REMOVAL OF A CANCEROUS TUMOUR FROM BLADDER—RECOVERY.

Thomas G., aged 49, was admitted on August 1st.

Personal History.—The patient has always been a healthy man. About fifteen years ago he had an attack of "gout, accompanied with rheumatism." Since that date he has had occasional recurrences, but only one severe attack about seven years ago, which laid him up for over three months. His habits have always been temperate; he has taken a little ale, but rarely spirits; he has never suffered from privation of any kind. Thirty years ago he suffered from an attack of gonorrhœa, from which, however, he soon recovered. He has never had syphilis.

Family History.—Father and mother dead—both lived to good ages. No history of stone, or rheumatism, phthisis, syphilis or cancer. A sister suffered from gouty concretions at joints of the phalanges.

History of Present Illness.—About nineteen months ago patient began to pass a few drops of blood at the end of micturition. No notice was taken of this, until the amount became larger and the intervals of remission longer. It became also more completely mixed with the urine, but occasionally clots were also passed. He felt no pain at first, when blood was passed; but three months ago micturition began to be accompanied with pain over the pubes, of a dull character, together with a smarting and itching at the end of the penis. During the last three or four months, patient has had to pass water very frequently, sometimes as often as every half hour, and the quantity passed has been very small; the frequency is a little more at night than during the day. Six weeks ago he noticed something in the urine like a "piece of flesh."

Present State.—The patient is now micturating at the rate of about 24 or 25 times in the 24 hours; more frequently at night than during the day, and passes from two to three ounces at a time. There is pain over the pubes during the act, and itching at the end of the penis afterwards. This only lasts a few minutes, and it is less marked when he micturates in the sitting position. Some days there is no apparent blood in the urine, though a deposit always appears on standing. Patient occasionally passes small flesh-like masses. The urine is now of a smoky reddish colour; it contains a one-fifth albumen, and there is a sediment on standing. This deposit consists of mucus, blood corpuscles, triple phosphates, and a little pus. On passing a sound, the instrument is deflected to the left as it enters the bladder, and as the sound enters more deeply it is impossible to bring it to the middle line, until the back of the bladder is reached, on account of an irregular hard mass growing from the base and right side of the viscus. A small amount of bleeding followed the sounding. A stone could not be felt. It was thought that the mass detected by the sound could be felt with the hand placed above the pubes, and this was verified afterwards when the patient was anæsthetised, it being then possible to grasp the mass between the fingers of one hand placed over the pubes and the forefinger of the other passed into the rectum.

August 6th.—Under chloroform, after examination, Mr. Godlee opened the bladder by the median incision. On passing the finger in a large sessile growth was felt on the anterior wall of the bladder. This was extracted by means of a Thompson's bladder forceps. The hæmorrhage was rather free, but readily ceased after the injection of iced water. Chloride of zinc solution was applied to the interior of the bladder and to the wound, and iodoform was dusted on to the latter. A tube was inserted. It was not possible apparently to get away the whole of the growth. A morphia suppository was then administered.

August 7th.—The patient has been much relieved by the operation.

August 9th.—The tube was removed. The pain beneath the pubes has not quite disappeared.

August 20th.—The perinæal wound almost healed. The urine is passed per urethram. It contains a considerable quantity of pus.

August 22nd.—There has been a little tenderness in one testicle, for which fomentations have been applied, and which is now almost gone. He was discharged on the 26th. The temperature has been slightly above the normal throughout; it was not materially influenced by the operation. As to the tumour, on examination it was found.

September 11th.—Patient was seen to-day. He is much improved in health, having now a good colour, whereas before he was pale and anæmic. He has no trouble with his water, except that a certain amount still leaks through the perinæal wound.

Remarks by Mr. Godlee.—It is questionable whether a surgeon is justified in attempting the removal of a tumour of the bladder which is so large that it can scarcely be hoped to remove it entirely. The justification of such a proceeding in the present case appeared to be the fact that the man was rapidly losing strength as a result of the hæmorrhage and suffering great discomfort from the pain and frequency of micturition. The free application of chloride of zinc and of iodoform kept the bladder perfectly sweet, and the patient thus suffered from no constitutional disturbance after the operation. The question of a second operation may possibly arise, as the nature of the growth was unquestionably epitheliomatous.

Medical Times and Gazette.

SATURDAY, SEPTEMBER 27, 1884.

On Wednesday week the 28th annual congress of the Social Science Association was opened by the President, Mr. Shaw-Lefevre with an address, characterised both by breadth of view and by minute attention to detail. He began by showing the methods by which social science works, and pointed out how acts of legislation play therein the same part that experiment plays in physical science, a fact, we may add, which should render an interfering parliament secure of the gratitude of social scientists. The president next said that democracy, so far from showing jealousy of the Executive and a preference for destroying institutions, had trusted and extended the powers of the State, and in this it had been encouraged by the modern school of political economists, who had largely departed from the views held by their predecessors. Mr. Shaw-Lefevre then proceeded to classify and to consider the different methods of State intervention, and the legislation by which it had been carried into effect between 1867 and the present year. The first class, in which the State undertook or allowed local authorities to undertake functions previously performed by private agency, included education, the post office and telegraphs, water and gas supply. The second class, imposing restrictions on certain industries in the interest of safety, health or morals, included the factory acts, the liquor laws, and the regulation of the mining and shipping industries. In some respects the results of these acts of legislation had been disappointing. The third class, that of sanitary legislation, was dealt with at some length, and in touching upon the measures for improving the dwellings of the poor, Mr. Shaw-Lefevre decided that it was a long stretch of the rights of ownership to admit the title of persons who had allowed their property to become a nuisance, to full compensation at the cost of the public, when it was determined to take such properties out of their hands. Other classes of State intervention dealt with fell under the heads of freedom of contract and loans by the State. But the most important part of the address was that in which the author discussed the benefits of all this legislation. Here he was able to show that in the last ten years, nearly half a million people survived who would have died if the previous rate of mortality had been continued, while in the same period pauperism had decreased by 30, and serious crime by 22 per cent. Finally he entreated his hearers to enter upon their subsequent discussions "in the best spirit of philosophic fairness and of enlightened scepticism, seasoned with sympathy for our countrymen of all classes."

On Tuesday, Dr. Norman Chevers delivered his address as President of the Health Section. He began by arraigning our "sanitary system," questioning whether it had the right to be recognised as a validly working system of health. He instanced the state of the Thames, the sewage system of London, the terrible smells of Covent Garden, the filthy and dilapidated condition of the dwellings of the poor, the high death-rates of the "slums," especially among infants, and asked whether a foreigner would not be justified in wondering whether "these worthy, self-satisfied people can seriously boast that they exist under a sanitary system." Of all vain conceits the most loathsome and futile was that of Sanitary Brag; pretentious quackery and dishonest assumption of power that we do not possess would never effect the real triumphs of sanitary reform. He was no pessimist; he had studied and practised sanitation, lovingly and hopefully, for forty years, but he recognised the disheartening fact that without powers, full almost to benevolent absolutism, the benefits of sanitary administration must always be very tardy in their advance and narrow in their scope. He insisted on the necessity of persuading—would that he could say of *compelling*—the world's blockheads to act upon scientific teaching. He strongly advocated the appointment of a Minister of Public Health, invested with great powers, against which all narrow self-interested opposition would be futile, and commanding large means, and he confidently anticipated that in a very short time after such an appointment being made, nothing more would be heard of sewage-poisoned rivers, smoke- and fog-blocked cities, or of public buildings and attractive suburban retreats constructed upon burial grounds, quagmires or abandoned lay-stalls. Amongst the benefits that would follow would be the publication of medico-topographical and sanitary reports for all towns and districts in the United Kingdom; the sanitary administration of our cities on a uniform plan; and the reform and strict regulation of our systems of medical education and practice. Duly empowered, Britain's Minister of Public Health would soon be able to declare that the health of England was at length protected and administered by measures which worthily claimed to be distinguished as a "sanitary system."

The special questions selected for discussion in the Health Section, presided over by Dr. Norman Chevers, were:—(1) What is the best method of dealing with (*a*) town sewage, (*b*) the products of house and street scavenging, and (*c*) the products of combustion? (2) What are the best means, legislative or other, of securing those improvements in the dwellings of the poor, which are essential to the welfare of the community? (3) How far may the average death-rate of a population be considered an efficient test of its sanitary condition; and by what means can the high death-rate of children be reduced? In connection with the first question, papers were read by Mr. T. Pritchard, C.E., who described the various methods of sewage disposal and expressed the opinion that no particular system could be adopted for universal use; by Mr. Lawson Tait, who gave an elaborate account of the system employed, with considerable promise of financial success, at Birmingham; and by Captain Douglas Galton, who dealt with the problem of smoke abatement, concluding that it could only be secured by resorting to the use of gaseous fuel.

The second question was introduced by a paper by Mr. John Hamer, who described the work of the

Mansion House Council on the dwellings of the people, and, pointing out that the sanitary authorities at present exist for the removal of nuisances rather than the prevention of disease, advocated strongly the creation of a Ministry of Health and Education. "The health of the people and the education of the people" he concluded, "are so vital to the whole nation that their regulation should be a national, in other words, a State affair." A long discussion followed, the general opinion seeming to be adverse to the erection of dwellings by local authorities, an opinion in which Mr. Shaw-Lefevre fully concurred.

In connection with the third "Special Question" Mr. Noel Humphreys read an elaborate paper, in which he examined and analysed the various objections to the use of death-rates as a test of health condition. His investigations led him to conclude that they afforded a numerical test of health condition sufficiently approximate and trustworthy to be useful as a stimulant of the public interest in health progress. Death-rates at groups of ages had a greater scientific value than the death-rate at all ages, but were not available as numerical tests of health. Dr. Herbert Page, of Redditch, in a paper on the same subject, called attention to the varying conditions which modified the test, and showed the importance of having special regard to the relative sex and age groups of the living to those of the dying in the same or similar populations. The remainder of his paper was devoted to a consideration of the means for reducing child mortality, a subject also treated in a paper by Dr. H. Ashby. Both authors contended that the causes of infant mortality were the health and life conditions of the parents, unsanitary conditions of dwellings, improper feeding, employment of mothers in mills, bad effects of burial clubs, poverty, degradation and drunkenness of parents. As a means of reducing the high death-rate, Dr. Ashby suggested improvements in the surroundings and homes of the working classes, checks on burial clubs, and improvement in the habits, status and education of the poor; while Dr. Page, in addition, insisted on the necessity of regulating the employment of women after childbirth, of registering cases of infectious disease, of enquiring medico-legally into the causes of the deaths of children; and, lastly—though this was a delicate point—of imposing some check on marriage to prevent the transmission of an enfeebled heredity. In the discussion which followed, Professor Gairdner said that the best test of sanitary condition was the death-rate of infants under one year, Mr. Neisser suggested a national registration of sickness, and the Chairman, believing that much infant mortality was due to the inexperience of mothers, advocated the registration of the deaths of first-born children apart from those of others.

Some other important papers were read in the Health Section. Surgeon-Major Pringle dealt with Asiatic cholera, epidemics of which, he held, almost invariably originated in Lower Bengal, and spread by human intercourse, "though not in the contagious and infectious manner seen in small-pox, &c." As to treatment, he believed in elimination, and was strongly opposed to the use of opiates and stimulants. He concluded, in opposition to Sonsino, whose views on the subject we publish in another column, that there was no such stage as that of premonitory diarrhœa. Nursing was the sheet-anchor in the treatment. Prevention consisted in removing the causes which produce diarrhœa and dysentery, and in the careful and independent inspection of the passengers in infected ships and at railway stations and halting-places. In another paper the same author considered "vaccination and revaccination." He believed that vaccination carefully and systematically carried out had lost none of its protective power, instancing the case of Meerut, with a population of 120,000, in which not one case of small-pox had occurred after a single vaccination. Except for vaccination, he said, no European force could hold India. He did not believe revaccination necessary where the primary vaccination had been made with fresh vaccine. In a paper "On Hospital Ships," Dr. P. Murray Braidwood dealt with the construction of these vessels, and showed designs of different types of ships. He strongly advocated the advisability of building special ships for the treatment of the sick and wounded at sea, in preference to using converted steamers for this purpose.

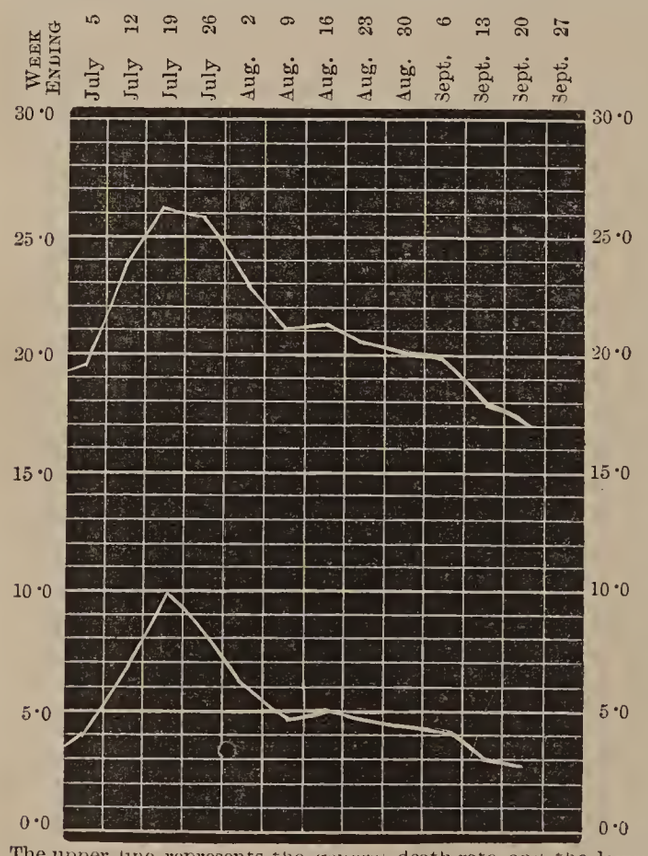
In a thoughtful paper "On the Future of some of the London Hospitals," with the views expressed in which we fully sympathise, Mr. R. Denny Urlin, Member of the London School Board, anticipated that, as London grew, and contributions fell off, some of these institutions would probably collapse. If this fate befell some of the small special hospitals, it would be no great loss; but there were others which from their position and mode of operation had become public necessities, and, if they were to be maintained, there must be sooner or later a subvention from public funds. This would certainly bring with it some degree of inspection and control which would be advantageous. At present a hospital might be planned, built, and carried on without any due security for the safety and health of the inmates, and solely at the caprice of a Secretary and a Board. As hospitals were built for the public, and mainly supported by the public, it was fair that they should be regarded as public institutions, and subjected to inspection and audit accordingly. Inspection for sanitary and other purposes should be compulsory in the case of all such structures, while audit should be imposed as the condition of obtaining any grant from Government or local funds. Mr. Urlin looks a long way ahead, and his expectation of obtaining Government grants in support of hospitals will be regarded by some as chimerical, but the radical consideration of the whole question will probably be forced upon us sooner than we expect. Meanwhile it is satisfactory to find that someone has taken time by the forelock.

The Sanitary Institute, treading close upon the heels of the Social Science Association, will open its congress and exhibition of sanitary appliances at Dublin, on

Tuesday next, most of the meetings being held within the precincts of Trinity College. The President, Sir Robert Rawlinson, will deliver his address on the first day at 8 p.m. On the second day the section of Sanitary Science and Preventive Medicine will hold its meetings, under the presidency of Dr. Grimshaw, the Registrar-General for Ireland. On the third day the meetings of the section of Engineering and Architecture will be held, while the section of Chemistry, Meteorology and Chemistry, presided over by Dr. Charles Cameron, will have its innings on the fourth day. In the evening of that day Dr. Alfred Carpenter, the Chairman of Council, will deliver a lecture entitled "Education by Proverb in Sanitary Work." The proceedings will be varied by public feasting and a conversazione.

Dr. Oliver Wendell Holmes celebrated his 75th birthday on August 29th. He received the congratulations, personally, by mail and by telegraph, of a large circle of friends throughout his own country and Europe.

The Registrar-General's return for last week shows that the deaths in London were 101 below the corrected average for the week, a result contributed to no doubt in great measure by the steady and fine weather that we have been having. The decline in the zymotic death-rate still continues, so that last week the deaths under this head only gave a rate of 2·7 per 1,000. Small-pox is accredited with six deaths which appears to be the normal amount, so that the epidemic may now be considered to be practically over. The deaths from measles and scarlet fever both



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the first twelve weeks of the current quarter.

showed a slight rise, the former going from 11 to 18, and the latter from 23 to 26. Diphtheria claimed 21 victims and that is leaving out of consideration 11 children under 5 years of age who were certified as having died of croup. The deaths from diarrhœa, which have been steadily diminishing for the past month, still further fell to 86. Enteric fever on the other hand caused 27 deaths, as compared with 26, 20, and 16 in the three weeks immediately preceding. The anti-vaccinationists of Leicester can point to the highest death-rate for the week, 29·9, being just 1·1 per 1,000 higher than that of any of the other 27 great towns.

The annual distribution of prizes to the students of the Pharmaceutical Society will take place on Wednesday next, at eight p.m., when the inaugural sessional address will be delivered by Mr. Thiselton Dyer, F.R.S.

The opening of the Medical Session will be made the excuse for the usual festivities at most of the London hospitals. There will be the usual monster *soirée* at Guy's on October 1st, and on the following evening the staff and lecturers of St. Mary's Hospital Medical School will give a large *conversazione*, at which there will be a display of electric domestic lighting. The arrangements for this, as well as the decoration of the school for the purpose of the entertainment will be superintended by Mr. Noble Smith. At St. Bartholomew's Hospital the old students' dinner will be held under the presidency of Mr. Holden, while the analogous reunions in connection with University and King's Colleges will be presided over respectively by Sir William Jenner and Sir William Bowman. There will also be the usual feasting at several of the other hospitals.

At a meeting of the Glasgow Town Council held on the 22nd inst., an exhaustive report was submitted by Dr. Russell, the Health Officer, on the present outbreak of enteric fever in Glasgow hospitals. The matter was first brought under the notice of the Health Officer for the city by the Superintendent of the Western Infirmary. Similar outbreaks were afterwards reported from the Royal Infirmary and Belvedere Fever Hospital, and as the city generally showed no signs of a similar epidemic, Dr. Russell came to the conclusion that the appearance of the fever was due to one source, which, after careful investigation, he declared to be the milk supply. The three institutions above-named are supplied by the same agent, and among the farms from which he obtains milk, is one in the parish of Kilwinning, the water supply of which appears to be singularly impure. Speaking of the district in question, Dr. Russell says that its condition is a matter of public notoriety, and a glaring proof of the hollow farce of rural sanitary administration. It is by such paths that cholera would find its way into our large cities. To show the extent of the outbreak it may be stated that no less than 104 cases were reported from the three hospitals, viz.: Western Infirmary 44 cases, of which number 17 are officials, including 10 nurses; Royal Infirmary 29 cases (3 officials of whom one, a nurse, died in the Belvedere Fever Hospital); Belvedere Fever Hospital

31 cases. It is hardly necessary to say that the remainder was made up of those who were already in the hospitals as patients for other affections than typhoid fever.

There is trouble brewing again at the Glasgow Royal Infirmary, and this time the staff seem to have been even more flagrantly overridden than on previous occasions. It appears, as may be seen from a paragraph in our news column, that the members of the staff, whose duty it is to admit patients, decided, after due consideration, to refuse admission to a case of typhoid fever, on the ground of its being an infectious disease, which would be more appropriately treated at the Belvedere Fever Hospital. This decision of theirs was at once overruled by the superintendent, which, to any one who knows the inner working of the institution, is equivalent to saying, by the lay manager of the infirmary, Mr. William McEwen. Subsequently numerous cases of the same fever were admitted, and patients suffering from other diseases turned away, though it was known that such action was disapproved of by the medical staff. The doctors have sent in a protest, but will probably get no satisfaction unless they resign. If they should be driven to this extremity, they will, no doubt, be unanimously supported by the whole profession in Glasgow.

At a meeting of the Glasgow Dean of Guild Court held on the 11th instant, the Lord Dean, McEwen, called attention to the condition of the drainage of the city, and expressed the opinion that considerable improvements might be made in a sanitary direction. He suggested that an officer should be appointed to see that the orders of the Court as to drains were properly carried out, otherwise the house or houses with defective drains will not be passed as fit for habitation. This is a subject of grave import at all times, but becomes doubly so when Glasgow is in danger of being visited by cholera. It is a notorious fact, that even amongst the fashionable quarters of the city, the drains are in a more or less deplorable state, not even excepting the residence of the Lord Dean of Guild. The builders build for the purpose of making money, regardless of either comfort or safety to health; their chief end being "mak siller honestly *if* possible; but, by all means, mak siller."

Some relics of the once celebrated Webb Street School of Anatomy were discovered by some workmen, in St. Thomas's Street, Southwark, on Monday, in the form of a quantity of skulls and bones, which had evidently been used for dissection. The coroner was advised of the fact, but wisely determined to take no official notice of the discovery.

Why does not someone write a companion sketch to Mr. Brudenell Carter's recent letter in the *Times* on "The effect of civilisation on the eyesight," terming it, for the sake of harmony, "The effect of civilisation on the nose-smell?" It is very evident from the vile odours in which the poor of great cities habitually move and have their being, that their sense of smell is quite as degenerate as their sense of sight. They could not otherwise live without their gorge rising against the fusty and sickening stenches which surround them. It is a law of physiology that the unintermitting call upon a function dulls it, while intermittent exercise cultivates it. If comparative trials of the sense of smell in different classes of the population were instituted, we make bold to say that the Eton boy would far outstrip his contemporary of the slums. And yet the sense of smell is not a useless or merely ornamental faculty which we can afford to let atrophy like our canine teeth. Sight and hearing can give us warning of the grosser shocks and perils that threaten humanity, but they are comparatively useless as sentinels against those more subtle dangers that lurk in polluted air and decaying food. For warnings against these we must trust to the less highly organised senses of smell and taste. The drain-smell which is all too common and unregarded in the houses of the poor shows that they have allowed one of these useful sentinels to go off guard, while the fact that bowel-disorders from the use of putrid food are common amongst hospital patients, but very rare amongst those of a better class, seems to prove that the other sentinel—taste—is equally little on the alert. As *Punch* appositely asks this week "What has pale Poverty to do with taste?" It is evidently important that in an all-round culture some attention should be paid to the improvement of these two useful senses.

The officers of the Indian Medical Service are intending, we hear, to present a piece of plate to Mr. Gibson, M.P., in recognition of his efforts to bring their grievances under the notice of Parliament and the public, and to obtain redress of them from the Government.

We are glad to learn that the financial account of the late Annual Meeting of the British Medical Association has been most satisfactorily wound up. The profession in the North of Ireland have reason to be proud of the success of the meeting from every point of view. It was perhaps the first time in the history of Belfast that its medical brethren were called upon to undertake the reception and entertainment of so many foreigners, and medical men from all parts of the kingdom; and we recently expressed ourselves in very favourable terms of the happy result. We were, however, quite unprepared for the rather unusual and unexpected state of matters as disclosed in the report of the Honorary Treasurer. There was not any guarantee fund provided for the expenses, the members of the profession alone were invited to subscribe, and it was, from the beginning, resolved that subscriptions should be strictly confined to the medical men in Belfast and Ulster, and a most liberal and hearty response was the result. The gross expenses of the meeting amounted to upwards of 1,300*l.*, and after all accounts were paid and the total expenditure met, the treasurer found himself in the rather unique position of being able to return one-fifth of the original subscription to each donor and still retain a balance to be handed over to a benevolent institution.

Hospital Saturday in Belfast was an entirely novel feature to the inhabitants, who seemed to be taken by surprise at the sight now so common in London and the great centres of English industry. Latest accounts show that a sum of nearly 600*l.* was realised. Considering the population of the town (250,000), this sum, which even for the first trial of the movement compares most favourably with the amounts raised in most places where this yearly method of subscription has been adopted, will doubtless be further increased in future years. The gross amount goes to the support of the Belfast Royal Hospital, whose funds urgently require an increase. One of the most active charities in the town also feels its finances crippled. The Ulster Hospital for Diseases of Women and Children, a teaching institution recognised by the Senate of the Royal University, is in the position of having its annual income seriously short of the annual expenditure. The committee met this week, and recognising fully the financial difficulty, decided to levy a small tax upon every extern patient, of whom there are about 8,000 yearly attending the institution. This resolution is considered by the medical staff as fatal to the working and usefulness of the charity, especially as in the large extern connected with the children's department, the little patients are from the very poorest districts of the town.

We have received from E. H. Schröder, of Berlin, lithographs of two pictures of medical interest, which he has recently published for the adornment of the consulting room. One is a reproduction of Rembrandt's well-known picture "The Anatomy Lesson," the original of which, at the Hague, is admitted to be one of the finest masterpieces of the Dutch School. The disposition of light and shade, and the character in each of the faces, which are the two most striking points in the original, have been faithfully reproduced in the lithograph. The other picture, by E. Hamman, is of a less pleasing nature, and is but little known in England. It represents Vesalius, a man of stern and rugged features, with a dead subject before him. With one hand he grasps the arm of the corpse, while with the other he is about to seize an instrument with the view of opening the head. But his glance and with it his hand are arrested by the sight of the crucifix upon the wall. The balance of the two emotions is admirably pourtrayed, but it is, we think, an uncanny though a powerful picture. The sight of it would shock most consulting-room visitors. The lithographs are cheap and the two can be bought and framed for considerably less than a guinea fee.

"Death from blood-poisoning following vaccination." Such was the verdict in an inquest held at Fulham a few days ago. If we substitute for "following" the word "after" we shall probably give a more correct version of the true state of the case. The infant in question was vaccinated on the 19th of August, and died on September 13th. Had the erysipelas of which the child died been due to the vaccination it should have made its appearance much sooner than it did, for a week after the vaccination there was no sign of it, the arm merely appearing as if it had been rubbed. When one bears in mind the rough and ready manner in which mothers amongst the lower classes dress and undress their infants, and when, further, the dirty state of their clothing is taken into consideration, the wonder is, not that children get inflamed arms after vaccination occasionally, but that they ever escape them. In the present instance there is nothing in the evidence to show when the erysipelas set in, or whether the parents obtained medical advice for the infant, a point of some importance in regard to such a disease as erysipelas.

What is Texan fever? Is there such a disease, and if there is does it matter? Such are some of the reflections which recent occurrences in Birkenhead, both last week and three weeks ago, will naturally suggest to the minds of the reading public. Last week the meat inspector for the Corporation of Birkenhead applied to the magistrate for an order to destroy the carcase of an animal which, he asserted, bore traces of having suffered from Texan fever. He described the carcase as deeply bile-stained, and the liver and spleen as being much enlarged, the latter weighing at least three times as much as the healthy spleen should do, and in the fourth stomach he had found several erosions. He said that the appearance of the meat alone would not have enabled him to recognise the disease, and he should have passed the carcase as sound had it not been for the condition of the viscera. He was followed by two or three scientific witnesses, who took the same view as he did, viz., that the animal had undoubtedly been suffering from Texan fever. On the other side were ranged a host of witnesses, some scientific, others practical; one of them, for instance, deposed to having eaten the meat about which a similar dispute had been raised a fortnight before, without having experienced any ill effects from so doing. These witnesses deposed that they considered the meat to be perfectly sound. One well known pathologist had put it through its facings, so to speak, under his microscope, and had been unable to discover any sign of disease, and they almost all expressed their readiness to eat some of it if necessary. This evidence, coupled with the fact that to his unaided senses the meat looked perfectly good, led the magistrate to decline to condemn the meat, though admitting that the case was a proper one to have been brought forward. Let us hope that the defendants did not celebrate their victory by a luncheon to their witnesses off the animal in question.

In the *Archives Générales* for September, Dr. Auguste Ollivier, physician of the Hôpital des Enfants Malades, at Paris, publishes the report which he addressed to the Conseil d'Hygiène Publique on "Measles in Paris, its incessant progress, its mortality and the necessity of prophylactic measures." Alluding to a former report of his on diphtheria which had procured the employment of such measures, Dr. Ollivier observes that unfortunately diphtheria is not the only contagious disease which weighs heavily on the infantile population of Paris, for there is also measles, which is even more common, but which

everyone, so to say, seems to regard as an inoffensive malady. Traditionary prejudices concerning it have descended from the middle ages, according to which it is usually looked upon as a necessary disease of no great danger. How erroneous this view is seen in the fact that of 57,024 deaths which, in 1883, occurred in Paris, 1,058, or nearly 2 per cent., were due to measles, this indeed ranking next to diphtheria with its 1,951 deaths. The fatality of the disease is also greatly on the increase, for while in 1865 there were but 343 deaths from measles, or 18·8 per 100,000, the proportion has progressively increased to 1,058 or 47·1 per 100,000 in 1883. This increase of the disease is owing chiefly to the greater facilities offered for the spread of its contagion by the increase of population and of the greater assemblages now attending schools, hospitals and dispensaries, without any means of isolation, even in the actual presence of the disease. Moreover, an erroneous idea generally prevails with respect to the period during which contagion is possible, this being almost always limited to the actual presence of the eruption, and especially the stage of desquamation. But the period at which transmission is most easy and probably most frequent is that of invasion. It is now admitted almost as a law in pathology that the catarrhal secretions form excellent vehicles of contagion, and we know how abundantly these are produced at the period of the invasion of measles, while, as often but little fever exists, no attempts at isolation are made. Measles, however, is not a disease of the same danger at all periods of life, and from a table given by Dr. Ollivier it is seen that while during 1883, and the first quarter of 1884, of the 1,399 deaths from measles 1,387 of these took place in subjects below 15 years of age, only 12 deaths occurred in those above that age. This may supply the refutation of the popular fallacy that the disease is a beneficial crisis, and that the sooner it is passed through the better. To say nothing as to the possibility of escaping it altogether, it is surely preferable to have it at an age at which it is almost always cured than at one at which it so often proves fatal. In devising prophylactic measures, therefore, while protection should of course be extended to all, it should be directed with special solicitude to young children against one of the diseases which proves most fatal to them.

However useful may be the reiteration of the above views and facts, when we come to prophylactic measures we fear that Dr. Ollivier has little that is new to suggest. As regards measles occurring in private families, he admits that all he can do is to endeavour to dissipate the ignorance which at present prevails concerning the disease. One suggestion, however, that he makes may be useful, namely, to place private schools under medical inspection which at present is confined to public ones. Little or nothing is known about their sanitary conditions, and it is to be feared that these and their provisions in contagious diseases do not compare favourably with those of the public establishments. With respect to hospitals, however, Dr. Ollivier, insists that the various forms of *isolation* may and should be carried out with much greater vigour than at present, and that it is to such means alone that we can look for a diminution of mortality from contagious diseases like diphtheria and measles. The formation of isolated pavilions, such as have been erected at the Hospice des Enfants Assistés, would be an important improvement at the two Hôpitaux des Enfants Malades. Another would consist in the provision of a separate pavilion for the large number of children who are brought for consultations, separating again those among them who are or who seem to be the subjects of contagious diseases.

In a recent number of *L'Encephale*, Professor Ball has a short but interesting and very valuable communication on twin madness, that is to say, on a form of mental derangement arising almost simultaneously in twins, with the same kind of delirium and perfectly spontaneous in each. His paper was based on the observation of twin sisters in whom acute mania, with hallucinations and mystic ideas, developed itself at an interval of only a few days. These occurrences are far from common, and not many instances are to be found in current literature. Professor Ball concludes, after a reference to the naturally intimate union that prevails in reference to twins, that it is to heredity that such instances must be attributed, and that insanity in twins is but the highest expression of heredity.

The arbitrary appointment of Dr. Schweninger to a professorship in the Berlin Medical Faculty by the Minister of Public Instruction at the instigation of Prince Bismarck, to which we recently alluded, has at last called forth a protest from the Faculty, although the Berlin journals pass it by, either because they do not think it worth attending to, or too delicate a matter for them to meddle with. What effect the protest will have remains to be seen, but it is *well* that his colleagues feel at last their position in having a man thus foisted upon them who has no scientific eminence and whose professional character is under a cloud. His advancement was not to stop here, for he was also made a member of the German Sanitary Board without any qualification for the post whatever, and against the protest of the Director, Dr. Struck (also formerly a medical attendant on Prince Bismarck), who, in consequence, resigned his post. Dr. Koch has also, on account of some unpleasant circumstances connected with the affair, given up his seat on the Board, after having declined to be nominated as Struck's successor. Koch, however, will be much more suitably placed as Professor of Hygiene at the new Hygienic Institute which is about to be established. According to the correspondent of the *Allgemeine Wiener Medicinische Zeitung* his present payments are very inadequate. "It seems incredible, but yet is true, that the famous *Bacillenvater* Koch, whose name is received with general recognition to the ends of the earth, received only a salary of 2,000 thalers (300*l.*) with a personal addition of a hunded marks."

That the disciples of Hahnemann of the present day have practically given up their belief in the efficacy of infinitesimal doses, has not yet been realised by that section of the public who believe in homœopathy. It

will dawn upon them some day, gradually no doubt; but if a recent occurrence in Melbourne could be brought before their notice, it is probable that the process of enlightenment would be somewhat hastened. It appears that a young woman died there from the effects of a dose of morphia prescribed for her by a homœopath. She had been suffering from sleeplessness, and, owing to a mistake on the part of the chemist, had taken a powder containing ten grains of hydrochlorate of morphia at a single dose. The practitioner in question Dr. Günst, stated at the inquest that he had intended to order her half a grain of morphia, that is to say a full medicinal dose, the dose according to the "British Pharmacopœia" being from $\frac{1}{12}$ to $\frac{1}{2}$ of a grain. This will rather startle the not inconsiderable proportion of believers in homœopathy who pin their faith to it on the apparently very safe proposition that at any rate it can't do anybody any harm. The modern homœopath who prescribes the ordinary Pharmacopœial doses, is a person who sails under false colours. It is a nice point as to whether he could not be convicted of obtaining money under false pretences, when treating a patient otherwise than in accordance with the laws of Hahnemann.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

It must be obvious to all sensible men, whatever their bias, that the discussion on the over-pressure question ought not to be allowed to remain where it has been left by the publication of Dr. Crichton Browne's report and Mr. Fitch's memorandum. In such a case a verdict of "not proven" cannot be considered as annulling the need of further consideration, and we are glad to see such a cautious journal as the *Guardian*, which no one will accuse of being prejudiced in favour of medical views, declaring that "the whole subject stands much in need of further and more impartial enquiry.' In our last issue we advocated the appointment of a special Commission to consider the question and to take skilled evidence upon it in all its bearings, a suggestion which has met with some support from the lay press. But it is quite to be expected that the Education Department will set its face stolidly against such an enquiry, unless fresh evidence is brought forward to show the necessity for it. In another column we publish some letters on the subject from physicians to our large children's hospitals, who, it will be generally admitted, are of all men the most competent to form and express an opinion upon it, and we shall be glad to receive further correspondence from those who have special experience of children's disorders, whatever be the opinions they have arrived at. Mr. Fitch would probably object to such evidence, because the writers have had no special experience of school work or school management, but such an objection is mere pedantry. If the evil results of school pressure force themselves on the attention of those whose business it is to take note of, and treat them, it is beside the question to affirm, as Mr. Fitch has done in the case of Dr. Crichton Browne, that the witnesses have no knowledge of the mechanism by which such results are produced. It would be as reasonable to object to our setting down drink as a cause of Bright's disease because we are unfamiliar with the inside of public-houses. On the other hand, should these observers state that they find no evidence of the effects of school pressure, much will be done not only to gratify Mr. Fitch, but also to allay the prevalent alarm; for there is no doubt that if the complaints alleged do occur, it is in the out-patient departments of children's hospitals that they will make themselves heard.

Another argument in favour of further enquiry is this, that, whether there be such a thing as educational over-pressure or not, the better informed parents of School Board children have got it into their heads that there is, and it is desirable in the interests of education itself, either that such a notion should be proved in open day to be groundless, or else that the cause of the over-pressure should be removed with equal publicity. Speaking with some experience of a children's out-patient department, we maintain that within the last few months the complaints of parents against school work have materially increased, and that the statement is much more frequently volunteered than it used to be, that over-work at school has been the cause of the symptoms for which advice is sought. It is not contended that such voluntary statements are sufficient to prove the existence of over-pressure, but it is contended that they prove the existence of a certain impression in the minds of parents, which it is worth the while of the Education Department to take note of. Evidently the work of the Board Schools cannot be carried on efficiently without the hearty goodwill of the better educated parents. Medical testimony on the subject may be lightly set aside or argued down, but the prejudice of parents is not likely to be removed by any display of dialectic talent, and, if the wheels of our educational system are to run without friction, the first requirement is to convince the parents that the system is one which favours or at any rate does not injure their children's health.

FREEDOM AND HEALTH.

It is a comparatively modern idea that in our present stage of development absolute freedom is incompatible with perfect health. In the case of the individual indeed it has been recognised for ages that self-control in the matter of appetite and desire is a necessary condition of health and happiness. But it is only in this latter half of the nineteenth century that men have come to realise that the same rule is as applicable to the community as it is to the individual, and that if we wish to have a healthy nation we must be content to surrender a certain amount of personal liberty. The doctrine is a hard one, so hard that the most advanced thinker of modern times, Mr. Herbert Spencer, has set his face against it, and declared war to the knife against the whole body of legislation which is the practical outcome of its acceptance. Writing as we do for medical readers it is quite unnecessary to enter into the facts and experiences by which the doctrine has approved itself to reasonable men. The striking statistics quoted by Mr. Shaw-Lefevre, in his address to the Social Science Congress,

furnish experimental demonstration of its truth, and we may safely challenge the opponents of State interference to prove that similar results could have been obtained without infringing individual liberty. It is quite possible, however, to admit the axiom, and yet to question the advisability of carrying it to its logical conclusions. Health and freedom are blessings, the relative value of which it is difficult to assess, and according as men prefer the one or the other they will class themselves with the party of State interference or that of *laissez faire*. We may pause a moment by the way to deplore the introduction into our political vocabulary of a foreign phrase for a policy which to our thinking would be much more appropriately described by that of "State neglect." It would be easy enough, perhaps, to adjudicate between the rival claims of health and liberty, if it were merely a matter of personal preference. A French peasant before the Revolution, an American slave before the War of Secession, probably thought lightly of health in comparison with freedom; while a confirmed dyspeptic of to-day would no doubt be glad enough to change places with either if with it he could escape his torments. The question, however, is not one of individual preference, but depends on ideal and altruistic rather than egoistic considerations. The health and the freedom involved are national, not individual, and it is naturally more difficult to make up one's mind on a subject which appeals rather to the imagination than to the feelings. These considerations will serve to show in some measure the difficulty of obtaining a universal assent either to the policy of State interference or to that of State neglect.

Doctors are, we believe, as a rule, apt to attach an undue importance to the value of health as compared with other national endowments. They see so much of the waste of life and money, the impairment of faculty and the misery caused by sickness, that they go over without hesitation to the extreme left of the party of State interference, forgetting the thousands of healthy men with whom they seldom come into contact, but with whose personal freedom the State measures that they advocate must of necessity seriously interfere. They see, too, so vividly the effect of sanitary improvement upon the health of a community that they become willing to secure it at any price, ignoring the disadvantages—the expense, the officialism, and often the incompetency—which have been found to be inseparable from State interference. Those of us who are apt to forget or unwilling to allow for this bias of ours, have recently had a striking instance of one of the mischiefs of State interference in connection with the Education Department. Let them imagine for a moment the state of things reversed and an extensive system of sanitary improvement arraigned by the schoolmasters because it interfered with the education of children. Suppose it had been shown that this system was giving us a generation of men and women in robust health who could not read the names of the streets or count their week's wages. Would not the profession have sympathised in such a case with the official view as unanimously as in the over-pressure question they sympathise with the medical and non-official view? And to the impartial observer would not such sympathy have rightly seemed just as wrongheaded as the indomitable bias and official blindness of the educationalists seem to us? Then as to the expense of State interference. The increase of taxation demanded by each increase of officialism is little felt by men with middle-class incomes, but it may be a serious fine upon less well-to-do classes. A pure water supply, an expensive drainage system, palaces and convalescent mansions for infectious cases, and other appliances of health are excellent in their way, and to the community as a whole they no doubt fully repay their cost, but to the struggling clerk and his family they may mean leaky boots, insufficient food, and the renunciation of all those little luxuries and means of pleasure which they need so much to soften their hard life. But such considerations only appeal to a sympathetic imagination, and are apt to be overlooked by the medical hobby-rider.

There must then be a limit at which the advantages of State interference from the sanitary standpoint are counterbalanced by disadvantages from the social and political points of view, and the ends of health will be best served by not pushing its national pursuit to the point at which it would arouse a reaction, such as might defer sanitary reform for generations. It is undeniable that there is a large and not altogether an inarticulate party which views interference with the liberty of the subject in any interests whatever with profound jealousy, and it is the business of practical politicians and those who advise them in matters of sanitary legislation—in other words the highest medical authorities—to see that all measures of State interference work with as little friction and wastefulness, and press as lightly upon the people as possible. With this end in view it is undoubtedly advisable that every form of administration which deals with the national health should be concentrated under a single authority instead of being scattered over many departments as at present, and we are glad to find this view of the question taken up by Dr. Norman Chevers in the admirable address which he delivered before the Health Section of the Social Science Congress on Tuesday last. Medical writers have for years insisted on the advisability of the appointment of a Minister of Public Health, whose duty it would be to take under his official control all those rapidly multiplying details of sanitary administration, which now, in spite of their costliness, fail to obtain the results that might be expected of them for want of a responsible head. Dr. Chevers has shown that there would be enough and more than enough to fill the hands of such an official. He fully "recognises the disheartening fact that without powers, full almost to benevolent absolutism, the benefit conferred upon our suffering fellow-countrymen even by the most enlightened administrators of the public health, must always be very tardy in its advance and very narrow in its scope." But to our mind the most convincing argument in favour of the benevolent absolutism he advocates is to be found, as we have been at pains to show, in the fact that such absolutism will be much more lightly felt and much less seriously resented if it be placed in a single hand, than if it be allowed to remain as at present divided amongst a dozen authorities, each convinced that his own special department is the most important of all,

each distracted by other considerations than those of health, and viewing with jealousy the power and revenues placed at the disposal of rival departments. Surely the health of the nation is a sufficiently important interest to merit the undivided attention of a man of the highest political rank.

THE APPENDIX TO THE REPORT OF THE ARMY MEDICAL DEPARTMENT.

The papers in the appendix have a double interest. They express individual opinions while the report embodies the impressions of numerous medical officers condensed by, and stamped with the authority of, the Principal Medical Officers of stations. And the appendix also gives us later news. For instance, we find a medical report on the Eastern Soudan Expedition, of the present year, by Brigade-Surgeon E. G. McDowell. It is the story of a sharp, short campaign, of hardly more than one month's duration; but it was long enough to demonstrate the pluck of the combatants, and the professional skill, self-denial, and devotion to duty of the non-combatant doctors. The expedition which started from Trinkitat on the 28th February, had special advantages and disadvantages. True, the Navy was at hand to help the Army, and H.M.S. *Orontes* was fitted up as a base Hospital to receive casualties, but the advance to relieve Tokar had to be made into an unknown country, difficult for transport, and short of water. The enemy, too, enormously outnumbered the British force, and it seemed impossible to secure the safety of the rear while the column forced its way onward; so an order was issued that during the advance all casualties were to be taken forward with the fighting men, with the aid of any transport available. A march of three hours' duration brought on a storm of case, shell, and rifle fire, and within a few minutes the medical officers were hard at work. The wounded had always to be carried inside the "Square" to avoid massacre, and as the formation swayed hither and thither, but ever forwards, the dressing places were always shifting, and now and again a wounded soldier would be left "in the open," but by his side was a medical officer with his stretcher party to be found, until opportunity offered for the patient to be carried into the comparative safety of the "Square." We think the endurance of the medical contingent, to whom the Red Cross would have been worse than no protection, can bear comparison with the military ardour of the fighting men. The bearers were short in numbers, and the doctors had to lend a hand to carry the stretchers, and tired of being shot at without shooting in return, we can fancy they found the occupation a relief. After three or four hours of this work, the enemy was put to flight, and the wounded grouped at El Teb. The dressing station equipment could now come up from the rear, and the patients got full treatment and comfortable rest at last. There was plenty to be done that night, for there were 14 officers and 146 non-commissioned officers and men among the wounded. Two capital operations were performed, numerous bullets extracted, and sword and spear thrusts dressed; and we find that all serious operative treatment was performed under chloroform. On the following day the sick and wounded were sent back, while the troops went on to Tokar to find it undefended.

On the 5th of March the troops had again concentrated at Trinkitat. They did not stop long, however, for Suakin was threatened, and thither the troops proceeded, to try conclusions with Osman Digna. Again the Navy was ready to offer a hospital ship, although luckily it was not required. On the 10th of March "the Royal Highlanders" commenced the advance, accompanied by two guns and a few Engineers; and we notice that, owing to the sultry weather, not less than 40 men of the small force "fell out," overcome we must suppose by fatigue, since we are told that only five of the cases could be attributed to heat. It seems to us that it was "too hot" for the other 35 men, whether their symptoms could be classified or not. The remainder of the force marched for the first Zariba, or halting place, on the 11th of March, and on the 12th the troops advanced to bivouac at the second Zariba. There all the field hospital equipment, most of the pack mules, and the ambulance waggon, had to be left. The transport to accompany the expedition was reduced to the cacolets, ten pack mules, a mule to carry water, a pair of field panniers, and a supply of bandages and field appliances. On the following day the battle was commenced. Again the "Squares" pressed stubbornly onwards, and again the wounded had to be carried forward to encounter fresh dangers in their helpless state, and again the doctors shared the extra danger when wounded men were for a time left without the shelter of the protecting squares. But the battle was won, and the victory was so complete, that the sick and wounded had not to be hurried to the base Hospital, and with an escort were the last to leave the camping ground. Once more did British sailors lend a hand, and 200 tars arrived from Suakin to act as stretcher bearers. Even then the want of transport was severely felt, and nearly "a company" of the Royal Highlanders had to be employed to assist the Medical Department. The Army had also to thank the sister service for supplies of condensed water at the base Hospital, for Surgeon Major Catherwood detected considerable quantities of chlorides in the wells; and he and the naval authorities must share the credit of the marked immunity from serious disease which follows a bad water supply. Once more, on the 23rd March, the troops advanced to search for Osman Digna. Again on the march did the troops fall out in large numbers, but on the 27th, when the battle was expected, not a man straggled from the ranks, Osman Digna would not fight, and the campaign was over. We must notice that during the expedition the Eastern Telegraph Company forwarded telegrams free of all charge. Army, Navy, and civilians were true to each other and England throughout. Amongst the papers in the appendix an exhaustive report by Dr. F. de Chaumont on the Hygienic Exhibition at Berlin in 1883, deserves mention, but it is not necessary to dwell upon it, for the author himself says —"there is comparatively little that could be usefully adapted in our own service." His observations, however, on the "Drying Apparatus" of Oscar Schimmel and Co., of Chemnitz, deserve the attention of the Military authorities, and even more that of Municipal authorities and Medical Officers of

Health. The report on the cholera outbreak in Egypt in 1883, by Surgeon-General Irvine, is extremely interesting. It commences with the origin of the epidemic, due, probably, to the Fair at Damietta, where the crowds alternately fasted and feasted on putrid fish and diseased meat, and drank the Nile water, polluted by the carcases of hundreds of bullocks, which had died of bovine typhus. The report does not speak of the agency of flies, as carriers of corruption, but we should suspect them grievously in Egypt. We notice the spread of the disease along the branches of the Nile, and we see that an increase is attributed to the mistaken measure of driving out the inhabitants from infected localities. This is suggestive, for it touches on the great remedial measure adopted in India, and followed now in Egypt, of moving troops from infected places. We are told—"In nearly every instance, the movement of troops was followed by the outbreak of cholera in camp." Still we find that on a second or third change of station the spread of cholera was stopped. Did the improvement arise, we wonder, from some locality being at last reached where the cholera germ could find no breeding place; or had the troops found a better atmosphere to breathe; or, finally, had the disease exhausted itself? We notice that at the outbreak of the epidemic at Cairo, a *sudden atmospheric change* took place, "the air became heavy, hot, and motionless, bird-life ceased in the vicinity, and the heat became greater and the wind force less." We are told that some have asserted that the movement of troops into camp in Egypt was too long delayed, but we think there is much to be said in explanation. In India vast tracts of country are available, in Egypt they are limited. Native labour is cheap and easily procurable in India, and dear or not procurable in Egypt, and an Indian march through the wildest country is a different thing from an Egyptian tramp through the hot sand. Whether the movement of troops to avoid cholera is right in India and wrong in Egypt, we cannot determine, but we know that it would be impossible in England; and at home it becomes all the more necessary to guard against polluted air, food and water, and at least leave no congenial soil for the cholera "germ" to develop itself. Against atmospheric disturbance we must be to a great extent helpless. We notice that in Egypt those who attended on the sick suffered *out of all proportion* to the other branches of the service. A strong opinion formerly prevailed that the attendance upon cholera patients involved *no extra risks*. We observe that "Cordons" were found useless, "but the burning of large fires produced good results," and with regard to treatment, nothing new was more successful than the old tried remedies which have so often failed. There is another report on cholera at Ramleh, by Deputy-Surgeon-General Fox, but, although it is worth reading, it introduces, we think, no point on which we have not touched. We observe, however, that the state of the *weather* preceding the epidemic is again noticed. Once more enteric fever crops up. Surgeon-Major Godwin describes an outbreak among the crew of the War Department ship *Stanley*, on her return from the Mediterranean in September, 1883. The cause is not only a matter of doubt, but also of angry dispute, as to alleged facts, and we can therefore venture no opinion. There is a second paper on enteric fever at Athlone, by Surgeon-Major Knox. He gives bad water as the cause, and also notices the long period of incubation of the disease. There are some other interesting papers on remarkable "cases" in the appendix, but we have no space to spare. We believe we have said enough to show that the supplement is as worthy of attention as the report itself.

REVIEWS AND NOTICES OF BOOKS.

SONSINO ON CHOLERA.

Appearing at a time when all Europe is contemplating the oncoming of a foe who has long obtained a foothold within her boundaries, and whose victims are now beginning to be counted by thousands, Dr. Sonsino's pamphlet *On Cholera in Cairo in* 1883,[1] will be read with interest by everyone anxious to be *en rapport* with the literature of the present day on that subject. And although at the very commencement Dr. Sonsino disclaims the discovery of any facts that may with strict accuracy be termed new and important, the wide experience of so good a clinical observer is of the utmost value in these latter days when the discovery of a new bacillus seems to be of more importance than the life of a patient. As Physician to the Kasr-el-ain, and Ibraim Pasha Hospitals, Dr. Sonsino had abundant opportunities of research during the epidemic of 1883, and the results, shortly embodied, were read at the *Società Medico-fisica* of Florence at the meeting of the 13th July last. We may at once say that these results are, on the whole, reassuring, and though as yet the true specific for cholera, if any such exists, remains undiscovered, the disease, if treated from the very onset, need not show a higher death-rate than pneumonia in those attacked. That the epidemic has in Naples assumed proportions little short of appalling cannot be denied, but it is not to be wondered at when the insanitary conditions of that city are borne in mind. The acme of airlessness, squalor, filth, and bad drainage is, in Europe, reached only in the purlieus of Naples, where conditions exist which can alone be realised by those who have actually been brought face to face with the horrors of the Mercato. To argue from the death-rate in such localities would be unfair, but even in the Cairo hospitals the mortality was only from 50 to 66 per cent. of those admitted; the admissions being, it must be borne in mind, almost without exception in the stage of collapse. But in cases where treatment was adopted from the outset, the most favourable results were obtained. Of only ten cases attended by Dr. Sonsino in private, not one proved fatal; and the experience of his colleagues in a large number of similar cases was nearly as fortunate.

Dr. Sonsino recognises four well marked stages of cholera, namely, premonitory diarrhœa, cholerine, collapse and reaction, and it is this first stage of initial diarrhœa, or rather the timely treatment of it, which

[1] Sul Cholera in Cairo d'Egitto nell' anno 1883. Ricordi del Dott. P. Sonsino. Communicazione fatta alla Società Medico-fisica Fiorentina nella seduta del 13 Juglio, 1884.

forms the keynote of his pamphlet. He insists upon its almost invariable occurrence, and has but little belief in the so-called cases of *cholera foudroyant*. We are certainly inclined to think that a close investigation of this class of cases would in the great majority of instances reveal the existence of previously unnoticed intestinal derangement, and Dr. Sonsino has well adduced in support of his opinion the fact of the almost constant presence, *post-mortem*, of alterations in the small intestine which could by no possibility have been produced in the course of a few hours. In all cases where it is practicable, therefore, in schools, barracks, penitentiaries, and so forth, he would have the strictest watch maintained, in order that all cases of diarrhœa may be at once placed under treatment, for it is by these means, and these means alone, in his opinion, that an epidemic can be stamped out.

Passing to a general consideration of the disease, it is of the highest interest to note that in the only case in which he was able to make a microscopic examination of a cholera dejection immediately after emission, Dr. Sonsino recognised the presence of the *Cercomonas hominis*. These protozoa were, it may be remembered, described and figured by Davaine, in his *Traité des Entozoaires*, as having been found in the stools of cholera patients so long ago as 1854. But little attention appears to have been paid to the subject since, and owing to the complete breaking up and destruction of these minute organisms immediately on the cooling of the *dejecta*, the greatest care in the examination is necessary for their recognition. It is indeed, as Dr. Sonsino remarks, impossible to estimate the importance that this parasite may have in the pathogenesis of cholera, and it is greatly to be desired that the attention of all future investigators should be directed towards the elucidation of this point.

A clinical fact of considerable importance was the invariable rise in the rectal temperature of patients in the third stage, the elevation being in proportion to the gravity of the case. In one instance, shortly before death, the thermometer registered 104° Fahr. and in no case at the height of the algid stage was the temperature in the mouth and axilla observed to sink below 95·4°, though it is possible that this may have been partially owing to the high atmospheric temperature that obtained during the epidemic. Anuria was a constant phenomenon, and in Dr. Sonsino's opinion one of the most common factors in the production of a fatal issue. The retention in the blood and tissues of the waste products of the body leads to the so-called *stato tifico*, in other words to uræmic intoxication, and on this account he would not advise the checking of the vomiting by means of drugs, regarding it as a vicarious means by which the organism is relieved from those injurious products which would otherwise have been excreted by the kidneys. Diphtheritic ulceration of the vulva and vagina came twice under notice, and in both instances death ensued. Urticaria, roseola, erythema simplex, and erythema nodosum were observed, and in general it was noticed that the appearance of these eruptions in the stage of reaction was of favourable import.

The *post-mortem* appearances characteristic of the disease may be described as those of a special acute catarrh of the small intestine, and call for no particular remark, but as a contribution to helminthology it is very interesting to note that in not less than one-fourth of the autopsies, Dr. Sonsino recognised the characteristic appearances due to the infarction of the ova of *Bilharzia hæmatobia*, their chief seat being the bladder, ureters, and vesiculæ seminales. Such a proportion appears enormous, but it is important as tending to show that the affection is not necessarily of such serious omen as it is generally considered.

In common with almost everyone who has had any large experience of the malady, Dr. Sonsino has no belief in the infectiousness of cholera. In the large Kasr-el-ain Hospital but one case occurred during the whole epidemic, and in hospital at Bulacco there was likewise a single case. The value of these facts in the prevention of such unreasoning panics as characterised the onset of the epidemic in the South of France is incontestable.

The Pathology, Diagnosis, and Treatment of Diseases of the Rectum and Anus; by CHARLES B. KELSEY, M.D. Surgeon to St. Paul's Infirmary for Diseases of the Rectum, New York, 1884. Sampson Low, Marston, Searle, and Rivington.—If the title of this book were altered by omitting the word pathology, it would be more accurate and less deceptive to its readers. The pathology is of the worst kind, a compilation without practical knowledge of the subject in hand. The old and new views are hopelessly mixed and no intelligent interpretation is made of the various opinions extracted from different authors. We have not seen a single histological drawing which is original. This seems scarcely fair from an author who has given pathology the leading place in the title to his book. There are a number of woodcuts, but they are all borrowed from other published works. One would have thought that a surgeon who had any practical knowledge of pathology would have examined microscopically a few of his cases, and given us the benefit of his opinion as to the present state of pathological knowledge upon the subject about which he is writing. On the other hand, the diagnosis and treatment are very fairly written. They show that the author has had practical experience in the treatment of the diseases with which he deals, that he has weighed well the various opinions held upon the subject, and that he has formulated a definite line of action for himself after careful consideration. The book opens with 35 pages on the anatomy and physiology of the rectum and anus, which seems to us totally unnecessary, especially where the pathological anatomy is so feebly and inefficiently treated. The congenital malformations which follow next in order are shortly described in the usual manner. The author advocates an early resort to inguinal colotomy, and gives his reasons for the preference of this to the lumbar operation, when the surgeon fails to reach the bowel from the peritonæum. He says also that attempts at establishing an anus in the anal region after the performance of colotomy are attended with great danger, and are generally unsuccessful. This is true, but he does not say what we think is a common experience, that the child rarely lives long enough for the surgeon to attempt such an operation. They seem generally, even in the favourable cases, after colotomy to fade away and die in the course of two or three weeks. No peritonitis is found to account for this. The usual rules regarding examination and operation are given in a separate chapter, and call for no special mention. The inflammatory affections follow next, the author taking great pains to draw prominent attention to the difference between a deep pelvic abscess, and abscess in the ischio-rectal fossa. The anatomy is very properly introduced to explain the different courses such abscesses are likely to follow. A few cases are also given in detail to illustrate the deep pelvic abscess in the male, which is certainly a rare but well known disease, taxing the diagnostic powers of the surgeon to the utmost in its early stage and his

boldness of treatment when fully formed. Ischio-rectal abscesses and fistulæ obtain the requisite amount of notice and their treatment is fully and carefully discussed. The chapter on hæmorrhoids is disfigured with some ghastly coloured drawings. They are really quite unnecessary, and serve no useful purpose whatever. The frontispiece is if anything more offensive, as it is in a more prominent position. If they were of any practical value they might be tolerated for the knowledge they convey, but no one would allege that they are of any use either to the student or practitioner. In the internal treatment of hæmorrhoids, the author advocates the injection of carbolic acid on the ground that, when properly employed, the patient need not be confined to bed but follow his usual occupation. He recommends a solution of five per cent., of which five drops are to be injected by a hypodermic syringe vertically into the substance of the hæmorrhoid. This is to be done once a week till all the hæmorrhoids have begun to shrink and disappear. He describes the treatment both by ligature and by clamp and cautery, but he evidently thinks most highly of the treatment by injection and has rarely resorted to any other. For prolapse also the author advocates the use of carbolic acid with the hypodermic syringe. There is a very useful and interesting chapter on rectal hernia and rupture, cases collected from various publications are quoted and much information given that does not ordinarily appear in English works on the rectum. The rest of the book is very feeble from the evident absence of pathological knowledge. But the treatment of non-malignant stricture by external proctotomy is strongly and forcibly advocated. There is also a good *résumé* of the operations for the relief of cancer of the rectum and sensible conclusions are drawn as to the kind of cases in which extirpation is suitable. Altogether this is probably the most useful part of the book and may be highly commended for the clear and satisfactory manner in which a difficult subject is handled. The book closes with a long list of foreign bodies which have been found in the rectum. Some useful formulæ are also given for rectal alimentation.

London Water: A review of the present condition and suggested improvements of the Metropolitan Water Supply: By Major-General A. De C. Scott. Loudon: Chapman and Hall, 1884. Pp. 119.—The question of the London Water Supply involves the provision of not less than 150 million gallons of potable water to a population of over 4 million persons, with means for a future increase of the supply to 200 or 250 millions. General Scott approaches it from the standpoint of a consumer, one of the public who, though not a chemist, yet as a member of a scientific department of the service, is competent to form a judgment on questions of a scientific character, and to weigh the evidence and opinions of experts. The work opens with a sketch of the parliamentary history of the water companies, and of the several Commissions appointed to report on the water supply. The third chapter contains a number of well authenticated instances of the communication and spread of disease by means of polluted water, especially of cholera, and typhoid fever, from the cholera epidemics of 1832, 1848, &c., down to the outbreak of typhoid at Caterham. The author next discusses the rival processes of water analysis, and comes to the conclusion that though chemical analysis alone may lead to fallacious inferences, and is quite incapable of detecting specific poisons, yet, taken with a knowledge of the source and previous history of the particular water, it may afford valuable information. Here, as elsewhere, he is inclined to place most reliance on the procedure and opinions of Dr. Frankland and the Rivers Pollution Commission, of which Dr. Frankland was the soul. Sewage purification, whether by irrigation, filtration, or chemical treatment, has never, he maintains, succeeded in producing an effluent that could safely be admitted into a river used for the supply of water for domestic use. He properly gives the preference to broad irrigation, but we cannot but think that he scarcely does it justice. He has no faith whatever in the self purifying power of running water, maintaining with Dr. Frankland that the apparent reduction in the organic matter is due simply to dilution by the increased volume of the stream, and that the disappearance and subsequent reappearance of the dissolved oxygen is a purely local phenomenon in which the organic matter takes little or no part, brought about by the evolution of H_2S from putrescent deposits. An excellent description of the geology and hydrology of the Thames basin is followed by an account of the various schemes that have been proposed for the supply of the metropolis with pure water from distant sources. Those for bringing water from Wales or the Lake District he considers quite feasible from an engineering point of view, and not more costly than many irrigation works in India and Italy. He makes also the pertinent observation that the unconditional condemnation of the Thames and Lea as sources of water which could be fully justified by the palpable evidence afforded by analyses of the utter failure of the efforts of the Conservators to reduce, or even to check the increased pollution of these streams during the last twenty years, would depreciate the value of the existing companies' property enormously. The valuation would no longer be based on the prospective profits of these undertakings, as was the case in 1880, but simply on capital expenditure, and the appraisement of so much of the works as would be still available for the distribution of the new supply. The schemes for drawing on the water-bearing formations of the Thames basin he views still more favourably since, in addition to the foregoing considerations, they could be carried out gradually and tentatively, and, moreover, might prompt the present companies to anticipate the action of the State, or central authority of the future, with a view to enhancing the purchase value of their property by following the example of the Kent Company, and substituting wells and other unimpeachable sources for their present river intakes. Even should such sources prove insufficient, the money would not be lost for, in the event of the Welsh or Lake District schemes being resorted to, the surplus waters would be easily sold to provincial towns. A double supply, however, of pure water for domestic and of impure for general purposes he considers open to overwhelming objections. But the constitution of a representative authority for the whole metropolis with its suburbs, having plenary power to deal with the water question, and that without waiting for the passing of a London Government Bill, is, in the author's opinion, an urgent and absolute necessity.

Report on the London Water Supply for 1883; by W. Crookes, F.R.S., Professor Odling, M.B., F.R.S., and C. M. Tidy, M.B.—In presenting their third annual report on the waters of the seven companies who derive their supply wholly or in part from the Thames and the Lea, the authors take occasion to animadvert somewhat severely on the language employed by Professor Frankland in his official reports. They do not object to his process or to his results, for they now employ the former as well as their own, and his results and theirs substantially agree; though they do consider it open to exception that official work should be conducted in a private laboratory by Dr. Frankland's own son instead of as heretofore in a public institution and by independent assistants. But while acquitting the professor of any intentional misrepresentation or motives other than what he conceives to be the public good, they complain that, as it seems to them, he "fails to recognise the judicial character of the position he occupies as a quasi referee between the public and the water companies, and that accordingly he does not hesitate to use his position as a means of directly or indirectly advocating his own individual views on water supply." They object to his use of the expression "*during* the month" when all his samples are taken on a single day which may be exceptionally unfavourable, whereas they make an optical examination of each water daily (Sundays excepted) and every day one full analysis by their own and by Dr. Frankland's method of a sample taken from each company's water in rotation, *i.e.*, a weekly analysis of each. But the gravest count in their accusation is that "Statements and comparisons, of which the verbal accuracy cannot be impugned, are made use of to suggest conclusions which would not bear being put forward definitely on the strength of the analytical results made use of for their suggestion." Though for own part we have no hesitation in stating that we cannot view with complacency the use of a river

that has received the sewage of over half a million persons in the crude form, and of as many more after some process of purification, we must agree with the demurrers here. There is no reason to doubt that a *pure* lacustrine or fluviatile water is as wholesome as, if not more so than, one drawn from deep wells highly charged with calcareous matter, and that in judging of the quality of a river water from the indications of analysis (of the validity of which we need not here express any opinion), it would be obviously fairer to compare it with one of acknowledged purity of the same kind than with water derived from a totally different source, and consequently of different composition. For example, if the waters of Loch Katrine and Thirlmere be unimpeachable, they, and not the Kent Company's deep chalk wells, should be the standard by which to judge those of the Thames, the Lea, and new rivers. But while it answers Dr. Frankland's purpose to state that they contain 2 to 3½ times as much "organic impurity" as that of the Kent Company, he persistently ignores the fact that the Glasgow and Manchester waters frequently contained more than those of the Chelsea and Grand Junction Companies, though their entire freedom from "previous sewage contamination" no one ventures to dispute, certainly not Dr. Frankland, who has often advocated the use of such lakes as sources of the purest water. Again, in reporting on the River Companies' waters, nitrates and nitrites are always represented by him as indisputable evidence of sewage pollution; but he finds it convenient to pass unnoticed the fact that his favourite Kent Company's water generally contains a still larger proportion of these. Lastly, he always mentions the presence of "moving organisms," in suggestive association with sewage pollution, &c., though when speaking of the Manchester water he declared that they had no hygienic significance whatever. They are, in fact, always found in lake and river waters, though naturally enough not met with in that derived from deep wells. Such special pleading is really unworthy of a man of science.

THE INTERNATIONAL MEDICAL CONGRESS.

XII.—Section of Dermatology and Syphilis.

(*Continued from page* 415.)

At the sitting on Friday, August 15th, papers were read by Drs. Bockhardt, of Würzburg, and Neisser, of Breslau, on the Infectiveness of Chronic Gonorrhœa and its duration; also by Dr. Wulff, of Strasburg, on Psoriasis. Interesting discussions took place on both these papers of which the following is an abridged report.

Discussion on Chronic Gonorrhœa.

Professor Neisser (Breslau) said that it was true, as Bockhardt had asserted, that gonococci were present in chronic cases of gonorrhœa, but this was not always the case. It was not absolutely certain that the gonococci always meant gonorrhœa, but the difficulty of answering this question was certainly increased by the fact that they are very difficult to diagnose from other micrococci. He had examined many old cases, some as old as 14 years, and in 77 of those in which he could be sure that no re-infection had occurred, he found gonococci 51 times, while in the remaining 26 cases he could find none. Several of these he had examined only once, while in order to be certain it was necessary to examine during a period of 7 or 8 days always using an oil-immersion lens. In other cases, however, in which this had been done, he could still find none, and these were presumably non-infectious; but in a separate set of four patients he was unable to discover any cocci, although it was certain that they had infected women. The cervical glands of women (Bumm) and the ducts of the glands of Bartolini (Neisser) are very favourite lurking places for gonococci, but he doubted if it were possible to diagnose gonorrhœa in women by the examination of the secretion.

Professor Bergh (Copenhagen) thought this was perhaps partially due to the size of the gonococci, which were markedly smaller in women than in men.

Professor Janowsky (Pragne) found gonococci in 22 instances of 30 cases of chronic gonorrhœa which he examined. Sometimes he had to examine during an interval of from 14 to 20 days before finding them, no coitus having taken place during that time. Once he found a mass of gonococci where there had been no coitus at all. He agreed with Neisser that an oil-immersion lens was necessary for the examination.

Dr. Michelson (Königsberg) did not believe from his experience that chronic gonorrhœa was capable of absolutely causing gonorrhœa or generating gonococci in another.

Professor Neisser was not himself quite sure as yet about the power of infection in such cases. He thought it was probable but not necessary. He knew of undoubted cases of infection from chronic cases. Janowsky's sudden outburst of gonococci probably resulted from the liberation of a mass of them which had been mechanically pent up for some time in a fold of mucous membrane or in the mouth of a gland.

Dr. Unna believed that blenorrhagia cervicalis of prostitutes was the common cause of gonorrhœa among men, and considered that all prostitutes should be examined for blenorrhagia in every corner before being passed.

Professor Pick (Prague), as the result of a very large experience, believed that cervical blennorrhagia in prostitutes was not nearly so common as was generally stated. He believed that the most common seat of the secretion was in the folds around the urethral opening. He knew of cases where no gonococci had been found for 14 days, but believed the negative results to be always due to insufficient examination. The cases should be examined carefully each day.

Discussion on Psoriasis.

Dr. Wulff (Strasburg), who opened the discussion, said that Lang (Innsbruck) was the first to suggest a definite standpoint in the confused ætiology of psoriasis, when he asserted it to be a parasitic affection due to a fungus which he described and named epidermophyton. This discovery had received little confirmation, but Wulff was now able to find the fungus in every case of psoriasis which he examined. It had been objected that the heredity of the disease and its incapability of transmission precluded the possibility of a fungous origin, but he held that the heredity was merely a predisposition, and that the inability to be transmitted was shared by pityriasis versicolor, an undoubtedly fungous disease. Köbner had extended psoriasis by scratching and irritating the skins of psoriasis patients; this extension was not, however, produced by nervous irritation, but by affording a good hold for the fungus in the skin. It was the fungus which caused the white patches to stand out from the brown when chrysarobin was applied to the skin; by this means it could be detected on the skin before the eruption had appeared. Wulff believed, although he could not prove, that the fungus affected the blood primarily, and in passing outwards irritated the skin. He would class it provisionally with pellagra.

Professor Neisser (Breslau) had tried repeatedly to find the fungus described by Lang but had never succeeded. The patches of white colour might be the sites of old morbid processes only partially stained by chrysarobin; he had had such a case. He opposed Wulff's theory of propagation from within outwards, for the fungus was only found in the outer layers of the horny layer.

Professor Pick agreed with Neisser, but could always find the fungus in abundance in cases of psoriasis; he had however found them in equal abundance in cases of squamous eczema. There was nothing about the fungus to support Lang's hypothesis. At present we had no standpoint concerning the cause of psoriasis. It often followed scabies, eczema, &c.; in these cases he always found psoriasis, or a suspicion of psoriasis, in some member of the family. The white patches he believed to be simply due to the action of the alkaline secretion of the skin on chrysarobin. He saw no analogy between pellagra and psoriasis.

Professor Lipp (Graz) had tried to transmit psoriasis, but had never succeeded, nor did transmission occur in family life, between married people, or among doctors having charge of psoriasis cases. The successful treatment by antipsoriatic remedies, as arsenic internally in small doses, also spoke against its parasitic origin.

Dr. Jamieson (Edinburgh) had never been able to find the parasite in the skin, but only on the scales.

Dr. Unna related a case in which three children of a family were affected with psoriasis after the entry into it of a servant girl suffering from the disease. He agreed with Pick about the chrysarobin staining; he had frequently observed the white spots where he had covered the whole body with the drug.

Professor Lang (Innsbruck) said that the hypothesis of a fungous origin did not necessarily imply the easy curability of the disease; pityriasis versicolor, a superficial fungous disease, was difficult to cure. Disposition played a most important part, hence the difficulty of contagion or inoculation. He was of opinion that the fungus came from without and not from within, otherwise some of the internal organs would be affected; it was floating about in abundance in the air, but only occasionally found a suitable propagating ground. Probably the favourite spots were those in which it obtained the firmest hold, *e.g.*, on the knees and elbows, and also in squamæ, like those of chronic eczema. There were indeed two types of psoriasis, one appearing on the knees and elbows, the other, an eczemoid psoriasis, appearing on the elbow and knee flexures, axilla, and groin. He could see no resemblance between this disease and pellagra; in the one the skin affection was the primary trouble, in the other it was quite subordinate to the general bodily condition.

Professor Pick held that the question could not be further discussed until the capability of inoculating the disease by means of this fungus had been demonstrated.

Section of Medicine.

On Chronic Diarrhœa and Dysentery in persons returned from tropical to temperate climates.

Sir Joseph Fayrer (London), and Dr. Joseph Ewart (Brighton) dealt with this subject in a conjoint paper. After discussing the pathology, causation, and symptomatology of these complicated and grave affections, their treatment by means of a pure milk diet was considered. Beyond the occasional employment of lime-water, five minim doses of laudanum and a saline aperient, when indicated, to remove portal plethora, no other medicine is demanded. In chronic dysentery, the opiate is best administered in the form of a small enema. In both affections complete rest, and the preservation of an even body temperature, in an airy and well ventilated room, are essential. Milk alone, or diluted if necessary, at first in small quantities every half-hour or every hour, and gradually increased until three or four quarts are consumed in twenty-four hours, promotes rapid recovery in a vast majority of cases. When, in chronic dysentery, the ulcers are healed under this management, convalescence is more speedy than is that of chronic diarrhœa, apparently for no other reason than that the degenerations of the peptic and intestinal follicles, the villi and liver-cells are less apparent in the former than in the latter disease. A series of cases is furnished in support of the treatment recommended.

Section of Military Medicine.

Sunstroke and Thermic Fever.

Sir Joseph Fayrer, in a paper on these conditions, divided the subject into three heads—(1) Syncope from exhaustion. (2) An analogous state in which the respiratory centre is seriously implicated. (3) Thermic fever, or great overheating of the whole body. The general effects of exposure to a high temperature in occasioning impaired health was also discussed. Treatment consists in reducing the exalted temperature of the body, but in doing so, undue depression of the vital powers is to be avoided. The lesions of insolation and thermic fever are often more or less enduring. Hence, care must be exercised in advising those who have suffered from them to return to work in tropical countries. As a general rule, it will be found that they are permanently disqualified for further occupation in the tropics or sub-tropical regions.

Typhoid or Enteric Fever among Soldiers in the Tropics.

Dr. Joseph Ewart (Brighton) read a paper on this subject. Until Scriven recognised the disease in Europeans, and himself in natives of India, more than thirty years ago, it had always been grouped among continued and remittent fevers. It now causes more deaths among the troops than cholera! Its prevalence is altogether independent of malaria; but intimately connected with rise of temperature. The term "typho-malarial" is objected to. It would be as reasonable to call a case of small-pox ushered in by ague, liable to recur, and modify the course and character of the exanthem, if not controlled and checked by quinine, variolo-malarial fever. The ætiology is exhaustively disposed of, and it is pointed out that, as contended by Sir Joseph Fayrer, and many others, "it is quite possible that the fæcal filth theory of causation may not cover the whole ground, and that the poison may perhaps thrive and propagate in other kinds of filth."

ABSTRACTS AND EXTRACTS.

PNEUMONIA.[1]

This report, which has been drawn up by Dr. Octavius Sturges and Dr. Sidney Coupland, deals with a total of 1,065 cases, of which 192 proved fatal. The exact proportion of males and females cannot be given because some of the observers omitted to mention the sex in their reports, but 704 were known to have been males and 356 females, the proportion of males to females being thus as nearly as possible as two to one. As regards habits, of 655 returned as temperate 114 died or 17·4 per cent.; of 267 returned as total abstainers 28 died or 10·4 per cent.; whilst of 105 returned as intemperate there died 45 or 42·8 per cent. As regards food, of 988 stated to have had sufficient food 175 died or 17.7 per cent.; whilst of 60 said to have had insufficient food 15 died or 25 per cent. The coincidence of other diseases in the same house at the same time with a case of pneumonia was rare; as the reporters say, no disease occurs in the same house with pneumonia so frequently as pneumonia itself; the only diseases at all apt to be present were found to be bronchitis and tonsillitis. As regards a family history of lung disease, phthisis was met with in from 17 to 18 per cent. of the cases. It is quite exceptional, the report says, to find subjects of pneumonia who are of phthisical family exhibiting apex pneumonia. In the few instances where this actually happened, the seat of disease, judged by its course and termination, did not display any phthisical character. Enquiry into the previous diseases of the patients did not reveal anything of importance except the frequency of previous attacks of pneumonia. Out of 967 in whom the point was ascertained, 101 had suffered from pneumonia previously, and of these 19 died; only 16 persons were returned as having had more than two attacks of pneumonia, of these 4 died. The presence of a rigor at the commencement of the disease was noted in 782 cases, and its absence in 193, the point not being determined in 90; a further enquiry as to its relative frequency according to the part of the lung affected showed that in apex pneumonia a rigor was present three times out of four, and in basic pneumonia four times out of five. The right lung was affected more often than the left and the left more often than the two together, the right base being by far the most common seat of the disease, and next in order of frequency the left base. The crisis occurred most frequently on the seventh day, and with equal frequency on the sixth and eighth days, it occurred on the fifth day rather more frequently than on the sixth or eighth day, and twice as often as on the ninth day. It took place on the fourth day more often than on the ninth, and on

[1] Report of the Committee on Pneumonia. The Collective Investigation Record, Vol. II., 1884.

the ninth more often than on the tenth. From the eleventh to the fourteenth day subsidence by crisis was extremely rare. Gradual subsidence was more common than sudden in the proportion of about four to three, the latter being especially seen in cases of apex pneumonia. Of the 175 deaths in which information as to the day of the disease was given, 70 died on the sixth, seventh or eighth days. Amongst the general conclusions of the reporters we note in reference to sanitary conditions, first that defective house drainage and sewer gas poisoning may both cause and favour the spread of pneumonia, and secondly that the affection when of this origin is not of exceptional severity or high mortality. Alcoholic excess is stated to be not only an important factor in determining the issue of pneumonia, but is often of itself the actual exciting cause of the affection. Fatigue and mental emotion rank next to alcoholic poisoning as the most unfavourable vital conditions wherewith to meet it. As to the infectious character of pneumonia they think that it may exist under certain insanitary conditions including thereby deficient ventilation, but they state at the same time that pneumonia as commonly seen has no infectious character. They do not find that there is such a thing as an inherited tendency to pneumonia, or that there is any other form of lung disease to be met with in excess in the direct family history of the patients. As to the seat of the disease they say that the apex is as favourable for the patient as any other, that no tendency is observable on the part of patients of phthisical family to exhibit pneumonia at that seat, and that in the exceptional event of pneumonia occurring in a patient of phthisical family, such pneumonia shows no tendency to degenerate into phthisis, but undergoes resolution as quickly and as completely as another. They conclude their report with the following statement:—(1) Of pneumonia as a local affection there are examples in plenty, especially in early life. Its onset is sudden, and due to some notable chill or exposure of the body; it has all the characters of acute inflammation with a marked tendency to spontaneous recovery, and is largely dependent on certain meteorological conditions which are productive also of other forms of lung inflammation. (2) Distinguished from these are examples of secondary pneumonias which arise in the course of many acute and specific affections and which do not at present concern us. (3) In addition to these two well recognised forms of the disease, clinical observation, we think, bids us recognise a third variety—a pneumonia due to causes not directly injurious to the lung, but operating through the blood or nervous system. It too is properly a secondary pneumonia, for it is but the signal and expression of anterior vital changes; yet owing to the absence (or the apparent absence) of any other organic lesion, it is not so accounted. Although anatomically indistinguishable (so far as we know at present) it deserves separate recognition in virtue as well of its distinctive origin as of the fact that it has a variable rate of mortality, and a gravity which is not commensurate with the extent of lung tissue involved.

GONORRHŒAL RHEUMATISM.

M. Terrillon, lecturing at La Charité, observed that by a curious chance he had two patients in his wards suffering in a very similar manner from this somewhat rare affection. They were both young men who had been for a few weeks the subjects of subacute gonorrhœa, when they were seized with severe inguinal pain with fever and *embarras gastrique*, one of the patients feeling considerable pain and tenderness on pressure in the vicinity of the hip-joint, while in both the movements of the joint were somewhat impeded, and in both there was a deep-seated doughy resistance in the inguinal region. The conclusion arrived at was that the bursa situated beneath the psoas was the seat of pain, but this continued for some time rather obscure. This rheumatic affection is not merely a coincidence of the gonorrhœa, but a form of rheumatism which develops itself without any other cause whatever than the gonorrhœa. It is indeed not rare to meet with patients who, having been cured of a first attack of rheumatism occurring under these circumstances, do not suffer from subsequent attacks unless they contract a second blenorrhagia. This form of rheumatism has its peculiarities, for it attacks females very seldom, and nearly confines its attacks to the large joints—the hip, knee, and elbow; the smaller joints only suffering secondarily. Moreover, it is generally monoarticular. Sometimes it is attended with effusion into the joints, while at others it gives rise to anchylosis in even 10 or 15 days, the rapid formation of fibrous adhesions rendering this incurable. This rheumatism may, however, affect other parts than the joints. Thus (1), what seems to be an articular affection may really be one affecting the neighbouring tendinous sheaths, a tendinous synovitis with swelling and effusion. (2) It may invade the muscular system, the muscles of the neck, the deltoid, or even the motor muscles of the eye being affected. (3) It may manifest itself in the serous bursæ, near the joints, as the hip, patella, or elbow. (4) It may attack the sciatic nerve, and this is not very rare. (5) M. Guyon first pointed out a doughy state of the cellular tissue that may occur, accompanied by pain and heat. (6) Many examples exist of its attacking various tissues at once in the same region. Gonorrhœal rheumatism, moreover, is peculiar in not giving rise to any visceral phenomena, so that affections of the chest do not result from it. It is also fugaceous and does not reappear, except after a new gonorrhœa. The relation between it and the discharge is somewhat curious, for in some patients who had had abundant discharge, this diminishes as soon as the rheumatism is manifested; but this is not constantly the case. As to its prognosis, the disease may be said to be of but slight importance when it attacks only the tendinous sheaths, the bursæ, and the muscles; but this is far from being the case when a joint is invaded, for so liable is it for anchylosis to take place, that our first object should be to place the limb in the most favourable position in case this should occur. Even when anchylosis does not occur, stiffness of the joint is one of the most common sequences, and this, accompanied as it often is by muscular atrophy, is long in disappearing. In these cases we must allow the joint to gradually resume its movements and not endeavour to force this by violent measures, under pain of finding the fibrous tracks increase in number and thickness. This state of atrophy and stiffness is much benefited by electrical currents, by *massage*, by sulphurous douches, and by a course of mineral waters at Aix. The treatment of gonorrhœal rheumatism is not the same as that of ordinary rheumatism in which salicylic acid is the heroic remedy. Here it is of no avail, and we have to content ourselves with revulsives, chiefly blisters, repeated as many as three times at intervals of two or three days. When the effusion is abundant we should not hesitate to puncture the joint which is an excellent proceeding, relieving it at once of a mass of liquid which would require at least two or three weeks for its absorption. After the puncture effectual compression should be applied. Finally, the disease leading to a considerable depression of strength in the course of a few days, its subjects should be carefully "tonified" and the tonic *par excellence* in such a case is the sulphate of quinine.—*Gazette des Hôpitaux*, August 7.

PATHOLOGY.

Chyliform Ascites.—Under the somewhat lengthy heading of "Mitral disease, cardiac cachexia, asystolism, enormous liver, anasarca, double hydrothorax, chyliform ascites, paracentesis of the abdomen giving exit to two litres of milky fluid," Dr. Letulle describes a very interesting case of this rare affection in the *Revue de Médecine* for September. The patient was a boy aged eight who had had two attacks of rheumatism which had left him with mitral valvular disease. When he came under observation there was a good deal of cardiac dyspnœa, and some effusion into both pleuræ, but the effusion into the abdomen was the chief source of distress. The abdomen was considerably distended, and the skin marked by the enormous bluish venous networks. It was decided to draw off as much fluid as possible from the abdomen. Accordingly he was tapped with a Potain's apparatus, and an opaque, white,

or slightly yellowish, serous, non-fibrinous fluid withdrawn. It ran slowly and in about ten minutes two litres had been drawn off when it stopped running. Microscopical examination of the fluid in the fresh state showed that there was a large quantity of emulsified fat in it. After standing for some time, a deposit settled at the bottom of the glass, consisting mainly of red blood discs, which were noticed to have retained their normal shape and not to have become crenated or deformed. A few leucocytes were seen here and there. Ether dissolved the emulsified masses very slowly. After the red corpuseles had fallen to the bottom the fluid had a perfectly characteristic milky white appearance. On examination of the fluid the fatty matter could not be estimated, it was found to consist chiefly of stearine; there was no cholesterine. The albumen was not estimated. The child died about a fortnight later, and unfortunately there was no *post-mortem* examination. The author then proceeds to discuss the theories that have hitherto been put forward to explain these cases. He rejects the mechanical theory, as also that which would make all these cases to be secondary to purulent effusion, and believes that such effusions are chyliform *ab initio*. He then passes briefly in review some of the cases that have been previously recorded with the object of showing the importance that attaches to previous lesions of the serous membranes, and he infers from a study of them that every chyliform effusion, whether primary, as seems most probable to him, or secondary, is always of an inflammatory nature, at any rate so far as the pleura and peritonæum are concerned. He would prefer, therefore, to drop the term ascites, and call these cases chronic peritonitis with chyliform effusion. His general conclusions are thus summed up: (1) All cases of chyliform ascites known up to the present time, and followed by *post-mortem* examination, are cases of chronic peritonitis, tubercular, cancerous or simply fibrous. (2) The existence of chronic inflammatory lesions represents then one of the most constant elements in the origin of pleurisy or peritonitis with chyliform effusion. (3) The granulo-fatty retrogression of the effused inflammatory products is probably sufficient to account for the whole of the emulsified fat.

Chylous Deposit in the Abdomen.—A case of this kind is recorded in the *Boston Medical Journal*, August 14th. The patient, a male, aged 55, had always enjoyed good general health, and although his work at one time necessitated much heavy lifting, had never developed hernia. In January, 1877, he experienced sudden severe pain shooting from the lower part of the back forwards through the abdomen, accompanied with vomiting. Examination revealed a tumour giving the idea of the distended bladder, but the catheter withdrew only a few drops of limpid urine. Aspiration then brought away four pints of milky fluid, with entire relief to the patient and collapse of the tumour. Throughout the attack there was no febrile action and all the excreta, &c., were normal in character. The man resumed work in a day or two, as well as ever. Similar attacks were experienced in March and in October, 1877, and in July 1878, the pain lasting for about three days on each occasion, and the quantity of fluid continuing to diminish so that scarcely 20 ounces were withdrawn on the last aspiration. Throughout this period the patient was liable to a dull ache in the lumbar region easily converted into a sharp pain shooting forward towards the site of the tumour by long walks or much riding, by not at once satisfying the desire to defæcate, and sometimes when micturating. Vomiting of the same milky fluid occurred at intervals; and, when this was profuse, general weakness followed for a few days. The patient drank milk sparingly and disliked fat also. The fluid withdrawn by aspiration presented the general appearances of milk. It was odourless, alkaline, of a mawkish taste, sp. gr. 1018. After standing for a few hours it exhibited a soft and generally diffused coagulum. After a week's exposure to the air at a temperature of about 60° F. to 68° F., it showed no signs of decomposition. It was an emulsion of very finely divided fat, containing numerous variously-sized granular corpuscles, a little cholesterine, and a considerable amount of an albuminous substance precipitated by nitric acid, and resembling caseïn; no urea, or urinary pigment. The patient's last attack of pain and vomiting occurred in March, 1883, accompanied with a loose discharge of the same milky fluid from the bowels; since this date he has been well in every way. References are given to Professor Busey's work on the subject; and to cases reported by Georgevic, Langenbeck's *Archiv für Chir.*, vol. xii., p. 641; Weichselbaurn, Virchow's *Arch. f. Path. Anat.* v. lxiv., No. 2; Donald Monroe's Essay on Dropsy, Lond., 1865; Percival's Essays, Medical, London, vol. i., 1878; Quincke, *Deutsch. Arch. f. Klin. Med.*, vol. xvi, p. 121; *Jour. Amer. Med. Assoc.*, August 4th, 1883; and *New Eng. Jour. of Med. and Surg.* vol xii., p. 4.

Cystic Degeneration of the Kidney.—In the *Birmingham Medical Review* for September is a paper on this subject by Dr. Jones-Bateman. As regards adults he says that the disease is commoner in men, the most likely age being from 35 to 50. In the majority of recorded cases there was no history of pre-existing kidney disease. Both kidneys were always affected and the organs usually became large enough to be made out by palpation during life. Attacks of hæmaturia and albuminuria seem common, the urine is generally increased in quantity, pale and of low specific gravity; no casts can be found, and upon this he lays some stress as a point of diagnostic importance. After passing in review the different theories that have been hitherto propounded in regard to the pathology of the disease, he thus describes what he believes to be the sequence of events. The epithelium of the kidneys, under the influence of some irritant acting through the blood, acquires a tendency to proliferation. This proliferation spreads mainly in a circular manner; the central cells, becoming separated from their blood supply, undergo colloid degeneration; the cells at the periphery at the same time multiply, and so cause a gradual enlargement of what has by this time become a cyst, which then becomes invested with a fibrous layer by the irritation set up. Whether the process commences in the Malpighian capsules or in the convoluted tubes, or in both simultaneously, he regards as of no importance. He agrees therefore with Dr. Goodhart in regarding the cysts as adenomata.

REPORTS OF SOCIETIES.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Friday, July 4th, 1884.

Dr. Thudichum, President, M.D., F.R.C.P., in the Chair.

This being the annual meeting, Dr. J. L. W. Thudichum delivered his address. "The society," he said, "may look back upon the session just accomplished with satisfaction and pride, and take from its success the assurance of a future in which its usefulness will increase and its importance develop. Our proceedings have not been tinged by the slightest want of harmony; on the contrary there has been a universal concurrence of goodwill on all sides, and I particularly have received from all officers, from the council, and the society at large, the most generous support, which has made my office a pleasure as well as an honour. In founding the Cavendish lecture the council laid down the principle that it should be dedicated, not only to medical but also to general philosophical objects. Perhaps it might be thought that a man, whose life was mainly devoted to the elucidation of facts, should not be made the patron of philosophical ideas; but this doubt will vanish when it is considered that such work as Cavendish performed is imperishable as well as lucriferous. True, Cavendish remained an adherent of the doctrine of phlogiston to his end, which occurred in 1810 after an active life of 79 years' duration. But stability was

the tenor of his mind, and when he studied an object he seized it with tenacity, and held it as long as it yielded any results by the most varied treatment. Unlike Priestley, his great contemporary, he was of a retiring disposition, and several of his discoveries were not published early enough to assure him his well earned priority. Many of the questions in chemistry, raised by Priestley's observation, Cavendish treated successfully, as regards the discovery of new facts, although the phlogiston theory did not allow him to develop their correct bearing. But what he found allowed at once the truth to be seen, says Kopp, as soon as it was considered by an enquirer like Lavoisier, whose view was no longer dimmed by that splendid hypothesis. This would not be the time for entering upon a consideration of the discoveries of Cavendish at any great length, but we may well cast a glance upon the most important of them. He confirmed Black as to the peculiarity of fixed air (carbonic acid), 1766. In the same year he showed that the combustible air from metals is also a specific body. He formed hydrogen by bringing zinc or iron in contact with dilute acids and found stoichiometric relations; equal weights of zinc with sufficiency of either of different acids, gave equal volumes of gas. Equal weights of different metals, zinc and iron, gave unequal volumes of gas; the relations of these to each other were estimated with remarkable accuracy. He found the burning air explosible when mixed with common air; he observed its lightness, a low specific gravity, as one-eleventh of common air (correctly one-fourteenth). This led to the consideration of the specific weights of gases as a means of their distinction from each other. He dried his gases and when measuring their volume observed pressure and temperature. He used mercury as an isolating liquid. He examined chemically water from a London well (1767) and discovered incidentally the solubility of lime carbonate by an excess of carbonic acid. In 1783 he published an analysis of common air. This was so accurate that he stated air to contain 20·8 volumes of dephlogisticated air (oxygen), actually 20·9. In 1781 he investigated the cause of the disappearance of dephlogisticate air; the phenomena of the oxydation of metals, the combustion of sulphur and phosphorus. When he exploded a mixture of combustibles with common air he obtained moisture; when he exploded two volumes of combustible with one volume of dephlogisticated air he also obtained moisture, and no air was left. Thus the composition of water was discovered. In 1785 he found the formation of nitrous and nitric acid by the agency of the electric spark. He retired from the active pursuit of chemistry after the new views had prevailed over the hypothesis of phlogiston. Let us hope that a future Cavendish lecturer may make his discoveries, and their experimental illustration his subject." The speaker then alluded to the influence of Darwin on facts and theories, and deduced as the main result that our endeavours must be to establish firm facts or data before constructing any far reaching hypotheses or theories. In this endeavour our future was secure of results which would advance our science.

Disputing a Doctor's Bill.—A curious case came before the County Court judge at Poole, last Monday, in which a medical man brought an action to recover 21*l.* for medical attendance. The defendant instead of paying the account accused the doctor of having poisoned the patient, who was suffering from Bright's disease, by giving her strong acid internally. The defendant's case was argued by his wife who, however, had no facts whatever wherewith to support the charge of poisoning, and the result was a verdict for the plaintiff for the full fee charged.

CAMBRIDGE MEDICAL SOCIETY.

Friday, August 8th, 1884.

J. B. Bradbury, M.D., in the Chair.

Two cases in which alarming symptoms occurred during the willing game.

Mr. Deighton related the following case. In November of 1883 he was summoned in urgent haste to see an undergraduate. He found him surrounded by his friends, who said they had been playing the willing game, and that he had been blindfolded and willed; soon afterwards he became tottery on his legs and went off into a state of convulsions. When seen he was tossing about on a sofa, with face slightly flushed, the movements of the arms and legs being most irregular, almost equally exaggerated on both sides. The muscles of face and neck were least affected, but he spoke in a jerky way, and on putting out his tongue it was protruded and withdrawn suddenly. He was quite conscious, clear and collected, and said that he tried to prevent himself tossing about, but could not help it. The pupils acted to light and were natural in size. He was ordered a bromide draught and told to go to bed. The next morning he was quite well again. He said he had spent a bad night, tossing about until 5 a.m. before he got to sleep, but there was now only an occasional twitching in the legs. He was of a nervous and excitable disposition, but never had fits or rheumatism or chorea. The heart sounds were normal. He was liable to excessive frequency of micturition on any excitement. The facts were against this being an attack of hysteria; the patient was a man, the movements of the body were so irregular and continuous and the patient's mind was throughout calm and collected, trying to control himself. On the other hand the attack had all the appearance of chorea, the short duration of the seizure being the only difficulty to that view. Mr. Deighton thought that if chorea was regarded as a functional affection in which a mere exaggeration of those muscular movements which are constantly taking place in the body occurred, and that a shock by removing the controlling power of the higher centres allowed the lower centres to have full play, then this case was in the same way capable of explanation.

Mr. Wherry said that the symptoms in his case, though not so definite as in Mr. Deighton's, were nevertheless sufficient to alarm the patient's friends. He was sent for one evening to see an undergraduate who had become suddenly ill during the willing game. It appeared that his friends had blind-folded him in the usual manner and were willing him to do some simple action, when all on a sudden he became weak in the knees and had to be helped to a seat. The handkerchief was removed at once, but the patient did not seem at all himself. He found him leaning against the mantel-shelf, looking fixedly downwards in a dogged and morose attitude; he answered questions in monosyllables in a hesitating way, not stammering, but with a jerk and without expression. Usually, his friends said, his manners were natural and polite. The pupils were dilated, with no action to light and his memory was a blank as to the details of the game. He was sent to bed, and when seen the next morning, he was better; his pupils normal and active to light, but his manner was still odd and his speech remarkable. When advised to leave Cambridge for a few days change, he refused rudely, but was afterwards persuaded by his friends and returned quite well. Mr. Wherry remarked upon the strange state induced by this willing game; the dogged and morose manner, slow replies, no action of the pupils to light, rapid recovery, and no recollection of the period during which he was being willed; altogether a condition which he was informed corresponded with the hypnotic or mesmeric state and one of which as medical men we should like to know more.

Case of Ulceration of Cæcum with Pyæmic Abscesses in the Liver.

Dr. Bradbury related the case of W. H., aged 30, an engine driver, who was admitted to the hospital on May 28th. He was quite well until April 25th, when he was attacked by pain in the left side of the abdomen. During

the first week of his illness he had two or three violent fits of shivering, and vomiting had been present from the first and continued until about a week ago, and he had also had some diarrhœa. He had lost much flesh, and was troubled with a slight cough. On admission he was much emaciated, skin hot; tongue dry and brown; pulse 84; temperature 101·8°. Abdomen lax, tender on pressure especially in left iliac fossa; no spots. A patch of dulness over the base of the left lung behind, with deficient breathing and fremitus. Liver dulness normal. Splenic dulness from the seventh to the eleventh rib, extending back nearly to the angle of the scapula. The urine contained no albumen. On June 2nd, he had a rigor, with pain in the abdomen and diarrhœa, and profuse sweating afterwards. The rigors and sweats were repeated for several days and the temperature chart showed great diurnal variations, on one occasion dropping from 106·6° to 96·4° in less than twelve hours. The physical signs remained about the same, except that on June 18th the liver dulness extended from about the fourth rib to a quarter of a inch below the edge of the ribs, and on the 23rd to two inches below the ribs, and at one time slight jaundice was noticed. The sweats and rigors continued and the patient became very prostrate. On June 25th the abdomen was swollen and very tender, and peritonæal friction was perceptible over the upper part. He remained in much the same condition until July 9, when he was suddenly attacked with severe pain near the right nipple, the pain recurring several times with dyspnœa, and friction sound was audible. July 10 the physical signs showed a large effusion into the right pleural cavity, with tenderness over the liver, and swelling of the legs. Death took place on July 16th. The *post-mortem* showed the right chest to be full of pus, of yellowish colour and very offensive. A communication was found through an opening in the diaphragm with an abscess in the liver. The liver contained many abscesses of various sizes, the largest about the size of a lemon, which had burst through the diaphragm. In the intestine close to the junction of the vermiform appendix and cæcum was an ulcer, the size of a split pea, surrounded by congested mucous membrane. The intestinal wall was not perforated. The cause of the ulceration was not apparent and the appendix was natural. The cæcum was bound down in the right iliac fossa by adhesions of old date. The hæmorrhoidal veins, and the inferior mesenteric above were filled with breaking down clot and pus. There was no evidence of any disease in the rectum or small intestines. The spleen weighed thirteen and a half ounces. Dr. Bradbury in his remarks alluded to the obscurity of the symptoms in the early history of the case and the difficulty in diagnosis; the peculiarity of the pain complained of in the left side of the abdomen, and the comparatively small size of the ulcer in the bowel, the cause of the fatal pyæmia. He showed the liver and the ulcer in the cæcum.

Great Enlargement of Prostate.

Mr. Carver showed this specimen. It was removed from a gentleman, aged 67, who only suffered from prostatic symptoms for three or four years before death. He had consulted several medical men on account of diabetes from which he suffered in addition. The patient first consulted him in 1882 when he was unable to empty his bladder, and was troubled with frequent micturition. A catheter was used three times a day and the diabetes treated by dieting. In 1883 an abscess formed in the ischio-rectal fossa, from which he suffered much pain. Early in 1884 he became much emaciated, and in May an incision was made and a large amount of fœtid pus escaped, but he gradually sank. The prostate was larger than any in the museum, the enlargement being chiefly of the lateral lobes.

Dr. Koch it was reported some days ago had received a call to the University of Leipsic, as successor to the late Professor Cohnheim. The *Cologne Gazette* is glad to be able to state that Dr. Koch has declined this honourable call and resolved to stay in Berlin. It is probable that he will soon be appointed Professor of Hygiene in Berlin University.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

Sir,—The evidence in regard to over-pressure is so conflicting, that the time seems opportune for those whose daily business is with the sick children of the poor to bring their testimony into comparison with that of a widely circulated Report, made for a special purpose, and which its author describes as being necessarily fragmentary and limited in extent.

Dr. Crichton Browne's conclusions have been charged with exaggeration; whether truly or not I will enquire in a moment. Certainly exaggeration is easy; for the children of the poor here in London are exposed to so many noxious influences in their food, their dwellings and the uneven tenour of their home life, that we need great caution in attributing such symptoms as headache, sleeplessness or mental distress to the injurious effect of school. It is only upon the most direct evidence that these common complaints of children, and especially of London children, are to be put to the charge of what is called over-pressure.

And assuredly such direct evidence is not wanting. Instances of nervous injury from over schooling are, I am persuaded, far from infrequent, and they are all of one pattern, girls suffering in far larger proportion than boys. Let the initial cause be hard lessons, or lessons which, without being hard, are to be learnt at home, where "home," as a matter of fact, is not a place suitable for study, but is put to far other uses; or let it be the fear of punishment or the excitement of competition in school examinations, the effect is broken and uneasy sleep disturbed by visions of sums and spelling, loss of spirit and appetite, and presently general failure of health. And it is very curious, as well as very pitiable, to notice how symptoms like these, once started, are kept going, so to speak, of themselves. Children so affected are seldom brought to hospital until a long course of suffering has developed some complaint or other to which a name can be attached. But once overmastered in this way, all hope of recovery is taken away until the child's true condition is recognised, for there is daily failure and disgrace along with daily increasing inability to perform the allotted task. This is strikingly shown in the case of chorea, which of all formulated diseases is perhaps the one which may with the greatest certainty be attributed to school pressure. The muscular disobedience which is the essential feature of this affection is for a while put down to carelessness or ill-temper, and gets treated accordingly, while the child, half alarmed already at finding its limbs in such strange rebellion, has to endure rebuke and penalty which, being wholly undeserved, add to the rest of the suffering that which children feel very keenly, the sense of injustice. I have seen scores of such cases.

But when this much has been said, I believe that almost all is said in reference to the evil effects of our present system of school teaching. Let it be remembered that the affections we are speaking of, serious and even cruel as they are, are not, or at least are very seldom, permanently injurious. I will take upon me to affirm, from personal observation during many years at the Hospital for Sick Children and elsewhere, that those ailments which are most indubitably associated with over-schooling, sleeplessness, chorea, some forms of headache and the like, are as a general rule recovered from com-

pletely sooner or later when their exciting cause is removed. Dr. Crichton Browne would adduce the increased prevalence of diabetes, kidney disease and rheumatism, diseases which, as he says, are sometimes of nervous origin, as proof to the contrary. It must be answered, however, that of the nervous relations of rheumatism we know too little as yet to serve the purpose of any argument of this kind. As regards the other two affections the interval between school troubles and the earliest symptoms of diabetes or renal disease, speaking generally, is too wide to justify such an inference. It is indeed matter of ancient clinical knowledge that the mental causes provocative of diabetes (and more recent observation would include some kidney affections as well) are not the trials of childhood, but, as was said two hundred years ago, "sadness and long sorrow," the disappointments, shocks and bereavements of later life, forms of mental suffering to which little children are happily strangers.

Again I would demur to the statement that acute hydrocephalus is a common result of over-schooling. It may be so; but from the nature of the case the fact is exceedingly difficult of proof. Let it be considered that acute hydrocephalus is almost always of tubercular origin; that its favourite subjects are recognisable by feature and temperament; that the lives of such children are always in jeopardy, protect them as we will; and that large numbers of them die before the schooling period is reached. It must always, I say, be hazardous to assert positively of children such as these, bright, excitable and fond of books as they are, that death is caused or even accelerated by brain fatigue. How easily may the restlessness and delirium which are in fact the signs that the disease has commenced be misconstrued and made to appear as its antecedents and direct provocatives. In common with my fellows I have seen a very large number of children die of acute hydrocephalus, but I can hardly think of one where it could be affirmed that school work had a notable share in the fatal result. Not the less, of course, ought delicate children of this sort to be carefully guarded against the possible dangers of over-pressure. I only wish to point out that the circumstances of the case so arrange themselves that to the half-informed observer almost every child dying of acute hydrocephalus during its school time may seem to die a victim to over-pressure. We have only to raise a cry of that sort, and the poor, nay, both rich and poor, would readily adopt it in explanation of a disease which to them is so mysterious and unexpected, and which selects the most intelligent and the most studious of their children.

There are, indeed, two methods of investigating this subject and determining the actual results of over-pressure. One is to take a series of observations as to the present condition of a number of school children at a single sitting, to repeat this operation at several schools, to form certain conclusions thereupon, and to supplement these by inferences drawn from the Registrar-General's reports. The other is to observe school children continuously over a period of years; to note how and why they get ill, how long and in what manner they suffer, how they recover and how they die. Both methods have their advantages. But if in the end the two results should not be found to tally, I should certainly be disposed to prefer the latter.

Yet while in my belief the ill-effects of too much schooling are, as a rule, neither fatal nor permanent, I would not for a moment seek to minimise either the prevalence or the cruelty of over-pressure. Dr. Crichton Browne has done good work in calling attention to it. What remains is to point out to teachers and parents the particular signs of injurious pressure, and to educate them in a more intelligent observation of the natural characteristics and the needs of childhood. My object in writing, however, is not to discuss remedies, but to venture my opinion as to the extent and nature of the evils complained of, and I will add no more to a letter already too long.

I am, Sir, yours, &c.,

OCTAVIUS STURGES,
Physician to the Hospital for
London, 23rd September, 1884. Sick Children.

[To the Editor of the Medical Times.]

SIR,—From a considerable experience in hospital practice among children, I am inclined to the opinion that an appreciable amount of nervous disorder is probably to be attributed to what has been called "over-pressure" at school. This notion has forced itself upon me in the course of my work. I have never set myself to collect evidence for the purpose either of illustrating the effect of school-life on health, or of disproving allegations as to its harmful results. The few remarks, therefore, that I have to offer you in answer to your letter, will be of no value as demonstrative evidence on the point at issue, the important question of the *proportionate* number of children affected being left out of consideration; but they will, I think, be at the same time free from the taint of professional bias. My tendency at the outset of my work among children was to discredit the complaints of parents regarding the over-work imposed upon their children by the Board schools; and my sympathies are strongly with the principle of compulsory education. I have often refused to fill up the certificates necessary for absence from school which were brought to me by parents for the sake, often very obviously, of having their children at home; but equally and perhaps more often, especially in recent years, have I caused the parents against their will to procure such certificates for immediate signature, on the conviction that a temporary cessation from work was absolutely requisite for the children concerned.

That it is antecedently probable that developing children would suffer in their nervous system from a given degree of brain-work and physical restraint, more than the fully-formed adult, may be regarded as beyond doubt. This point, however, though not requiring emphasis here, is apparently quite ignored by many professed "educationists," and the positive evidence brought to bear upon it is consequently regarded in the same suspicious light as though it were offered on behalf of a paradox.

The chief expressions of nervous disorder that I have observed in children, and have referred directly to their school-life are, mainly, headache, inability to sleep well, and an excitability, often accompanied by a considerable degree of uncontrolled muscular movement, which, though it may not commonly pass on to obvious "chorea," is but hardly to be distinguished from the warnings and remnants of that affection.

With respect to *headache*, I have seen a large number of cases where I was able, after careful enquiry, to exclude other causes than school-work, which ceased very soon after an intermission of school attendances; the "*propter hoc*" in this observation being rendered all the more plausible by the fact that the enquiry was, as a rule, unvitiated by the administration of drugs. In such cases as this I have frequently been asked by the parents to permit their children to continue work till after the examination they were so anxious for them to pass. The headaches were almost always frontal.

Disturbed sleep I believe to be a not infrequent accompaniment of these headaches, occurring, however, also alone. It is often attended by "somniloquence," and not altogether rarely by somnambulism. My strong impression is that the patients in whom this latter symptom shows itself are mostly predisposed to nervous disorder, as shown by family history. Prolonged inability, too, to go to sleep at all for some hours after going to bed is no uncommon complaint.

On the subject of uncontrolled *muscular movements* I can say that I have observed these phenomena, both with and without one or more of the symptoms above referred to, in many cases where there was good reason to believe in the existence of over-pressure at school; and further, that I am well assured that several cases of pronounced chorea that I have seen were distinctly due, as to their main exciting cause, to such over-pressure, especially in connection with examinations.

As an illustration of some of the affections to which I have alluded, I may give short notes of two new cases which came under my notice not long ago in one day in the ordinary course of out-patient work.

Case I.—Phœbe A., æt. 12. Brought because of frontal headache coming on every night about 8 o'clock. Loss of appetite, and sickness after solid food. Has not taken any solid food for a fortnight. These symptoms have continued for several months, but completely disappeared during a recent month's holiday. The last four weeks, since returning to school, they have been worse than ever before. An examination has just been passed. No other discoverable cause for headache. Child looks pale and worried, her eyes filling with tears on being spoken to. Has been diligent at her school, which is not a Board school.

Case II.—Henry L., æt. 12. For the last year has been subject to headache, chiefly on the left side of forehead, but sometimes all over it. Headache comes on only in the evening, and lately has occurred every evening. The boy has been working for an examination. Has no headaches in the holidays. He gets on well at school, and is now in the fifth standard at a Board school, five years since entry in the lowest. The boy has a listless look, and is pale. No other cause of headache discoverable or any fact remarkable in his history other than that his father is subject to headaches.

The question as to the probability of permanent structural lesions of the brain being due to over-work is one which, though interesting, should in my opinion be passed over for the purpose of the present enquiry, in common with all discussion of very doubtful and remote results. It would appear, now, to be enough were even such mere impressions as those I have alluded to, which coincide with the opinion of Dr. Crichton Browne and probably of many others, either fully corroborated or satisfactorily disposed of by disproof. If it be indeed true that our national system of education is so false to its name as to *hinder* the proper mental development of but twenty per cent. of its subjects, surely an urgent case is made out for investigation in spite of our being unable to prove that any are actually killed by it.

I am, Sir, yours, &c.,
H. B. DONKIN.
Physician to the East London Hospital for Children.

[To the Editor of the Medical Times.]

Sir,—In his report to the Education Department, Dr. Crichton Browne expresses some surprise and disappointment that he had not met with any cases of chorea in the course of his enquiry into the existence or otherwise of overpressure in the Board Schools, and he refers to the general belief that chorea is one of the diseases which is liable, or thought to be liable, to be set up by overwork at school.

It occurred to me that I might be able to furnish some interesting and possibly useful information on this subject by tabulating the notes that I have taken of cases coming under my own observation. They do not, however, by any means possess the value that I had hoped they would, and for two reasons mainly. In the first place in the vast majority of my cases I have no note of any enquiry as to school work at all, and in the second place in those instances where there is good reason to refer the attack of chorea to overwork at school there is no evidence to show that the school in question was a Board School. In this respect perhaps my figures gain in value as being clearly not the result of enquiry conducted with a preconceived bias. From the standpoint of the medical observer, however, it matters not what the name of the school may be; it is sufficient for him that a child is suffering from an undue demand upon his intellectual capabilities.

Having said thus much by way of preface, I have only one further remark to make and that is that my cases were all observed at the Hospital for Sick Children, Great Ormond Street, during the years 1879 to 1883 inclusive, with perhaps the exception of a very few in the year 1878.

In all, I have notes of 136 cases; in 111 of these (91 girls and 20 boys) there is no statement as to the existence or otherwise of overwork. Of 9 children (6 girls and 3 boys) it is definitely stated that the attack was not due to overwork in school, in some of these for the very excellent reason that the child was too young to have gone to school. In the remaining 16, there seemed to be good reason to connect the attack with the lessons. In this category there were 12 girls and 4 boys. The following are some of the notes in reference to the point in question.

F., aged 8, "was working very hard at school for her examination when this came on." F., aged 11, "used to have more sums than she could manage, had been 'stood up' in school for not getting them right." F., aged 8, "was working up for examination when this came on." M., aged 10, "is very studious, was working up for a prize." M., aged 10, "supposed to have been working unusually hard for examination." M., aged 7, "no cause known unless the excitement of preparing for examination." I need not take up your valuable space by quoting from the other cases, suffice it to say that the notes in regard to them are very similar. Thus, assuming that in all my cases in which the notes are silent on the point, which I take it is assuming a great deal, assuming that in these cases overwork at school had no share in the production of the disorder, the fact yet remains that in 11 per cent. there was good reason to believe that overwork at school was the exciting cause. If I were asked for an explanation of the fact that Dr. Browne did not meet with any cases I should be inclined to attribute it to this, that as a rule chorea is at an early stage recognised by the parents, inasmuch as the children are very awkward and drop things, and the disease is then discovered either at a hospital or by some wise neighbour, who is only too ready to volunteer a diagnosis.

I have only dealt with the subject of chorea, because that is the only one in reference to which I possess any

facts, but headache is an infinitely more common sequel or accompaniment of examination fever than chorea.

I am, Sir, yours, &c.,
JOHN ABERCROMBIE,
Assistant Physician to the Hospital for Sick Children,
September 23rd, 1884. Great Ormond Street.

THE MAKING OF BOOKS.

[To the Editor of the Medical Times.]

SIR,—During the last fortnight I have been somewhat pestered by a firm of publishers who hail from over the Atlantic and have taken lodgment in London, to contribute a volume to an "International Medical Library." First there came to me, as doubtless to others, a circular, in which commercial enterprise was concealed under an appeal to a presumed sense of vanity as one of the "best authors and most successful teachers," giving a list of no fewer than 67 suggested topics from which I might choose one or more as the theme of an *original* work; secondly, there followed an urgent request that I would lose no time in answering their appeal; and lastly, comes now another circular, making certain announcements of forthcoming works, of successful baiting by the firm, and proposing some dozen other subjects upon which an actual "treatise" is deemed suitable for my pen.

Now this sort of thing may be all very well from the publisher's point of view, and if common report be true that authors in this country have hitherto made next to nothing by their books, it may be a taking prospect for future writers to receive ten farthings for each and every copy of their original works, but what can be said of it in the interest of a reading, enquiring and long-suffering profession? Can this mercantile venture—for it is nothing less, the project of a house of business to establish a footing in London, of which as such it is not my desire to complain—have any other result than to induce the needless making of books, and the flooding of our already overstocked medical market with yet more works on subjects of which the ground is in many instances already well, and more than well, occupied? Is it not one of the banes of our profession to-day that medical books are so often written before the requisite experience has been gained, authors forgetting that the writing of a book ought to be a matter of serious, of well-nigh solemn, concern, to be undertaken only after experience has given that sanction which it alone can give a man to instruct his fellow men? Cast an eye down the weekly columns of advertisements of our medical books, and no one who has the power of observation can fail to see how few are the authors who can have had more than a very minimum of experience of the subjects of their original works, how few are the books which have a more worthy aim than the advertising of those who made them! A further development of this evil is simply appalling. I see in it no germ of good, and I wish to protest against a scheme which encourages the very worst form of making of books, which, by attractive promises of advertisement and remuneration, compels those to authorship who have no warranty to write or teach, and thereby does the whole profession a grievous harm.

I am, Sir, yours &c.,
M.A.

September 22nd, 1884.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received a Certificate to Practise, on Thursday, September 18th, 1884:—

Frank Greasley Armson, Yoxall, Burton-on-Trent; William James Townsend Barker, 106, Redland Road, Clifton; Charles Basham d'Eyncourt Chamberlain, University College Hospital; Isaiah Henry Jones, 53, Maida Vale, W.; George Augustus Garry Simpson, 50, Maryland Road, Sutherland Gardens, W.

UNIVERSITY OF ABERDEEN.—The University Court has appointed the following six gentlemen to be extra-professorial examiners in Medicine for next year, viz.:—Dr. John Alexander, Glasgow; Dr. A. Campbell, Dundee; Dr. Alfred H. Carter, Birmingham; Dr. J. A. McWilliam, London; Mr. Frederick Treves, London; Dr. Francis Warner, London.

NAVAL MEDICAL DEPARTMENT.—The following appointments were announced on September 18th:—Staff Surgeon—Bernard Renshaw, to the *Boscawen*. Surgeons—Herbert G. Marsh, to the *Alexandra*, additional; John Brunt, to the Royal Marine Artillery Division at Eastney; and the following appointments on September 19th:—Surgeon—George R. D. Charleton, to the *Lily*. Mr. John J. O'Doherty has been appointed Surgeon and Agent at Cushendun and Cushendall.

ARMY MEDICAL DEPARTMENT.—Surgeon Major J. G. Altera is granted retired pay, with the honorary rank of Brigade Surgeon. Brigade Surgeon John George Faught to be Deputy Surgeon-General, *vice* Francis Holton, M.D., retired upon temporary half-pay. Surgeon Patrick Joseph Gallwey, M.D., has resigned his commission.

VACCINATION.—Dr. Guy, Public Vaccinator, Norwich, has received from the Local Government Board a grant of 111*l.* 17*s.*

GLASGOW ROYAL INFIRMARY.—The admission of upwards of 30 persons suffering from typhoid fever into the Royal Infirmary at Glasgow has been carried out in spite of a strong remonstrance from the resident assistants, and qualified medical practitioners. On the 9th instant, they addressed the following letter to the managers:—"Gentlemen,—We, the undersigned resident assistants and qualified medical practitioners, beg to call the attention of the managers to the following question, and wish to be advised thereon:—In the rules and regulations, page 22, rule 1, it is stated that 'no person shall be admitted as a patient into the Infirmary without examination by the medical attendants, to ascertain that the case is a proper one. Under no circumstances shall a person suffering from any infectious disease be admitted. The assistants will examine and admit the patients, if found proper for admission; but if an assistant should be of opinion that any applicant ought not to be admitted, he shall, before refusing admission, have his opinion confirmed by that of another assistant, and transmit to the superintendent, signed by himself and such other assistant, the reasons why admission was refused.' Referring to this rule, we beg to inform you that a patient applied for admission into the infirmary on 5th instant, and on examination by the acting assistant for the day, was found suffering from an infectious disease (enteric fever). This diagnosis was confirmed by another assistant, and as a consequence the case was refused, and the reason for refusal was transmitted to the superintendent. The superintendent refused to recognise the reason as a sufficient one, and passed the case into the house. The assistants referred to were informed that by refusing such cases they were 'open to dismissal.' We therefore ask the advice of the committee regarding how we should act when persons suffering from enteric fever should apply for admission into the house. It seems to us that the rule as above stated is quite plain on the point. The Sanitary Authorities of the city are always willing to admit such persons into their Fever Hospital at Belvidere, an hospital specially fitted up for the treatment of infectious disease. Further, by admitting cases of enteric fever, the resources of the hospital are spent in the treatment of cases which would with more propriety be treated elsewhere, and other cases are deprived of admission into the house which are proper for receiving into a general hospital. It may be here mentioned that a case considered suitable for admission by the receiving assistant, and passed into the house on the 5th instant, was refused by order of the superintendent, though there were vacant beds, these being retained specially for the admission of cases of enteric fever. We may state that there are over 20 cases of enteric, or supposed enteric, fever in the house.—We are, &c., J. J. Murray, M.B., C.M.; John Orr, M.B., C.M.; Richard H. Quine, L.R.C.P.E., S.G.; Ben. Blaine, M.B.,

C.M.; John Brown, M.B., C.M.; Thomas Howard, M.B., C.M.; T. Kennedy Dalziel, M.B., C.M.; R. Rankin Hunter, M.B., M.R.C.S.; David W. Torrance, M.B., C.M.; Alexander Peacock, M.B., C.M." We understand that the result of several other communications between the doctors, the superintendent, and Lord Dean of Guild M'Ewen is a curt intimation from the secretary to the Royal Infirmary that if the medical practitioners are not satisfied they can—resign!

Dundee Water Supply. — Suspicion having been aroused as to the quality of the Dundee water supply, samples of both the waters supplied to the town were forwarded to Dr. Tidy, London, for analysis. He states in his report that Monikie water contained 6·76 grains, and Lintrathen water 4·02 grains of solid matter per gallon. This matter consisted of small quantities of sulphates and carbonates of lime and magnesia, with common salt and organic matter. These constituents are harmless, and so far as mineral matter is concerned, its presence in the water is beneficial to the animal economy. He is of opinion that both waters are of good quality. Speaking as a chemist, he considers the waters of good quality, and as a medical man, that they are perfectly wholesome.

Typhoid Fever Epidemic at Kidderminster.—An official inquiry was held at Kidderminster on Monday by Dr. Parsons, of the Local Government Board, into the typhoid fever epidemic now prevailing, and which has attacked from 400 to 500 persons. Dr. Parsons met the sanitary committee of the Town Council in private, and afterwards the medical men of the town were invited to a conference. During the day Dr. Parsons three times visited the lower pumping station, from which the main part of the water supply is derived. The well of water, which has been pumped night and day, is situated in the area of the sewage pumping works, within 70 or 80 feet from where the whole sewage of the borough is pumped. The well is to be no longer used, but water will be taken direct from a bore-hole till an increased supply is otherwise provided. One doctor states that the majority of his patients were teetotallers, thereby suggesting that the water is the great cause of the outbreak. There are, however, defects in sewer ventilation and other matters requiring attention, and it is stated a heavy outlay will be necessary.

Treatment of Diarrhœa.—Ordinary clear vinegar is recommended as a valuable remedy for diarrhœa, given in doses of ʒij for an adult. Not long since it was extolled as an efficient hæmostatic in cases of post partum hæmorrhage—its virtue having been accidentally discovered owing to the effects which followed the administration of a wine-glassful given in mistake for brandy.

Recovery from Bite of a Cobra.—It is not often that a person who has been bitten by a cobra lives to tell the tale. The *Pioneer*, however, gives such an instance. Very recently, it appears that an officer of the 1st Goorkhas, while staying at Kangra, was bitten by a cobra in the hand. With great fortitude Mr. R. seized his gun and blew off the finger that had been bitten. Nevertheless, when medical aid arrived, he was almost insensible; and it was only by keeping him walking about all night and administering large doses of brandy and ammonia that he he was pulled through. Mr. R. has now been sent back to Dharmsala, where, it is to be hoped, that he will speedily recover.

French Population in Canada. — However much non-procreative ideas may prevail in France, that they have gained no access to the French inhabitants of Canada, where an "enormous fertility" prevails, is evident from some figures published by the *Mineral*, of Montreal. "The French population is constantly increasing in the province of Quebec, while the English population diminishes in a sensible proportion. The French were only 3,000 in number in 1653' and 60,000 in 1763. Since that date the emigration from France has ceased, and we have even to regret the departure of a great number of our compatriots who have reckoned upon the advantages offered by the United States. Notwithstanding these advantages, there are at present 1,298,929 French inhabitants distributed in the Canadian provinces as follows:—Quebec, 1,073,820; Ontario, 102,743; New Brunswick, 56,635; New Scotland, 41,219; Prince Edward's Island, 10,751; Manitoba, 9,919; Territories, 2,896; English Columbia, 916.—Total, 1,298,929.

Vital Statistics of Brussels During 1883.—On 1st January, 1883, the population amounted to 166,351 inhabitants, viz., 77,387 males and 88,964 females, the difference in favour of the latter being 11,577. During 1883 there were 5,546 *births* registered, viz., 2,783 males (2,082 legitimate and 701 illegitimate) and 2,763 females (2,061 legitimate and 702 illegitimate). Of the total births, therefore, 4,143 (74·40) were legitimate and 1,403 (25·30) illegitimate. There occurred 66 twin-births or 1·19 per cent., 34 being males and 32 females. During the year 1,470 *marriages* were celebrated, and 49 divorces granted, 1,236 of the marriages having taken place between celibates, 111 between widowed and celibates, and 45 between widows and widowers. The *deaths* amounted to 5,407 (2,873 males and 2,534 females). There were also 334 infants born dead (191 males and 143 females). The 5,407 deaths were an excess of 55 of the decennial mean (1871–80), 3,370 of them occurring at home and 2,037 in hospitals. Of this mortality the children and celibates and the widowed furnished nearly two-thirds, 3,875, viz., children and celibates 3,035 and the widowed 840, while the deaths of the married amounted to 1,519, and of the divorced to 13. To sum up, the daily mean of the births was about 15·2, of the marriages 4·0, of the deaths 14·8, and of the born dead 1. The excess of births over deaths was 139. The annual rate of births per 1,000 inhabitants was 27·65 and of deaths 26·4, a difference of 1·25. The number of violent deaths was 128, viz., 3 by homicide, 75 by accident, and 50 by suicide. Of these last 41 occurred in males and 9 in females. In 18, hanging was resorted to, in 11 drowning, in 13 firearms or cutting instruments, in 4 poison, and in 4 precipitation.

APPOINTMENTS.

Body, Henry Marten, M.R.C.S. Eng., and L.S.A. Lond.—Medical Officer to the Tedburn St. Mary District, St. Thomas' Union, *vice* Dr. Charles Fenwick, resigned.

Bradshaw, T. R., M.D., M.R.C.S.—Assistant House Surgeon to the Liverpool Northern Hospital.

Braine, G. M. P., M.R.C.S. Eng., L.R.C.P. Lond.—Second Assistant Medical Officer of the Worcester County and City Lunatic Asylum, *vice* J. H. Douty, M.R.C.S. Eng., L.S.A. Lond.

Bull, Coulson, F.R.C.S., M.B., L.R.C.P.—Resident Pathologist and Registrar to the General Hospital, Birmingham.

Cooper, A., F.R.C.S.—Consulting Surgeon, West London Hospital.

Dean, Francis, M.R.C.S. and L.S.A., Medical Officer to the Workhouse, Northleach Union, *vice* Mr. H. G. Webb, resigned.

Douty, J. H., M.R.C.S. Eng., L.S.A. Lond.—Senior Assistant Medical Officer and Deputy Superintendent of the Worcester County and City Lunatic Asylum, *vice* R. Atkinson, F.R.C.S. Eng., resigned.

Furse, Edwin, M.R.C.S. Eng., L.S.A., Lond., Medical Officer to the Workhouse, South Molton Union, *vice* Mr. J. Flexman, resigned.

Ranson, W. E., M.R.C.S. — House Surgeon to the Staffordshire General Infirmary, *vice* F. Marsh, F.R.C.S. resigned.

Robins, George Norman, M.R.C.S. Eng., and L.R.C.P. Edin., Medical Officer to the Rippingale District, Bowin Union, *vice* Mr. G. N. Adams, resigned.

VACANCIES.

Bournemouth Cottage Hospital and Dispensary.—Resident Medical Officer and Secretary. Salary £120 per annum (with an increase of £20 the second year), with rooms, coals, gas and attendance. Candidates must possess both a medical and surgical qualification. Applications with testimonials to be sent in on or before September 29th.

Brighton, Hove and Sussex Throat and Ear Dispensary, 23, Queen's Road, Brighton. — Honorary Surgeon. Applications, accompanied by copies of testimonials, to be sent to the Honorary Secretary, Mr. C. Challis, 23, Queen's Road, Brighton, on or before September 30th.

Huddersfield Union.—Medical Officer for the Honley District, in succession to Mr. Andrew Daly, resigned. Area, 2,435 acres. Population, 5,070. Salary, £16 per annum.

Manchester Royal Infirmary.—Resident Medical Officer. (*For particulars see Advertisement.*)

National Dental Hospital, 149, Great Portland Street, W.— House Surgeon. Salary, £50 per annum. Candidates must be Licentiates of Dental Surgery. Applications, with testimonials, to be sent in on or before September 29th.

St. Peter's Hospital for Stone and Urinary Diseases, etc., Henrietta Street, Covent Garden. — House Surgeon. The Appointment will be for six months. Honorarium, 25 guineas, with board, lodging, and washing. Candidates must be M.R.C.S., and have held the position of House Surgeon at a Public Institution. Applications with testimonials to be sent to the Secretary, on or before September 30th.

SWANSEA HOSPITAL.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28.

TYNEMOUTH UNION.—Medical Officer to the Wallsend District, in succession to Mr. James Aitchison, deceased. Area, 2,728 acres. Population, 13,756. Salary, £40 per annum.

UNIVERSITY COLLEGE, LONDON.—The office of Surgical Registrar in the University College Hospital will shortly be vacant. Applications and Testimonials to the Secretary, Talfourd Ely, M.A., on or before September 30th.

DEATHS.

KEMPTON, J. W., M.R.C.S., L.S.A., at 5, Cambridge Terrace, Burnt Ash Lane, Lee, on September 14th, in his 76th year.

NOTES, QUERIES, AND REPLIES.

COMMUNICATIONS RECEIVED—

Dr. D. W. FINLAY, Helensburgh; Dr. OCTAVIUS STURGES, London; Dr. FELIX SEMON, London; Dr. BRAIDWOOD, Birkenhead; Messrs. J. BALE & SON, London; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; Mr. H. WOLLERS, London; Dr. SAWYER, Birmingham; THE SECRETARY OF THE APOTHECARIES' SOCIETY, London; Messrs. P. BLAKISTON, SON, & Co., Philadelphia; Dr. ROBERT LEE, London; Dr. DICKINSON, London; Mr. A. J. HARVEY, London; Dr. THOMPSON, Tasmania; THE SECRETARY OF THE MATER MISERICORDIÆ HOSPITAL, Dublin; Dr. GEE, London; THE HON. SECRETARY OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY, London; Mr. LAKEMAN, London; M. A.; Mr. E. MARRIOTT COOKE, Powick; THE DEAN OF THE MEDICAL FACULTY, KING'S COLLEGE, London; E. H. SCHROEDER, Berlin; Mr. R. WALKER, Aberdeen; THE PRESIDENT OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, London; THE REGISTRAR-GENERAL, London; THE REGISTRAR-GENERAL, Edinburgh; THE SECRETARY OF THE OBSTETRICAL SOCIETY, London; Mr. L. RUEGG, Sherborne; Mr. DAVIDGE, London; Mr. W. YOUNG, London; THE BEDELL OF THE ROYAL COLLEGE OF PHYSICIANS, London; Dr. GUY, Norwich; THE EDITOR OF THE BOURNEMOUTH OBSERVER, Bournemouth.

BOOKS RECEIVED—

Twenty-eighth Annual Congress of the National Association for the Promotion of Social Science.—Proceedings of the Philadelphia County Medical Society.—On the Causes and Mechanism of the Cardiac Impulse, by James Barr, M.D.—Remarks on the Pathology and Treatment of Tubal Nephritis, by James Barr, M.D., L.R.C.S.—Reduplication of the Cardiac Sounds, by James Barr, M.D., L.R.C.S.—Friendly Societies' Provident Medical Institutes and their Medical Officers, by J. Mounsell, M.D.—Che Cosa si Può Fare in Tempo di Colera, C. Tommasi-Crudeli.—Use and Abuse of Pessaries, by Geo. G. Bantock, M.D.—On the Application of Dental Science in the Detection of Crime, by Robt. Reid, L.D.S.—Report on the Health of Kensington, from Aug. 9th to Sept. 6th—The Natural Mineral Waters of Pedras Salgadas, in Portugal.—On Sclerosis of the Spinal Cord, by Julius Althaus, M.D., M.R.C.P.—Tumours of the Ovary, &c., by Alban H. G. Doran, F.R.C.S.—On Some Important Points connected with the Surgery of the Urinary Organs, by Sir Henry Thompson, F.R.C.S., M.B. Lond.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medicin—Philadelphia Medical News—New York Medical Journal—New York Medical Record—The Edinburgh Clinical and Pathological Journal—Centralblatt für die Medicinischen Wissenschaften—Berliner Klinische Wochenschrift—Louisville Medical News—Weekblad—Maryland Medical Journal—The Philadelphia Medical Times—Journal of Cutaneous and Venereal Diseases—L'Hygiène Pratique—Students' Journal and Hospital Gazette—The Liverpool Daily Post, September 18—The Detroit Lancet—The Therapeutic Gazette—Revista de Medicina—Journal of the Scottish Meteorological Society.

APPOINTMENTS FOR THE WEEK.

Friday, September 26 (this day).

Operations at St. George's (ophthalmic operations), 1½ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

INTERNATIONAL HEALTH EXHIBITION (HYGIENIC LABORATORY), 4 p.m.—Mr. Charles E. Cassal, F.I.C., F.C.S., on "Bad Food."

Saturday, September 27.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, September 29.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, September 30.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal South London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, October 1.

Operations at Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, October 2.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

Friday, October 3.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 p.m.—President's (Mr. F. Lawrance) Address, and "A Case of Forcign Body impacted in the Foot;" Mr. Bernard Pitts, "Foreign Body in the Air Passages, followed by Abscess of the Lung—Recovery;" Mr. A. Litton Forbes, "Pharyngeal Deafness, its Pathology and Treatment, with analysis of cases;" Mr. Gunton Alderton, for Mr. M. Thompson, "Case of Retention relieved by Railroad Catheter—Fever—Death in three days."

Contents.

INAUGURAL ADDRESS DELIVERED IN ST. THOMAS'S HOSPITAL,

By Sir J. RISDON BENNETT, M.D., LL.D.,
Fellow of the Royal Society.

Gentlemen,—It was, I believe, a saying of Dr. Johnson that "to judge rightly of the present we must oppose it to the past." Certainly, to judge rightly either of St. Thomas's Hospital and its School, or of medical science of the present day, it would be needful to look back, I will not say to bygone centuries, but at all events to the beginning of the present century. And to one standing in the position of him who has the honour of addressing you on this occasion, there are many temptations to take a retrospective view and indulge in past memories. Nor should I despair of making such a retrospect interesting to many, perhaps to most, of my auditors. The history of such an institution as this cannot be devoid of either interest or instruction, not merely to members of our profession, but to all thoughtful men, to all true lovers of their country and mankind. For what would be the character of such a history? Would it not be the history of a long series of benevolent efforts to succour the destitute, heal the sick, and alleviate the ills of mankind? Would it not be the history of men whose lives were devoted to doing good to their fellow-creatures—of men whose efforts had been spent in investigating the secrets of nature and making every advance in science available for the benefit of humanity? Would it not be the history of one of the grandest and most venerable of those institutions which are the direct outcome of our common Christianity and the glory of our land?

But I do not propose to offer you any attempt at such a historical sketch, whether for the purpose of congratulating you on the present position and prospects of your hospital and school, or at the risk of posing as a *laudator temporis acti*. I wish rather to be allowed to ask you, as I asked myself after my former pupil, your distinguished and respected Teacher and Dean, had requested me to give the address on the opening of the present session, what is it that those who are entering on the medical profession are about to undertake? What is comprised in the preparation needed for rightly fulfilling the duties that will devolve upon them? These, surely, are questions that every one entering our profession should put to himself. But how few do so or give to them due consideration. It is only when we have entered on the duties of our calling, and by experience are made aware of the magnitude, nobility, and responsibility of the office we have undertaken that in our thoughtful moments we become to any adequate degree sensible of the requirements which our profession demands. The subject is far too extended and serious to be adequately treated

in a brief address. But some very general considerations on a few points admit of being submitted for future thought; and if these should help you in any measure more adequately to realise what it is that you who are entering on your profession have undertaken, I shall be satisfied.

The poet tells us that "the proper study of mankind is man," but man is in a special sense our study; man in his entirety, physical, intellectual, and moral; man not only as the highest type of the animal kingdom, a constituent part of the created universe, and therefore subject to its laws; but man also as an intellectual and moral agent, subject to other and higher laws of the Great Lawgiver, of Him whose will is the one and only source of all law, whether physical or moral. Like all other living beings, we are subject to those laws and conditions on which life depends, and as intelligent and moral beings, members of a society of fellow-beings, subject to laws whose maintenance is essential to social life, not to mention those higher laws by which we are linked to a higher and more enduring life. All of us, therefore, must become more or less practically acquainted with the conditions under which we live, whether as individuals or members of society, and must learn, more or less accurately, the consequences of infringing the various laws to which we are subjected. The degree in which such knowledge is essential will differ in different circumstances and callings in life; but absolute ignorance is incompatible with either individual or social life. We, whose office it is especially to study all that relates to the life and health of our fellow-men, have to study man not only as an organised being in all his relations to the external world, but also as endowed with reason and a mental constitution with which his physical nature is combined, by which his material organisation is constantly influenced, and by which he is capable of influencing and is influenced by his fellow-men.

It requires but a very slight acquaintance with the practice of our art to learn how greatly the equilibrium of health depends on the due regulation of psychical as well as physical causes, and how much the influence and success of the medical adviser depends on the exercise of those subtle powers which are not to be weighed by grains and ounces. In common with all men, we are bound to be just, manly, gentle, and loving towards all men with whom we have to do; but as members of a high and noble calling, to whom not only the lives and health, but to a large extent also the private and social interests, of our fellows are entrusted, we are under moral obligations of special and solemn stringency. We must learn not only how to regulate our own mental and moral powers so as to exercise our art with the fullest benefit to our patients, but must make it an important part of our study to watch, analyse, and estimate aright the various and ever-varying mental manifestations of our patients. It would be a great mistake to suppose that mental and moral philosophy, the study of the intellectual powers, were required for those only who intend to devote themselves to psychiatrics. Nor is it merely as contributing in no small measure to our therapeutic power that such studies are important. In the more strictly scientific departments of the investigation of disease—ætiology, diagnosis, and prognosis—they are of equal moment. There is good reason for believing that in our present state of civilisation many more of our most important diseases than we have hitherto imagined have not merely a nervous, but a strictly mental origin. Happily, through the labours of such men as Bell and Marshall Hall among others, and by means of experimental physiology, our knowledge of the nervous system has been greatly advanced. The influence of mind over body is indeed no new discovery, though of late much more has been affirmed than can be proved of the influence of the material on the immaterial. Where the initiatory steps in the production of disease take place, and what is their precise nature, are indeed questions which physiologists and pathologists alike confess to be involved in mystery. But that in many instances their first manifestation is in the nervous system there is good reason for thinking, and that mental states and impressions do not only induce functional disturbance even to the extent of sudden arrest of function and consequent death, we have abundant proof. The action of the heart, respiration, and secretion are all greatly influenced by mental states. Moral emotions that may cause the death of the mother by sudden arrest of the heart's action may also destroy the life of the infant at her breast by poisoning the nourishment that she supplies. The effects of remedies are largely determined by mental states. They become potent, modified, or inert, according to the mental state of the recipient, and this constitutes no small difficulty in determining their true action.

It is therefore not merely as a part of that general culture and preliminary education required of all who claim to be well educated that it behoves us to give mental philosophy or study of intellectual powers a place in our curriculum. Nor is it merely as members of society and fellow-workers that we are bound to be guided by sound views of moral philosophy or ethics. For the direct purposes of our profession we need to give due regard to the reciprocal influences exerted between mind and body, to the moral powers with which we are endowed, and the modes in which they can be brought to bear on the welfare of our patients. The will, the imagination, emotions, affections, and desires, hope, fear, moral habits and conscience, all exercise an influence on the aspect, course, and final issue of disease. They require each in their turn due consideration from him who would rightly fulfil all that duty demands, or ensure his own success.

How often do we not see an ignorant empiric succeed in cases that have baffled the efforts of legitimate scientific physicians, whilst we perhaps merely pity the credulity of the patient, or sneer at the ignorant pretender to science? His so-called remedies have probably been absolutely inert, but he has called into action powers to which we have attached too little importance, or have altogether neglected—the stimulus of hope, the sedative of confidence, or the mere diversion of the attention from objects which, by their absorbing and depressing influence on the mind, have enfeebled and exhausted every vital power.

But if on the part of our patients and in the ordinary intercourse of life it is important to avoid the two extremes of credulity and scepticism, it is doubly so for us who are engaged in investigating the complicated phenomena of life and all that concerns its maintenance on the one hand, and on the other all that relates to the origin, nature, and prevention of disease. How vast is the field of our observation. How varied, intricate, and often mysterious are the subjects of our investigation. How numerous the fallacies and errors to which we are exposed. How difficult to elicit even the most fundamental truths that are to be the basis both of our science and our art. How important is it that we should be provided with all that constitutes a well-trained and regulated mind, in order to secure and make available for our great purpose in life truth and truth only.

Both our science and art are largely based on the observation and collection of facts. Now, there is a great difference in the observing powers possessed by different individuals; but we all require to carefully cultivate these powers, and by habits of close and continual practice render them both quick and accurate. Having ascertained, as carefully as may be, the certainty of our facts, the utmost care and honesty of

purpose are required in tracing their mutual relations and drawing conclusions from them. All prejudice and preconceived notions must be excluded in determining whether any two facts stand in the relation of cause and effect, and in deducing general principles from any number of facts. Habits of close reasoning and the exercise of sound judgment are essential to our success. In medicine the difficulties are far greater than in the physical sciences in applying the strict rules of philosophy to the investigation and determination of truth. We have far greater difficulty in determining the uniformity of phenomena arising both from their greater variety and complexity, and also from our imperfect acquaintance with the influence of external agents on the living organism. We must still submit to be taunted with the uncertainty of medicine; but may, I believe, affirm with confidence that this uncertainty is daily decreasing, and may rest assured that it is only by the steady pursuit of knowledge along the strict lines of philosophical investigation, that truth and certainty are to be attained. Let me here ask you to listen to what Lord Bacon says of the mental qualifications for the study of truth.

"For myself, I found that I was fitted for nothing so well as for the study of truth; as having a mind nimble and versatile enough to catch the resemblance of things (which is the chief point), and, at the same time, steady enough to fix and distinguish their subtler differences; as being gifted by nature with desire to seek, patience to doubt, fondness to meditate, slowness to assert, readiness to reconsider, carefulness to dispose and set in order, and as being a man that neither affects what is new, nor admires what is old, and that hates every kind of imposture."

Now, gentlemen, do not suppose that by such observations as these I am anxious to lead you into the barren fields of metaphysical speculation, and encourage you to form theoretical views of medical science, and become speculative practitioners. Far from it. I would rather warn you against wasting your time and muddling your brains by so-called systems of philosophy, which minister questions that are insoluble, and are fertile only in raising doubts and spinning ingenious fancies and impossible theories. Such things may have a charm for some minds as affording intellectual recreation, and as possessing, indeed, a show of reason, but for the real purposes of life they are little better than verbal and vain janglings.

I wish simply to impress you, on the very threshold of your studies, with the importance of entering on them with that knowledge of your own intellectual powers, and those principles of mental philosophy which are essential in all scientific pursuits. I wish you to keep in mind that in the practice of your art you have to do with the intellectual as well as the physical constitution of man, that you have moral relations to your patients of the highest importance, both to their and your own welfare. If I might venture to recommend any particular books on these subjects, I would mention those of Abercrombie, particularly his admirable and instructive "Treatise on the Intellectual Powers."

When entering on the investigation of man's physical constitution as the highest type of organic life, you will soon be made aware how intimately connected are anatomical or structural studies with those relating to function, both healthy or physiological, and perverted or pathological, and you will soon learn that whilst acquaintance with the principles of almost every department of physics and natural science is required rightly to understand the structure and actions of the human frame, we have at the bedside to do with something that cannot be studied in the dissecting-room and on the *post-mortem* table. The history of medicine sufficiently demonstrates indeed how little could be ascertained of vital actions or the nature of disease, so long as the structure of the body and the physical alterations effected by diseased action were unknown, But with all the progress that has been made in recent times in our knowledge of our bodily organisation, and the flood of light thrown on the nature of those actions by which life is maintained through the advance in physical science, we are encountered at every step in our studies by evidence of the existence of powers and actions which all our physical science has hitherto proved inadequate to explain. Life is still the great mystery. And life, as we know it here, is ever passing into death. The very actions, so far as we know them, by which life is maintained are ever working by sure and inevitable steps to the destruction of life. All we can do is in some measure to modify those actions and avert those causes that interfere with life, and so to prolong for a short space its continuance, and render it at the same time a more unalloyed source of enjoyment, a means of greater benefit to our fellow-men, and of fulfilling the great end of our existence. Day by day we are learning more and more how inadequate is our most intimate knowledge of structure to explain the real nature of those vital actions by which our frame is built up with materials obtained from without the body, and dead matter converted into living, and how small a portion of that pathological knowledge we so much need is derivable from the examination of morbid structures. But, happily, we have acquired much, and hope to obtain more, knowledge of the exciting causes of many diseases, and can in numerous cases assert their action. We can understand much of the ways in which perverted nutrition and altered structure interfere with healthy function and endanger life. We can effectually remedy some of these things, and in important degrees diminish the perils arising from others. We can alleviate the pain and inconvenience associated with many diseases, and can save many lives from immediate and inevitable death. By our knowledge of the influences of external agents on living organisms we can diminish their danger to life and health, and make many otherwise impossible occupations compatible with human welfare. We can prolong the duration of human life, and have added to its sum total. We can comfort many an aching heart, solace many a weary mind, and bring joy and gladness into many a home in a way that no other body of men can. The benefits that we can confer, the good that we can do by our science and art are as extensive as humanity, and all ranks and conditions of men in ages yet to come will have cause to bless our Harveys, Hallers, Hunters, and Jenners.

But why do I venture to indulge in this strain of seeming self-laudation? Because I do not wish that you should be discouraged by the extent, variety, difficulties, and mysteries of the studies on which you are entering, but rather that you should congratulate yourselves on having adopted a course of life worthy to engage all the highest powers of man, and capable of conferring the greatest blessings on mankind. A life it is that will indeed not be free from care, anxiety, toil, and self abnegation, but fraught with pleasures and satisfaction of the purest kind.

The connection and relative importance of the different departments of your studies and the present aspect and position of our science you will learn from their respective teachers. The facilities and advantages which you possess in the present day for carrying on your study in the various subjects that lie at the foundation of all your professional education are very great; but with all these aids you must be prepared to find some of them at first irksome and devoid of much apparent interest. By industry and resolution you will soon get beyond those first steps that are always more or less rough and difficult. As you advance

your progress will be easier, and if you are at all worthy of your calling each step will be found of increasing interest and delight. On the actual position and prospects of our science in its various divisions I shall not attempt to enter. In some the outlook is more encouraging than in others. In some of the special subdivisions the practical application of our science has been followed by results of the most gratifying and salutary kind, whilst with respect to others sceptical outsiders are prone to exclaim "*Cui bono?*"

On one or two points I venture to offer a few remarks. Histological investigations have for some time been pursued with great ardour and diligence, and with undoubted and important increase of our knowledge both of function and structure, but whether with a corresponding augmentation of our therapeutic powers may be doubted, and whether such studies have not too much diverted our attention from the general laws of disease and the broad principles of practice is a grave question. At all events it is, I think, not a needless caution in the present day to warn you against coming under the description of Goldsmith's "puny pedant, who finds one undiscovered property in a polyp, or describes a hitherto unheeded process in the skeleton of a mole, and whose mind, like his microscope, perceives nature only in detail." I am speaking to those who are supposed to be preparing themselves for the practical duties of their profession rather than to scientific investigators. Again, many of the subjects of scientific enquiry in the present day are of such surpassing interest, and I may say fascination, as well as importance, that they are calculated to occupy the student's mind so as to interfere with other topics, and give a colour to his views both of science and art detrimental to his therapeutic success. Still more do we need to be on our guard against being influenced by the mere fashions and notions of the passing day, and taking up the endless whims and baseless theories that happen to have gained the ear and secured the patronage of the public.

It is certainly remarkable how little of our most trustworthy therapeutics has been the direct deduction from our scientific knowledge. Nay, how many of our most valuable and best-tested remedies have been acquired by accidental observation! How entirely ignorant are we of the mode of action of some of the most reliable! Quinine or bark from the time of its discovery has held its place as one of our most valuable and certain remedies, and we have recourse to it with the utmost confidence in intermittent fevers and neuralgias, knowing nothing of the real nature of its operation. The most philosophical physician, and one of the best of men whom I have ever known, the late Professor Alison, at whose feet I had the privilege of sitting, and under whom I acted as clinical clerk, gave it as his opinion that we must look mainly for the advance of practical medicine to more accurate knowledge of the exciting causes of disease, and to the discovery of fresh specifics which may exercise the same influence over diseased actions as cinchona in intermittent fevers, citric acid in scurvy, and vaccination in small-pox. Two remedies that have come into use since his day, iodide and bromide of potash, approach nearest to the claim of being considered as specifics, and have proved of inestimable value; but their employment has not resulted from scientific induction either from physiology or pathology. It is also deserving of remark that in proportion as any medicine is found to be adapted to any particular morbid state, it is well borne by the economy, to the extent even of entirely masking or overcoming its ordinary physiological action. But experimental physiology and pathology have thrown much light on the action of many medicines, and we have thus gained no small amount of reliable information on the means at our disposal for modifying vital actions and controlling disease. The danger to life and the destructive course of disease are in many instances mainly referable to excess or defect of particular functional activities, which admit of being controlled by remedies proved to be capable of exercising the required influence. The incalculable blessings conferred by anæsthetics have been obtained by experimental investigations into their chemical constitution and influence on the nervous system. These and other instances of important augmentation of our therapeutic resources are a sufficient answer to the objections now so frequently and mischievously raised by mistaken opponents of experiments on the lower animals. Again, in the case of parasitic diseases, our knowledge of their true causes and nature has led to the discovery of appropriate and efficient remedies. And there can be no doubt that in other and more complex forms of diseases in proportion as we know their essential nature, our therapeutic powers will be increased.

Although there cannot, I think, be any doubt that by a judicious combination of medicines we often obtain advantages that could not be gained by single drugs, polypharmacy has been a great evil; but its days are well nigh gone, and the greater simplicity of our present practice is no doubt conducive to more accurate knowledge of the real therapeutic value of medicines. But whilst admitting the urgent need of still further careful observation and experiment in this field of enquiry, and though far from underrating the power of controlling, and even curing, disease already afforded us by many drugs, I would urge you ever to remember that therapeutics are no more comprised in the due administration of drugs than is pathology in a knowledge of morbid structures. It is well that young practitioners should see and appreciate the truth and depth of meaning in the dictum of Celsus,—*Optima medicina est non uti medicinâ*,"—a maxim which a certain class of practitioners have very dexterously turned to their own no small advantage.

Therapeia with the ancients comprised all that related to the care of the sick with a view to their comfort and relief; and in the present day hygienic rules, diet, and regimen are comprised under the head of therapeutics. It is here that we have met with most success and have won our greatest triumphs. It is here that all our labours in the investigation of structure and vital action have borne fruit; it is here that we have been able to profit by all the advances in physical sciences. Fuller knowledge of the exciting causes of disease has enabled us to make important steps towards their prevention; a more intimate acquaintance with the laws of morbid action, and the natural history of disease has enabled us to foresee results and promote or obviate their occurrence. A closer acquaintance with nature's powers in maintaining health and repairing injuries has helped us materially in promoting her efforts and warding off all those influences that tend to interfere with or frustrate them. Surgery perhaps affords us the most signal and indubitable evidence of this; but some of the most complicated, and still in some respects inscrutable, forms of disease that fall under the care of the physician—specific fevers—might also be cited. More attention to the influence exerted on the aspect and course of disease by different circumstances and conditions of life, by differences of season and general epidemic character, have shown us the fallacy of supposing that the same disease is always to be treated in the same way, and thus leading us to prescribe for a name rather than for the particular case under view. If we take so common a disease as pneumonia, for example, of the nature, course, and general manage-

ment of which we know more than of many other diseases, how different is its mode of access in different cases, the degree and kind of danger attending it; how different its progress; how different the constitutional condition of the patient, his hygienic and moral circumstances. Manifestly the plan of treatment and the action of remedies must correspondingly vary. Theoretical or scientific views of pathology and therapeutics must here give place to the sagacity, experience, and judgment of the physician, even at the risk of his reputation by running counter to popular views and received rules. It is evident that when encountering new forms of disease, or which are new to us, we must be guided by analogy rather than by definite rules.

It may perhaps be questioned how far the varied aspects presented by disease at different periods will account for or justify the abandonment of remedies and plans of treatment that have been found successful in other times; or how far we are influenced consciously or unconsciously by theoretical views into which we have been led by recently discovered scientific facts. In practice we must still to a large extent be guided by those broad general principles that have been best established by observation, and stood the test of long experience. In our art, *vixerunt fortes ante nos;* and we have but to look at the records of the past to be convinced how large a part of our most trustworthy practical knowledge has been transmitted to us by men who have gained the admiration and gratitude of their posterity by their sagacity and powers of patient accurate observation rather than by the theoretical views and systems associated with their names. Systems of medicine have passed into limbo, and we are happily free, in the present day, from their shackles; but we cannot ignore or neglect knowledge accumulated in the past, because we cannot make it harmonise with our more advanced physiology or the marvellous discoveries in the field of microbiology.

During your studies here you will have but little time for reading beyond what is comprised in text-books, and that little had better be devoted to general literature as a source of mental recreation from professional occupations. But the leisure hours of future life will be profitably employed in learning what has been thought and done by the great men of the past. In the history of medicine you will find much to interest as well as to instruct you. Stores of wisdom are to be found in the writings of bygone observers that may be made practically available at the present time, and assistance often obtained on questions of the day by learning the errors and mistakes, as well as the discoveries, of the past.

In practice each individual case of disease to which we are called must be made a special study. It is not enough to ascertain that we have to do with gout, pneumonia, or typhoid fever, whichever it may be; each example of disease and each patient must be made a special study. We have to take into consideration all that relates to the climate, season, hygiene, and social condition of the patient, his hereditary and constitutional characteristics, his idiosyncracies and past history, so far as we can learn them. And in the management of each case there is scarcely any circumstance, however trivial apparently, that may not exert an influence on our success, any and every source of irritation, whether bodily or mental, the position of the patient or his bed, the aspect as well as the nature of his food, his prejudice in respect of a particular medicine, his liking or aversion for a particular attendant, and all that relates to the nursing and economy of the sick room.

It is not enough to lay down rules of diet. You require to know that the food is properly prepared as well as its special adaptation to the patient's case; and to these ends you must know the principles of the science as well as the art of cookery. For cookery is a veritable science as well as an art. Among the poorer classes there is not only grievous waste from ignorance or neglect of the right methods of obtaining the full amount of nutriment from each variety of food, but many unfounded and hurtful prejudices against the use and best modes of preparing such food as is needed in sickness. You will render no mean service to your poorer patients by instructing them on such points, and will greatly enhance your therapeutic powers by a knowledge of the chemistry of food and the best means of preparing it for the purposes of nutrition. Your personal influence in the sick room will be more or less in proportion as you learn to exercise in each case the precise moral control that it requires; and whilst to secure the confidence, good opinion, and gratitude of your patients are in all cases legitimate objects, their real welfare and the fulfilment of your duty must ever override all considerations of your own social success. Assumed and affected manners are to be deprecated, whilst a kind and sympathetic manner should be sedulously cultivated. Gentleness should be combined with firmness, cheerfulness with sobriety, caution with confidence. and a general deportment consistent with the gravity of your office, and the particular requirements of the sick should be your habitual study.

In such a profession as ours every well-conducted and fairly qualified man may look with confidence to a certain amount of social success and opportunity of benefiting his fellows, may secure the esteem of the worthy and the blessing of such as were ready to perish. It is not indeed given to all to make discoveries in science, or effect important advances in our art; but each may do something, and it is imperative on all to make it an object, and consider it a duty, so to live that those who come after us may be the better for our labours. Some by the particular circumstances in which they are placed may have opportunity for special observation and investigation of particular forms of disease which should not be lost. All by careful trustworthy observation of nature and truthful records of work may contribute somewhat to the common stock of knowledge; but such records must be made, not with a view to a fleeting reputation or the gratification of personal vanity or ambition, but with the object of eliciting truth that shall prove to be for the good of man's estate. Whatever the genius of some or their special advantages may enable them to effect, it is by that close observation of nature, which all may and are bound to cultivate, that most of us can hope to attain what should be the desire of everyone.

"Where natural logic prevails not, artificial too often faileth," says that quaint old philosopher, moralist and physician, Sir T. Browne; "where nature fills the sails the vessel goes smoothly on, and where judgment is the pilot the rate of insurance need not be high; where industry builds upon nature we may expect pyramids; where that foundation is wanting the structure must be low. They do most by books who could do much without them, and he that chiefly owes himself unto himself is the substantial man."

Queen's College, Galway.—The report of the President of Queen's College, Galway, for the session 1883–4, has just been issued as a Blue-book. In referring to the condition and the progress of the College, the President regrets to report a continued decline in the attendance of students, there now being 103 against 144 the previous year. For a diminution so large and sudden, he says, it is easy to find an adequate cause in the dissolution of the University organisation of which this college formed a part. The decline is stated to be almost exclusively confined to the faculty of medicine.

INTRODUCTORY ADDRESS DELIVERED AT THE MIDDLESEX HOSPITAL.

By DAVID W. FINLAY, B.A., M.D., M.R.C.P.

Senior Assistant Physician to the Hospital, and Lecturer on Forensic Medicine and Public Health in the Medical School.

Gentlemen,—Not the least of the difficulties besetting the position which I have been called to occupy on this occasion lies in the choice of a suitable subject on which to address you. This arises partly, no doubt, from the embarrassment attending on riches, and partly because the thousand and one of such addresses standing on record forbid, to me, at least, much in the way of novelty. One part of my duty, however, is easy as well as pleasant, and that is to offer you all, on behalf of my colleagues and myself, a hearty welcome to these benches, and to congratulate you on the choice of an honourable and self-sacrificing profession.

In many respects it is the noblest calling in which you could engage, and it is one of correspondingly high privilege and responsibility—privilege in numberless opportunities of doing good—responsibility in making the best possible use of your powers to this end. Cicero's words still remain true as when they were first uttered: "Homines ad Deos nullâ re propius accedunt quam salutem hominibus dando." What constitutes, as it appears to me, the chief attraction of the profession of medicine is that it satisfies both the intellectual and sympathetic side of our nature; for while the field for acquiring experience and also for research is boundless, the results arrived at are made directly serviceable in the treatment of our fellow men, in relieving pain, in restoring function, and in saving life.

Although it cannot be said that it is a very lucrative occupation, still, even on this lowest platform, it will bear favourable comparison, in one respect at least, with most other professions; for of the trinity of Physic, Law, and Divinity, I think we may look upon the first-named as the one which, when student days are ended, offers the most reasonable prospect of immediate remunerative employment. In exercising it a few of you may attain to wealth, most will acquire a comfortable competence, and there is probably no one to whom it will not bring at least a livelihood if its objects are pursued with steady industry, even although unaccompanied by much natural gift.

A wide field in the domain of medical practice is open to your choice. Many of your predecessors have entered the Medical Department of the Army and Navy; the Indian Medical Service has attracted others. The Mercantile Marine, besides giving an opportunity to many for the exercise of their profession, offers facilities for foreign travel, for the building up of health after the labour and anxiety of study and examination are over, as well as for that enlargement of the mind, which, to the observer of men and manners, always comes from seeing strange lands and rubbing shoulders with men of all kinds and classes. The multitude of the colonies also lies before you; and for those who prefer to settle down quietly in the old country with its teeming populations, there need be no lack of opportunities of advancement and distinction, although where competition is keen pressure is high, and tear and wear of body and mind are correspondingly great.

But no prosperity, nor distinction, nor anything else worth having will be gained without honest and steady work; and I beseech those especially who come here for the first time to make a good start by cultivating habits of application and industry and method from the very beginning of their studies.

I have never forgotten the sentiment contained in one of Ovid's couplets, which I used to read as a boy at school, which I would commend to the notice of you all—

> "Quæritur Ægisthus qua re sit factus adulter
> In promptu causa est, desidiosus erat."

The idle man has his mind open to attacks of all sorts of folly, and temptations to idleness and worse than idleness abound in every large city. There is no surer way of keeping clear of all such entanglements as may lead in the end to moral loss and wasted lives than to have your minds preoccupied with something that is good and useful, and you will find the time allotted for your curriculum none too much for the acquirement of the knowledge necessary for passing your qualifying examinations, and fitting you for your start in life. Habits of idleness are too often acquired in the first year, and the subject of them is overweighted in succeeding sessions; he probably fails to pass his primary examination at the proper time, and if he ultimately makes up for lost opportunities, it is only after a grievous expenditure of time and irksome labour. It is not too much to say that the amount of labour necessary for merely overcoming the bad habits acquired in his first year would have carried him safely through all the quicksands of his qualifying examinations.

In referring thus particularly to examinations, I would not wish you to take any exaggerated view of their importance. Look upon them only as means to an end, but means without which you cannot even enter upon that end. You can have no independent professional life until you obtain a legal qualification, and hence anything which will conduce to your certainty and comfort in this matter is not to be lightly set aside.

In this connection I would strongly advise you to lose no opportunity presented to you of taking part in both written and oral examinations. I have long been convinced that students often fail before examining boards not because they have not a "pass" amount of knowledge, but from failure to display to the best advantage the knowledge they possess. From whatever cause arising, this is best guarded against by the familiarity which you will have abundant facilities for acquiring during your curriculum as students, for here, as in everything else, "practice makes perfect."

Let me also impress upon you the value of regularity and punctuality of attendance in your classes. By the neglect of the former you squander your own time, by unpunctuality you waste also that of others.

In enforcing this point I will quote the words of the late Sir Robert Peel, addressed to a gathering of students: "Practise the economy of time; consider time, like the faculties of your mind, a precious estate,—that every moment of it well applied is put out to an exorbitant interest. When you have lived half a century you will have seen many instances in which he who finds time for everything—for punctuality in all the relations of life, for the pleasures of society, for the cultivation of literature, for every rational amusement, is the same man who is the most assiduous and the most successful in the active pursuits of his profession. Estimate also properly the force of habit. Exercise a constant, an unremitting vigilance over the acquirements of habit, in matters that are apparently of entire indifference, that perhaps are really so, independently of the habits which they engender. It is by the neglect of such trifles that bad habits are acquired, and that the mind, by tolerating negligence and procrastination in matters of small account but frequent recurrence, matters of which the world takes no notice, becomes

accustomed to the same defects in matters of higher importance."

I do not propose to say much as to the way in which you should pursue the study of particular branches of your curriculum, but one or two remarks may not be out of place.

And firstly with regard to Anatomy. It is hopeless to expect to acquire any useful knowledge here without regular and patient dissection. Demonstrations, of course, you will have to help you, but you must not fall into the error of supposing that these can ever take the place of personal acquaintance, if I may so put it, with the parts of the human body themselves. The more and the more carefully you work at dissection the better will your knowledge of anatomy be, the more firmly will the multitude of its facts be imprinted upon your memories, and the surer will be the foundation upon which the superstructure of your professional learning generally has to be built. In this, as in all other departments of knowledge, you must remember that—

"Study is like the heaven's glorious sun
That will not be deep-searched with saucy looks."

Besides the advantage I have spoken of, you will acquire habits of self-reliance the benefits of which will remain with you all your lives, and not only of self-reliance, but also of care and neat-handedness, which in intricate surgical operations is of the greatest value.

You ought also to strive to be well grounded in Physiology and Pathology. The former teaches you what is the normal function of the parts you have dissected, the latter concerns itself with abnormal function and the changes produced in the organism by disease. And just as I have said Anatomy cannot be learned away from the dissecting-room, so you cannot attain to a serviceable knowledge of Pathology unless you give unremitting attendance in the *post-mortem* room. Here you will see and handle the results of disease, and in a very literal sense—

"Rise on stepping stones
Of your dead selves to higher things."

In histology too, which you will find opportunities of studying in connection with these, you will gain still further the methodical care and neat-handedness of which I have already spoken; in addition to which the microscope will open up to your view wonders of minute structure normal and abnormal, as interesting as anything you could conceive.

These three, Anatomy, Physiology, and Pathology, may be looked upon as corner stones apart from which you cannot build anything better than a house of cards, but there is no part of your curriculum which you can afford to neglect, if you would reap all the advantages possible from your career as students.

I would advise you to have as little as possible to do with "coaching" and books of "cram." "Aids" they are called, on the principle I suppose "lucus a non lucendo." In regard to the former, if you follow the principles I have advocated you will not need it; as to the latter they are only fitted to impart a superficial smattering of knowledge of a very evanescent kind. Synoptical summaries of compared and contrasted facts are very useful, but you should construct the summaries for yourselves. In this way they become imprinted on your memory as the essence of your own reading and observation, and are never forgotten.

Be your own "coaches." Among your companionships you may easily form yourselves into small classes for mutual help, for receiving and imparting information; and such associations, besides enabling you to reach the immediate end in view, may form the basis of life-long friendships of inestimable value.

Most of you are aware that there is in connection with the hospital and school a Students' Medical Society, by the way the oldest of its kind I believe in London; and I mention it to express the hope that you will all not only become members of it but make conscience of taking part in its work. If you do you will find that the writing of papers and taking part in the discussions which are carried on in connection with it, will give you a clearness and conciseness in expression, and readiness in debate which you will probably have no such opportunity of acquiring in after life.

In addressing you last year my predecessor expressed the hope that by this time the Medical Bill which has been so long looked for would have become an Act, and that I might have to point out its bearing upon your studies. But this hope has not been realised, and legislation upon the subject seems as far, perhaps rather farther, off now than it was then. And if we regard the mischief that had been, and was likely to be, worked on the Bill by compromises actual and proposed before it arrived at its last surviving stage, we need not perhaps greatly regret that the vessel foundered before port was reached.

At the same time all the labour expended upon it, and the day-light which has been let in upon some of the licence-granting bodies, have not been fruitless. Many of the Corporations have been led to set their houses in order; and what is perhaps of chief interest to you is the fact that a scheme for the conjunction of the two Royal Colleges of London for the purpose of granting qualifications has been elaborated, and will probably be put in force as soon as it has received the sanction of the Medical Council. You will then have only one examining body to face in order to gain a double qualification. If by some change in their constitution these colleges could only obtain power to confer degrees in medicine and surgery the scheme would be complete, but there are always vested interests and difficulties to be overcome in the way of all such reforms.

I may not close this part of my remarks, having special reference to ourselves, without alluding to the removal from among us of one whose kind and thoughtful face was so often seen at our annual gatherings. Dr. J. Hall Davis, for more than twenty years Obstetric Physician to the hospital, died, peacefully as he had lived, since last we met on an occasion like the present. The son of a distinguished obstetric physician he followed in his father's footsteps, and became one of the most trusted of the leaders of obstetric medicine in the metropolis. He joined the staff of this hospital and school as Obstetric Physician and Lecturer on Midwifery in the year 1863, and only severed his connection with the former by resignation a few days before his death, which occurred suddenly on March 19th last, after a slight premonitory attack of illness from which he seemed to have completely recovered. He had filled in turn some of the highest offices open to the department of practice with which he was connected; and in every walk of life his kindliness, skill and calm judgment were conspicuously displayed. His character was spotless, and professional jealousy had no part nor lot in him. As has been stated elsewhere he was esteemed most by those who knew him best, surely the highest tribute than can be paid to any man.

No one who contrasts the state of medical science now with what it was twenty or even ten years ago, can fail to see that in this, as in other things, we live in an age of progress, and that the science is advancing in an ever increasing ratio. In illustration of this I may point to the discoveries which have been made in the field of bacterial pathology; to the development and extension which have taken place in connection with abdominal surgery; to the greater precision which has been given to diagnosis in the matter of cerebral localisation; and, as regards therapeutics, to

the rapidly extending anti-pyretic treatment of febrile diseases both by internal and external remedies.

And in the domain of Preventive Medicine, State Medicine, Public Health, or whatever it may be best called, no less activity has been observable.

I am led to refer more in detail to this department of medicine for several reasons.

Firstly, on account of its rapidly increasing importance.

Secondly, because it has been brought so prominently before the profession and the public in connection with the Health Exhibition, and it is a good maxim to "strike while the iron is hot."

Thirdly, because my duties in the matter of lecturing bring me specially into contact with it, and lastly, because I have found that students, as a rule, appear unwilling to give to it the attention which its importance deserves.

The last-named reason, I take it, arises from the fact that it is not a compulsory branch of study in the medical curriculum, and this will, I fear, be operative more or less until it is made so. It may be said that the curriculum is too full already, and that to introduce another subject of such wide range as Public Health, would place upon the student a burden greater than he is able to bear. I am not prepared to deny this, but then a method of relief might be found in lightening his load at some other point. And it seems to me that this is a question which those who have the regulation of such matters will soon have to face, unless the aphorism *Salus populi suprema lex* has lost its force.

In pleading for a greater amount of attention to this department of medicine, it must surely be a strong argument if it can be shown that a notable diminution in the death-rate, which we may take roughly as a measure of disease, and consequent saving of life have already resulted from the system which has been established in this country, and the work which has been done under the various acts relating to the Public Health. Although great antiquity may be claimed for some of the branches of Preventive Medicine, but little was done in regard to it in this country until the great cholera epidemic of 1832 alarmed the community and "led the way to sanitary enquiries and ameliorations." Among others it helped towards the system of compulsory registration established in 1837.

Within a few years commissions were appointed, one on the sanitary condition of the labouring population of Great Britain, which reported in 1842; another on the health of towns, which reported in 1844 and 1845; and a third, the Metropolitan Sanitary Commission whose report appeared in 1847–48.

Then came the passing in the latter year of the Public Health Act, the object of which was to improve the sanitary condition of towns and populous places. By it provision was made for the constitution of Local Board Districts, and a Central Authority, the General Board of Health which was to exist for a period of five years. This board was continued for ten years, however, its functions being then transferred to a department of the Privy Council under the presidency of a medical officer.

Following upon this, in 1871, was passed the Act establishing the Local Government Board to which were transferred the powers and duties of the Poor Law Board and of the medical department of the Privy Council. The following year saw the passing of the Public Health Act which provided for the division of the country into urban and rural sanitary districts, and the appointment of medical officers of health who should be legally qualified medical practitioners, inspectors of nuisances also, and such other officials as might be necessary for the efficient carrying out of the provisions of the Act.

Further progress in legislation was made three years later, in 1875 namely, when the great Act came into operation "for consolidating and amending the Acts relating to Public Health in England." This is still the chief statute under which the Public Health service of the country is carried on.

Legislation has not stopped here, however. A number of Acts have found a place in the statute book having for their object more or less directly the promotion of health and prevention of disease. Among these are the Alkali Act, the Artisans and Labourers' Dwellings Improvement Act, the Sale of Food and Drugs Act, the Rivers Pollution Prevention Act, the Public Health (Water) Act, the Public Health (Interments) Act, and many others.

Such is a very brief sketch of the history of legislation of the subject, and that it was what was chiefly needed in the conflict with disease and dirt, may be gathered indirectly from the quaint remarks of Captain John Graunt, F.R.S., penned more than 200 years ago, which are to be found in an old collection of the yearly Bills of Mortality of the City of London. These remarks show (and the same might be said emphatically still) that a knowledge of what was beneficial was far in advance of the means of compelling its application for the production of good. Speaking of the freedom of London from the Plague and discussing the causes of this freedom, he says:—

"Whether we are become less apt to breed or to receive this dreadful evil, one of the causes of this happy event seems to be the greater freshness and purity of the air of London, since the rebuilding of it after the great fire, the streets being made wider, and the inhabitants not crowded so closely together; as it is perhaps owing to its being more thinly peopled than the rest of the world, that America has never yet been visited with the plague, while the crowded and filthy cities of Cairo and Constantinople are seldom free from it. Another, and probably the most effectual preservative has been the great quantity of water from the Thames and the New River, which for the last century has washed the houses so plentifully, and afterwards running down into the kennels and common sewers, constantly hinders or weakens the tendency to putrefaction; and if more water could still be derived into our houses, streets, and common sewers, it might perhaps fully make amends for the imperfections of quarantines, arising from the thoughtlessness, negligence, avarice, and obstinacy of those who may have the direction of them, or of those by whom they should be performed."

It remains now to look at the results which have flowed from our legislation, and from the increased and increasing spread of sanitary knowledge which has been both its cause and consequence. Well, the advantage which has resulted to the country (I am speaking of England and Wales alone) may be seen firstly in the general death-rate, which on an average has been steadily declining for the last twenty years, most rapidly and strikingly, however, since the passing of the Act of 1875. The incidence of epidemics and other causes forbid that the rate of improvement should be absolutely and uniformly continuous, but steady average progress since 1875 is conspicuously apparent, the fall being from 22·8 in 1875 to 18·9 in 1881 and 19·6 in 1882, the last year for which the complete returns of the Registrar-General have been published.

Stated in numbers, the following results are brought out, taking for comparison with the years subsequent to 1875, the average death-rate of the ten years 1866 to 1875 inclusive, 22·2 namely. The same rate in 1876 would have meant the death of 30,699 persons who were alive at the close of the year. In 1877 47,821 additional persons would have died; in 1878 15,860, in 1879 36,981, in 1880 42,226, in 1881 86,619,

and in 1882 69,714. If these figures are correct we have here a total of lives saved amounting to more than 329,000.

So much for the general death-rate. Referring, by the way, to the last three cholera epidemics, we see further ground for the influence claimed for sanitary medicine in diminishing mortality. The epidemic of 1848–49 was responsible for 54,398 deaths ; the fatality of that of 1854 was represented by 20,097 ; while in that of 1865–66 only 14,378 lost their lives—a large number still, but only about a fourth of the mortality of the first named epidemic.

If we take now the statistics of some of the zymotic diseases similar results are brought out. This of course is only what we should expect, even more conspicuously, if the position which I have laid down is to be maintained, for zymotic and preventable may be regarded, so far as hygiene is concerned, as in some sort interchangeable terms.

For illustration here, I take typhus, enteric fever, and the so-called simple and ill defined or simple continued fever of the Registrar-General's reports—typhus and enteric fever because we know perhaps more about them and how to prevent their spread than is the case with most other diseases of the same class. We know that the potency of the typhus poison is destroyed by fresh air, and that with pure water supply and unimpeachable drainage enteric fever makes no headway. With regard to the other, surely it is misnamed. The simplicity of a fever ending in death is not very obvious, and to call it "simple" and "continued" is to use two epithets mutually destructive. It would be interesting to know how many cases were relegated to this class after *post-mortem* examination. I think we may safely conclude that almost all the cases appearing under this heading are cases of enteric fever. Nearly as much as this indeed is admitted by the Registrar-General in his report for 1879.

Corroboration of this view may be found in the fact that the total number of deaths included under simple and ill-defined fever has diminished much more rapidly than those ascribed to enteric fever, probably from increased accuracy in diagnosis. Thus, since 1869, the first year when the classes of disease I am speaking of were returned under different headings, the number of deaths from simple and ill-defined fever have decreased from 5,310 to 1,016, while enteric fever has only decreased from 8,659 to 6,006. This would not seem any great result in the case of the latter ; but if we add the totals of the two together as I think may fairly be done, for the reason I have already stated, the decrease is from 13,969 to 7,052, a difference in favour of the last year of 49 per cent. In regard to typhus the difference is still more marked. Here the decrease has been from 4,281 in 1869 to 940 in 1882, or rather more than 78 per cent. Even this result, enormously favourable as it is, does not give a fair statement of the case, for if we take the average of the three preceding years, which is only 538, we get a decrease equal to 87·4 per cent. A comparison of results in these two classes of cases furnishes of itself a strong argument in favour of the claim I make for sanitary medicine, for we may look on typhus as probably the most preventable disease of the zymotic class.

I will now compare the results just arrived at with what we find to be the case with regard to some of the diseases which are not included among the zymotics.

If we find that there is no decided and tolerably regular improvement with them, the case which I seek to prove must be greatly strengthened.

For illustration here I have taken rheumatism and diseases of the respiratory system (excluding phthisis and croup, which are now returned separately in the Registrar-General's tables).

Comparing the mortality curves for the same years of these diseases with the zymotic diseases to which reference has already been made, it will appear that while in regard to the former there is a certain amount of fluctuation, owing probably to climatic influences, there is no average tendency to diminution in the rate. In the case of the latter, on the other hand, there is an almost unbroken progress downwards from first to last.

The difference in the rate of decline in the deaths in urban and rural districts furnishes another argument. Taking from the Registrar-General's table the averages of the years 1847 to 1850 inclusive, the three decennial periods 1851 to 1880, and calculating in the same way the average for the years 1881 and 1882, the range is from 26·9 to 20·7 for the urban, as against 20·6 to 17 for the rural, the rural being 23·4 per cent. below the urban for the former period and only 17·8 per cent. for the latter. This shows that the towns have been gaining on the country districts in the matter of health. The inference is that sanitation has been better attended to in the towns, and also perhaps that in them, owing to density of population and other causes, there has been more room for improvement.

No better proof here could be adduced than the case of the city of Glasgow, where, owing to the sanitary work so ably inaugurated by Professor Gairdner, of the University, the first appointed Medical Officer of Health, and no less ably carried on by his successor, Dr. J. B. Russell, the "fever" death-rate has fallen from 16 per 10,000 in 1871 to 4·3 in 1881 ; and, whereas, in the epidemic of 1847, 11,425 cases of typhus were admitted into hospital, the average for the ten years 1873–82 has barely reached 310. Similar remarkable results are shown in regard to small-pox, from which there have been only 25 deaths in seven years in a population approaching half a million.

If it be asked what proof there is that these improvements in healthiness are due to the progress of preventive medicine and the increase of sanitary knowledge, I can only reply by asking to what else they could be ascribed ? It may be that the lessened consumption of alcohol which the revenue returns of late attest, and the spread of general education may have had some share in the result, although even here the influence of instruction in sanitary knowledge is not wanting ; but the considerations which have been adduced are sufficient, I think, to compel the belief, that in the main, improved sanitary organisation and the advance of the country in the ways of health stand to each other in the relation of cause and effect. But it must not be supposed that we have even now arrived at the summit either of our ambition or our ability, and what we have got ought only to make us desire and strive for more. There never was a time when there were so many workers in the field ; and with the researches which are being pursued on all sides into the ætiology of the more preventable diseases, with the philanthropy and statesmanship which are being brought to bear upon some of our most difficult social problems, we may well cherish the hope of as great an advance in the future on our present position, as our present is upon that which existed when preventive medicine was hardly thought of, an advance which will realise the estimate of eminent sanitarians of a death-rate not exceeding fifteen per thousand of population. Translated into numbers this would mean a saving of upwards of 100,000 lives in a year, over the lowest rate that has yet been reached in England and Wales.

There is also plenty of good work yet to be done, and opportunities are likely to occur in the practice of every one of you. You have brilliant examples too in such men as the late Mr. Netten Radcliffe, in whose comparatively early death the world of sanitary science

deplores the loss of one of the ablest and most indefatigable workers in the field of epidemiology.

Do not forget that there is personal as well as public hygiene, and that even inculcating cleanliness and the value of ventilation upon those classes of patients who are little likely without such teaching to be impressed with their importance will not be done in vain. Nor will you go far without meeting with examples of defective sanitation in the construction and arrangement of dwelling houses. When we find rats and mice in drinking water cisterns, over-flow pipes from the same led directly into soil pipes, house drains untrapped before entering the main sewer and unventilated, all of which I have seen lately in this West End of London in highly-rented houses, you may appreciate the scope there is for improvement, and the need for the diffusion of health knowledge among those at least who construct our dwellings.

A case which came under the notice of Mr. Balding, of Royston, is so remarkable that I refer to it more in detail.

Diphtheria recently occurred in a country house where from time to time there had been outbreaks, although not severe ones, of sore throat and diarrhœa. In making an investigation into the probable cause of the diphtherial attack, the drainage arrangements were overhauled and the following condition of affairs was found.

Close to the house was a large sewer into which the drains from the house and one from the stables emptied themselves. The house drains opened directly into parts of the house, one of them into a cellar communicating with the dairy, and they were neither trapped nor ventilated. There was an enlargement on the main sewer into which the house drains passed, and it was found that this part had not been cleaned out since the year 1811. In endeavouring to clean it out when the recent investigation was made sewage flowed back into it in great quantity, coming from the further part of the large sewer which was 125 feet in length and ended in a chalk pit that distance from the house. This sewer deepened at its further end where it contained over 8 feet depth of sewage material, the greater part being solid and estimated to amount to 1,700 cubic feet. It was ascertained that this part of the sewer had not been cleaned out for more than 80 years.

Cases like these point to the necessity of adopting some such plan as has quite recently been proposed in Glasgow, which seems in this as in so much else connected with advanced sanitation to be destined to take an honourable lead, of the appointment of an official whose duty it should be to survey the construction of the drainage arrangements of new buildings at least, without whose certificate a licence for their occupation should not be granted.

In contemplating the picture I have presented of what Preventive Medicine may be held to have achieved we must not, however, forget that even with the most sanguine anticipations realised we shall have disease, like the poor, always with us. Hence Curative Medicine will always retain its importance, and there is surely room for improvement also here. With increased precision in diagnosis, which we may hope for, we must attain to more successful therapeutics —and I include in the word everything, surgical as well as medical, that makes for healing—because our treatment of disease will rest upon a foundation of accurately observed facts. The recent advance in knowledge of cerebral localisation, with which Dr. Ferrier's name is honourably associated, points, as has been more than once suggested, to the possibility of successful surgical operations in this region. Who can doubt that if we could always come to an accurate diagnosis in the early stage of acute intestinal obstruction, which I may surely designate the opprobrium of medicine and surgery, the results of our treatment would often be more satisfactory? And is it too much to hope that with early diagnosis and immediate abdominal section the lives of some of those who now perish from perforations of the stomach or intestines might be saved?

In conclusion let me say that there are noble traditions connected with the school which you have chosen as the home of your study; where, to speak only of the illustrious dead, Sir Charles Bell, Campbell de Morgan, and Charles Murchison have laboured and taught; and we look to you to keep those traditions bright, and to reflect credit upon your foster-mother and your profession wherever your lot may be cast. If I may repeat anything I have said, it would be to urge you again to earnest work, remembering that whether your talents be ten or one, you will have to give an account of the use you make of them to a higher than any earthly power, and that although "art is long, life is short." In the words of the oldest and best of text-books, "Whatsoever thy hand findeth to do, do it with thy might; for there is no work, nor device, nor knowledge, nor wisdom in the grave, whither thou goest."

INTRODUCTORY ADDRESS DELIVERED AT UNIVERSITY COLLEGE.

By W. R. GOWERS, M.D., F.R.C.P.

Assistant Professor of Clinical Medicine in University College.

[Abstract.]

After a few words of welcome to the students, the lecturer said that he had too much sympathy with the interests that were foremost in their minds to pass in his remarks beyond the occasion that had brought them together, or to inflict upon them any scientific dissertation, even though he, in so doing, risked the charge often levelled at introductory lecturers of "talking platitudes." So he would begin with the most common place of questions and ask what was the study of medicine which they were there to commence? Even in outline the process was formidable. This was the first of many lectures to which they would have to listen. He was almost afraid to say how many they were—not less than two thousand. It was not their teachers' fault. It was ordained and prescribed by the "powers that be" that they should learn all things by oral instruction. Many subjects could not be taught otherwise. As regards others he for one thought that more latitude might be shown and that the method in which knowledge was acquired might be left in larger degree to the choice of the student. Nor was the prospect less formidable if the nature of their work was looked at. Those who aimed at the higher qualifications had to know something about half the sciences into which human knowledge was divided, and of many they would have to acquire not an elementary but a practical knowledge. Indeed the sciences were few that have no application, direct or indirect, to the vast subjects of disease, its prevention and its treatment. Almost every branch of knowledge, whether it dealt with earth, or air, or water, with the physical properties of matter, or the phenomena of organic life, with the processes of thought or the social economy of communities, touches at some point the varied problems that present themselves to the practitioner of medicine. Nor could it be otherwise. Their life-work was to be the prevention, cure, and alleviation of the diseases of man. "What-

ever else man is," the lecturer continued, "he is part of the material world, and is, moreover, the highest, most complex phenomenon yet discovered, or likely to be discovered, that in which the interactions of force attain the highest elaboration known to us. The most complex form of matter, the most delicate adjustment of force is presented by a nerve cell of the brain. Of the slow, never resting tide of creative development, sweeping on, through ages far behind us, ebbing and flowing, and yet with sure advance, moulding into new forms and higher phases the mysterious elements on and in which it works, with the ultimate result, the highest issue is the subject of your study. But high position entails corresponding instability. The exquisite capacities of organic bodies are obtained by a delicate adjustment of restrained energy, ever striving to gain some lower and more stable state—held in an equilibrium that is destroyed by the slightest change, and is indeed in constant process of destruction and renewal. Hence by altered constitution and function a living organism responds to every variation in the conditions outside it, to every change in temperature, mechanical forces, chemical constitution of its surroundings, and doubtless, although more obscurely, to every alteration in electrical and perhaps magnetic states. To every change in earth or air the human frame is sensitive. Each motion of our rolling world, each wave of light from the far-distant sun, each wind that bears to us the warmth of tropic seas or cold of mountain snows, determines some change in us. An alteration in the soil on which we live may modify completely the processes of life." Hence they might see how wide must be laid the foundation of a general acquaintance with the sciences that deal with the material world before an intelligent superstructure as of special knowledge could be reared. The lecturer then spoke of the double object of their work. "You are here for education as well as for instruction. You are here to acquire the knowledge of fact and rule and theory that you are to apply hereafter in the daily work of your lives, but you are here also to obtain the mental training needful for that application, needful to enable you to use your knowledge under conditions that are ever new and ever changing, to distinguish fact from fancy when they present themselves in unfamiliar aspect, and often in borrowed garb—to trace new facts, new laws among the manifold combinations of phenomena that will be around you in every day's work. Happily, in each department of science the mental training needed to pursue it may be gained in the acquisition of the facts already known. No separate education is needed. If you study well, both wisely and thoroughly, the subjects that form your course, you will be, at the end of the time, qualified, not only in the diplomatous, but, in the fullest sense of the word, to enter on independent work. But the extent to which you obtain this training is chiefly dependent upon yourselves. It is at once an important, perhaps the most important, part of your work, and it is that in which your teachers can do least for you. They can put before you fact and reason, but they cannot, or can only in small degree, compel you to observe, to realise for yourselves the value of evidence, to distinguish fact from theory, and to be on guard against the lurking fallacies which bristle on all sides. They can test your knowledge, and they or others can 'coach' you and 'grind' you, but the process of the instillation of facts represented by these somewhat inapt metaphors may leave you wholly untrained for subsequent work. Your "coach" may carry you through the lofty portals of Lincoln's Inn and Pall Mall, or the lower archway at Blackfriars, and leave you altogether unfitted for independent progress. Your 'grinder' may pass you through his mill with such success that you emerge a flabby mass of factitious atoms kept in the semblance of form by the sack of a diploma, but it is only by your own continuous effort that you can gain cohesion and the power of organic growth. And this effort must be made from the commencement of your studies. Each of the subjects that occupy your earlier years has its own method, and yields you a separate training. In each facts are ascertained and theories verified in a different manner, and this you should endeavour to keep before you in your daily work. This subject has been often dwelt on, and once here with an ability that I cannot hope to rival. I would refer you to, and urge you to study carefully, an introductory lecture that you will find in the library, bearing the revered name of Parkes, and I will content myself with a few instances to show you what I mean."

The various subjects of study were then passed in review, and the special value of each subject, as a means of mental training, was pointed out. The lecturer then urged upon the students the importance of endeavouring to entering into the feelings and modes of thought of the sick so as to ensure considerate tenderness in dealing wite them. "To enter," he continued, "fully and deeply into suffering, with the sympathy that is not only intelligent, but 'with suffering' is impossible. A doctor's work would then be simply beyond human endurance. To him, as to no other, the darkest side of human nature is ever open; in his ears the deep undertone of sadness rings through every chord and melody of life; now in the wail of pure distress, now the discords of passion, now rising into the sweet but still sad music of patient resignation and self-sacrificing love. Well is it for the world that it is possible to understand without enduring, or the helpers would be few. As it is our lives are often saddened by the suffering that we cannot but share. No statement more untrue was ever uttered than that familiarity with suffering destroys the known capacity for sympathy in medical men. It is one of the many statements that are made regarding the members of the medical profession, their actions, their feelings and their motives, which could not be made of the character of the profession as a whole if the value of its work were duly appreciated." Some illustrations were then given of the value of medical work to the community. About twenty thousand medical men were in actual practice in Great Britain and Ireland. Taking into consideration acute diseases, accidents, the perils of childbirth, and diseases avoided by timely warning, it was probably under the mark to assume that each practitioner was instrumental in saving one life per week. If that was thought excessive let them take half that number, 25 lives a-year. A large number of practitioners demonstrably saved that number in childbirth only. But in the aggregate even that represented no less than half a million of deaths prevented every year. Was not this a service to the community before which many others, more highly honoured, pale? And to this must be added the far more numerous cases of disease prevented or relieved. Take again the progress of sanitary science which has added to the average longevity of the nation. To whom was this due? Sanitary work had passed so largely into special hands that it was almost forgotten that the movement was all but entirely due to their profession. Medical science had furnished the knowledge of the causes of disease which had shown the way for prevention. It was chiefly to the efforts of practitioners of medicine that they owed the stirring of public opinion by which the progress of sanitation had been rendered possible, and to-day in town and country over the face of England, in the form of crowded cities and in the fairer cottage homes, where Nature spreads her beauty over man's neglect, it was the members of their profession who

laboured untiringly in the cause, against the obstructions of ignorance, prejudice, and almost criminal apathy, obstruction too often successful until the neglected warning received some fearful emphasis, as by the present outbreak at Kidderminster, or the awful avalanche of death that had fallen on the city—of all in Europe the fairest and most foul. And in this labour, which was part of their ordinary work, their motive was pure benevolence. If the efforts they were at present making with their whole energy, were at once successful, one half of the practitioners of medicine must starve or find some other calling. Search where they would, in the wide scenes of the present or the narrowing vistas of the past, they would not find another instance of such a body of men making it a main and constant object of their lives to deprive themselves of half their livelihood. But the fact, of course, excited no surprise, because every man who entered the profession, in so doing, put self and self interest aside so far as his work was concerned, and placed the welfare of others before his own. To approach his work in any other spirit would be monstrous and intolerable if it were not inconceivable. And this, being a matter of course to themselves, was taken by the public as so much a matter of course to them, that it was almost ignored in the public estimate of medicine. Medicine was ranked the lowest of those callings that were by courtesy termed learned, and the highest social dignity conferred on her most honoured members was the lowest that could be offered.

It has been stated that many of the lives they preserved were worthless to the nation. But when every allowance was made for these, the residue of useful workers saved, whose existence was the nation's strength, was vast enough to startle the most indifferent, if assessed at the lowest estimate of its money worth. But the objection suggested a wider survey of their work. If they looked not at the individual or the nation, but at the race, what were they to say of the influence of the art of medicine? The question was part of another of the highest interest, but also of profound obscurity—the part played by disease in the physical progress or deterioration of the human race. The problem was one towards which many lines of discovery converged, and its elucidation would be their grandest crown. It was sometimes said that the influence of their art upon the race was to promote its deterioration, by saving from death many sufferers from constitutional maladies, or from actual disease many who possessed a morbid tendency, by whom that tendency was passed on to their offspring, and thus the area of liability was slowly widened. It had even been urged, and this repeatedly, that the influence of modern civilisation, and of the medical art as part of it, was to cause an infraction of the great law of the survival of the fittest. But fitness was always relative. If the conditions of life were so changed that the weaker might survive, the change in the conditions at once transmuted the unfitness that would be fatal to the fitness that secured survival. Whatever the influence of medicine in favouring the extension of morbid tendencies, it was simply an instrument of the moral force that increases with human progress, finds its repression in benevolence and philanthropy, and had become a recognisable factor in moulding the future of the race. But he thought it open to question whether the gloomy forebodings were justified. Their knowledge of the influence of heredity was constantly increasing, but this afforded no evidence that the influence itself was increasing. The facts on one side of the question were obtrusive, on the other inconspicuous. Even in families with strong predispositions it was the common rule for many more to escape than to suffer, in each generation. There was a constant tendency for the race to clear itself of disease, as a polluted river purifies itself as it flows. Were it not for this, civilised man would long ago have disappeared from the earth. And was it too much to hope that the growth of social wisdom and the progress of medical science might succeed in augmenting this influence to a power far greater and more effective than at present? In another province, that of zymotic disease, the promise of the future was still more distinct, and few could doubt that the investigations now in progress, and the discoveries already made, discount them as they might, would be followed by practical results of the first importance, although another element in the causation of these diseases, the strange fact of specific liability, remained as obscure as ever.

The lecturer then passed from the work of medicine to its rewards. These were small enough, as recompense was weighed in the common balance. A living; that was something. Bread, with cheese, perhaps, to each who wisely selected and patiently pursued his course of work, placing duty before pleasure, fitness before inclination; permitting no errant impulses, no distaste for dirty labour, to determine his career, or any fancy-fledged ambition to tempt him to a flight in which he could not hope to soar. They had other rewards, if they did not close their eyes to them. Much of their daily work might be drudgery, some might be repulsive, but the subjects that engaged their energies were of transcendent interest. The knowledge they had gained opened to them the world of nature. Human life, in its development and its decay, and the ever-varied phenomena of disease, presented problems of the highest interest. But greater still should be the consciousness of the character of the work they were doing. Failures must come, and, baffled in many a struggle, they might despair, but they should remember that the good they did was always greater than they could see. Their failures were obtrusive; their greatest triumphs almost imperceptible. "Nature effected a cure," it was often said, and said correctly, but it was certain that nature would often effect a death, were it not for the guiding, although often imperceptible, influence of medical treatment. Hundreds of persons were every day saved from disease without the fact being known either to themselves or to those who saved them. The choice of a sphere of work which the students made or ratified that day, would leaven their whole future life, and the knowledge that the world was better for each hour's labour might be and ought to be to them a constant and enduring satisfaction.

In conclusion the lecturer said, "There may be—nay there must be—many here to-day for whom the words of welcome with which I commenced should be changed to those of farewell. Your student life is almost over; the graver work for which you have been training is close at hand, and soon in town or country, upon sea or shore, you will have entered on it. Wherever your lot may be cast, it may be near, it may be far away, under strange stars, in unfamiliar scenes, your college looks to you—and will not look in vain— to keep her name unsullied, to make your place of study a passport among members of your calling, a guarantee of honour and trustworthiness. She looks to you—and will not look in vain—to carry on the high traditions of her past, to keep the torch she hands you brightly burning, to lighten the dark places of human life. She looks to you—and will not look in vain—to take your part, humble or high, in the great contest with disease and death, in the great work of gathering the knowledge that is power, and the wisdom that is life. Vast is the field of labour; no hand unwelcome, no effort to be spared. Fierce is the contest, unremitting; ever spring afresh the hydra-heads, and

for no moment can the sword be sheathed. But it is not for ever, not at least in present inequality. Who that reads, with thoughtful eye, the signs of this century's advance, can doubt the issue? Though still the storm clouds gather, and the sky is dark, yet far away, and slowly coming nearer, there is light. Not we, nor our successors for many generations yet to come, may see it, save in glimpses few and faint, but come it will, and you may aid its advent. You may lessen the present gloom, and you may hasten the dawn, which, now flushing only here and there a mountain-peak, shall surely broaden into perfect day."

INTRODUCTORY ADDRESS DELIVERED AT ST. GEORGE'S HOSPITAL.

By FRANCIS H. CHAMPNEYS, M.A., M.B. (Oxon), F.R.C.P.,

Assistant Obstetric Physician to the Hospital.

[Abstract].

THE lecture was addressed to the students, and touched on various subjects, devoting considerable space to midwifery as a mental and moral training. It opened with a "lost fable of Æsop," which the lecturer, as a graduate of a "lost medical school," thought a not inappropriate contribution. After a word of welcome to the new students, joined with the assurance, from the lecturer's personal experience, that before many days were past they would feel as if they had been at St. George's all their life, Dr. Champneys referred to Dr. Barclay and Mr. Cæsar Hawkins, both of whom had died within the year, alluding particularly to the cultivation of prognosis by the older school of physicians, a study much despised by the modern student, although of paramount importance. After enumerating the work and results of Mr. Cæsar Hawkins' life, he said: about his character there is but one opinion, and that is that he was a man of noble mind, whose strength of will and tenacity of purpose was only equalled by his sincerity and unselfishness. It is perhaps owing to the absence of self-seeking, which was one of his characteristics, that he died undecorated, except by the judgment of the highest court of appeal, that of his peers.

He then referred to the various motives for entering the medical profession. Some enter it because they are the sons of medical men, while, with others, the life of hard work and few relaxations which they have witnessed, acts as a deterrent. Others enter it because they are not allowed to become soldiers or sailors, and hope to join the army or navy as medical officers, with the view of healing the injuries which it was their earliest ambition to cause. Some join the profession from the love of it; and it is at least free from the class which selects one or two of the other learned professions simply with the view of gaining a certain status in society, and losing the identity and surroundings of the individual under the generic term of the profession to which he belongs. Among the motives which may influence men in choosing a profession, are included these two; first, the hope of being stamped or marked by the profession, and, secondly, the hope of leaving their stamp or mark upon it; and in proportion as we accomplish the second, we help to accomplish the first, both for ourselves and for others. The second of these objects depends partly on eminent skill, partly (as the world is constituted) on what is called success, but far more on the honour and uprightness, which perhaps attain their highest development in the best (not always the decorated) members of the medical profession. It is a pity that questions of national importance on the subject of health and disease should be at the mercy of class prejudice or vulgar popular oratory, but this seems in a fair way to be remedied. On the whole, a learned, honourable and chivalrous doctor is probably not less honoured and valued than a learned, honourable, and chivalrous lawyer or clergyman. For whose approval should we work? The world is the assembly of those least competent to judge; but, laying aside the highest appeal, we should make up our minds to act in such a way as to earn our own approval, to win, in any reasonable way, the approval of our peers, and to trouble ourselves but little beyond this. If we reverse this order, we may win applause in the lowest court, but we shall jeopardise our standing in the court of our peers, and shall inevitably lose our self-respect. As a money-making concern, medicine is inferior to business, and fortunes made nominally by medicine are often, in fact, the result of a nucleus judiciously manipulated in the neighbourhood of Capel Court. It speaks volumes for the interest and attractiveness of the profession, that our ranks are constantly swelling, and swelling with men whose education and social status appear to improve every year, in spite of the fact that its members are comparatively poor. Professional advertising is an abuse against which every member of the profession should set his face. There are three things (it has been said) which a poor man cannot afford to keep: pride, a horse, and a conscience. All undoubtedly involve an outlay, or, in other words, a loss of money; but the first and the third must be kept at all price, and the second acquired when necessary. The lecturer then gave hints to the students as to the mode of pursuing their work, warning them against premature specialisation, such as the exclusive study of microscopy. He then described the "microscopical man," the "practical man," and the "roi-fainéant." He advised them to play football, but regard dancing with suspicion.

"I should not feel that I had discharged my duty," he continued, "did I not devote a few words to the department of work to which I am more particularly attached; and, first, I would remind you all that the various licensing bodies, having a short time ago succeeded in grasping the fact in elementary statics, that a body propped on two legs is almost necessarily in a state of unstable equilibrium, have added to the two previous legs of medicine and surgery the third leg of midwifery. The result is, on one hand, a great addition to the stability of medical education, which is now tripod; but, from your point of view, it amounts to the fact that it is now practically impossible to gain possession of any respectable diploma without the acquisition of a tolerable knowledge of midwifery and the diseases of women. Whatever your line of practice may hereafter be, you cannot avoid it. Nor, indeed, is it right that any practitioner should be ignorant of any of these subjects, neglect of which is apt to be followed by grotesque and egregious blunders, which may prove disastrous to him who makes them. In general practice you will find that this knowledge, almost more than any other, will stand you in good stead; and early in your career you may have cause to bless the nights which you spent, perhaps unwillingly, surrounded maybe by squalor, alcohol, and the heteroptera. As a subject for instruction, I know none which surpasses midwifery; its problems are largely exact, involving, as they do, mechanical principles which can be actually demonstrated by diagrams and models; and in practice, diagnosis and prognosis are quickly illustrated by the event. The nine months' cycle of pregnancy carries us into one of the most interesting regions, in which physiology is so modified

as to border on, and therefore to illustrate, pathology; while in embryology (with part of which we necessarily deal), we are brought face to face with the most vitally interesting speculations. In the sub-department of the diseases of women, our interests are different; this is still in its infancy, and the greatest discoveries lie almost beneath our eyes—if we could only see. This subject, the paramount interest of which lies with the investigator, appeals to us, therefore, in a different way.

"As a moral training, and as a training for practice, midwifery seems to me again most valuable. The student or the practitioner is brought into close and intimate relation with his patient, and he learns to be patient with her—not to be brusque with her, but considerate; even to endure reproaches unjustly uttered during paroxysms of agony, knowing that a patient in pain is a patient insane. To be patient too in waiting. No sooner will his patient be rid of her troubles than her gratitude will make up, and more than make up, for any inconsiderate utterances. And here I must testify to the patience and kindness of students, often the last to lay claim to these, or, indeed, to any other virtues, which has repeatedly instructed me. Not once or twice have I known the fire lit, food bought and cooked, and the tenderest care displayed in the maternity department by students to those from whom they had nothing in the world to expect. In the course of your practice, you will probably have to treat some of the poorest, and you may have to treat some of the highest. You may think it will be difficult to be ready with the appropriate manners for each. Not at all; it would, of course, be an error to treat a duchess like a charwoman, but there can be no harm in treating every charwoman like a duchess, and you will be right all round.

"To be a good practitioner you must also have 'clean hands (antiseptically as well as ethically) and a pure heart.' And while recognising the fact that Nature generally manages her own affairs best in her own way, and that your duty in most cases is to watch how she does it, you must be minutely acquainted with her ways, or you will not detect the first beginnings of mischief, and will not be prepared to help her when she is untrue to herself. For this reason the study of the normal anatomy and physiology of pregnancy, labour, and lying-in is of paramount importance, and cannot be too conscientiously pursued. Indeed, without this, your understanding of abnormal conditions and processes will necessarily be lamentably inadequate."

AN ADDRESS, DELIVERED AT THE OPENING OF THE WINTER SESSION AT QUEEN'S COLLEGE, BIRMINGHAM.

By JAMES SAWYER, M.D. Lond., F.R.C.P.

President of the Clinical Board, Senior Physician to the Queen's Hospital, and Professor in the College.

I HAVE the honour to address this assembly of the friends and of the students of Queen's College, upon the occasion of our formal inauguration of a new academical year. I am sure we may congratulate ourselves, with unqualified confidence, upon the continued growth and prosperity of the Birmingham medical school, and particularly upon the progress and promise of this college. As an old student of Queen's College, I am proud to note that my *alma mater* was never sounder in her constitution, nor stronger in public and professional confidence. For many years our college has pursued, with unbroken success, a broad and enlightened educational and administrative policy. As the central home and authority of the Birmingham medical school, our college has proved that that school can only be enduringly strong while it is inclusive and united. The college has sought, with much and signal success, to draw within and around it, in individuals and in institutions, all that is best in the teaching strength of our great community. In its wise coalescence with the Sydenham College, in its intimate connections with the General and the Queen's Hospitals through the Clinical Board, in its well organised dental department, in its reciprocal arrangements with the Mason Science College, by which our medical students have access to the unsurpassed educational advantages of that great institution, and in the extension and specialisation of its own teaching, the Queen's College at Birmingham has so developed and consolidated its resources that it stands confessed to-day, without question, and beyond cavil, one of the largest, one of the most advanced, and one of the best equipped schools of medicine in this or in any other country.

Examination is the dominant "note" of our current medical instruction. Two or three generations ago the leading principle of medical education was imitation. Now the student has set before him examinations he has to pass; then the apprentice had before him a master to imitate. Now our teaching is professorial, and to a class; then it was more personal, and to an individual. There is much that is good, doubtless, in our present system of medical education; but I am afraid we have scarcely preserved all that was good in the system we have set aside. I daresay we have been gaining in professional knowledge. Have we not been losing somewhat in professional wisdom? We have been growing in scientific precision. Have we not sometimes been loosening, and are we not in danger of losing, some of our best traditions?

I have been asked to say a few words especially addressed to the medical students who are here this evening, and who are about to begin or to resume their professional studies. To them I say—fellow students, you come to our school to get knowledge. It will not, I am sure, be the fault of our school if each of you do not get in it, in fair proportion, the knowledge it offers you. In our laboratories, and in our books, in our museums and in our lecture-rooms, and in our hospital wards and mortuaries, your several teachers, in their expositions and in their practice of the sciences and arts they profess, will continue to submit to your senses—to your eyes and to your ears, to your hands, to your noses, and to your mouths—an endless store of objective facts in the sciences and arts of medicine; and in each of you it will depend upon himself—upon your capacity, and upon the motives which guide your conduct—how much or how little of this objective knowledge you shall hold and make your own.

I am not going to urge you to seek knowledge for its own sake. Knowledge, like money, health, justice, truth, and virtue, is not an end in itself, however startling this fact may be when you first apprehend it. Knowledge, in its final appraisement, is only an intermediary means, which many good people are in the habit of mistaking for an end. Now, why do you come to seek the knowledge, the particular knowledge, which we offer here? Because you want to become members of the great profession of medicine; and you are probably impelled to seek entrance into our profession for no single or separate reason alone, but rather as the resultant of a variety of motives, amongst which, scientific interest, honourable pursuit of worldly

means, and pursuit of distinction, are probably the most powerful.

Now I am afraid many of you are apt to imagine, as most people do when they begin preparation for a particular career in practical business or professional life, that all you want now, that all you need seek, as students, is knowledge. You have heard very often that knowledge is power, and you are prone to think that if you have knowledge all things else will be added unto you. But surely this is not so. Knowledge is not power ; but only its material. Knowledge is only power when wisdom points its employment. Even now and here, when and whither you have come to seek and find knowledge, you must seek and find wisdom too, if you would grow in the skill and grace which the life you have chosen requires of you. "Knowledge comes, but wisdom lingers." As a psychological product, wisdom is infinitely more elaborate than knowledge. It is knowledge kneaded with exquisite complexity into every phase of your consciousness. Wisdom is knowledge which patient experience has intimately blended with your emotions and with your desires, with your volitions, and with your beliefs. It is knowledge polished and finished, qualified and refined, tested and checked, proved and guided, by every pleasure which has thrilled you, by every pain which has cast you down, by every consideration you have felt of fitness and of prudence, of utility and of duty.

The systematic knowledge we offer you here in this medical school, in our instruction in the sciences and arts of medicine, is a matter-of-fact knowledge ; it is a duly arranged aggregate of objective experience, which we present, through your senses, to your minds. Take care, take most watchful care, that you get a clear and certain perception of every fact which is placed before your understanding ; for clearness of reproduction is impossible without previous clearness of perception. But the wisdom I ask you to seek, even now, is more than knowledge ; it is far different. When you have begun to apply knowledge, in thought and action, to the best ends and true purposes of life, you have begun to be wise. When your self-love, your search after your own happiness, has been tempered by knowledge into prudence, and when your sympathy for others has been tempered by knowledge into duty, you have begun to be wise, for you have been putting down your pride, learning the love of mercy, and growing in the power to judge and act rightly. But, you may say, tell us how to do so much; how to get knowledge, to learn prudence and duty, and to be wise to do rightly. I answer, make it your business, even now, while you study to get knowledge in this college and in our hospitals, to study also the words, the acts, and the lives of some of those of our profession who, without trifling with truth, and without pliancy of principle, have achieved success, and honourable competence, and the love and confidence of their brethren, and so you shall learn how to prepare for professional life, as well as for professional diplomas.

Medical Times and Gazette.

SATURDAY, OCTOBER 4, 1884.

An unusually large gathering of past students met in the Great Hall of St. Bartholomew's Hospital on Wednesday evening to keep up the old established custom of dining together. Mr. Luther Holden presided, and in all there were about 150 present. Sir James Paget, in proposing the health of the chairman in a most felicitous speech, alluded to the fact of his close friendship with him during the past half century. After dinner the company adjourned to the library where, for the first time, the fragrant weed was not forbidden.

The winter session at Guy's Hospital was duly inaugurated on Wednesday, October 1st, by a *conversazione* held in some of the large medical wards and in the museums and class-rooms. A very large area being thus devoted to the purpose, the somewhat inconvenient crowding which marked the same event last year was avoided. The decorations of the wards, if somewhat sombre in tone, were arranged in excellent taste and formed a picturesque background to the tables upon which the objects of interest were displayed. A very considerable exhibit of surgical, microscopical and electrical instruments formed the nucleus of a miscellaneous collection of articles of greater or lesser interest. Of the former class may be mentioned Hearson's Thermostatic Nurse, which excited much curiosity. The prizes and certificates were distributed to their respective winners by the Treasurer, who in a subsequent speech gave a somewhat gloomy account of the state of the hospital treasury. A feeling reference was made by Dr. Wilks to the loss which the hospital had sustained by the death of Dr. Hilton Fagge, since the last opening-day, and to the influence for good which his example and character had exercised upon the Medical School.

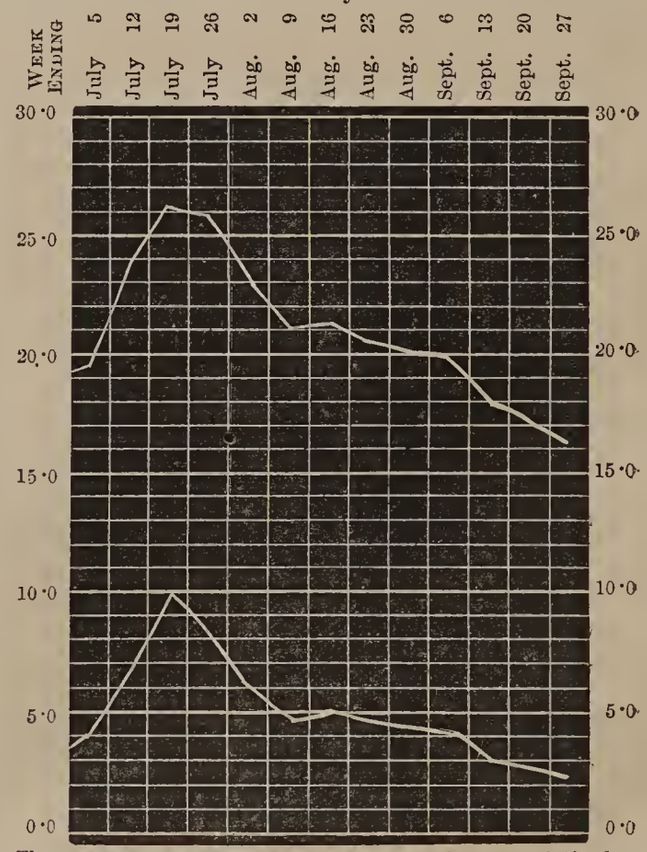
The opening of the Medical Session at King's College followed the time-honoured lines of distribution of prizes, introductory address, and dinner of old students in the evening. The meeting in the afternoon was well attended, new students and old gathering in force to give welcome to the new Principal of the College, Dr. Wace, who had been invited to give the address. The Dean of the department, Dr. Curnow, having presented the prizemen and scholars, the serious business of the address commenced. Dr. Wace justified his position by reference to the strong personal ties which had bound him to the medical profession through his friendship with the late Dr. Anstie. He then passed on to make reference to the changes which had taken place in the social status of various members of the College staff, the baronetcies conferred on Sir William Bowman and Sir Joseph Lister, and the transference of the late principal to the important post of Metropolitan of Sydney. The advantages of the union of the medical school with the other departments of work in the College were touched upon briefly and then the address turned to the work of medicine in recent times, the great strides which had taken place since Harvey's famed discovery in the last century, and the work of modern times in the hands of Koch, Klein, Pasteur and Lister. A happy allusion to the work of Ferrier, "touching the very springs of mental action in the brain," was greeted with much applause. The line of argument then turned to the need of "sympathy" in medicine and to the cultivation of those qualities which should prevent moral as

well as intellectual failures. Dr. Wace very naïvely remarked that he had come to the conclusion that brains were very common and very cheap articles, that there existed any amount of them running to waste about the Strand at the present time, and by a well chosen simile of the various forms of knives, those combining both handles and blades being the most serviceable, he pressed home the importance of not neglecting the healthy frame of mind while caring for the healthy state of the body. Both conditions are to be cultivated, the former no less than the latter. Amid a sympathetic silence he concluded by a touching reference to the illness of Dr. Baxter, "a typical example of a King's College man." The address, which had throughout commanded the attention of those present, received the customary vote of thanks, moved by Sir Richard Wilbraham and seconded by Sir William Bowman. In the evening a very well attended dinner of Old King's College Hospital students was held at Limmer's Hotel, Sir William Bowman presiding; he was supported by the various members of the staff and numerous old students, Surgeon-General Partridge, Dr. Buzzard, Dr. George Johnson, Dr. Bartrum, Professor Wood, and others, proposing and responding to the various toasts. It is satisfactory to learn that the new medical session thus happily inaugurated already shows signs of a satisfactory accession of new students.

We publish this week some more letters on Educational Over-pressure, and we hope to publish a further series in our next issue. We again repeat that the subject is too serious a one to be allowed to be burked by official optimism, and we have reason to believe that some of our leading politicians outside the Education Department are not altogether disinclined for an enquiry such as we have advocated. It lies mainly with the medical profession, and especially with those members of it who have large experience of children's ailments, to bring forward the evidence that will convince our leading statesmen of the necessity for an investigation. The lips of the teachers will be necessarily sealed until Government bids them speak, but we are glad to see one of their organs, the *Educational Times*, cordially supporting our suggestion. It holds that "it is quite time that the effect of the educational arrangements on the general health should be investigated by professional and disciplined enquirers, and be reported on with judicial impartiality." It cordially supports Dr. Crichton Browne's proposal to institute a sanitary and medical inspection of schools, a periodical measurement and medical examination of the children; while it fully realizes the importance of medical opinion in connection with the subject. "The medical profession," it says, "may render great service to education at the present time by collecting observations on the question of the effect of the present educational arrangements on the general health; but it should at first aim simply at tracing the nature and extent of the alleged evils, and the causes to which they are immediately due, leaving out of the question, for the present, the ultimate causes and the apportioning of blame between the different bodies who are responsible for the educational administration."

It is not only in England that the subject is attracting attention. In the section of Psychological Medicine, at the recent International Medical Congress, a report of which we publish in another column, Dr. Kjellberg, of Upsala, gave a startling description of the effects of excessive brainwork on the health of school children. The symptoms he had noticed were much the same as those met with in the out-patient rooms of children's hospitals in London and our large towns, viz., headache, sleeplessness, intellectual torpor, change in character, muscular weakness and spasm, culminating in hallucinations, and very often in sudden loss of consciousness. Statistics have been collected in the schools of Switzerland with the result that the cases of over-pressure are found to be so numerous that the cantonal governments are considering how best to modify a state of things so threatening. In most parts of the Continent, and especially in the Swiss republic, education has reached a much higher state of development than with us, and the results may be expected to be more striking. Let us take warning in time, and if possible seek to forestall the appearance of such startling effects as those described by Dr. Kjellberg. It would be deplorable if our efforts to get on in the world should result only in a nation characterized by "physical and intellectual torpor."

The deaths in London last week, the last of the third quarter, were 159 below the corrected average, and gave a rate of 16·1 per 1,000, a lower rate than has been recorded for three years. The deaths attributed to zymotic diseases numbered 190 in all, including 10 from small-pox, or 4 more than there were last week. Of the other infectious diseases, measles only reckoned 12 victims instead of 18 in the previous



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the third quarter of the present year.

week, scarlet fever had 26, or 44 less than the number that past experience would have justified us in expecting. Whooping cough is credited with 15, and diphtheria with 14 victims. The deaths from enteric fever were 18 as compared with 27 in the previous week. Amongst the non-zymotic, but still we would hope preventable, causes we notice that the deaths of 8 infants under one year in London are attributed to suffocation. Only three of the 28 great towns show a lower death-rate than London, viz.: Norwich, Brighton, and Huddersfield. The eight principal towns in Scotland cannot show nearly such a low mortality as London does, but they have a clean bill of health in the matter of small-pox, and the deaths from diphtheria in all taken together just equal those in London alone.

Dublin has been *en fête* this week, not less than two Congresses having assembled in that hospitable city. One of these was the Library Association of the United Kingdom, which assembled on Tuesday in one of the Halls of Trinity College, under the presidency of Dr. John Kells Ingram, Librarian of the College. The other was the Sanitary Congress, which met on the same day, under the presidency of Sir Robert Rawlinson, C.B. The first general meeting of the Sanitary Institute of Great Britain took place in the Lecture Theatre of the Royal Dublin Society, at 8 p.m., when the president, Sir Robert Rawlinson, delivered an inaugural address.

He alluded at the commencement, as in duty bound, to the improvements that had been wrought in the sanitary state of Dublin during the last few years on which matter his knowledge was of course most accurate, seeing that he was on a Royal Commission appointed in 1879 to enquire into the whole subject. The purification of the Liffey, however, he said, still remained to be settled, and here, as in the case of the Thames, he is a strong advocate of taking the sewage out to sea, instead of wasting money in trying to get a little out of it, or, as he said, spending thirty shillings in order to earn twenty. One of the great objects of the sanitarian of the present day he declared to be to check the prevalent sanitary ignorance, and under this head he referred to the enormous amount of money that had recently been spent in the South of Europe, as well as inconvenience caused, in the vain attempt to check the spread of cholera by quarantine. The proper remedies against that disease consisted in improved ventilation and daylight, a good supply of pure water and good sewerage and scavenging.

On Wednesday, Sec. 1, "Public Health," was opened with a paper by Dr. Grimshaw, the Registrar-General for Ireland, on the statistical measures of the Health Communities. The first point he dealt with was the fact that the death-rate did not by any means represent the amount of sickness in a district, some diseases, such as influenza, having no death-rate at all, so that as a means of estimating the amount of sickness in a district it was not always very reliable. Unfortunately, however, no other method had yet been discovered which would furnish results that could be used by the benefit societies. A death-rate of 40 per 1,000 did not necessarily mean that the place was twice as unhealthy as one which had a rate of 20 per 1,000; it indicated that the people of the latter had a more robust constitution, but nothing else. It was amongst people employed at unhealthy occupations, or in places where there was a large proportion of the very young or the very old that a high death-rate would always be found. A low infantile death-rate might be found with a high rate of mortality, and indeed that was actually the case in Dublin, the reverse of what was found in England. The explanation of these facts he thought lay partly in the emigration of the healthier adults from Ireland, and partly in the fact that in England mothers were much more liable to go out to work and leave their children at home.

On Thursday morning, Mr. C. P. Cotton, C.E., was to open Section 2 — "Engineering and Architecture"—with an address, and on Friday morning, Dr. Charles A. Cameron, Medical Officer of Health for Dublin, was to inaugurate Section 3 — "Chemistry, Meteorology and Geology" — in a similar manner. On Friday evening it was intended that Dr. Alfred Carpenter should deliver a closing lecture to the Congress, to which working-men were specially invited. In each section there was a good promise of papers and discussions.

The festive aspect of the Congress was not overlooked. On Tuesday there was a Public Luncheon. On Wednesday evening the Right Hon. the Lord Mayor and the Lady Mayoress entertained the members and a large number of citizens at a *conversazione* at the Mansion House, Dawson Street. On Thursday there was a banquet at the Shelbourne Hotel, at which His Excellency the Lord Lieutenant was present. To-day (Saturday) is devoted to excursions, and in the evening a Hospital Fête is to take place at the Agricultural Buildings, Ball's Bridge.

And this leads us to say a word about the most interesting feature of the Congress—the Sanitary or Health Exhibition, which is being held in connection with it, and which will remain open for three weeks. The Health Exhibition at Ball's Bridge was formally opened by the Lord Mayor, on Tuesday afternoon. It is under the auspices of the Sanitary Institute, and in it the latest improvements in sanitary appliances are exhibited and their utility practically tested. There was a large attendance at the opening ceremony, when also the awards of the judges were made. The judges are H. C. Bartlett, Ph.D., F.C.S.; Professor W. H. Corfield, M.D.; Professor de Chaumont, M.D.; W. Eassie, C.E.; Rogers Field, B.A.; J. W. Peggs, M.A.; H. S. Snell, Ernest Turner, Henry Law, and Dr. Louis Parkes.

Dr. William Moore, President of the King and Queen's College of Physicians in Ireland, has been appointed a Justice of the Peace by the Right Honourable the Lord Chancellor of Ireland.

***

Miss Mary Wardell's Home for Scarlet Fever Convalescents, which was opened by Royalty in July, will be ready to receive its inmates in the course of a few days. We recently had an opportunity of quietly inspecting the home, and examining the very complete arrangements made for the health and comfort of the patients, all of which bear testimony to the anxious care and thought, as well as to the funds, that have been spent upon them. The home stands on the very top of the high ground north of the village of Edgware, and, in the language of the estate agent, commands extensive views of the whole surrounding country. Built originally a year or two ago for a private residence, it has been adapted with great skill to meet the requirements of a convalescent hospital, while retaining much that reminds one of a country house. The drawing-room has been converted into a day-room for the poorer patients, whose interests in such a home as this must necessarily be regarded as paramount, and we are sure that they could not wish for a more cheerful one in which to complete their peeling. The other rooms on this floor are devoted to the private patients and the offices. On the second and third floors are the bed-rooms for both classes of patients, all of them airy, lofty, and well-lighted rooms, distinguished from one another by bearing each the name of one of the Committee or Medical Council—Alcock, Fayrer, Stewart, Broadbent, Squire, Billing, Bevan and others. A large room on the first floor, lighted from above, and originally destined for a billiard table, has been fitted up as a play-room, and will soon resound, we hope, with the pattering feet and happy laughter of children, in place of the click of the balls and tramp around the green cloth, which were the sounds intended for it by the builder. Below it is the kitchen. The bath-rooms, with their large and little baths, remind one of the Three Bears, and close by, but cut off from the house by a ventilated passage, are rows of earth-closets, with a lift, by means of which the soil can be removed direct to the garden. The bath water and other slops are conducted into the grounds and distributed by an arrangement of drains to the subsoil. All the sanitary arrangements have been carried out under the superintendence of Mr. Rogers Field, and a plentiful water supply has been obtained from the Colne Valley Company at a cost of 250*l*. The grounds, which may be considered as one of the most important features of a home of this sort, are as extensive as need be, and will furnish many of the children with such a playground as they seldom get a chance of disporting themselves in. We may add that the home is intended exclusively for women and children, and that the scheme which Miss Mary Wardell has made her life-work cannot be considered complete until a home has been provided near by for adult males. Funds, however, are as yet not forthcoming for this extension; indeed, they are much needed to carry on the present home with due efficiency.

At the meeting of the Metropolitan Asylums' Board, on Saturday, Messrs. Bull and Son's tender of £79,000 for building the proposed Convalescent Scarlet Fever Asylum, at Winchmore Hill, was, after some discussion, definitely accepted, and it is to be hoped that the work will be commenced without delay. It must be remembered that this new asylum is only an instalment of the works which must be undertaken if the recommendations of the Royal Commission on Infectious Asylums in the Metropolis are to be carried out. It is estimated that between 25,000 and 30,000 persons are annually attacked by scarlet fever in the metropolis, and for the vast majority of these cases accommodation must be provided by the Asylums' Board, if proper isolation is to be secured. Each case must be kept in hospital at least eight weeks if it is not to prove a disseminator of the disease when discharged, and from this, by an easy calculation, it will be seen that the beds available for scarlet fever cases in the institutions of the Asylums' Board ought not to be placed at a lower figure than 3,000. Even when the new asylum with its 500 beds is opened, the Board will not have more than 1,500 beds for scarlet fever, or half the estimate. There will still remain at large in the metropolis an average of 1,500 scattered cases of the disease, for the most part inefficiently isolated and inadequately treated. As new blocks of artisans' dwellings are erected, in most of which cases of scarlet fever are not allowed to remain, the call on the Board's resources will still further increase. The prospect to the ratepayers is appalling; but speaking of London as a whole, it only means taking out of one pocket to put it into the other.

Everyone will be glad to hear that the plumbers have at length been roused to a sense of the new responsibilities thrown upon them by the increasing complexity of our sanitary appliances. It was high time, for almost everybody has a tale to tell of disease, or at any rate discomfort, caused by the disgraceful neglect or ignorance of some worker in lead. The plumber bears pretty much the same relation to one branch of preventive medicine that the chemist holds to one branch of therapeutics; but while we take care to examine and certify every drug compounder, we have no guarantee whatever of the knowledge or competency of the plumber we employ. His work, it is true, is open to inspection, which is more than can be said of the work of the chemist; but inspection is very generally neglected, and even where it is carried out, it proves too often little but a solemn farce. The Plumbers' Company have at length taken the matter up, and will probably hold a conference at the Health Exhibition in the middle of October, in combination with the National Health Society and the Sanitary Institute, with the view of discussing the available remedies for the present unsatisfactory conditions. The establishment of boards of examiners of plumbers' work, the registration of journeymen plumbers, and the advisability of applying to Parliament for the extension of certain Sanitary Acts, will be among the subjects of debate.

It is always well to see ourselves as others see us, though sometimes it is possible we have a much quicker eye for our own shortcomings than any of our critics. This is what Mr. Thiselton Dyer—who by the way is not altogether a layman in relation to medicine—said in the course of his address to the

Pharmaceutical students on Wednesday. "I have a strong suspicion that it is the mediæval flavour, if I may so express it, that hangs about our pharmacy which has of late engendered a considerable scepticism about the action of drugs altogether. And this is by no means a popular heresy only, but it is an attitude shared by many very capable members of the medical profession. With such men I am afraid the interest of a case rather seems to stop with what they call 'the confirmation of the diagnosis.' The practical and common-sense world will, however, always demand that the medical art shall go further than this. I am bound to say I am entirely of the same opinion. It is for this reason that I am anxious to see our list of first-class drugs—such as quinine and ipecacuanha—very much increased. I can conceive an ideal therapeutics, in which we should have drugs in our *répertoire* which would stimulate or inhibit every function of the organism. An unfortunate obstacle comes, however, in the way in the shape of the fact that there is in this country surprisingly little disposition to engage in the investigation of new remedies. The study of rational therapeutics can hardly be said to exist; at the most it is attacked in a disconnected or spasmodic fashion by men who have too much else to do." We cannot help thinking that Mr. Dyer's reading of the phrase "rational therapeutics" is somewhat different from that attached to it by the leading minds in the medical profession.

The new rules and regulations for the future management of the North West London Hospital, which have been drawn up with the aid of Sir Spencer Wells, Mr. Marshall, and Mr. Ernest Hart, were submitted to a special general meeting of the Governors on Tuesday last, and at once adopted. With this, a disagreeable incident in the history of the hospital terminates, one that seriously crippled its usefulness and did not reflect credit on any of the parties concerned. Let us hope that a prosperous career is in store for it.

A Royal Warrant is about to be issued by the War Office authorities, changing the designation of the Army Medical Department and the Army Hospital Corps to the Medical Staff and Medical Staff Corps respectively. The alteration will date from October 1st, a date we hope of the best augury for the future prosperity of the department.

Dr. Sykes's elaborate report for the Borough of Portsmouth for 1883 has lately been placed in our hands. The total number of deaths was 2,446, giving a death-rate of 18·6, which is unusually low, though not the lowest on record. Southsea, as usual, is the healthiest part of the borough. As regards infectious diseases, there has been a wonderful immunity; it is true there have been a few cases of small-pox, the disease having been introduced on three separate occasions, but on only one of these did it spread at all, and none of the cases proved fatal. The epidemic of scarlet fever which Dr. Sykes foretold last year, did not make its appearance, and the borough has now for seven years enjoyed a comparative immunity from that disease. Enteric fever seems to be the only one of the preventable diseases which has been at all rife throughout the year, and there is no denying that 93 deaths from this disease reflects unfavourably on the sanitary arrangements. A satisfactory scheme seems to be on hand for the disposal of the sewage, and only awaits a little more money before it is put into execution. As last year, so this, Dr. Sykes is able to report good progress in the matter of house drainage, and he says that in some parts of the borough whole rows of houses may now be seen provided with efficient ventilation, shafts, and intercepting arrangements. The compulsory notification of infectious diseases has been introduced during the year, and Dr. Sykes anticipates great results from it when it shall have been got into thorough working order. He points to the opening of the Milton Hospital for the isolation and treatment of infectious diseases as of immense importance in preventing the spread of infectious diseases. There is an elaborate chart, showing the number of fatal cases per week from infectious diseases and from disease of the respiratory organs throughout the year, and a map of Portsmouth, marking the houses where cases of enteric fever, diphtheria, and scarlet fever have occurred, or at any rate come under the notice of the Sanitary Authority during the year.

The latest reports from Italy record, on the whole, a diminution, though with slight fluctuations, in the cholera at Naples. Wednesday's bulletin noted 136 new cases and 57 deaths, including, however, 26 who were already under treatment. At Genoa, 52 cases with 30 deaths were reported, a rather high rate of mortality it will be admitted, the total number of cases in the province of Genoa amounting to 102, with 53 deaths. The returns from the other infected provinces show a decided diminution of the epidemic. A contemporary announces that between August 21st and September 26th there occurred in all 10,486 cases, with 5,548 deaths.

THE OCTOBER ORATIONS.

Everyone must admit that the method of opening the Medical Session which prevails at the majority of the London Hospitals is not altogether satisfactory. The most that can be said for it, is that it is more satisfactory than the method which prevails at the minority. We should be sorry to see the introductory addresses given up until some one has invented a ceremonial of equal impressiveness and more vitality. At present, the writing of the inaugural address often falls to a man who undertakes it more as an irksome duty than as a privilege. He is conscious of having little or nothing to say, and it bores him to say it, or rather to write it. In such a case he can hardly expect his audience of all ages to be otherwise than bored by listening to it. Even the lecturer who feels that he has something to say, and takes some pleasure in saying it, is not in a much happier predicament. If he addresses himself, as he is more or less bound to do, to the freshmen the chances are that he fails to interest his older hearers; while, if he writes for the senior students for the profession and for the public, what he says will certainly be above the heads of the

newly entered students. It needs little short of genius to combine these two incompatible functions. It is easy for any one who has passed through the medical curriculum to give valuable words of advice to those who are just entering upon it. It is not difficult for a man of talent to say something original on the thousand and one matters of pregnant medical interest which will be worth the attention of the profession. But to deal with commonplaces in a way that shall interest both students and practitioners is only within the power of a man who combines the highest gifts of thought and expression. Such a man is not often found amongst the class from which inaugural lecturers are usually chosen. Their *mêtier* is an entirely different one, and to expect them to deal with platitudes with the golden mouth of a trained and polished speaker is to hope to get a square peg into a round hole. Round pegs which will fit that particular orifice are few in number, and the attempt to find a dozen every year to fulfil the necessities of all the hospitals would meet with lamentable failure. To us the moral is obvious. If we cannot amalgamate the medical schools for the purposes of education, as we have more than once advocated, it should at least be possible to amalgamate them one day in the year for the purposes of an introductory lecture. We can imagine no ceremonial which would more happily impress the new students with the importance of the step they have taken, or make them more vividly realize the magnitude and importance of a medical education than a monster meeting, presided over and addressed by one of the great masters of thought and eloquence in our own and other callings. They would remember such a day as one of the great landmarks in their lives, and the burning words of a Gladstone, a Liddon, a Huxley, or a Paget would rouse in them thoughts and emotions, and leave behind them memories, such as can hardly be expected of more than a tithe of the addresses now delivered. Why can it not be done?

But it is time to turn from these speculations to the more special subject of this article—the actual addresses delivered on Wednesday last. Several of these we publish in full or in abstract in the present number, and a glance at them will be sufficient to show that scarcely one of them satisfactorily fulfils the two functions of an inaugural address as stated above. The high-toned and eminently sensible address delivered at St. Thomas's Hospital by Sir Risdon Bennett is one which will be read throughout the profession with the greatest interest and appreciation; but its author would probably admit that, with the exception of scattered sentences, it is entirely above the heads of the raw boys, who have come fresh from the schoolroom to join the great profession of Medicine. Dr. Gowers, in the almost too eloquent address which he delivered at University College, probably succeeded in interesting both classes of his hearers better than Sir Risdon Bennett, but it must have needed a very clever and thoughtful student, even amongst those to whom he was bidding farewell, to have followed him appreciatingly into his interesting speculations on the apparent opposition between the medical art and the Darwinian doctrine. Dr. Finlay, at the Middlesex Hospital, gave most valuable advice to the students, and his clear account of the triumphs of preventive medicine can hardly have failed to interest the more advanced of the freshmen. But there are few topics in the domain of medical science which can be made intelligible to the juniors, and yet be treated in such a way as to interest the seniors. What success Dr. Finlay achieved in this respect he owed both to his happy choice of a subject and to his lucid mode of dealing with it. At the Westminster Hospital Dr. Hughes Bennett delivered an address eminently adapted to his audience, entitled "The study of Medicine as a source of intellectual gratification as well as of practical utility." He sketched with a faithful pen the disadvantages of the calling of Medicine as compared with other professions, and then in words, which we trust have deeply stamped themselves upon the minds of his hearers, showed the compensating advantages—its purity and dignity as a science, the fascination of searching for and acquiring information, the opportunity it gives for the culture of all the faculties, for the play of the imagination, and for the display of originality or invention. "There is probably no human pleasure," said Dr. Bennett, "which is so permanent, or which reaches so lofty a degree, as that which emanates from an ardent and successful career in scientific research and discovery." And lest it should seem that he was painting a prospect which could only be enjoyed by the chosen few, he went on to illustrate the fact that it is quite an error to suppose that vast intellect and learning are necessary to appreciate and profit by a study of the phenomena of Nature. Medicine, in short, though the most contemptible of trades was the most noble of professions. All this, it is true, has been said before, but it is a theme which will bear repetition, especially when treated as Dr. Bennett treated it. Dr. Champneys' lecture at St. George's Hospital was a good example of the students' address pure and simple. It abounded in happy points and was replete with excellent advice. The address delivered by Dr. Sawyer, at Birmingham, short as it is, contains sentences which at once bring it up to, if not above, the level of the longer addresses. Take these for instance,—"Knowledge is not power; but only its material. Knowledge is only power when wisdom points its employment." "Wisdom is knowledge which patient experience has intimately blended with your emotions and with your desires, with your volitions, and with your beliefs. It is knowledge polished and finished, qualified and refined, tested and checked, proved and guided, by every pleasure which has thrilled you, by every pain which has cast you down, by every consideration you have felt of fitness and of prudence, of utility and of duty." In these extracts we seem to hear the man of the world rather than the man of science; but that is the fault of the men of science and not of Dr. Sawyer. From the Rev. Dr. Wace, who delivered an admirable address at King's College on the 1st, we naturally expected considerations of that sort, and we got them. The fault of the majority of introductory addresses is the want of the "human" element, and we are glad to point to two addresses this year which are distinctively informed by it.

PHOSPHORUS IN THE TREATMENT OF TUBERCULAR DISEASE.

Tubercular meningitis is generally admitted to be one of the most hopeless of the diseases which a physician can be called upon to treat. This, doubtless, is the explanation of the fact—which comes also as a somewhat humiliating commentary on the present limitation of our knowledge and the instability of our theories as to the cause and nature of the malady—that the recommendation of a certain preparation of phosphorus, made a short time since by a correspondent of one of our contemporaries, led, in the course of two or three days only, to the exhaustion of the whole of the stock then in the hands of the manufacturers as well as of the retail dealers. The value of some combinations of phosphorus, of the hypophosphites especially, has been lauded by several competent observers, in the treatment of pulmonary and other affections which were believed to own a tubercular origin, although we experience some difficulty in assigning its just value to the specific adjective in this connection, inasmuch as one of the advocates of the hypophosphite treatment has recently stated his belief that the drug is only of real curative value in those cases in which the typical bacilli are absent. Phosphorus, pure and uncombined, however, is seldom or never administered as a curative agent in cases of tubercular meningitis. The remedies now most employed may be said to be chosen mainly with the object of avoiding or of allaying those symptoms of cerebral irritation which are usually the most painful, as they are apt to be the most conspicuous, features of the disease. This, of course, is treatment only of a palliative sort; it does not, admittedly, go down so far below the surface phenomena as to attempt to deal explicitly with the formation, the growth, the very existence of that tubercular plasm whose presence is the exciting cause of the symptoms by which we have learned to recognise its nature. And palliative treatment, in cases such as these almost invariably are—cases in which the hopelessness of recovery is so enormous, and so generally admitted, that it effects and seems almost to justify a therapeutic paralysis — really resolves itself, if we dare to look the matter in the face, into a barely-disguised ordering of euthanasia. Cases of complete and permanent recovery from "tubercular" affections of the lungs (whatever be the precise nature of the lesions grouped under that rather vague terminology) occur much less rarely than the pathologist of a generation since would have believed possible. Good observers hold that there is evidence of similar favourable results having been attained in some cases of encephalic tuberculosis, despite the greater delicacy and importance of the structures involved in the cacopraxis, and this even in patients of an age at which the nervous centres are specially susceptible, and the whole bodily economy less capable of resisting the depressing influences of disease. But such observers are, as a rule, the first to admit that these instances are among the rare and happy surprises—the fortunate accidents—and by no means the rule of practice. Their total is so few, and their occurrences are so far between, as to force us to the conclusion that recovery, when it does take place, is in spite of, rather than because of, the therapeutic measures which have been used; a conclusion which is only further strengthened if we admit, as some would have us do, that many recoveries from tubercular disease pass unnoticed simply because the disease itself has not been recognised.

Phosphorus, given in the uncombined state, is recommended in various conditions of ill-health which are supposed to be connected with some form of "nervous" disorganisation. No one doubts that the pure drug is at least potent; and there is ample evidence that, in some cases at all events, it is valuable. Phosphorus is generally regarded as a nervine stimulant; when given in therapeutic doses it probably has no claim to such a qualification. One at least of the stimulant properties with which it is commonly credited—an aphrodisiac action—is, as Dr. Phillips insists, simply non-existent. It is probably far less an excitant than a corroborant or conservator of nervous energy; and hence, in appropriate cases, its action is strengthening rather than exhausting. There is a form of "nervous" headache in which phosphorus gives prompt relief; in that condition of langour and undefinable *malaise* from which some young people of a tubercular diathesis are apt to suffer, it often proves most useful; and in certain neuralgias, and especially in the neuralgia of nursing women, to whom the usual hæmatinics have perhaps been given in vain, it commonly acts like a charm. We are scarcely justified then, it seems, in regarding phosphorus as a direct stimulant to cerebral activity; its action is less perhaps on the nerve cell than on its surroundings, and especially on its blood supply; and if its therapeutic effect is displayed rather in the husbanding of static nervous energy than in securing its too ready dissipation, we should have less dread of administering it in those conditions of disease in which the nervous centres are apt to be simultaneously excited and exhausted. The popular application of the *ohne Phosphor keine Gedanke* theory scarcely accords with the teachings of modern science, which again attaches less importance than formerly to the two per cent. with which phosphorus is accredited in the composition of brain-tissue. Indeed, we might say that phosphorus is more important to the maintenance of nervous energy than to the display of nervous activity; that it is less essential as a nerve food than as conditioning nerve nutrition; that it is more directly concerned with nervous health than with nerve work.

In addition to this view of the value of the drug, the possibility of its action as a directly curative agent in cases of tubercular disease is suggested by a consideration of the results claimed for phosphorus in the treatment of rickets. In 1872 Wegner published the results of experiments showing the effects of phosphorus, given in oily solution or in emulsion, in solidifying the growing bones of both animals and human beings. Kassowitz (*Arch. f. Kinderh.*, B. 5, H. 3 and 4) has repeated and extended these experiments. Like Wegner, he found that under the influence of very minute doses the compact was increased at the expense of the cancellous tissue; but he proved, in addition, that this increase was due to a shrinkage of the

medullary spaces, and not to any fresh deposition of bone. On gradually increasing the dose, however, a point is reached at which the action of the drug appears to be reversed, so that cancellous tissue is found even under the periosteum, and the medullary spaces are increased in size, with the formation of numerous greatly dilated blood vessels. The rachitic process thus artificially produced is an inflammatory one, and is displayed in the ends of the diaphyses. In some of the animals experimented upon, the sciatic nerve of one side had been divided; but as this made no difference in the results as affecting the two limbs, it may be concluded that the drug acts through the blood and not by nervous influence. Since 1879 Kassowitz claims to have treated 560 rachitic children by the plan thus suggested, giving $\frac{1}{120}$ to $\frac{1}{60}$ of a grain a day, with remarkable and uniform success. The value of this treatment of rachitis is supported by Soltmann, but is opposed by Schwechten, and by Weiss of Prague. The results of the experiments on which it is based, however, have a direct bearing upon the treatment of tubercular disease by phosphorus. If small does of this remedy produce marked constriction of the blood vessels, especially in young and rapidly growing tissue, it does not appear unreasonable to suppose a gradual starvation of tubercular nodules, with consequent shrinkage and desiccation. Cases of "cured tubercle" are recognised by the discovery of encysted caseous or cretaceous masses; and it is noticeable that those drugs which have been found useful in tubercular meningitis (although mostly given for other reasons), such as opium (Bristowe) codeia, (Harley), chloral, bromide of potassium, &c., possess the power of diminishing the calibre of the blood vessels. Practice is the only bar at which appeals of this kind can be judged; as yet we are still in the region of theory and empiricism on this question. We would raise no hopes, we have no ambition to see an addition to the list of so-called "specific" remedies. But tubercular meningitis is a very fatal disease, for which at present we know of no hopeful treatment. If we agree with Trousseau that "imminent peril justifies the extremity of daring," we may not unreasonably receive without prejudice a plan of treatment which comes before us with at least some theoretical advantages. Some interest freshly roused in this direction will at all events do good if it helps to secure for the new edition of the "Pharmacopœia" the details of some trustworthy and practical method of administering pure phosphorus. In this, as in some other points, the present edition is as misleading as it is behind the achievements of private enterprise.

REVIEWS AND NOTICES OF BOOKS.

THE THROAT AND NOSE.[1]

Four years have already elapsed since the appearance of the first volume of a text-book on the Diseases of the Throat and Nose, which, from its own intrinsic value and from the well known position of its author, at once obtained recognition as a standard work. The second volume, albeit somewhat delayed in its production, is now before us and completes the work as promised by Dr. Morell Mackenzie at the outset of his undertaking. In its arrangement it is modelled closely upon the plan adopted in its predecessor, and deals with the subject of the diseases and abnormal conditions met with in the œsophagus, the nose, and the naso-pharynx. Far more attention has of late years been devoted to these regions than was ever formerly the case, a result no doubt attributable to the more extended use of the laryngoscope as an ordinary instrument of diagnosis. Affections of the pharynx and œsophagus, which used formerly to be regarded more as subjects for discussion than for treatment, have now been brought within the range of practical surgery, and an authoritative treatise, dealing with each in turn in a thorough and scientific spirit, is now a most welcome addition to the standard medical literature of our time.

To all who are familiar with the first of Dr. Mackenzie's volumes, it will be sufficient for us to record the fact that his second volume is compiled in a no less thorough and painstaking manner than its fore-runner and hence possesses an equal value as a work of reference. Apart from its usefulness in this respect, however, we must confess to a slight feeling of disappointment in its perusal, to which we may take occasion to refer later on. Divided into three sections, dealing respectively with the gullet, the nose and diseases of the naso-pharynx, the work is arranged in a series of shorter or longer chapters, in which each affection is described in systematic order. Again, as in his former chapters upon the pharynx, larynx, and trachea, Dr. Mackenzie prefaces his subjects with a brief *resumé* of their history. Perhaps the most important part of his work is that which treats of the affections of the œsophagus, or gullet, as he prefers to style it throughout the book. Of all parts of the alimentary canal, the gullet is the most difficult to deal with surgically, and even from the physician's point of view has received, until quite recently, a smaller share of attention than has fallen to the lot of the more accessible parts within the abdomen. With the introduction of new methods of diagnosis, however, fresh facts are brought to light not only with respect to pathological changes, but also to the variations of the normal physiological processes which do not indicate disease. Among these methods, auscultation naturally takes a prominent position and has, within the last few months, become the subject of closer investigation at the hands of Kronecker and others, whose labours will doubtless find ample recognition in any subsequent editions of the work before us, which at present contains but little more upon the subject than is to be found in the general text-books. The unfortunate occurrence of a devastating fire in the warehouse of the printer has effectually prevented Dr. Mackenzie from taking advantage of the most recent researches, destroying, as it did, a whole edition of his book on the eve of its publication several months ago. Of another and still more direct means of investigation, viz., œsophagoscopy, a more novel account is given. The use of the œsophagoscope, in various forms,

[1] A Manual of Diseases of the Throat and Nose, by Morell Mackenzie, M.D. Lond. Vol. ii. Diseases of the Œsophagus, Nose, and Nasopharynx. London: J. and A. Churchill, 1884.

appears to have been only occasionally successful until in 1880 the author devised the plan of introducing an ingenious form of skeleton speculum, by which he was enabled to inspect the interior of the œsophagus in 37 out of 50 cases. The natural difficulties which combine to oppose the introduction of foreign bodies into the gullet, however, will probably render the most perfect form of œsophagoscope an instrument of only occasional usefulness, and it is a significant sign to that effect, that throughout his book Dr. Mackenzie only mentions one or two cases in which its use has been followed by any important result unattainable by other means.

The diseases of the gullet are discussed in turn, each being fully described and in a few cases exemplified by typical instances occurring for the most part in the author's own experience. These chapters form a most complete summary of the principal facts that have been established with respect to the different diseases by observers and workers throughout the world, and in every instance a full reference is appended to the original article or book referred to. But herein lies a part of that feeling of disappointment to which we have before alluded. The chief desire of the reader of Dr. Mackenzie's work is to ascertain the views and to profit by the recorded experience of a practical physician who has had exceptional opportunities of studying and observing the diseases of which he writes. The reader will find in the present volume a vast store of information, each item carefully arranged and scrupulously ticketed with the name of its presumably rightful owner, but he will at times be inclined to pause and reflect upon the advisability of accepting the assertions of these authorities not otherwise known to fame, and will look for guidance to the composer of the book. It must be confessed that in very many instances he will look in vain.

The discussion of stricture of the gullet opens up the subject of the respective merits of the operation of œsophagostomy and gastrostomy. In common with all practical surgeons, Dr. Mackenzie gives the preference unhesitatingly to the latter, and describes the indications for the operation and the details of its performance with some minuteness. While making mention of the service which Mr. Howse has rendered to the profession in combating the dangers and difficulties of gastrostomy, it might perhaps be more clearly noted that the essential point in its success, viz., the delay in making the opening into the stomach until after adhesions have formed, was entirely original in his hands. The subject of paralysis of the gullet is one which is probably unfamiliar to a large section of the profession, and the author's observations upon it will be read with much interest. He would classify several forms of palsy, according to their central, peripheral or local origin, the former occurring chiefly in association with other grave lesions about the medulla oblongata. The local forms would appear to be of frequent occurrence. A more detailed account of a few illustrative cases would however be welcome out of the large number of patients to whom Dr. Mackenzie incidentally refers as being cured annually by electricity.

Passing now to the middle section of the book, which deals exclusively with affections of the nose, we must again recognise the immense amount of labour and care that has been expended in the preparation of the work. In his anxiety to do justice to his predecessors in the field, the author never omits to unite the name of the authority to the record of the fact, theory, or observation for which each is responsible. *C'est magnifique, mais ce n'est pas Mackenzie.* The perusal of the minor differences of opinion between lesser lights than he, is a poor compensation for the store of information and thought which even the labour of compilation alone must have engendered. That one practitioner in Illinois has twice treated nasal polypus with perchloride of iron, while another has been no less successful in Baltimore with chromic acid, strikes us as a form of difference which may fitly be compared to the immortal contention of Tweedledum and Tweedledee, and certainly forms a sorry substitute for the deliberate opinions of Dr. Morell Mackenzie. With respect to operative interference in cases of nasal tumours, an account is given of the theory and practice of a long series of operators, and the relative merits of evulsion, abscission, and removal by galvanic cautery are discussed. While giving a decided preference to the latter in certain cases, the author would still make free use of the forceps in removing the deep-seated tumours, and especially those which are firmly attached to bone. It cannot be denied that this subject of the treatment of non-malignant tumours in the nose is one of very considerable importance, and we may express the hope that in any future edition of his book, Dr. Mackenzie may find room for some further details with respect to the operative proceedings necessary for their removal, even though it be at the expense of some of the chapters dealing with less familiar conditions.

The chapter upon "hay fever" is practically identical with the shilling pamphlet on the subject, published by the author in the early part of the present year. The most important parts of the article are derived from a paper published in 1873 by Blackley, of Manchester, a work which the author describes as a model of scientific investigation. This fact was however somewhat overlooked by the chorus of daily and weekly newspapers, which combined to trumpet forth Dr. Mackenzie's praises during the month of May last. "Some," said Malvolio, "have greatness thrust upon them," and, perhaps, we ought rather to condole with the author on thus having been compelled to pose as an original authority on the strength of his epitome of the works of others.

The concluding section on the naso-pharynx contains a store of information upon the affections of that somewhat neglected region. The extreme frequency of adenoid vegetations upon the vault of the pharynx has only become generally recognised of late years. The important physiological and even anatomical disturbance to which their presence may give rise, renders their proper treatment a matter of serious importance to the patient. Dr. Mackenzie's chapter on the subject, albeit he prefers to recount the experience of others in preference to his own, will do good service in calling more prominent attention to the disease.

As in the case of the first volume of the book, a German translation of the second has been published, simultaneously with the original, by Dr. F. Semon. Although the translator has faithfully rendered the text of his author, he has introduced in the form of annotations several important considerations in support of his views upon those subjects in which he differs in any material degree from Dr. Mackenzie. Of these, the most important are in relation to the removal of polypi and the treatment of adenoid vegetations. They may be read with advantage in association with the articles to which they are appended, and will be found to add very materially to their value as guides to treatment.

Of the complete treatise on "Diseases of the Throat and Nose" we must speak in terms of high praise. It is a monument of painstaking research and skilful arrangement. In reviewing it, we have ventured to suggest some points in which it might profitably be curtailed or expanded, but while still owning to a distinct feeling of disappointment at the scanty expression of the author's own opinions, and to the somewhat meagre dole from the treasures of his case-books which he has vouchsafed to us, we cannot but admire the splendid industry and perseverance which have been combined to place before the profession so complete and scholarly a summary of such a wide and varied field of research.

THE INTERNATIONAL MEDICAL CONGRESS.

Section of Laryngology.

(*Continued from page* 415.)

Dr. Bosworth (New York), Vice-President, in the Chair.

The Treatment of Bronchocele.

Dr. Morell Mackenzie read a paper on the Treatment of Bronchocele. The necessity of accurate diagnosis in the first place was insisted on as being the only basis of successful treatment. The following is a summary of Dr. Mackenzie's conclusions, which, it must be observed, do not embrace exophthalmic goître or malignant bronchocele: —(1) Simple goître (enlargement of the thyroid body) of recent origin and occurring in young persons, can, in the absence of endemic influences, generally be cured by the administration of iodide of potassium, and in many cases by counter-irritation. (2) Fibrous goître is best treated by parenchymatous injections of tincture of iodine. (3) Cystic goître can be most readily cured by conversion of the cyst into a chronic abscess, which is effected by emptying the sac, injecting a small quantity of a solution of perchloride of iron and allowing it to remain within the sac for three or four days. (4) When the cyst is of considerable size it should not be emptied at once, but should be tapped two or three times before the injection is used. (5) Removal of the thyroid body is a dangerous operation, which should never be performed for mere cosmetic purposes, nor even for the relief of urgent dyspnœa, except when less radical measures have failed. At the conclusion of his discourse, Dr. Mackenzie showed the instruments which he was in the habit of using, viz., the trocar and canula for tapping cysts, and a syringe of peculiar construction for injecting perchloride of iron without risk of the entrance of air.

An interesting discussion followed, in which many members of the section took part, Dr. Schäffer (Bremen), in particular, expressing the opinion that justice had not been done to the efficacy of galvanism, by means of which he had succeeded in curing many cases of goître.

Professor Ribbing (Lund) read a paper on the same subject, in which he maintained that there were many cases in which no mild measures were of use, and excision was therefore the only resource.

Photographing the Larynx.

Dr. Thomas R. French (Brooklyn) presented a communication on "A perfected Method of Photographing the Larynx." He stated that he had been making experiments in connection with this subject for more than two years, and after overcoming many difficulties, his endeavours had been crowned with complete success. He could now with perfect facility obtain sun-pictures of the human larynx, both in health and disease, and so rapidly that only one minute was required for each photograph. Dr. French claimed for his method the merit of being exceedingly simple—little, if any, knowledge of photography being necessary—and so easy in the working as to be available in ordinary every-day practice. The apparatus was described as consisting of—(1) a cone of metal containing two lenses for the concentration of the sunlight; (2) a small camera with the throat-mirror attached, which is held in the hand whilst the photograph is being taken; and (3) an ordinary laryngoscopic reflector. The concentrator is placed in the window in such a way that the sun's rays pass through the lenses, the light thus produced being very intense, without being at all hot. This stream of light is caught on the mirror fixed on the operator's forehead, and from it reflected into the throat of the subject. The small mirror connected with the camera is then placed in the proper laryngoscopic position, and when the larynx is seen to be properly illuminated the operator by pressing with his index finger on a spring, releases a shutter which in falling makes an instantaneous exposure. Dr. French exhibited his apparatus and demonstrated its manner of working; but, unfortunately, he was prevented from giving a public proof of his skill in laryngeal photography by want of sunlight. He showed, however, two portfolios containing a large number of photographs of the larynx both healthy and diseased. These had been taken from twenty-five different individuals. One set was particularly interesting, as being the result of a series of experiments on professional vocalists, and as showing the state of the parts during the production of different notes. The soprano, tenor and bass registers were represented in the utterance of each note through the compass of an octave and a half, and the contralto was shown throughout two octaves and a half. These photographs had been taken both with the subject's tongue protruded, and whilst it was kept in the natural position inside the mouth. Dr. French had also succeeded in photographing the posterior nares and exhibited several views of that region.

Galvano-Cautery.

Dr. Bayer (Brussels) read a highly interesting and practical paper on "Accumulators and Galvano-Cauterisation." He stated that accumulators, or secondary piles, made the practical application of galvano-cautery very simple; that they were easy to keep in order, and at once more durable and less costly than any other galvano-caustic apparatus, whilst they could always be depended on for certainty and efficiency of action, besides being extremely convenient for many different purposes, as for carrying about in private practice, electric illumination, &c.

Treatment of Diphtheria.

Dr. Seifert (Würzburg) presented a communication on the treatment of diphtheria. He maintained that the practitioner must be guided by the appearance of the throat, and that therefore the treatment must be essentially local in character. The diphtheritic product must be either dissolved by proper medicaments, or rendered harmless by antiseptic applications, but cauterisation must never be employed.

A paper dealing with the same topic was read by Dr. Berlème Nix (Denmark). Starting from the position that diphtheria is primarily a local disease, generated by specific

contagion, the point of invasion being the throat, and the system being secondarily infected by the false membrane, he argued that whilst the general condition must be carefully attended to, the principal part of the treatment must be the removal of the false membrane. For this purpose Dr. Nix maintained that no reliance could be placed on either caustics, solvents, or astringents. The treatment which he recommended was cleansing of the throat by means of gargles, syringing the parts with disinfectants, and removal of the false membrane with sharp spoons, followed by the application of lunar caustic to the scraped surface. Dr. Nix also spoke very highly of the results of Dr. Morell Mackenzie's method of treatment by exclusion of air from the false membrane by means of varnishes. In addition to the local measures, isolation of the patient, nourishing food, and fresh air were insisted on. Internal medicines were useless, except tonics and stimulants which were indicated in some cases.

The Training of the Singing Voice.

Besides the communication on the structure of the tonsils which has already been referred to, Dr. Bosworth (New York) read a paper on the proper method of training the singing voice. He contended that the importance of the larynx in the production of the singing voice was exaggerated, the fact being that the whole extent of the upper air-passages constituted the true organ of phonation. The use of the laryngoscope had led to faulty modes of teaching based on narrow conceptions of the mechanism of voice-production. Voice-culture, to be successful, must be grounded on physiological laws. Dr. Bosworth's chief practical conclusions were that training of the voice may be begun at an early age, provided it was restrained within prudent limits; that methods which over-develop a single factor in voice production are essentially vicious; and that compass of voice is to be gained by training the notes which the pupil *easily* possesses.

Laryngeal Paralysis.

Dr. Cadier (Paris) read a paper on paralysis and paresis of the larynx. He said that he had frequently observed cases of slight temporary paralysis—generally affecting the tensor muscles—of the vocal cords. Most of these had occurred in gouty subjects, and as a rule the speaking-voice was extremely little, if at all, affected. In singing, however, weakness and some degree of hoarseness in the upper notes were discernible, whilst on local inspection, congestion and deficient tension of the cords could be recognised. The causes of the condition were cold, overstrain, or even mental emotion, and Dr. Cadier had found that the most successful treatment consisted in the use of a moderately strong continuous current.

Dr. E. J. Moure (Bordeaux) read a paper, in which he strongly condemned the habit which many practitioners were in of treating tubercular disease of the upper air-passages, as well as other laryngeal affections, with sulphurous medicaments. The action of these on the larynx was irritative, *i.e.*, they caused congestion, and although this might be beneficial in certain conditions, it was absolutely contra-indicated in laryngeal phthisis. The only effect of such treatment must be to quicken a chronic disease into a state of acute mischief and so hasten the fatal issue. Dr. Moure did not hesitate to affirm that the worst examples of laryngeal phthisis which he had met with had been in cases where patients had been subjected to the sulphur-treatment (sometimes during no longer than a week or a fortnight) for a slight hoarseness, the cause of which had, as a rule, been misunderstood.

Dr. Ernest Schmiegelow (Copenhagen) related a case of nasal calculus occurring in a man aged 58. The patient had had an offensive discharge from the left nostril for sixteen years. On examination, a rhinolith was found curved around the lower turbinate bone. The stone was crushed with a lithotrite and removed. It was found to have no nucleus and to consist chiefly of inorganic matter (phosphate of lime, phosphate of magnesia, a little carbonate, with traces of chloride of lime). Dr. Schmiegelow drew attention to a curious symptom that had existed for a considerable portion of the time during which the patient had suffered from the complaint, viz.: frequent profuse perspiration on the left side of the head.

A mannikin for the practice of intra-laryngeal manipulations was exhibited by Dr. Garrel, of Lyons, and Dr. Michael, of Hamburg, showed some ingenious instruments intended for use in the operation of tracheotomy and in the application of local remedies to the larynx.

In conclusion we have great pleasure in stating that it was the unanimous opinion of the members of the section that the brilliant success of its meetings was in a large measure due to the admirable arrangements made beforehand by Dr. Wilhelm Meyer, and to the unflagging zeal, painstaking attention to detail, and uniform courtesy with which the Secretaries, Drs. E. Schmiegelow and H. Mygind (assisted by Dr. Hooper, of Boston, and Dr. Krause of Berlin) discharged their trying duties.

Section of Psychological Medicine and Neurology.

Morphinism and its Treatment.

Dr. Obersteiner (Vienna) on August 11th read a paper on this subject. The treatment, he said, varied according to the individual; most generally it was best to diminish the dose gradually; sometimes one might suppress the use of the drug altogether, suddenly, without any bad result. Throughout the whole treatment the employment of cocaine would be found beneficial. Sometimes one could foretell that even if one succeeded in checking the use of the poison, the cerebral phenomena which had already made their appearance would continue just the same after the withdrawal of the drug. In such a case it would be better to leave the matter alone, and not to undertake a long and tedious treatment which would be fruitless.

Professor Adamkiewicz (Cracow) communicated his researches on the pathological nature of *locomotor ataxy*. According to him the lesion always commences by two symmetrically placed S shaped zones of sclerosis towards the middle line and a little above the posterior radicular fasciculi.

Cerebral Affections due to Excessive Brain Work.

Dr. Kjellberg (Upsala) on August 12th communicated two papers on this subject; the first was headed "On the Influence of School Discipline and the Present Methods of Teaching on the Health of Youth," in which he showed that this discipline constrained the pupils to spend the greater part of the day in intellectual labour, that work so assiduous was to be considered as very dangerous for the normal development of the child, and that the lack of sleep and the sedentary life exercised a pernicious influence on his physical development. He then narrated instances of cerebral affections caused by excessive brain work, and demonstrated the remarkable analogies which their respective courses showed. Taken in chronological order these symptoms were headache, insomnia, intellectual and physical torpor. The character of the scholar changed completely; very soon there appeared muscular weakness, spasmodic movements, hallucinations, and very often sudden loss of consciousness. The determining cause was a partial chronic cerebral congestion of the grey substance of the hemispheres chiefly, caused by the excessive attention sustained too long and by insomnia. Statistics collected in the Swiss schools showed that the cases were so numerous that the various governments were considering how to modify a state of affairs so dangerous.

Bodily Exercise in the Treatment of Mental Disease.

Dr. Kjellberg made a second communication on the value of bodily exercise in the treatment of mental diseases. If one took the admission list and compared it with the discharge list, excepting the general paralytics, it would be seen that from 40 to 45 per cent. remained incurable from the date of their admission into the asylum. This lack of result was not to be attributed so much to the nature of the maladies under consideration as to the defective treatment adopted. The best form of bodily exercise was undoubtedly work proportioned to the strength and health of the patient. Every one knew the good results obtained in agricultural

districts, but there were a great many patients always for whom this admirable exercise was not available. There always remained in the asylum a number of idlers (not less than 50 per cent. of the whole number) for whom special arrangements were almost everywhere wanting, especially in respect of space large enough for long walks, and the establishment of a complete gymnastic apparatus. The essential condition to make this system of treatment effective was that during the night the patients should have complete rest, and therefore the system of large dormitories ought to be abandoned.

M. Paetz (Alt-Scherbitz) read a somewhat similar paper on the use of country establishments in the treatment of the insane. He insisted, even more forcibly than the previous speaker, on the part which such establishments were destined to play in the future in the treatment of lunatics. Even those whose disease ran a rapid course would derive great benefit from that open air exercise, the benefits of which it was no longer necessary for him to demonstrate.

M. Luhier said that the country establishments had likewise produced very good results in France, but in order to avoid disappointment it was desirable not to send thither indiscriminately all sorts of patients. It was desirable that these establishments should not be too far from the great centres in view of the difficulties of transport, and the incessant necessity for supervision which was required.

M. Steenberg gave a statistical review of the mental diseases and psychiatric institutions of the countries of the North. The points to which he especially alluded were the frequency of suicide in Denmark, and of suicide by strangulation, the form of melancholia which mental diseases generally assumed, and the predominant part played by syphilis in the ætiology of general paralysis.

Dr. Rohmell (Denmark) also affirmed that syphilis was very constantly found in the antecedents of the general paralytics, and that it was largely implicated in the origin of these mental disorders. This syphilis, he said, which at the commencement of the paralytic symptoms was usually of some years' standing, had often been of a very mild character, though it might also sometimes have given rise to serious troubles. The essential lesions found at the autopsy in these cases were adhesions of the meninges and atheroma of the basilar arteries. Specific treatment did not cure the disease, it only retarded its evolution. Perhaps one might suppose that the syphilis underwent some peculiar modification in its nature.

M. Magnan spoke of the great number of this class of patients who came under his observation. The antecedents of each patient were always carefully enquired into, and syphilis was found to be in a position to be accused in not quite as large a proportion as that given by the two previous speakers. The numbers, which he could not then give, were not, he thought, too high to be explained as a mere coincidence. When heredity, the great predisposing cause was present, syphilis might be the occasional cause, it was not the efficient cause, and it never was in any case. Syphilis might give rise to limited cerebral lesions, which might stimulate general paralysis, but in these cases the group of symptoms so characteristic of the disease was never complete. Besides, in these cases iodide of potassium produced excellent results, and both the authors had admitted that in their cases anti-syphilitic treatment had been without avail.

M. Gilles de la Tourette presented, on behalf of M. Charcot, an album containing photographs of all the cases of interest observed at the Salpetrière, and made a communication on salivation in nervous diseases, from a physiological point of view.

Lateral Amyotrophic Sclerosis.

Dr. Friedenreich (Copenhagen) on August 14th read a paper on this subject. He did not deal with the lesions of this disease now well known, but contented himself with offering some considerations referring at once to the pathological anatomy of the disease and its clinical aspect. Thus, according to him, the alteration of the white substance was not limited to the pyramidal fasciculi, but occupied in less degree the whole of the antero-lateral columns, especially in their deeper parts. Cases with progressive muscular atrophy could then be divided into four classes: (1) The hereditary or infantile progressive muscular atrophy with or without excessive development of fat (pseudo-hypertrophic paralysis). (2) The so-called juvenile form, rather a rare one, and one of which there had been but very few *post-mortem* examinations which appeared to be analogous to the infantile form. (3) Lateral amyotrophic sclerosis, a common disease with well defined lesions. (4) Protopathic spinal amyotrophy, the anatomical lesion of which was atrophy of the motor cells of the cord without lesion of the white substance. M. Friedenreich believed that these latter might be regarded as typical instances of lateral amyotrophic sclerosis.

M. Roth (Moscow) also made a communication on lateral amyotrophic sclerosis, somewhat analogous to that of the last speaker. The author, in his classification of muscular atrophies, almost denied the existence of the form known as that of the Duchenne-Aran type (our progressive muscular atrophy), which he said had not been clearly defined by clinical observation backed up by *post-mortem* examinations. In reference to infantile muscular atrophies, M. Roth admitted a hereditary form with or without pseudo-hypertrophy, and relying on a single case where lesions of the nervous system had been absent, substituted for the non-hereditary form (infantile paralysis) a new form of progressive muscular atrophy essentially protopathic without nervous lesions.

M. Gilles de la Tourette said that both from a clinical and a pathological stand-point it was impossible for him to subscribe to the views of the two last speakers, and more especially to those of M. Roth. If it was true that the discovery by M. Charcot of a spinal affection as well defined as lateral amyotrophic sclerosis had contributed not a little to throw a new light on the whole group of progressive muscular atrophies, it was no less certain that protopathic muscular atrophy (Duchenne-Aran) had come out of this trial victorious. Clinical observations, of which there were plenty, showed that this type had a special course of its own; and there was one characteristic in particular on which M. Charcot insisted, and that was the absence of exaggeration of the tendon reflexes, which was one of the characters of lateral amyotrophic sclerosis even when ankle clonus had not as yet appeared. The progress of the two affections was not the same, lateral amyotrophic sclerosis rapidly affected the medulla and led to a fatal termination much sooner than the proto-pathic form. It had been said that there had been very few autopsies. The speaker regretted that he was not in a position to bring forward statistics of the cases recently observed by experienced persons. In the same way he thought that tephro-myelitis, better known as infantile paralysis, ought not to be connected with pseudo-hypertrophic paralysis (even without hypertrophy), as M. Friedenreich proposed, or replaced by a new form on the strength of a single case as suggested by M. Roth. Clinically there were vital differences between them, both in regard to mode of onset and to course, whilst from the point of view of pathological anatomy, from the writings of M. Duchenne the younger, of Roger and Damaschino, and of others whose ability for the task could not be gainsaid, infantile paralysis must be acknowledged to be a well defined affection.

Religious Rites in the East.

M. Zambaco read a paper on this subject. He said that in Islamism there were several routes or *tariks* leading to Paradise, by special methods of adoring the Deity and the prophet. Numerous confraternities, having at their head *chehs*, gave themselves up to prayers with demonstrations, varied according to the body to which they belonged. These *chehs* were holy men, gentle, amiable, and intelligent. The religious exercises of these fraternities led to nervous excitement and neuropathic manifestations, resembling the hysterical outbursts of Christendom in past centuries, which might still be met with at the present day in some Christian lands. The sect of the Naxi-Bendi was one of the most important; assembled in their chapel, they would fall on their knees, facing the *cheh*, who watched them during the whole ceremony, which lasted about two hours, during which period all the worshippers had their eyes closed, the *cheh* alone excepted. The latter commenced by

offering up a short prayer, then came an interval for meditation, followed by a hymn, after which various nervous manifestations would make their appearance. Some would be seized with partial convulsions, others with epileptiform attacks. One would commence a violent rotation of his head, moving it 400 times a minute; another would strike his knees with his hands 200 times a minute, saying each time he did so "Allah," another would be seized with violent laughter, another with lamentations and a flood of tears. Some would be found in various attitudes, others would utter discordant cries. In the place set apart for women the scenes that took place were even more extravagant; every stage and variety of hysteric contortion could be seen, including catalepsy, choreiform movements of the head, and epileptoid attacks. Ultimately they all became calm, worn out with exhaustion. Towards the end of the performance, the *cheh*, after reciting some prayers in a low voice, would blow with all his might on the chest of those supposed to be exorcised over the region of the heart, and at each blast of his breath, which sounded as if it came from a metal tube, the subject would tremble. In this way the *cheh* treated a crowd of patients, mostly neuropathics. He also would go out into the village to those who were not able to be moved, but he did not exclude the calling in of medical practitioners. He also blessed the linen and clothes of patients, that they might recover their health by wearing them. Another favourite method of treatment with him was to write some prayers on a piece of paper, which would then be placed in a glass of water and be swallowed by the patient. There were other sects whose religious manifestations would be of interest to the neurologist, notably the Bavais, who fell into convulsions after having leaped and danced and oscillated in every possible direction, and cried aloud for whole hours together. When the paroxysm was nearly over, they were so analgesic that the skin and the limbs and trunk might be pierced with a brooch without their feeling any pain, and they would swallow bits of glass, living scorpions, and the leaves of the cactus.

In the discussion which followed the reading of this paper it was pointed out by some of the speakers that men as well as women were subject to typical attacks of hysterical nervous phenomena.

The Section would up its labours by an excursion to the Asylum at St. Hans, about half-an-hour's ride from Copenhagen, an asylum built to accommodate about 800 persons, under the supervision of M. Steenberg, the director, who, after showing his guests over the building, entertained them most hospitably at dinner.

INTERNATIONAL HEALTH EXHIBITION.

ARTICLE XVI.

Food.

Food, dressed and raw, natural and artificial, diets of prisons, of workhouses, of soldiers, of sailors—the luxuries of the west, side by side with those of the east—dinners illustrative of far away eating customs and manners and the manifold curiosities of food used by omnivorous man, have been displayed on a scale and with a lavishness never before possible in the whole of the world's history. The articles dealing with food in this journal must now be brought to a close, not from any dearth, but rather surfeit of material. First there are, however, a few miscellaneous matters which are important enough to deserve a brief notice.

Meat Extracts.

Liebig is the father of beef extracts; his analyses of flesh extractives and views thereupon gave the requisite impetus to the commercial manufacture on a large scale of extract of meat. Messrs. Brand, of 11, Little Stanhope Street, Mayfair, exhibit essence of beef, potted meats, sauces, and all sorts of specialities for invalids. These, so far as our examination goes, seem to be without exception of the highest excellence. Messrs. H. W. Brand, of 5, Vere Street, Oxford Street, also have a very similar exhibit, and so far as genuineness and palatability are concerned, their samples leave nothing to be desired. It may be well to observe, that although the two Brands are similar in name and business, they are altogether distinct firms.

Carnrick's Beef Peptonoids is practically a dessicated meat extract; the peptonoids are presented in the shape of a brown dry powder, with but slight odour and feeble taste. In portability and permanence a dry powder has advantages over a sticky extract. That it is equal or superior to ordinary meat extract has not yet been satisfactorily proved; as with so many other things of the same kind, actual comparative feeding experiments by perfectly uninterested observers are requisite to form a correct judgment.

Kreochyle is an entirely different preparation from any of the above. In the manufacture of ordinary meat extracts the fat, the soluble albumen and the fibrin are all as much as possible removed, the result being that beef-tea made from extract has been considered rather as a stimulant than a food. By infusing meat in water, kept always under the coagulating point of albumen, filtering, and then evaporating the fluid down to the consistence of a syrup in a vacuum pan, it is of course possible to obtain all the extractives together with the soluble albumen, and this we presume is something like the process adopted by the Kreochyle Company, who by this means, or some other, have succeeded in supplying a substance which is very fairly described as "liquid meat." Kreochyle then should be tried. It certainly ought to be found most useful in the treatment of wasting maladies, in inanition and in the artificial feeding of the insane.

Self Digestive Foods.

The idea of assisting the nutrition of a body inherently weak, by doing work outside the stomach and intestines which in robust health should be done inside, is essentially modern. Physicians have now not alone a goodly array of imperfectly known substances, such as ingluvin, ptyalin, pancreatin, diastase and pepsin, but also more or less completely digested foods at their disposal.

Messrs. Savory and Moore exhibit, among many interesting objects, a little case containing a thermometer and all appliances for "peptonising" foods. In the ordinary domestic manipulation of foods containing diastase or pepsin, but little attention is paid to the temperature of the water added in the first place or to the subsequent digestion; but provided with Messrs. Savory and Moore's case, any ordinary nurse would be able to prepare the food in a suitable manner. The same firm also display soluble meat jelly, infant's food, fluid meat, pepsin, peptone, and several other valuable preparations and principles.

Benger's peptonised beef-jelly, the well known and really active liquor pancreaticus, as well as the "self digestive food," all three exhibited by Messrs. Mottershead, are typical examples of the group of artificial digesters.

The action of diastase on oils and fats has not been sufficiently studied. The writer made a single experiment once upon cream and malt extract digested together at blood-heat. A splendid emulsion was obtained, and apparently the fat was partly broken up, and even the nitrogenous constituents in a way digested. If this really be the case, malt extract may be more valuable as a digestive and a remedy than hitherto supposed. Whatever interesting chemolysis results, the main practical fact that oily matters can be thus acted upon by means of malt extract was early found out by the manufacturers; as for example, in the Cod Liver Oil Milk of the Maltine Co., and in Loeflund's Cremor Hordeatus. Whatever the value of these preparations may be, they are of considerable interest, indicating a possible method of disguising the taste of the most nauseous remedies.

"Canned Foods."

"Tinned," or as the Americans term them "canned," goods are to be judged not alone by the quality of the preserved edible, but also by the presence or absence of corrosion of the metallic lining. The conditions favouring

the solution of tin are chiefly scratches or flaws in the lining, solder setting up galvanic action, and above all the amount and kind of acidity. In a tin of very sour apricots, sold at a low price, the writer found as much as 11 grains of tin per pound of fruit in solution; in this case all the above favouring conditions were present. On the other hand the comparatively feeble acidity of meat juice only dissolves mere traces of tin, so small that no one save a homœopath could conceive such traces as physiologically active. The canned goods of different importers naturally vary much in both quality and metallic contamination. We have made a special examination of Messrs. Moir's tins, and find them excellent in quality, and even their vegetables, with juices of considerable acidity, yield but feeble evidences of metal.

While speaking of canned goods, the excellent tinned mutton imported by Messrs. Walsh, Elliott, and Rennie, may be referred to as equal in flavour and quality to the best we have ever tasted.

The writer, while denying the ill effect of very carefully prepared "canned" goods, must emphatically state his conviction that after all the best material for use is glass or earthenware. Messrs. Blanchflower show jars hermetically sealed by an ingenious form of stopper, which they are using for their potted meats. The samples of fish and fowl which have reached us from this firm, preserved in the way mentioned, are deserving of high commendation.

Other Food Exhibits.

The artful amalgamation of hot peppers, spices and flavours, so as to please jaded palates, has been brought to perfection by Mr. Edmunds, who manufactures all kinds of curry powder, sauces and baking powders. Some of these substances are of an extremely complicated composition; and the receipts remind one of mediæval potions. However empirical the principle of composition, the legion of medals carried off by this fortunate "epicier" shows that success has been attained.

Rose's Lime Juice Cordial is largely used in our ships and consists of a very pure lime juice, which keeps clear and free from ropiness for an indefinite time.

The A B C cereals now constantly figure at all food exhibitions. They consist of very fine selected samples of oatmeal, maize, &c., ground in a particular manner. The only fault that can be found with these cereals is that the price is somewhat above the ordinary brands.

Messrs. Blaxall have an imposing exhibit of confectionery jams, and preserved fruits. The jams have been carefully examined, both by chemical analysis, and also by the staining process lately introduced. They were found free from foreign pulp, genuine and wholesome.

Mr. Torrance exhibits rusks made not alone of pure materials but of the best quality. Rusks, and generally speaking dessicated bread stuffs, are found to be useful in the treatment of many forms of indigestion; palates loathing almost everything, are yet not repelled by dry toast, dry biscuits or rusks.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—I am glad to see in your issue of last week an attempt being made to record the experience of those connected with Hospitals for Sick Children, on the subject of over-pressure in elementary schools, as such records cannot fail to be of great value as an important contribution towards the elucidation of this much debated question. At the risk of repeating what has already been said, I will send you the impressions made on my own mind, during the last two years, since public attention has been directed to the question, in the out-patient room, and also while seeing something of the children both at school and at home.

In the first place, is chorea a commoner disease among children than it was ten or twelve years ago, before the present Board School system commenced its operations? As an attempt to answer this question, I have searched the records in the out-patient department of the General Hospital for Sick Children, Manchester, with the following results:—

1871,	40 cases of chorea admitted,	9101 total out-patients.	
1872,	39	,,	7957 ,,
1873,	56	,,	8227 ,,
1881,	55	,,	5773 ,,
1882,	66	,,	6916 ,,
1883,	80	,,	7602 ,,

From these figures it would seem that the number of cases of chorea admitted as out-patients has risen from 4·3 per thousand, in 1871, to 10·5 per thousand in 1883. I am well aware of the fallacies which may lurk in such figures, and in any attempt to work out such a question by statistics; and even granting the inference as correct that chorea is a commoner disease than it was, it does not necessarily throw the onus of producing it on the Compulsory Education Code. But my own enquiries made in the out-patient room have convinced me that school work, whether "forced" or not, is frequently the exciting cause in producing chorea. I believe this is more especially true with regard to the milder and more irregular forms which are treated as out-patients, rather than in the severe forms which are admitted to hospital. Indeed, I have been surprised to find, in looking over the histories and enquiring of friends, how comparatively seldom the question of overwork has been mentioned in the severer forms of chorea; and how, when it has, it has rather been that the twitchings began after a scolding, or at the sight of the master's cane, than from any hard brain-work. It has often happened that after the movements have ceased, they have quickly recurred after going back to school.

I can corroborate also the experience of your correspondents with regard to *frontal* headache. I have again and again seen girls suffering in this way, their headaches being connected, in the minds of the parents, with school-work, and who have quickly got well with rest at home. So severe was the headache in one case, that I admitted her to the hospital under the impression that there might be organic disease. But these cases have mostly had one condition in common, *i.e.*, more or less marked hypermetropia. They have been quickly relieved by rest, and in most cases permanently so by suitable glasses. I do not think I have seen any cases of headache, other than the above, which were evidently the result of straining the accommodation, rather than from over-worked brains.

I fully agree with the remarks of Dr. Sturges on tubercular meningitis, diabetes, nephritis, &c.

I do not believe for a moment that over-pressure at school is responsible for the production, or is the exciting or predisposing cause of any of these ailments. Tubercular meningitis is the final scene of a general tuberculosis in the vast majority of instances, and its ætiology cannot be separated from the constitutional disease of which it is only an incident. The few cases of convex meningitis which I have seen and verified *post-mortem*, have been in subjects who were too young to have suffered from brain-forcing or overwork.

In considering this question it must not be forgotten how and where the children spend their time when absent from school. Is it better for many of our weakly and badly fed children to be under discipline and careful training in well-ventilated schoolrooms, even with some risk of over-working their brains, or to be running wild in the

slums or selling newspapers in the streets? I have written certificates for children to certify that they were unfit for school, and have seen them out next evening selling hot potatoes at the corner of the street!

Finally, to sum up, I believe there is ample evidence to show that the system of education in our elementary schools is productive, or has a share in the production, of functional brain disturbance of which chorea may be taken as a type, that damage is being done in some instances to the eye-sight of the scholars, which calls for the serious attention of the authorities, but I acquit it *in toto* of having any hand in producing organic brain disease or any other ills which threaten or seriously affect the lives of the scholars. Believing as I do that compulsory education is a necessity of our times, that examinations and various standards are necessary evils, and that the time which the children of our poor have to devote to learning is necessarily short, it is a matter of the greatest moment that the authorities, while insisting on a rigorous code, should take the greatest care lest they defeat the object they have in view by applying it blindly and without discrimination to the weak as well as to the strong.

I am, Sir, yours, &c.

HENRY ASHBY,
Physician to the Manchester General Hospital for Children.

Manchester, September 30th, 1884.

[To the Editor of the Medical Times.]

SIR—I have responded somewhat tardily to your request, because at first sight you seem to require detailed facts such as are not in my possession. But on further consideration, it may at any rate not be amiss to state a thought which came to my mind as I read Mr. Fitch's memorandum. If I mistake not that gentleman objects that some of Dr. Crichton Browne's conclusions were founded upon bases such as no lawyer would accept for a moment. Nor do I doubt the correctness of that assertion. But I do doubt whether this is a matter which lends itself to the satisfaction of such a requirement. There are a good many things in medicine at any rate which could not be proved to demonstration, the probable truth of which it would hardly be wise to reject; and in the matter of educational over-pressure it would be easy indeed for a logical mind to refuse to accept almost any number of such facts as can I think alone be offered. The subject is far too intricate to allow of the collection of facts in any number which shall be free from objection, and I fancy that if there is any truth in the idea of its existence, over-pressure will yet be established on the, to Mr. Fitch, but baseless fabric of Dr. Fell's impressions.

And having said this much I may be allowed a little further latitude as regards the question itself. I am not prepared to say that my experience has taught me that educational over-pressure exists among the children of the poor in any large number of instances, but perhaps it is worth saying that after reading the letters of your correspondents in last week's issue, the experience of Dr. Donkin almost exactly tallies with mine. I have repeatedly thought that school work was proving injurious, almost exclusively in the case of girls, and have had difficulty in persuading the mother to allow her child to absent herself, either because of a forthcoming examination, or the—perhaps imaginary—fear of the inspector.

I had thought that this was more the case in the earlier than in the later years of the application of the Code. At first there was considerable difficulty with certificates of absence; a certain form was printed, I believe by authority, but between the parent and the teacher it was not readily procurable. The certificate was worded in a manner which gave little countenance to ill health. It ran thus: I certify that A. B. is suffering from——and is unable to, attend school, but will be able to return in——weeks. And finding that this hampered my freedom in the matter of convalescence a form was ultimately printed for use at the Evelina Hospital which contained the simple statement that the child was ill and unable to attend school. I have not often found that parents have asked for their child to be needlessly examined.

I think, however, that the case which most needs investigation is that of the pupil teacher. I have several times, amongst my out-patients at Guy's Hospital, met with cases of young girls I considered urgently in need of mental rest; headache, nausea, bad appetite, wasting and sleeplessness being attributed to the continuous round of teaching and learning which this twofold duty necessitated. Further, I think there is evidence to show that the unremitting work at their time of life, in the fears that centre round puberty, tells prejudicially upon the male as well as the female, for I have often noticed, amidst ample opportunity for so doing, that youths who have been studying hard in the lower ranks of life to qualify them for the position of teachers, are, as a rule, a poor lot, pale, nervous, flabby and headachy.

This, however, is beyond the immediate issue, which is, how far the Board School system is causing over-pressure. On that head had Mr. Fitch confined himself to the criticism, "but what are these among so many?" I should have been disposed to agree with him so far that further evidence is imperatively called for before the question can be settled. That individual cases of over-pressure occur, I cannot doubt, but whether these are in any such large number as would demand some changes in the scheme in vogue, I do not know. I think it may even be questioned whether a certain amount of it can be avoided in these days of high pressure, when the weakest inevitably goes to the wall.

I am, Sir, yours &c.,

JAMES F. GOODHART,
Physician to the Evelina Hospital for Children.

October 1st, 1884.

[To the Editor of the Medical Times.]

SIR,—There is no doubt whatever but that a certain number of children are the victims of overwork in Board schools. In the out-patient department of the Hospital in Great Ormond Street, such cases are met with, not often but every now and then. The same has probably been observed at other Children's Hospitals. The impression produced on my mind by many years' experience of this kind, is that there is need of improvement in the relations existing between the visitors and the children of the poor; that there is a want of courtesy and consideration which is not calculated to make the School Board respected and valued, and that medical supervision is absolutely necessary. There is no way, it appears to me, in which the system of the School Board can be properly carried out without it. Fully appreciating as I do the value of education and its important influence upon the social and moral condition of the people, I have seen clearly for many years that the School Board will be obliged to adopt some plan of medical supervision to prevent the evils of overwork, and what in my opinion is more important still, to prevent the serious

dangers now existing from the spread of contagious diseases to which I have no doubt the Board schools contribute more largely than is believed.

I am, Sir, yours, &c.,
ROBERT LEE,
Assistant Physician to the Hospital for Sick Children,
Great Ormond Street.

6, *Savile Row, W.*,
September 26, 1884.

[To the Editor of the Medical Times.]

SIR,—I have of late often been struck by the fact that mothers, coming to this hospital, not unfrequently attribute many of the minor ailments of their children, such as headache and the like, to the overwork and worry of school life. Though this belief might, at first sight, be thought merely a passing wave of popular feeling, it is undoubtedly widespread, and there often appears to be considerable foundation in fact for many statements which it is impossible for one to ignore altogether. One mother will attribute the headache, loss of appetite, and general malaise of her son—a bright and forward lad in the sixth standard at a Board School—to the lessons he has to prepare at night. These consist chiefly of sums, which frequently keep him up till ten p.m. Subsequently, his rest is much disturbed, and he is often heard talking of his evening lessons in his sleep. Again, a not uncommon answer to the inquiry as to the presence of delirium at night in a feverish child is, "Yes, he was talking about his school all night." Instances like these are often brought to my notice, and might be multiplied indefinitely. They indicate a deep-rooted feeling, or it may be prejudice, on the part of the mothers in reference to home-lessons, and the general worrying of children as the times of examination approach. The hours in school, they complain, are already sufficiently long, extending, with an interval of an hour and a quarter in the middle of the day, from a quarter to nine in the morning to half-past four in the afternoon. No one who has had any extended experience of the homes of many of these children in one of the poorer districts of London can consider the further addition of home-lessons in the evening to be anything but an unmitigated evil. Carried on as they must often be in most unsuitable surroundings, they can serve no true purpose of education, and produce a condition of mental distress and sleeplessness which, in a conscientious and painstaking child, must be productive of the most painful results.

Attention was drawn in your journal last week to the influence of over-pressure in schools on the production of chorea in children, and a striking case in point is at present under my own care. The child, Lucy D., aged 11 years, is the youngest of eleven children, in none of whom any similar affection has occurred. At the last school examination she failed to pass into the standard above, and of late has been very distressed, according to her mother's account, about her school work, more especially the sums, or, as the child herself expresses it, "She can do multiplication, but not long division." She has frequently complained of headache on her return home from school, and has slept badly. Previously she had always been intelligent, but very timid, and has had no rheumatism or other serious illnesses, and no cardiac bruit is audible. The choreic movements commenced a few weeks since, and are very marked, and the child is also somewhat strange in her manner. The mother can suggest no other possible cause but the worry of the school work, and there is no history of any fright or any other painful emotion.

The general impression left on my mind by the observations and enquiries I have made for some time past is, that the injurious effects are not the result of the mere intellectual work, but rather of the worry and anxiety attendant on the periodical examination, in the ineffectual struggle of a young and sensitive, and at the same time often weakly or underfed, child to cope with difficulties too great for its powers. In such cases, I venture to think, that further appeal by the parents should be permitted to a competent medical authority.

I am, Sir, yours, &c.,
FREDERICK WILLCOCKS,
Physician to Out-patients at the Evelina Hospital.

October 1*st*, 1884.

[To the Editor of the Medical Times.]

SIR,—If you will allow me to depart somewhat from the direct line of the subject upon which you invite correspondence, I should like to say a few words as to the study of the brain condition of school children, leaving the question of the causation of such conditions. I recently visited four schools for the purpose of trying to ascertain the present condition of the scholars, and found the following methods of procedure work well. Briefly stated they were as follows:

(1) Note the more permanent conditions of the child, signs of good or ill development; the state of nutrition; anæmia, probable condition of eyesight; the general signs of a healthy or unhealthy body.

(2) Note the movements and results of movements, steadiness of the hands when held out, special postures or movements of the head, hands, eyes, face, spine, etc.; these are the *direct* indications of the present nerve-muscular condition.

Such observations can be tabulated. One head master to whom I have demonstrated these methods is trying to make observations for himself in his school; the head mistress of a high school is making anthropometric observations among her girls. It seems to me that we must determine with clinical precision the present condition of a child before we can detect the cause of that condition. Such methods as those given above I have practised and taught for some years.

To know the average brain condition of school children is of national importance; we must know their physical as well as intellectual state, and some such enquiry on a scientific bases ought to be called for in the public interest.

I am, Sir, yours, &c.,
FRANCIS WARNER,
Late Physician to the East London Hospital for Children.

28*th September*, 1884.

[To the Editor of the Medical Times.]

SIR,—It is proverbial that statistics may be made to prove anything. Dr. Abercrombie's letter in your issue of to-day beautifully illustrates this statement. He finds that 11 per cent. of all children suffering from chorea are described as working hard at school or preparing for examination, and therefore argues that school work and chorea stand to one another in the relation of cause and effect. But supposing I wished to prove that hard work at school prevented rather than caused chorea, I would argue as follows: All children are compelled by law to attend school, and no doubt at least 20 per cent. would be described by their fond parents as hard working. We should therefore expect 20 per cent. of all cases of chorea to be thus described, but as only 11 per cent. belong to this class, diligence at their studies protects from chorea to the extent of 9 per cent. of all

cases. Again, children are examined annually for their "standard," and would describe themselves as working for examination for some six weeks out of the year; 12·5 per cent. of the children are thus working for examination while only 11 per cent. of the chorea cases belong to this class. The protective influence of examination work is thus exemplified!

I do not wish to discuss the question of so-called over-pressure, but am desirous of pointing out the difficulties which must attend any investigation of the subject. While a large proportion of all children attend school, an equally large proportion attacked by any particular disease must be school children. On investigation we should find that a certain percentage of children suffering from scarlatina would be described as hard working, and that a considerable number would be preparing for examination, but no one would, therefore, conclude that scarlatina is due to over work. It is, I think, important for us as medical men to refrain from hampering the great work of national education by advancing as facts theories which are devoid of all scientific accuracy.

I am, Sir, yours, &c.,

Leeds, September 27, 1884. A. F. McGILL.

SKELETON INTRODUCTORY ADDRESSES.

No. I.

PREPARATION FOR THE STUDY OF MEDICINE.

In choice of subject may seem a little belated, seeing that the most valuable opportunities of preparation are past for you, and perhaps lost. But medicine a life study and never too late to prepare. School preparation for study of medicine, not what it should be. Reasons. Once only two professions, Arms and the Church. In old and more lucid days preparation well adapted to each, though now inextricably mixed. Later on education passed entirely into hands of clerics, and everyone educated as if to become one, or else education became purely literary—Chinese. Reaction. Now our soldiers educated as if to be clergymen; clergymen often as if to be soldiers. Birth of science and rise of new professions; till lately unregarded by educationists. Better, far, were everyone educated as if to be a doctor than as if to be a priest. Science = sublimated common sense; scientific observation and method applicable to every study; different in this from literary education. Scientific warfare, scientific law, science of theology, science of politics; but not literary law, literary warfare, or literary medicine; in the one case adjective complimentary, in other the reverse. Observation and method; former essential. First catch your facts; cooking a subsequent operation. Appreciation of "method" a late mental development; logic the final study in medical education. Hence scientific preparation consists mainly in training observation. "How to observe and what to observe, in the past and in the present, is the ever-recurring function of education through life." (Cf. Lord Reay's address to International Educational Conference.) The training of observation neglected in school education; unaccountably so, except for persistence of old idea that intuition more important than inference. Observation, a function of special sense. Training of eye; degeneracy of civilized eye-sight. Physical sight and intellectual sight. Training different in each case. Physical sight; training of accommodation; games. Intellectual sight; best training secured by reproduction of impressions; drawing, painting, description. Quotation from Ruskin. Clinical case-taking a grand preparation; but why not imitated in school education? Much truer training, for boy to describe his play-fellows, his school-room, his games than to write themes or verses on love of country. Training of hearing; this sense especially susceptible of culture and degeneracy; stethoscopists out of practice. Country life the best educator of hearing for boys. How many of you have learnt to know one bird's call from another? Not a mere accomplishment. Senses of smell, taste, and touch. The "tactus eruditus"—why not learnt at school? Smell, a very useful sense, especially for a doctor. Instances of diagnosis by smell. Smell of bloods of different animals. Smell, a sentinel. Quote Plato. Smell also best educated in country. Training of senses in combination, and in combination with muscular action. Sight and movement, drawing, laryngoscope: hearing and movement, musical instruments, percussion. Such training lost sight of in typical school education. Workshops in schools, a modern innovation with the highest scientific sanction. Training of memory. The kind of memory required in medicine very different from that required to remember Latin verses and historic dates. Visual, auditory, and tactile memory. Illustrations and anecdotes. All the above acquirements, though essential, only preparatory to exercise of intelligence — the tools and not the finished work. But more eminently cultivable than the higher powers of mind. A good observer may be made; a correct thinker is born. Do not then be despondent. If nature has deprived you of her "nascitur," she holds out to you boundless possibilities in her "fit." Fact is fact. Inference is, well, only inference.

No. II.

THE ART OF WORK.

Introductory Address—a compound of experience and prophecy. Experience of the teacher who has been a student: prophecy as to the student who may become a teacher. Nowadays prophecy considered reliable only when it reflects experience; you will become more familiar with this and other forms of reflex action as your studies advance. Experience of all kinds must be bought; is best and most cheaply paid for by honest work. His work often bewilders first year student by its scope and apparently inconsequent variety. This a false impression; all departments of his work connected; none self-limited; all inter-dependent. Similarly, no man's knowledge lies in a ring-fence—each learns of, for, and with others, no less than for himself. "Borderlands of Science," Borderlands of Work; both fascinating; both rich—for those so trained as to utilise them. Work in this sense not simply reading, or lectures, or dissection, nor all these together; but training of all the faculties. Dependent on method. See, observe, "Eyes and No Eyes"; gather, collect; note, examine, classify; digest and assimilate—make one's own. Must be to some extent omnivorous; should not be greedy,—"Enough as good as a feast," and, for the next day, much better. Surfeit entails indigestion; the chronic intellectual dyspeptic the most hopeless of invalids. So, true work includes care of body; care of implies respect for; respect incompatible with abuse. Main difference between the amateur and the skilled workman—the latter keeps his tools constantly in better order, and can thus turn out better work. Better to wear out than to rust out; but better still to wear well, long, and usefully. Hence value of social intercourse; its risks. Students' Clubs—their use and abuse. Work and recreation—recreation and work; in a perfect system the terms would be interchangeable. Necessity for caution, as to both men and things. Given a fact, find the explanation

of it—but is it a fact? Given an authority, accept his dicta, but is he an authority? Honesty in learning; honestly enquire into the truth, honestly accept it when found. Much must be taken on trust, but distinguish between facts and even honestly deduced conclusions. Your present duty is to lay a foundation; upon its stability and breadth must depend the value and security of that superstructure which your work in after life will rear.

No. III.

CONDITIONS OF FAILURE AND SUCCESS.

Welcome! Smiling young faces before me, carry one back to one's own first year. Wonder where you will all be ten years hence: may safely predict not all so smiling and hopeful as to-day. Most no doubt settled down into steady, serious, responsible practitioners; some diverted into happier or less happy grooves; a considerable percentage unsuccessful at examinations; a few, let us hope a very few, broken down in health—fallen from the ranks. Statistics: students annually entered and practitioners annually registered; pass and pluck lists; estimate of invaliding; Nature's pluckings. Survival of fittest; brain and body. Health a condition of success. Instances of celebrated medical men who have achieved success by help of good digestion. Instances to the contrary. Living by rule. People who have to do it, not to be envied. Mr. Gladstone and Mastication. The healthiest man, one who can adapt himself to his environment; approximating to colour of his surroundings like an animal. Limitations. A gentleman practising amongst the poor, a genius amongst the commonplace, not to sink to their level. Temptations of educated men living amongst uneducated ones. Want of intellectual stimuli; too often replaced by stimulants of other kind. Bush doctors. Other temptations; intellectual arrogance. Self-confidence and self-distrust; both necessary. Distrust of others, also necessary—not of their character but of their opinions. Healthy scepticism, and unhealthy scepticism. Unhealthy when it discourages one in searching for all the facts of a problem. Problems and theorems in medicine; Q.E.D., and Q.E.F. Answers to both not always attainable by the same mind; the diagnostician and the therapeutist. The theorems of diagnosis, and the problems of treatment, however, much more similar in nature than usually believed. Therapeutic "tips." More valuable to the patient than to one's own self-culture. Represent essentially symptomatic treatment. Medicine a science in proportion as it enquires into the relation of cause and effect. Treatment that only aims at palliating or antagonising effect not really scientific. Prevention the highest function of scientific medicine. Prevention of getting plucked not the highest function of scientific studentship. Much the same relation between study for examination and study for life's work, as between treatment and diagnosis. Both necessary, but hope you will all bear in mind that the latter is the more important.

No. IV.

BEING AND SEEMING.

Preface remarks with few words of welcome. Audience not entirely composed of strange faces; many stages of experience represented; some far greater than my own. All intent upon work in their various positions; to all a welcome. Old and young alike have a common object in view; some have attained to its fulfilment, others midway in the race; their example should be followed, but their method must be studied. A scientific committee now investigating methods which lead to old age. Let us collectively investigate art of success in life; distinguish clearly between notoriety and success. The former dependent upon what men say of you, the latter upon what men think of you; these things very distinct. Genuine success only follows genuine work, but the work must be applied in right direction; first aim of student to pass his examination; that a wrong direction; aim should be to learn subjects thoroughly; the rest will follow; start with firm grip of elementary subjects—that essential to success. Glories of London M.D. will not compensate for ignorance of ordinary anatomy. Surgery and Medicine studied in two ways—from books and from patients; the study of latter will repay you best; a sound and extensive acquaintance with them will render you free from any examinational terrors. Note-taking; volumes of notes of lectures only monuments of misapplied industry; careful records of personal observation will enable the student to teach the physician in after years. Habit of accurate observation one great secret of success; all great advances in science made by its means. Beware of theories; stick to facts. Professional talk, always popular among doctors, apt to lead to professional scepticism. Disbelief in efficacy of drugs too often exaggerated; the sick doctor always takes physic. Value of other people's opinions—generally depreciated at first and over-estimated afterwards. Never accept opinions at second-hand. Reputation in medicine is easier to lose than to make. Professional etiquette is capricious; hero-worship prevails. Junior men apt to copy their seniors too closely; vaulting ambition frequently o'erleaps itself from that cause alone. Medicine no longer to be practised as a mystery, hence the appearance of supernatural wisdom no longer essential at the bedside. Thorough investigation always appreciated; treatment generally suggests itself; if successful, make a note of it; but let others advertise it in public.

No. V.

THE DOCTOR AS ENEMY AND THE DOCTOR AS FRIEND.

After compliments; reference to well-known engravings "Death as the Enemy," and "Death as the Friend." The doctor viewed by different classes in the same lights; enmity and friendship, however, depend not on varying character of the doctor, who is uniformly a friend, but on mental pre-occupation of his critics—on medium through which he is seen. (1) The doctor as enemy. Prejudice against him (*a*) selfish (*b*) sentimental. (*a*) *Selfish.* Death in the woodcut, disturbing a revel. Similar part played by doctor. Warnings against drunkenness, gluttony, dirt, debauchery, sloth, avarice, overwork, fashionable distortion, &c., &c. The doctor the forerunner and, if heeded, the averter, of disease and death. To fools, an enemy. Illustrations. (*b*) *Sentimental.* Interference here not with selfish and senseless appetites but with sentimental preconceptions, often with a nucleus of sense. Here doctor regarded not in individual, but in collective capacity. General anti-scientific bias strengthens most of these enmities. Instances—Vaccination; Vivisection; Contagious diseases; Sanitary reform: Hygiene of Education; Notification of infectious disease, &c.; "Doctor-ridden," analogy from "priest-ridden." Where analogy fails. Question of *authority;* in priest's case final and indisputable; in doctor's case provisional and disputable, the evidence for it being open to all. Enmity therefore unreasonable. How

to diminish it? By approximating general education to medical. (2) The Doctor as Friend. (*a*) Individually. Pleasant relation of doctor to patient. Trust and gratitude. Obligations entailed by them. (Room here for considerable amplification). (*b*) Collectively. Doctor's place in State. Relation to State should resemble relation to private patient. Not so in practice. Trust and gratitude, conspicuous by absence. Instances not far to seek. Inadequate recognition of public services. Jenner, Parkes, Farr. Further considerations. The doctor, like Death, sometimes called in too lightly. Comparison between suicide and too facile resort to medical advice. Both result of nerve degeneracy. Modern neuroses. Fallacy of regarding them as modern. (Cf. Dr. George Cheyne on "The English Malady, or a Treatise of Nervous Diseases of all kinds." London: 1733). Concluding considerations. What the doctor can learn of his familiar, Death. To be no respecter of persons. Fearlessness of it and obedience to it. The euthanasia — ethics of. Anecdote of Napoleon at Jaffa; Dr. Desgenettes' reply to him. Peroration.

MEDICAL NEWS.

Calendar of the Royal College of Surgeons of England.—This annual compilation has just been published by the Council of the College, and with the usual care. From it we make the following analysis, which we think will be interesting not only to the Fellows and Members of the College, but to the profession generally, and indeed to the public, who will learn from it that there is no scarcity of doctors to look after their health, seeing that there is a small army of no less than 17,675 fellows and members on the roll of this one institution. Beginning with the Fellows of the College we find there are now 1,166, including 611 who have obtained the honour after undergoing the severe examinations; there are five who have been elected as members of twenty years' standing, under Section 5 of the Charter XV., Vict.; and three *ad eundem* fellows, viz., two from the Irish and one from the Scotch college. There are 16,509 members; the Licentiates in Midwifery remain at 969, the examinations for this distinction having been suspended for the last eight years. The Licentiates in Dental Surgery now number 553. The Board of Examiners in Anatomy and Physiology consists of nine members, annually elected by the Council from the Fellows of the College. It conducts the *Primary* examinations in Anatomy and Physiology for the diplomas of Fellow and Member, and during the past collegiate year has held eight meetings for the fellowship and forty-seven for the membership; at the former there were 134 candidates, of whom only 56 passed, 78 being referred for six months. For the primary membership there were 1,108 candidates, 733 of whom passed, whilst 330 were referred for three months, and 45 for six months. The fees received from the candidates for this examination amounted to 6,139*l.* 7*s.*, the Board receiving in fees 2,618*l.* The Court of Examiners consists of ten members, also elected by the Council from the Fellows of the College, all of whom however are members of the Council, except Dr. Humphry. During the past year the Court has held two meetings for the fellowship, and forty-five for the pass-examinations for the membership: at the former there were 45 candidates, 30 of whom passed, 15 being referred for twelve months. For the membership there were 804 candidates, of whom 348 were successful, and 303 rejected, viz., 77 for three months, 212 for six months, 11 for nine months, and 3 for twelve months. The fees paid by candidates amounted to 10,431*l.* 5*s.*; the fees paid to the Court of Examiners amounted to 4,707*l.* 12*s.* The Board of Examiners in Dental Surgery has held three meetings for the examination of 30 candidates, 22 of whom received their diplomas: the fees paid by them amounted to 346*l.* 10*s.*, of which the Board received 110*l.* 5*s.* The income of the College from all sources during the past year amounted to 22,111*l.* 10*s.* 9*d.*, derived principally, as already shown, in fees paid by candidates for the diplomas of the College, viz., 16,917*l.* 7*s.* Rents from chambers adjoining the College produced 1,530*l.* 18*s.* Fees paid by Members of the College on admission to the Fellowship, which formerly yielded a large amount, is set down as producing for the year only thirty guineas. Dividends on Stock amounted to 1,182*l.* 19*s.* 3*d.* From members of the Council and Court of Examiners on their election, 63*l.* The expenditure for the year amounted to 20,046*l.* 7*s.* 4*d.*, the largest item being in fees paid to members of the Court and Boards of Examiners, viz., 7,435*l.* 17*s.* The next largest amount appears in Salaries and Wages for the officers and servants of the College in the three departments, Library, Museum, and Office, viz., 3,784*l.* 14*s.* Taxes, Rates, Diploma Stamps and Insurance absorbing the large sum of 1,469*l.* 9*s.* 3*d.* In the extraordinary expenditure 700*l.* appears in honoraria to Dr Goodhart, and Messrs. Trimmer and Doran; under miscellaneous items 431*l.* 11*s.* 6*d.* appears as having been expended. There appears the respectable balance at the banker's of 2,065*l.* 3*s.* 5*d.* The metropolitan hospitals are represented on the Council by Messrs. J. C. Forster, *President*, T. Bryant, and A. E. Durham, *of Guy's*. *St. Bartholomew's* by Sir J. Paget, Bart, F.R.S., W. S. Savory, F.R.S., *Vice President*, H. Power and T. Smith. *St. George's* by T. Holmes, *Vice President*. *University College* by J. E. Erichsen, F.R.S., J. Marshall, F.R.S., C. Heath, and M. B. Hill. *King's College* by Sir J. Lister, Bart., F.R.S., and J. Wood, F.R.S. *The London* by J. Hutchinson, F.R.S. *The Middlesex* by J. W. Hulke, F.R.S., and G. Lawson. *St. Thomas's* by Sir W. MacCormac, J. Croft, and S. Jones. Sir T. Spencer Wells, Bart., and Messrs. W. Cadge, W. Allingham, and E. Lund are not attached to any of the recognised metropolitan hospitals. The oldest Fellow of the College is Mr. J. M. Arnott, F.R.S., a late President of the College, who was admitted a Member of the College so long ago as April 4th, 1817, and as he must have been 22 years of age at the time, he is consequently in his 90th year.

Poisoning by Canned Foods.—This subject was recently brought before the Medico-Legal Society of New York by Dr. J. G. Johnson, and discussed thereat at some length (*Medico-Legal Journal*, Vol. 2, Nos. 1-2). His attention was called to the subject by the occurrence of symptoms of irritant poisoning in a family of six persons who had partaken of some canned tomatoes for luncheon. About two hours after this they were all seized with pain in the pit of the stomach, intense thirst, dryness of the throat, retching and tenesmus. The family at the time consisted of the mother, her two daughters, two sons and a nephew; the boys all recovered in course of a day or so. The eldest daughter, who suffered most severely, had most violent tenesmus, and remained in a comatose state for several days, passing a good deal of blood by the bowel. Eventually they all recovered, and unfortunately the evacuations were not examined in any of the cases. By a process of exclusion it was shown that none of the other articles of food taken at luncheon on that day could have poisoned them, and the symptoms had come on in them all so definitely and so soon after the luncheon that the tomatoes were naturally suspected of being the cause. The tomatoes were not spoiled, as would naturally suggest itself to anyone as the most likely explanation, and for the following reason. When the food has been placed in the can and the lid soldered on, the goods are "processed." That is, they are put into a steam bath and submitted to a heat of about 250° F., till a pressure of 25 lbs. to the square inch is created in the can. An awl is then thrust through the centre of the cap and the gases are allowed to escape. The can is then soldered while hot; when it cools down the heads bulge in and stay in. If decomposition set in the heads would bulge out again, in such a case another hole would be made in the cap and the gases allowed to escape, the cap being then again resoldered; cans which had been thus treated were known in the trade as "swells," and could always be recognised by having two holes instead of one. The can from which these tomatoes had been taken had

only one hole. But even if the tomatoes had been spoiled the cooking would have prevented their doing any harm, so that the poisonous symptoms could not be due to decomposition of the tomatoes. It was found out that the daughter who suffered most severely had soaked her bread in the juice and had not eaten any of the solid part, the mother had done the same but she had not eaten much because she did not like the taste, she had noticed too that the colour of the tomatoes was rather a faded red, but she had not thought anything of it. On taking the cap to a tinsmith Dr. Johnson learned that the cap was not fastened to the head by a resin amalgam as the sides were, but that the amalgam was made of muriate of zinc; pieces of zinc were placed in muriatic acid till the acid could no longer attack the zinc, and this saturated solution of muriate of zinc was painted into the groove of the head of the can. The cap was then placed on and clamped whilst it was being soldered down. If too much acid had been applied to the groove then as the tin expanded with the heat, it (the acid) would be forced into the can, as it could not escape on the outside. On examination of the tin in question the inside of the head was found to be dull when compared with the rest of the can, owing, as Dr. Johnson considered, to the acid having got inside and attacked this part of the tin, so that a muriate of zinc and tin had been formed, and it was this which, being present in the juice especially of the tomatoes, had given rise to the symptoms of poisoning. Amongst the conclusions which he arrived at were these, viz: that these cases were of poisoning from muriate of tin and muriate of zinc, and that this poisonous amalgam ought to be abandoned; and further that every cap that had two holes in it should be rejected, and also every article of canned food that did not show the line of resin around the edge of the can, the same as was seen on the seam at the side of the can. An animated discussion followed in which several representatives from the houses in the canned food trade took part and expressed pretty strongly their objections to Dr. Johnson's criticisms. One speaker pointed out that the solution of muriate of zinc that was used was a very weak one and expressed the opinion that if it had any effect at all it would probably be a beneficial one. Another speaker said that the presence of two holes in the cap was no proof that the can had been re-processed, as several dealers were in the habit of opening their goods twice to ensure their keeping. And they nearly all called attention to the fact that Dr. Johnson had no chemical evidence in support of his theory, a deficiency which he accounted for by the fact that there was not enough left in the can to test, and the evacuations had unfortunately not been kept. A committee was appointed to enquire into and report upon the subject of canned fruits. The importance of the question thus raised will be gathered when it is stated that sixty millions of cans are annually exported. Professor Reese sent a letter to the Editor of the *Medico-Legal Journal* expressing the belief that the poisonous symptoms in such cases as those referred to by Dr. Johnson were more likely to be due to the action of a ptomaine than to poisoning by a mineral acid such as zinc chloride. Major-General J. P. Hawkins (U.S.A.) has expressed his views on this subject in the trade organ, and is very strongly of opinion that there is no ground whatever for the present outcry against canned foods. His contention is based mainly on the experience of the army, where canned foods are used to a very large extent. He states that no cases have ever occurred in the army in which bad symptoms arose through eating canned foods, and expresses the opinion that in those cases amongst civilians in which symptoms of poisoning are said to have occurred it would probably be found that the meat had been spoiled, and so spoiled as to be obviously unsound to the most casual observer; if under such circumstances people will eat the meat, he says they must expect to be ill, just as they would be if they ate a piece of tainted butcher's meat.

Royal College of Surgeons. — The library and museum of this institution were re-opened on Wednesday last, the 1st instant.

John Hunter.—Tuesday, the 14th instant, will be the anniversary of the death, in 1793, of the immortal Hunter.

Medical Sickness, Annuity, and Life-Assurance Society.—The first meeting of the Executive Committee of the Medical Sickness, Annuity, and Life-Assurance Society, since its formal election at Belfast, was held on Wednesday last, at 38, Wimpole Street. Mr. Ernest Hart (Chairman) presided. There were present Dr. Ord, Mr. Septimus Sibley, Mr. Major Greenwood, junior, Dr. Dolan (Halifax), Dr. Clibborn, Dr. F. de Havilland Hall, Mr. E. Noble Smith, Mr. Brindley James, Mr. Edward Bartlett, Mr. Wallace, Mr. Radley (Secretary). The minutes of the last executive meeting were read and approved. It was reported that 72 new members had been enrolled since June 30th, making a total of 567. The receipts since June 30th were reported to amount to 1,350*l.* 2*s.* 4*d.* (entry-fees, 37*l.* 16*s.*; and premiums, 1,312*l.* 6*s.* 4*d.*) The total amount of funds in hand had reached the sum of 2,782*l.* 10*s.* 9*d.* It was stated that the society had already received one sickness-claim, on behalf on which 4*l.* 10*s.* had been paid; the chairman's previous proposal that they should invest at least 2,000*l.* of the reserve-funds in hand having been approved, a list of the most approved securities was now presented; and it was unanimously decided to invest 2,500*l.* in first-class guaranteed securities of one of the English trunk-lines, in accordance with the conditions of the trust. It was resolved to send a neatly bound copy of the new rules to each member, free of charge. It was decided to hold the meetings of the General Committee of the Society on the same date as the meetings of the General Council of the British Medical Association; the first meeting to be called for October 15th, at 5 p.m.; and future meetings of the Executive Committee to be held on the second Wednesday in each month. The chairman reported that the premium income of the society now amounted to upwards of 6,000*l.* a year, and the rigid economy exercised in keeping the management expenses down to the lowest point, had enabled them to keep considerably within the margin of the management expenses usually calculated, and estimated by the actuary for the management of such societies. A handsome balance had already been secured to the credit of the management account. The financial result for the first half year's work was extremely satisfactory, and it was still more satisfactory to know that the society, being strictly mutual, the whole benefits accrue to the members. It was reported that letters had been received from Mr. C. H. Watts Parkinson, Wimborne Minster, stating his intention of bringing the society's aims and objects before the notice of the West Hants and Dorset Branch of the British Medical Association; from Dr. Alexander Dempsey (Belfast), offering to adopt the same course before the North of Ireland Branch; from Dr. De Vere Hunt, stating that Dr. Brierley had announced his intention of bringing the matter before the Manchester Medico-Ethical Society. It was further reported that, in response to an invitation, Mr. E. Noble Smith had undertaken to read a paper on the objects and benefits of the society at the West London Medico-Chirurgical Society on Friday, November 7th. Other communications were brought before the committee, and the secretary instructed with respect to them. The chairman congratulated the members on the solid progress of the society, and on the large career of usefulness which was opening before it, and the proceedings terminated.

The Josephinum Academy at Vienna.—The *Times'* Vienna correspondent states that the proposed revival of the Josephinum Medical Academy seems to meet with the greatest opposition. It was abolished because it did not answer its purpose of supplying a sufficient number of efficient medical men and surgeons, and because with the introduction of the general liability to military service a sufficient number of surgeons well taught in the public schools, and with considerable practical experience in the hospitals, were placed at the service of the army. When the Josephinum was built and endowed, the Austrian army was not one-tenth part so effective as it is now. Surgery and medical science, too, were in their infancy, nor did any one think much of the sanitary condition of the army, or even of the country in general. The revival of the hospital now would certainly be a curious anachronism.

NAVAL MEDICAL DEPARTMENT.—The following appointments have been announced: Fleet Surgeon—William J. Eames, to the *President*, additional; E. J. Butler, M.D., to the *Achilles*. Staff Surgeon—Robert W. Biddulph, to the *President*, additional. Surgeon—Otway P. Browne, to the *Asia*. Surgeons—Fredk. A. Trevor, to the *Indus*; Theodore J. Preston, to the Royal Marine Division at Chatham; Bowen S. Mends, to the *Téméraire*; John S. Thomas, to the *Superb*; Paul B. Bookey, to the *Hector*.

MEDICAL SCHOOLS.—At Guy's Hospital the Entrance Scholarship of 125 guineas in Arts has been awarded to Mr. Alfred Parkin, and that of 125 guineas in Science to Mr. James McDonald Gill. At the St. Mary's the Scholarships in Natural Science of 75*l.* each have been awarded to Mr. W. G. Holloway and Mr. F. W. Lewitt, and those of 50*l.* each to Mr. C. Graves, Mr. A. M. Hickley, and Mr. C. G. Mack. At University College the Medical Entrance Exhibitions have been awarded as follows:—100*l.* H. Caiger; 60*l.* H. M. Fernando; 40*l.* S. V. J. Brock. At the London Hospital College the Entrance Scholarship, of the value of 60*l.*, has been awarded to Mr. William S. Fenwick; and that of the value of 40*l.* to Mr. J. H. Sequiera.

APPOINTMENTS.

BOSWELL, JOHN IRVINE, M.R.C.S. Lond., and L.R.C.P.—Medical Officer to the First District, Faversham Union, *vice* Dr. W. E. B. Atthill, resigned.

GORDON, JOHN JOSEPH, L.R.C.S. and L.R.C.P. Edinb.—Medical Officer to the Infirmary and the Workhouse of the Hackney Union, *vice* Mr. J. C. Garman, resigned.

JELLY, F., A.M.B. and C.M.—Assistant Medical Officer to Wynford House Hospital for the Insane, Exeter, *vice* W. A. Moynan, M.D., resigned.

JOHNSTON, F., M.B., C.M. Glas.—Honse Physician to the Northern Hospital, Liverpool, *vice* E. W. Roughton, M.B. Lond., M.R.C.S., resigned.

KITE, E. W. D., M.R.C.S., L.S.A.—Honse Surgeon to the West Bromwich Hospital, *vice* R. K. Delancy, resigned.

MARTIN, J. P., M.R.C.S.—Junior Assistant Medical Offieer to the Wilts County Asylum, Devizes.

MCWILLIAM, ALEX., M.B., M.C. Aber.—Senior Assistant Medical Officer at the Somerset and Bath Asylum, *vice* W. C. Beatty, M.D. Durham, resigned.

PINK, THOMAS, M.R.C.S. and L.S.A.—Medical Officer to the Weldon District, Oundle Union, *vice* Mr. S. Stokes, resigned.

ROBBES, C. E., B.Sc. Lond., B.A. Camb., M.R.C.S.—Honse Surgeon to the Gravesend Hospital, *vice* R. J. Bryden, M.R.C.S., resigned.

SMALL, THOMAS, L.R.C.P., L.R.C.S. Edin.—Medical Officer to Tenth District, Hexham Union, *vice* Mr. C. J. Connon.

TREVES, FREDERICK.—Surgeon to the London Hospital, *vice* Mr. James Adams, resigned.

VACANCIES.

BRISTOL GENERAL HOSPITAL.—House Surgeon. Salary, £120 per annum, with board, washing and residence in the house. Candidates must be Members of the College of Surgeous of London, Edinburgh, Glasgow or Dublin, and also Licentiates of the Apothecaries' Company of London or Dublin, or some other recognised medical qualification and must produce testimonials of good moral character and ability and must send certificate of registration. Applications to be sent to the Secretary, on or before October 27th.

CENTRAL LONDON SICK ASYLUM DISTRICT.—Assistant Medical Officer and Dispenser. (*For particulars see Advertisement.*)

CHARING CROSS HOSPITAL, STRAND, W.C.—Assistant Physician. Also, Anæsthesist. (*For particulars see Advertisement.*)

DEWSBURY AND DISTRICT GENERAL INFIRMARY, DEWSBURY.—House Surgeon. Salary to commence at £80 per annum, with board, residence in the Institution, and washing. Candidates must be duly qualified in Medicine and Surgery. Applications with copies of testimonials to be sent to the Secretary, on or before Oct. 6th.

MALE LOCK HOSPITAL, 91, DEAN STREET, SOHO.—Resident House Surgeon. Salary, £50 per annum, with apartments and board. Applications with testimonials to be made to the Secretary, Female Lock Hospital, Westbonrne Green, Harrow Road, up to October 6th.

MANCHESTER TOWNSHIP.—Medical Officer to the First District, *vice* Mr. Robert Manners Mann, deceased. Salary, £200 per annum.

NORTH SHIELDS AND TYNEMOUTH DISPENSARY.—Housc Surgeon and Dispenser. Salary, £130 per annum, with house, coals, water and lighting. Candidates mnst be legally qualified. Private practice prohibited. For further information apply to the House Secretaries, to whom applications with testimonials are to be sent before October 15th.

RICHMOND HOSPITAL, SURREY.—House Surgeon. Salary, £80 the first year, with an annual increase of £10 to £100, with board and furnished apartments. Candidates must be medically and surgically qualified and registered uuder the Medical Act. Copies of testimonials, not exceeding six in number, to be forwarded to the Secretary, on or before October 10th.

ST. NEOTS' UNION.—Medical Officer to the Third District, *vice* Dr. Walker, resigned. Area, 3,854 acres. Population, 438. Remuneration by fees.

SWANSEA HOSPITAL.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates mnst be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28.

DEATHS.

BEACH, H. J., Brigade Surgeon, Her Majesty's Indian Army (retired), at Maryville, St. George's Road, Cheltenham, on September 29th, in his 52nd year.

CORY, W. G., B.A., M.D., at 27, West Mall, Clifton, on Sept. 25th, aged 57.

JACKSON, EDWARD, M.D., at Longsight, Manchester, on Sept. 24th, aged 82.

MASH, J., F.R.C.S., at 4, St. Giles's Square, Northampton, on September 27th, aged 87.

ROE, E. T., M.D., at 18, Kensington Crescent, W., on Sept. 28th, aged 64.

NOTES, QUERIES, AND REPLIES.

[TO THE EDITOR OF THE MEDICAL TIMES.]

WISE BIRDS.

SIR,—I notice in your article on the Appendix to the Report of the Army Medical Department, that Surgeon-General Irvine remarked upon *the cessation of bird life* at the commencement of the cholera epidemic in Egypt. A correspondent in the *Standard* of September 27th, informs us that the disappearance of birds during the plague at Athens, was observed by Thucydides, who is supposed to refer chiefly to vultures. Bnt Lucretius, speaking of the same event, says "birds were hardly to be seen at all." It would be interesting to ascertain if *all* bird life ceased at the ontbreak of the Egyptian cholera. I take it that the birds disappeared, and not that they ceased to live; and if so, it would be reasonable to suppose that the birds fled to avoid a poisonous atmosphere, rather than imagine that instinct enabled them to detect "comma-shaped bacilli" in the unfortunates who were doomed to be the victims of the terrible epidemic.

I am, Sir, yonrs &c.,
SENEX.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—Will you kindly inform me, through the medium of your columns, respecting the best means of preserving pathological specimens? As it is of paramount importance to have as little bleaching as possible, will you please advise me respecting the requisite strengths of solutions of boro-glyceride, corrosive sublimate, hydrate of chloral, rectified spirit or other matter that may be made use of?

I am, Sir, yonrs &c.,
L. GREY THOMPSON,
M.D., Snpt.

Launceston General Hospital, Tasmania, 2nd August, 1884.

[WITH regard to the various fluids used for monnting animal tissues none fulfil the requirement of retaining the specimen's original colour, and this for the simple reason that every specimen must be thoroughly cleansed before being mounted, otherwise the fluid would be so turbid as to prevent examination of the contents of the jar. We might suggest the adoption of a system of pseudo-tanning, with which in a few cases we have had some success. By soaking the viscus in a strong solution of carbolic acid and glycerine the colonr has been rendered fairly permanent. The first effect of this is to render the organ hard and white, bnt after the specimen has been immersed in spirit for a few days the original colour returns. There are patent fluids, as for example, Wickersheimer's solution, &c., which are said by their vendors to give excellent results. These have made no headway, for, in addition to their dearness as compared with spirit, they have not been found to work well in practice. We believe that a 5 per cent. solution of boro-glyceride has been recommended, but we cannot testify to its merits. It is quite possible that it may be worth a trial. Pure glycerine has considerable merit, especially with joints and bones. Hydrate of chloral we believe is chiefly used for vegetable preparations. Bnt nothing has been found to supersede spirit in preserving specimens. It is, however, useless to try to prevent its bleaching action; in fact, to make a specimen look well when mounted, the opposite course must be adopted, that is, the tissne should be quite blanched before it is put up. A strength of from five to ten degrees over proof is usually found most suitable for ordinary purposes.

Lastly we might mention that the neatest and easiest method of sealing up the jars is with a mixture of gelatine and acetic acid. This preparation has the additional advantage of allowing the glass top to be easily removed from the jar by the application of heat.—EDITOR *Medical Times*.]

REMARKS ON A CASE OF MECHANICAL CONGESTION OF THE LIVER, AND ON THE SO-CALLED NUTMEG LIVER, AS A RESULT OF INCOMPETENCE OF THE MITRAL VALVE.

By Professor v. BAMBERGER, Vienna.

Gentlemen,—I have lately brought under your notice several cases of disease of the liver, and to complete the series, I wish to-day to show you a case of mechanical congestion of that organ, the result of incompetence of the mitral valve. The patient complains of cough and expectoration, of short breath and general dropsy, which first appeared in his legs and subsequently in his abdomen. He is coughing a good deal, and his expectoration consists of small isolated opaque particles of a greenish colour mixed with a little mucus, but with no particular smell. On examining the sputum under the microscope, we find epithelial and pus cells and some mucous corpuscles. The chest walls are extensively œdematous, but the chest itself presents the usual configuration. The patient breathes mainly with his diaphragm; the chest walls indeed expand when he takes a deep inspiration, but their movements are not nearly so extensive as in the normal condition. We find no distinct dulness on percussion over any part of the chest, hence there is no congestion of the lungs. On auscultation of these organs we hear rough inspiration and dry crepitant râles with an occasional moist crepitus. From these symptoms we diagnose a diffused bronchial catarrh which extends to the minutest bifurcations of the tubes. The rough breath-sound is due to tumefaction of the bronchial mucous membrane while the dry crepitant râles show that at certain points in the lining of the bronchi there is a tough secretion, causing artificial stenosis of their lumen. From the moist sounds we conclude that the medium-sized bronchial tubes are occupied by loose collections of mucus, through which the air bubbles in expiration, and so gives origin to this phenomenon. You see that the præcordial percussion dulness extends over a large area, and measures more in the transverse diameter, than in the longitudinal, viz., 16 centimetres compared with 15. What are the conditions that may give rise to such an increase in the area of cardiac dulness? First, the increase may be produced by an enlargement of the heart itself, in consequence of dilatation, or hypertrophy, or a combination of these conditions, and this may occur on either side of the heart; usually we find that the auricle is enlarged as well as the ventricle. (2) An abnormal increase of the percussion dulness in the same region may be caused by fluid in the pericardium, due either to exudation or transudation. (3) There may be solid

tumours in this region; in such cases, however, the percussion dulness is usually irregular in outline. Where there is a collection of fluid in the pericardium the outline of the area of dulness differs from that found in the case of dilatation; the fluid first collects about the base of the heart and the area of percussion dulness assumes the form of a truncated cone. This is not so in the case before us. Further, if large quantities of fluid collect in the pericardium the action of the heart is diminished, its contraction not being felt and seen distinctly, as the liquid hinders the propagation of the impulse. As we do not find this condition here, we conclude that the abnormal increase of the cardiac area is caused by enlargement of the heart itself. Is the whole of the heart enlarged or only a part of it? If the left side of the heart only is enlarged, the enlargement takes place in the longitudinal direction, the chief axis of the left ventricle corresponding with that diameter; in such a case the transverse measurement is never longer than the longitudinal. In our patient the reverse is the case, the transverse diameter (16 centimetres) exceeding the longitudinal (15 centimetres), hence we infer enlargement of the right ventricle. The condition of the pulse will still further elucidate the point. If the left chamber is dilated or hypertrophied, it throws an increased quantity of blood into the arteries, giving rise to a full tense pulse. In our patient the pulse is small and very compressible. In dilatation of the left ventricle the aortic sounds, especially the second, are much accentuated; in dilatation of the right ventricle, on the other hand, the accentuation of the second sound of the pulmonary artery is greatly augmented. That this latter condition is present in our patient is further shown by his cyanosed appearance and by the enlargement of his liver in consequence of congestive hyperæmia, the blood of the superior and inferior venæ cavæ not being able to discharge itself into the right auricle in its usual way.

What kind of enlargement is present here, hypertrophy or dilatation? First, we know by experience that in the right ventricle dilatation is most common, whereas hypertrophy is chiefly met with in the left chamber, its walls being sometimes so enlarged as to measure an inch in thickness. In our case the percussion dulness is very much increased, which of itself suggests the presence of a dilatation.

On auscultation over the apex of the heart we hear during the systole a murmur with a rudimentary first sound; during the diastole there is neither a sound nor a murmur. Over the aortic cartilage both sounds are audible, together with a systolic murmur conducted from the mitral valve. Over the pulmonary cartilage we hear both sounds, the second sound being more accentuated than is usually the case. From the fact that the systolic sound at the apex is replaced by a systolic murmur, disregarding the insignificant rudimentary sound, we conclude that the mitral valve is incompetent, *i.e.*, that the segments of the valve are unable to prevent the blood from regurgitating into the left auricle. The latter chamber must therefore be considerably dilated, but we cannot prove it directly, owing to its situation, as in most cases it only comes in contact with the chest wall by its appendage. Stenosis of the left auriculo-ventricular orifice cannot be deduced from the conditions of the heart already mentioned, but can only be diagnosed if we hear a diastolic murmur over the bicuspid valve. In uncomplicated mitral incompetence the left ventricle is, in some cases, of normal size, in others it is a little larger, and the character of the pulse will depend on which condition is present. If the capacity of the left ventricle is normal, the whole quantity of blood which it contains is not thrown into the aorta on its contraction, and accordingly the pulse remains normal. If, on the other hand, the capacity of the left chamber is increased, the pulse may be nearly normal; for in spite of regurgitation into the auricle, a sufficient quantity of blood may be driven into the aorta. If, however, there is at the same time stenosis of the mitral orifice, the pulse presents conditions which are altogether abnormal. As in such a case the action of the heart is quicker than normal, the diastolic movement is of shorter duration, and the whole of the blood in the left auricle cannot pass in such a short interval through the contracted orifice, so that there is not so much blood as usual to be driven into the aorta. The pulse is therefore small in proportion to the degree of stenosis. As our patient's pulse is extraordinarily small and very compressible, we may diagnose, from the condition of the pulse itself, stenosis of the mitral orifice. In incompetence of the mitral valve, such as is present here, the right ventricle must work with a greater *vis a tergo*, in order to overcome the pressure in the pulmonary circulation. Hence we get hypertrophy and dilatation of the right ventricle and auricle, accentuation of the second sound over the pulmonary cartilage, and, finally, enlargement of the veins which run into the right auricle, viz., the superior and inferior venæ cavæ, and backward congestion of the liver.

The abdomen of our patient is distended, especially in the epigastric region. In the right hypochondriac region a hard body is felt, which extends as far as the umbilicus, and presents an outline like that of the inferior margin of the liver. The percussion dulness begins as high up as the nipple. The liver is therefore considerably enlarged, in consequence of the regurgitation of blood from the right ventricle and auricle.

There are two forms of hyperæmia of the liver: active or congestive hyperæmia, and passive or mechanical hyperæmia. Of the first much has been written, but even now we know very little about it. It may have its origin in an injury, it may also arise in consequence of the ingestion of excessive quantities of strongly-spiced food, and it may also depend on climatic conditions; in this case the blood assumes a venous quality, owing to its diminished content of oxygen, and collects chiefly in the portal vein. In severe forms of malaria there are symptoms which seem to point to active hyperæmia of the liver. The hyperæmia of the liver found in individuals who suffer from disturbances of menstruation, or from hæmorrhoidal losses is also supposed to be of an active character. But all these conditions are very difficult to explain, as they are never followed by death, so that we have no opportunity of getting a good and clear idea of their nature. The patients suffer from a feeling of pressure and heaviness, and from slight pains in the region of the liver. They are also distinguished by a slightly jaundiced skin, especially when they have lived in hot climates; they suffer from digestive disturbances, and their liver is considerably enlarged. If we find in such a case enlargement of the liver with pain, we may assume the presence of congestion.

Passive hyperæmic enlargement of the liver develops in most cases in consequence of heart and lung diseases, especially in the case of diseases which are associated with dilatation of the right ventricle. The liver in such cases is very considerably enlarged; it may reach quite low down in the abdomen. It is usually unattended by pain, but on firm pressure, or after bodily fatigue, it is apt to become painful. If the condition has lasted for a long time the patient does not complain of any pain, even on firm pressure. If the regurgitation is considerable, ascites may also develop, but it is then ordinarily general dropsy caused by a diseased heart. The liver in such cases presents a characteristic appearance, which we call "nutmeg liver"; yellow and red spots being found on transverse section. The red spots are the distended veins,

the yellow ones represent the liver-cells, which are usually the seat of fatty degeneration. The distended veins press upon the liver-cells, and so lead to this degeneration. In the later stages of this disease the liver, we find, presents an altogether different appearance, and gradually diminishes in size. The reason for this is that in consequence of long-continued stasis there is a considerable development of connective tissue around the hepatic veins, which is followed by a degeneration of the cells. At a later stage the hepatic veins atrophy and the smaller bile-ducts become compressed.

The prognosis in the case of our patient, suffering as he does from this enlargement of the liver, is undoubtedly a bad one. Treatment must be directed towards the condition of the liver, disregarding the "vitium cordis," the former disturbance being now the more prominent one. In former times we used in such a case to abstract blood, either from the liver-region, from the external abdomen walls, which is not to be recommended, or from the region of the anus. Relief can only be produced by derivation directed towards the abdominal cavity; we, therefore, shall not prescribe for our patient anything beyond energetic purgation.

ON STATISTIC MEASURES OF THE HEALTH OF COMMUNITIES.[1]

By THOMAS W. GRIMSHAW, M.A., M.D.,
Registrar-General for Ireland.

I HAVE to thank the Council of the Sanitary Institute of Great Britain for the honour they have done me in selecting me to preside over this important section of the Congress. It would be impossible to state what subjects might not be included under the comprehensive title of this section—namely, "Sanitary Science and Preventive Medicine." In the absence of any system of recording the prevalence of sickness, the only way we have of arriving at a general estimate of the health of any district is by making use of the information afforded by the number of the deaths among its inhabitants, the nature of the diseases of which they die, and the relative proportion of the causes of death to the total and to one another, and their relations to other conditions with which I desire specially to deal on this occasion. A death-rate does not necessarily indicate the amount of disease prevalent in a district; for instance, there are some diseases, such as influenza, which cause but few deaths, but which may almost suspend the activity of a population. Many are sick who do not know it, or who take no notice of it for a long time, and there is not yet any method of recording the sickness that is known. Indeed, it is improbable that any reliable record of sickness will ever be established. Nevertheless, many very effectual attempts have been made to estimate the extent to which sickness prevails in certain communities. From tables prepared by Mr. Sutton, the Actuary to the Registry of Friendly Societies, it appears that the average time of sickness among males during the working years is 1·314 weeks—that is, a small fraction more than nine days each in each year; and that among females it is yet a small fraction more. The result is that among males there is a loss of 9,692,505 weeks' work in every year, and among females a loss of 10,592,761 weeks. Thus we may believe that our whole population between 15 and 65 years old do, in each year, 20,000,000 weeks' work less than they might do if it were not for sickness.

No further proof is necessary of the great loss the community suffers from sickness, and therefore as death statistics are practically our only measure of the prevalence of sickness, and the only generally available statistical measure of the health of communities, it is of the utmost importance that we should know the exact value to be attached to these measures, and the fallacies to which we are liable in making use of them. We find that among the great towns of the world, the death-rate, taken upon an average over a series of years, varies from 19·9 in Christiania to 48·0 in Madras:—

Calcutta ..	30·9	Munich ..	34·0
Bombay ..	34·8	Vienna ..	27·9
Madras ..	48·0	Buda Pesth	37·1
Paris ..	26·4	Trieste ..	34·1
Geneva ..	22·6	Rome ..	28·6
Brussels ..	25·4	Turin ..	26·8
Amsterdam	25·9	Venice ..	28·5
Rotterdam	26·1	New York	27·7
The Hague	24·6	Brooklyn	23·6
Copenhagen	24·8	Philadelphia	20·6
Christiania	19·9	Baltimore	22·2
St. Petersburg	42·1	Naples ..	31·4
Berlin ..	29·0	Alexandria	42·4
Hamburg	25·8	London ..	22·0
Dresden ..	25·1	Dublin ..	27·9
Breslau ..	31·2	Edinburgh	21·4

Undoubtedly the death-rates published weekly, quarterly, and annually by my colleagues in England and Scotland, and by me in Ireland, are *primâ facie* evidences of the relative healthiness or unhealthiness of the population living in each of these, and no doubt a very high death-rate does in nearly every case indicate unhealthiness, and a very low death-rate indicates healthiness of a population to which it refers; but it does not at all follow that a death-rate of, say, 40 per 1,000 indicates double the unhealthiness that a death-rate of 20 does. To speak in common parlance, the high death-rate really indicates that the population to which it refers has a delicate constitution, and that with a low death-rate a robust constitution.

It is important, in the first instance, to enquire under what circumstances we may expect to find a low and a high death-rate respectively. If a people are well fed, well housed, and well clothed (in fact well off), and the district is well drained, and the climate moderate, we may expect, all other things being equal, to find a low death-rate. Yet, if the people are employed at unhealthy occupations, and if they contain an undue population of young children or very old people, the death-rate will be high. If, on the other hand, a population is badly fed, badly housed, and the district is badly drained, we may expect to find a high death-rate, even although the occupations are healthy, and the age constitution of the population duly proportioned. In estimating the value of death-rates as a test of healthiness, there are some elements to which too much importance appears to have been attached. It is too much the custom to attach exaggerated importance to the proportion of deaths from "zymotic" diseases of an infectious or catching nature as evidence of unhealthiness. I admit that the prevalence of infectious diseases and their fatality is a very important element in estimating the health of a community; nevertheless, if the death-rate from any particular group of diseases were taken as a single test of unhealthiness I should choose the constitutional, not the zymotic group, as the most reliable. If we take London and Dublin, for example, and contrast them as to the relative mortality from particular groups of diseases, we find that the deaths from zymotic diseases were 57 per 10,000 of the population in Dublin, and 51 in

[1] Address delivered in the Section of Sanitary Science and Preventive Medicine at the Sanitary Congress, Dublin, Oct., 1884.

London, or but slightly greater in the former than in the latter; whereas the deaths from constitutional diseases in Dublin were 43, while in London they were only 23, or little more than one half the same proportion. Nevertheless, the total death-rate in Dublin was 277, while in London it was 230, or 47 less. Again, the infantile death-rate is much relied on, but a low infantile death-rate is quite consistent with a high general death-rate—as, for instance, happens to be the case in Dublin.

Attempts have been made from time to time to estimate what should be the death-rate of a healthy community, but in my opinion all such efforts have been signal failures; and we are driven to depend upon comparisons of death-rates in various countries with one another, or to comparisons of different portions of the same community with the whole or with one another, as the only test of the healthiness or unhealthiness of such communities. Thus, the average annual death-rate of the population of England and Wales for ten years, 1871–80, was 21·4, while in London it was 22·5 In Scotland it was 21·6 for the same period. In Ireland for the same decade it was 18·3, and varied from 27·5 in Dublin to 14·1 in the rural districts of Connaught. Now, do these varying rates truly represent the relative healthiness of the different communities to which they refer? I state, unhesitatingly, that they do not; that in some of these districts the people are less unhealthy, in others more unhealthy, than the rates represent them to be. It is therefore of the utmost importance that when we find that *primâ facie* a community has a very high death-rate or a very low death-rate, or in many cases an average death-rate, we should minutely investigate all the elements which compose such an exceptional death-rate, and having hunted down the peculiar elements to their habitat in a particular place, class of life, age, sex, or occupation, we shall be in a position to rightly estimate the significance of the high or low death-rate, as the case may be. It will be necessary, in making such investigations, to consider the death-rate in relation to the following conditions:—(1) The locality in which the people live, its climate, soil, &c., its drainage, the density of the population, and the mode in which they are housed. (2) The wealth or poverty of the people, and their means of obtaining food and clothing. (3) The occupation and social position of the people, and the proportion of each class to the whole and to one another. (4) The age-composition of the population, the population living at each age, and therefore their expectation of life. (5) The diseases of which the people die. (6) The relations of births, marriages, and deaths to one another and to the population. I shall now endeavour to touch upon each of these questions, and consider how far statistical measures can be fairly applied to their solution.

We have no statistical measure which can be applied as a test of the healthiness of a particular locality as such, although we can state with a considerable degree of accuracy that we are not likely to find a healthy population living in swampy grounds, or in a low-lying locality which is not sufficiently drained. We also know that the inhabitants of a damp district may have their health materially impaired by the drying of the soil by drainage works. In the matter, however, of climate, we can apply statistical tests, and I would take the familiar case of Dublin and London to illustrate this point. In Dublin we have a delicate population as compared with London. If we take the temperature of the air as one of the most important elements of climate, we find that the means for Dublin and London are not very different, Dublin being somewhat more equable in its temperature, and therefore more favourable to delicate people, while in each district sudden falls of temperature and considerable cold, lasting for an extended period, are accompanied by material increase of death-rate; yet the addition to the death-rate in Dublin under such circumstances is much greater in proportion to the cause than it is in London; thus showing that the more delicate—in other words, the less healthy — population of Dublin is more easily injured by cold than the more robust population of London. Why this is so is a separate question, but the fact, I think, will be found proved, whenever tested, that a population whose death-rate is extremely sensitive to alterations of temperature is an unhealthy population, and has generally a high death-rate at all times.

It has long been known that a very general relation exists between the density of a population and its death-rate; in other words, where people are packed closely together there we expect to find a high death-rate. This at first sight appears to be a mere truism, but I am glad to say that the old sanitary, or unsanitary maxim, "that a dense population has a high death-rate," is becoming less true every day, as it has been proved by the operations of artisans' dwellings companies and others who have undertaken to provide dwellings for the working classes, that with reasonable precautions very dense populations can enjoy very good health and have very low death-rates. The very natural inference has been drawn that the principal zymotic, or infectious diseases (as they are popularly called), contribute largely to this high death-rate in dense populations. This influence, however, cannot be very potent, and, indeed, Liverpool is the only instance where it is well marked. It would appear that more can be done by re-arranging and re-distributing the dense populations within existing areas than by making futile attempts to diminish density.

The next question to discuss is the wealth or poverty of the people, and consequently their ability to obtain the necessaries of life, in the way of food, clothing, and house accommodation. I have made many attempts to establish statistical lists of these conditions, but the absence of reliable statistics of wages and the variations in the method of relieving the poor and needy through the Poor Law or otherwise, have quite baffled my attempts. Closely connected with the question of the poverty or wealth of a community, as a test of the significance of its death-rate, is that of the social composition of the community. It is a matter of the utmost importance, when applying death-rates as a test of health, that the relative numbers of the population belonging to each social class should be known. We are all, unfortunately, too well aware of the fact that the death-rate among the weekly wage-earning class, especially among children, is higher than in the classes above it. Now, although the census returns take note of the occupations of the people, they do not take note of the numbers of persons dependent for subsistence on each kind of occupation; thus, the census reports tell us how many blacksmiths there are in the United Kingdom, but do not tell us how many blacksmiths' wives and children there are, and therefore how many persons are supported by and dependent upon the trade of the blacksmith. Some years ago the Dublin Sanitary Association —which has had so much to do with the organising of this Congress—considered this question, and determined that when the next census period approached they would ask the Government to include returns of the social condition of the people of Dublin in the census returns for 1881. The variations in the death-rate between the classes and the sub-classes is remarkable. For example, in the "professional class" the death-rate is but 19·8 per 1,000, while in the "general service

class" it is 36·8 or nearly double. Among domestic servants, it is but 9·1, while among labourers it is 34·4, although both are drawn from the same stratum of society. These returns exist only for Dublin and in Dublin. This method of dealing with mortality statistics is only in an experimental stage, and therefore must have many imperfections.

The next point to be considered in the application of statistical measures of health is the age-composition of the community to which the measure is to be applied. The number of persons living at different ages differs materially in different communities. The number of very young people in England is relatively much greater than in Ireland, the number of children under five years being 135·5 per 1,000 inhabitants in England, as compared with 111·3 in Ireland. In the case of infants under one year it is more remarkable, there being 29 "babies" in England to 20·3 in Ireland, a fact which is at variance with commonly received opinions. At the other extreme of life we find that there are more old people in proportion in Ireland, where those above 60 number 106·2 per 1,000 of the population, than there are in England, where they number but 73·8 per 1,000. Now, as very young children die at a greater rate than older children, or persons in middle life, we might expect the death-rate of England to be much higher than Ireland, but it is only a little higher. And why is this? Because the old people, whose lives are also precarious, are more numerous in Ireland than in England. In both countries the highest death-rate is among children, the deaths under one year being 109·4 per 1,000 living at that age in Ireland, and 152·7 per 1,000 in England, as compared with the general death-rate of 17·4 and 18·9 respectively. The death-rate steadily decreases as age increases, until the age period of from ten to fifteen years is reached, when the rate reaches the minimum both in Ireland and England, being 3·7 in Ireland and 3·3 in England. After this period the troubles and risks of life are entered upon, and the death-rate steadily rises until the age of sixty-five is passed, when the rate increases by enormous strides. It is remarkable, on comparing Ireland with England, that up to the age of ten the death-rate of English children is higher than of Irish and after that period the Irish death-rate is in excess of the English. It looks as if the real struggle for existence were harder in Ireland than on the other side of the Channel. This, however, is not likely to be the case, and the difference is probably owing to the larger emigration from Ireland. It is well known that in all countries of Europe it is the most able-bodied, strong-minded, and enterprising who emigrate to seek wider fields for their energies than are afforded by the overcrowded countries of the Old World. This principle affects Ireland more than England, just in proportion to the number of emigrants; the able-bodied and energetic go, the delicate and less active remaining.

The higher death-rate among children in England as compared with Ireland cannot, however, be thus explained. Is it that Irish mothers are more careful of their little ones than English mothers? I trust that with all our differences there is none between Englishwomen and Irishwomen in their love and care of their little ones. Indeed, it would ill serve me to enter upon such a comparison, as my mother was an Irishwoman, and the mother of my children is an Englishwoman. The explanation is simple, though it may surprise some; it is the difficulty of bringing up healthy children in large towns, and the mothers leaving them, to work in mills or at other occupations. In England there are many more large towns than in Ireland. In England of the 25,974,439 people (according to the census of 1881), 14,626,131 live in towns having a population of 10,000 or upwards, and 11,348,308 live in country districts and small towns. In Ireland, of the 5,174,836 only 845,839 live in towns with populations over 10,000, while the balance, 4,328,997, live in country districts and villages. In other words 56·3 per cent. of the English people belong to town populations, and but 16·3 of the Irish people live in considerable towns. The following statement, showing the proportion of deaths under one year to 1,000 births, demonstrates the dangers to infant life in large towns, and shows that this danger is, as a rule, greater in manufacturing than in other towns:—

London ..	.. 154	Glasgow ..	.. 151
Birmingham	.. 167	Dublin ..	.. 170
Manchester	.. 176	Belfast ..	.. 147
Edinburgh	.. 135		

Again, with a view of testing the question further, I take two registration counties of England—namely, Lancashire and Somersetshire—the former of which contains a large population resident in towns, and the latter a small proportion of its population so residing, and I find that in the former case the infant death-rate was 167, while in the latter it was only 116. The differences in mortality cannot altogether be attributed to the peculiarities of a manufacturing population, for if we compare London and Dublin, neither of which can be considered as inhabited by populations *especially* engaged in manufacturing industries, the mortality of Dublin, at all ages, especially among infants, far exceeds that of London. Now why is this? I am unable, from want of information, to give a positive answer; but I believe that a great deal of the difference depends on the social condition of the communities, and the more prosperous condition generally of the lower social strata of society in London than in Dublin. This is, no doubt, a bold assertion, especially when we know how great are the miseries of outcast London. If, however, we look again to the social condition table for Dublin and to the mortality table, we see that the vast bulk of the infantile mortality takes place among the "general service" and "pauper class," which constitute nearly half (44·3 per cent.) of the population of the Dublin registration district. It is a melancholy fact, but nevertheless it is a fact, that the struggle for maintenance between the members of a large family (and indeed not unfrequently in a small family), among the lower strata of society, is so intense that it results in the injury of all its members, and the death of many. This is really one of the first questions of the day, and one which, unfortunately, has not been sufficiently attended to by many social reformers, but with which I cannot deal here.

In connection with the question of the effect of age-composition of a community in relation to its death-rate, I would draw special attention to some remarks on the subject in the summary of births and deaths of the Registrar-General for England for the year 1883. In this summary a very ingeniously constructed table is introduced, by which this effect of age-composition on death-rate of population is shown, and death-rates corrected according to standards derived from the age and sex-composition of the population of England and Wales, are given for all the large towns of England and Wales, and then compared with the recorded death-rates. In some cases the differences are very considerable between the two rates. I have had some experimental calculations made on Irish death-rates, based on the principles suggested by the Registrar-General of England, and there can be no doubt that such investigations will tend to throw further light on the statistical measures of the health of communities.

At the commencement of these remarks I said, when speaking of the importance attached to the death-rate for zymotic diseases as a means of health, that if I were to take the death-rate for any particular group of

*

diseases, I would choose the constitutional, not the zymotic, as the test. I would here again refer to the instances of Dublin and London as useful examples, the former being an unhealthy, the latter a healthy town population. It will be observed that in nearly every instance the death-rate of Dublin is somewhat in excess of that of London; in many diseases the excess is small. Thus, in the case of the zymotic diseases, the excess of Dublin over London is not, proportionately, nearly so great as in the case of constitutional diseases; in the former case the ratio is 57·1 to 50·6, in the latter 52·3 to 42·9. Among the constitutional diseases we find that the death-rate per 10,000 from phthisis or pulmonary consumption alone is 31·6 against 25·1, and closely connected with this we find that the death-rate from diseases of the respiratory organs is 55·8 in Dublin against 47·5 in London. This accords with my former remarks on the delicacy of the population of Dublin compared with London, as measured by the effect of sudden falls of mean temperature on the death-rate of these two towns. I believe that the prevalence of the class of diseases termed "constitutional," as measured by the death-rates from these diseases, will be found to be a better gauge of the health of the community than the prevalence of any other single class of fatal affections, and in this sense may be truly termed "constitutional," whatever objection there may be to the term when viewed by the scientific nosologist.

My remarks have now extended beyond the limits which should be placed on an address such as this, and I shall not attempt to analyse the statistics which are available regarding the relations between marriage-rate, birth-rate, and death-rate; but I think I may ask you to take my word for it that when these three rates bear an undue proportion to one another in any given community there will be found to be serious defects in the health of that community, and not improbably a serious defect in its moral as well as its physical health. The relation between cleanliness and godliness is deeper than many who use this common proverb are aware. In conclusion, I have a word to say about the contrast between the health of the inhabitants of town and country districts. I have recently been engaged upon an analysis of the returns of marriages, births, and deaths in Ireland for the ten years, comprised between the census periods of 1871 and 1881. The report on this subject has been recently presented to Parliament, and will soon be in circulation. From this analysis I find that the death-rates in the districts in Ireland comprising towns with a population of 10,000 and upwards, during the decade, was at the rate of 225·1 per 10,000 of the inhabitants, while in the districts which comprise no considerable towns it was only 166·5 per 10,000. It may be pointed out that the death-rate from nearly every cause is greater in the town districts than in the country districts. It is, however, specially worth noting that the deaths from consumption in town districts were at the rate of 27·7 per 10,000 of the mean population, and in the country districts but 16·4, and in diseases of the respiratory organs the ratio was for the former 38·4, and for the latter 22·6. I shall not venture to analyse any further the information contained in this report, which will be in the hands of the public in a few days. I must now bring these remarks to a close, and trust that I have not occupied your time unprofitably in asking you to consider some of the many and not a few of the most important points we have to take into consideration when applying statistical measures as tests of the health of communities.

The Library of the Royal College of Surgeons will be closed this day (Friday), and on Friday, Oct. 17th, for the purposes of the examinations, which commence earlier this year.

CRITICISMS ON THE EXHIBITS OF DISINFECTANTS AT THE HEALTH EXHIBITION.

By A. WYNTER BLYTH,
Medical Officer of Health for Marylebone.

Disinfectants are the shot and shell of the sanitarian.

Disinfection may aid but never replace cleanliness—an often repeated and ever accepted axiom; nevertheless, the pestilence that flies by night, the murrain falling on man and beast, require even more than cleanliness which is but a passive resistance. The war against hosts of the infinitely small is offensive as well as defensive. It is not sufficient to wash away the food of the enemy, he must also be harassed by shot and shell.

Old and new methods of testing disinfectants.

The older experiments on the activity of disinfectants but touch the surface. True it is that sulphur dioxide decomposes hydric sulphide, but a better knowledge is, will it neutralise or influence cholera or typhus? It is this better knowledge, one which it is no figure of speech to say will save myriads of human lives, that the new method aims at attaining. The new method cultivates in flask and test-tube pathogenic forms of micro-life in such a manner that they may be studied at leisure and in detail, and the influence upon their growth exerted by disinfectants observed.

This method, only of recent years possible, will give a precision to the science of preventive medicine hitherto unknown, and deal a blow at the reputation of many a disinfectant sold by cupidity and bought by ignorance.

Provisional classification of disinfectants.

Disinfectants, in relation to their influence on micro-life, might be divided as follows:—

1. *Sterilisers or Germicides.*—That is, agencies destructive of pathogenic micro-life, *e.g.*, heat, strong mineral acids, undiluted chlorine, corrosive sublimate.

2. *Agencies which as a rule* do not destroy pathogenic life, but act as inhibitors to the growth and multiplication of microbes generally, *e.g.*, dilute carbolic or cresylic acids.

3. *Deodorisers*, substances neither overpowering nor masking bad smells, but destroying them, *e.g.*, peroxide of hydrogen, chlorine.

4. *Antiseptics*, substances which arrest decay, *e.g.*, thymol, common salt.

Action of commercial disinfectants on anthrax cults.

During 1883, I experimented on the action of the ordinary commercial disinfectants on the anthrax bacillus. My paper, with full details, will be found in the "Transactions of the Royal Society of Edinburgh," but I will give here a brief abstract of the method employed, and will refer to the general results attained.

Anthrax bacillus was cultivated in gelatinised pork broth, until crops of spore-holding threads were produced. These spores were used to infect sterilised veal and mutton broth after being treated as follows:—Pieces of glass-tubing were drawn out in the flame so as to make capillary rods, each rod was tipped by sealing wax, and each little red bead of sealing wax was made to carry a minute "fluff" of sterilised cotton wool. This little fluff was infected by spore-anthrax, by dipping it in an anthrax cult; it was then submitted to the action of the disinfectant under examination for a definite period of time; after this the infected wool was freed from any minute trace of the disinfectant by careful soaking in suitable fluids, water, alcohol or ether, according to circumstances; lastly, the capillary glass rod, with its fluff, was plunged

into sterilised broth with all the well-known precautions necessary to prevent other contamination, and the broth submitted to cultivation. A large incubator, kept at blood heat night and day, permitted the simultaneous treatment of 20 to 30 cults. If the anthrax spore had been destroyed, no growth resulted; delayed development was discovered and estimated by cultivating, side by side, ordinary (control) cults.

The method I have so briefly detailed is the outcome of successive simplifications, and was convenient and satisfactory; but, on the other hand, I am not quite content with the main result of the investigation. Anthrax is in two states, the thread and the spore—the thread state is so delicate that all sorts of things, substances even with feeble claims to be considered disinfectant, will destroy it. Anthrax spores, on the other hand, are so resistant, that to compare disinfectants one with another by their action on the spores, is taking too high a standard. I hope to find for further experiments some micro-life, the vitality of which stands between these two extremes.

Method of ascertaining the deodorising power of disinfectants.

To ascertain the deodorising effect of a disinfectant, I proceed as follows:—Offensive liquid sewage is taken, and a litre put into a wide-mouthed stoppered vessel; the fluid to be tested is added to the sewage little by little from a burette, and after each addition; the vessel is well shaken, and allowed to rest a given time, and then the odour (if any) ascertained. This test is very rough, and as applied to any disinfectant having a strong odour, unsatisfactory, for there is ever a doubt whether the sewage-scent be masked or annihilated.

Carbolic, Cresylic Acid, and the Tar Principles Generally.

Messrs. Calvert's preparations.

I notice with commendation Messrs. Calvert's fine display of various carbolates, of phenol and of cresol. Messrs. Calvert hold, I believe, a strong opinion that the purer forms of acid are, for disinfecting purposes, superior to the impure; nor will anyone venture to gainsay this so long as a comparison is made between equal bulks; but it is a different matter if the competition lie between equivalent strengths, as, for example, between 100 parts of 50 per cent. phenol, against 50 of absolute. In such a case, according to my experiments, the crude mixture of acids goes farther than either the equivalent quantity of pure phenol or pure cresol, or a mixture of phenol and cresol, the reason probably being that the so-called impurities are, to a certain extent, disinfectant.

Effect of phenol and cresol on anthrax.

I have experimented on anthrax with both phenol and cresol. As chloroform and ether are the anæsthetics of higher life, so the tar acids are anæsthetics of microbe life. Under the influence of moderate amounts of either vapour or liquid, a state which may be compared to sleep is produced, but on complete removal of the acid, and on placing the microbe on a suitable soil at a suitable temperature, growth sooner or later developes:—

One per cent. solution of Calvert's carbolic acid, of the common impure commercial acid, and one per cent. solution of cresylic acid, were severally used to sterilise the infected "fluff" acting for various periods of time; but in each case subsequent development was almost as rapid as in the "control."

A five per cent. solution of these three acids gave results not dissimilar, save that growth was at first much delayed, but afterwards active.

A twenty-five per cent. solution in alcohol of either cresylic or carbolic acid seemed to destroy anthrax-spore life; that is, it made it incapable of germinating in broth.

Various tar-acid disinfectants.

Jeyes' perfect purifier, the concentrated carbolated creosote of Messrs. D. & W. Gibb, the kresylene described by Messrs. Mackey & Co. as a preparation of coal-tar creosote, pixene, and the thymo-cresol exhibited by Messrs. Ness & Co. (Darlington), have all the property of emulsifying with water. Jeyes' purifier was for some time tried in St. Marylebone urinals and drains, but the deposit left on the surfaces with which it had been in contact was found difficult to cleanse and inconvenient. I have made some experiments on anthrax, in the spore state, with the "perfect purifier." The solutions used were five to ten per cent.; the "fluff" had to be freed from the tenacious fawn-coloured deposit by alcohol. The result was very similar to what might have been predicted from results of experiments on the pure tar-acids, viz., growth was a little delayed, but never destroyed.

Pixene.

Mr. James Wheeler's pixene I was on the whole favourably impressed with. He claims to have condensed the whole of the volatile constituents of pure tar, and to have presented them in a form readily miscible with water. Pixene is of the colour and consistency of treacle, its odour is decidedly more agreeable than that of coal-tar, or of impure phenol. Anthrax spores soaked in a ten per cent. solution did not grow for some time.

I have made no very elaborate experiments on the other disinfectants of this class; they appear to me to differ but little from Jeyes' in their activity and properties. All either destroy or overpower (I know not which) bad odours.

Carbolic acid powders.

I have experimented on anthrax with Calvert's, Jeyes', and McDougall's powders, but even when a paste was made with the several powders, and the infected "fluff" allowed to remain therein twenty-four hours, no sterilisation resulted. On placing the wool in a proper medium, growth invariably took place.

A powder is, of course, convenient for transit, for storage, and for application, but I have not the slightest hesitation in expressing doubts as to the disinfecting activity of the carbolated powders.

Sanitas.

Sanitas.

Of all the substances introduced under the name of disinfectant, this is the most pleasant. Sanitas is chiefly in the form of sanitas oil and sanitas fluid; peroxide of hydrogen, thymol, camphoric acid, and terebene enter into their composition. Of the numerous sanitas preparations, liquid and solid, the oil seems to be the most active. Nothing replaces or destroys so rapidly the unpleasant odour which tenaciously adheres to hands contaminated by contact with offensive animal matters. It is also to be commended for use in stables, and as a corrective of dung-heaps, and of the sickly smell at times rising from the metropolitan wood pavement.

I made many experiments with sanitas on anthrax.

Spores soaked in sanitas fluid for twenty-four hours grew afterwards very freely. Spores placed in the undiluted emulsion, and afterwards removed, seemed at first to have their growth delayed, but in forty-eight hours growth commenced and ultimately became luxuriant. The oil itself gave similar results. Sanitas powder was also tried, but with no better success.

Allowing, as I said before, that anthrax spores are extremely resistant, nevertheless the very non-poisonous character of sanitas on which so much stress is laid by those interested in its sale, renders it unlikely to be a true steriliser, and in the present absence of evidence I would not rely upon it in serious disinfection, that is, in cases of disease.

Sanitas appears a good antiseptic, and I notice at the Exhibition meat preserved in it.

Eucalyptol. *Eucalyptol*, and *Eucalyptol powder* with sulphate of iron, or with copper or lime, exhibited by Messrs. Mackey, Mackey & Co., are suggestive of sanitas, and have all pleasant odours. In default of experience I pass them over for the present, reserving them for future trial. I may, however, state that, counter to general belief, sulphates of iron and copper are according to my own trials rather stimulant than destructive of micro-life; that is of course in the strength likely to be used in practice.

The Permanganate Class of Disinfectants.

Condy's fluid. Condy's fluid is of course exhibited. The delicate attractive red or pink colour, the property of giving up nascent oxygen, and the non-corrosive and non-poisonous characters of permanganate of potash will always ensure it a place among disinfectants.

Anthrax in the spore state is only attacked by permanganate when concentrated and hot, and it is doubtful whether the dilute form in which permanganate is used in practice would destroy any but the more delicate and feebler forms of micro-life; the maximum oxidising effect is only produced in the presence of either a strong alkali or a strong acid, and at a high temperature. Under these conditions, it is possible to oxidise the carbon of very complex and resistant substances into carbon dioxide. If, for instance, a little flour is boiled with strong sulphuric acid, and from time to time a crystal of potassic permanganate is added, a perfectly colourless solution may be obtained, without any visible particles of carbon; but these violent reactions belong to the laboratory, and are not to be attained in ordinary disinfection.

Chlorine and potassic permanganate. *Chlorozone* exhibited by the Chlorozone Fluids Company, and Messrs. Mackey's oxychlorogene, are very similar and their properties depend upon permanganate and chlorine. Twenty parts of either of these fluids fully deodorise 10,000 parts of offensive Marylebone sewage. I think these disinfectants are of some considerable power, and regret that I have not yet experimented with them on micro-life.

Hartin's crimson salt. *Hartin's crimson salt* seems to me nothing else save permanganate, and certainly possesses no virtues superior to an equal weight of potassic permanganate.

Sulphur Preparations.

Germicidal properties of sulphur dioxide. There is some evidence that sulphur dioxide, whether in solution or as gas, is destructive of the more tender forms of micro-life. Bucholz found that 1 part in 666 of a cultivation fluid inhibited the growth of ordinary putrefactive bacteria.

Braidwood and Vacher mixed vaccine lymph with a saturated solution of sulphurous acid, and with this mixture vaccinated twelve children; one alone "took." Koch found that under one per cent. of sulphur dioxide as a gas, destroyed the thread form of the anthrax bacillus, the micrococcus prodigiosus and the bacteria of blue pus; on the other hand, Koch, Abloing, Cornevin, Thomas and myself, have found the spore-holding threads unaffected, although exposed to an irrespirable sulphur atmosphere for long periods of time.

Sulphur fumigation. I do not put much faith in any form of sulphur fumigation, unless it is prolonged, the room first moistened by steam, and large volumes of the gas used. The disinfecting fluids about to be described are probably efficacious so long as they are allowed to act in their present tolerably concentrated form.

Various saturated solutions of sulphur dioxide. Messrs. Mackey, Mackey, and Co., under the name of liquid sulphur gas, sell a saturated solution, one volume containing about 400 of sulphur dioxide; such a liquid is certainly most convenient. The same firm have introduced "sulphenic acid," which is phenol saturated with sulphur dioxide, and it seems to me to be a promising disinfectant.

Prof. Tuson's disinfectants. Professor Tuson's two disinfectants, a liquid and a powder, exhibited by Messrs. A. Boake and Co., are, in a chemical point of view, highly ingenious. The liquid is of a light green colour, and consists of a solution of chloride of zinc, saturated with sulphurous acid gas. The powder is also tinted green, and is a mixture of sulphite of lime, sulphate of alumina, and sulphate of zinc; when moistened, whether by exposure to the air, or by being added to moist substances, a chemical reaction is set up, and sulphurous acid is slowly evolved.

I regret that I have only made some experiments on the deodorisation of sewage with these disinfectants, but intend at a future time to test their effect on micro-life. Of course the sulphur dioxide decomposes at once sulphuretted hydrogen, and any smell produced by mixtures of this gas would probably be at once annihilated; but I was surprised to find that the Marylebone sewage was not deprived of its offensive odour by treatment with a sufficient quantity of the liquid, to make the odour of the sulphurous acid very pungent, for through, as it were, the sulphur smell, the unmistakable sewage odour could be perceived. The powder as a deodoriser of sewage acted better than the liquid.

Chloride of zinc. With regard to one of the ingredients which make up the liquid, viz., chloride of zinc, Dr. Koch has expressed himself unfavourably, and states his astonishment that it should ever have been considered disinfectant; he found anthrax spores after a month's sojourn in a five per cent. solution grow and flourish.

I have also experimented on anthrax with zinc chloride. One per cent. solutions used in the manner detailed in the former part of this paper, most decidedly stimulated subsequent growth, the development being quicker and more luxuriant than in the control. A five per cent. solution acting for 24 hours had no influence one way or the other, while a twenty-five per cent. solution seemed, so far as artificial cultivation is concerned, to have arrested the life of the spore. I also dissolved chloride of zinc in thymol-water, but did not obtain by this combination any modification of the results.

It will of course be argued by the proprietors of Professor Tuson's disinfectants, that the combination of sulphurous acid and chloride of zinc will be found to possess more than the sum of the single action of each; this may be so, but it would be well to prove it.

Other Disinfectants.

Affinitan. "*Affinitan*," fathered by Mr. J. Alfred Shilton, F.C.S., should, according to my views, have its composition stated. I find among its constituents bromine, iodine, and ammonium chloride. The assertion on the label that it leaves no permanent stain is correct, whilst that it has no smell is not correct; the bromine odour is decided, though possibly not disagreeable.

There can be no doubt that the composition is powerfully disinfectant, but there is no novelty in the application of either bromine or iodine; the only question is, whether the particular form, strength, and combination has any particular advantage, or whether the price at which "affinitan" is sold is a reasonable one.

Camphorine. *Mackey's camphorine* consists of cam-

phor dissolved in a terpene. It is a pleasant fluid, and may be used for antiseptic and deodorising purposes.

Disinfection.

Much modern disinfection little better than the use of charms.

A practical study of the question of disinfection has profoundly altered my views, and I have an honest conviction that most of the disinfection by *chemical agencies*, as commonly practised, is worse that none. The reliance that even medical men of repute, still more the laity, place on a sheet wet with a little permanganate hung up before the sick room door, or on a feeble atmosphere of phenol, or a tablespoonful of Burnet's fluid to destroy things, the resistant nature of which is pretty well proved by their persistence, is astonishing. I question whether three horseshoes nailed over the lintel, by which some country folk keep the devil away, would not avail as much.

Effective treatment of excreta.

Specific excreta should be treated with the strongest chemical agencies. They may for instance be cast into the undiluted crude carbolic acid of commerce, which contains from 25 to 50 per cent. of real acids, and there digested for at *least two hours* before being thrown into the common sewer.

Disinfection of house drains.

House drains in the presence of zymotic disease should not be intermittently but continuously disinfected, so that the walls of the pipes be ever moistened with a disinfectant.

A non-poisonous germicide an impossibility.

A non-poisonous disinfectant is certain to be useless as a germicide. It stands not in reason, that a fluid harmless to mammals, rodents, and reptiles will be destructive of forms of life, some of which withstand a short exposure to the heat of boiling water.

Disinfecting quackery.

Rampant rides the quack in the fields both of preventive and remedial art. Quackery takes a well-known common powder, labels it with a grand mystic name, selling bright copper at the price of gold. Quackery finds a stink outstinking feebler stinks, and gives it forth as a disinfectant. Of all the substances gathered together under the name of disinfectants—solids, vapours, gases, and odours—a small percentage alone possess any value.

Contagion to be killed not "scotched."

Heat, chlorine, phenol, and corrosive sublimate are the sole practicable agents in which I put my trust as germicides, but to have due effect these must be used in a concentrated form, and for a prolonged period. To receive specific excreta in a five per cent. solution of carbolic acid, and then after a few minutes' interval to cast the substances so treated into drains or cesspits, is not likely to afford safety; for the disinfectant will be immediately diluted a thousand or million fold, and cease to inhibit pathogenic activity. The aim of the disinfector must be not to "scotch," but to kill, and this destruction should take place at the bedside of the patient; on the birth, as it were, of the fever egg.

PIECE OF COAL IN LEFT BRONCHUS ONE HUNDRED AND ONE DAYS.—PERICARDITIS.

By JAMES OLIVER, M.B. (Edin.).

Assistant-Physician to the Hospital for Women, Soho Square.

When a foreign body enters the air passages and becomes impacted in a bronchus, the right is more usually the seat of lodgment. This at first seems somewhat anomalous and difficult to explain, seeing that the left bifurcation is the more direct continuation of the trachea itself. The right bronchus is somewhat horizontal, but this, it would seem, is more than counterbalanced by the position, to the left of the median line, of the dividing septum. It is this deviation alone which apparently determines and favours the lodgment of foreign bodies in the right tracheal branches.

In the case in question the physical signs led to the determination of the seat of obstruction, and it is more especially to the changes occurring in the chest that I wish to draw attention. I shall not, therefore, enter into the details of the case in its entirety; suffice it to say that during the first two days, before impaction had resulted, the symptoms were those generally evinced under like circumstances — convulsive cough with dyspnœa, and occasional paroxysmal aggravations.

Complete occlusion of a fair-sized bronchus had resulted, evidenced by the fact that a partial emphysema had occurred, which interfered more or less completely with the respiratory function of the whole lung, the chest walls being maintained in a position of full inspiration. The left chest was fully expanded, the bulging at the side more especially being well marked, little or no change occurring during deep inspiration. Vocal fremitus was well marked over the right chest but barely determinable over the left. The percussion note over the left lung in front was hyper-resonant, and almost tympanitic, whilst posteriorly the note of this side was impaired, compared with the note of the right, a fact probably due to the compression of the air-cells posteriorly, the space previously occupied by them being encroached upon by the emphysematous lobules. The breathing all over the right chest was compensatory, and more or less puerile, whilst over the left, breath sounds were but faintly audible.

Inflammatory changes developed in the course of time in the neighbourhood of the impaction, and gradually spread by continuity and contiguity of tissue, the bronchus itself apparently participating but little in the change. The pericardium, however, eventually became involved, evidenced by a well-defined to-and-fro friction murmur heard plainly in the region of the third and fourth ribs over a limited area midway between the nipple line and the left border of the sternum.

On the 101st day the patient was seized with a violent fit of coughing, and the offending body again becoming liberated, symptoms of an alarming nature ensued; the little piece of coal, however, being eventually ejected, the sufferer obtained immediate relief.

Long before the offending body was got rid of, signs indicative of phthisis had developed. A gradual improvement, however, in the general condition of the patient followed its expectoration.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

THE MIDDLESEX HOSPITAL.

CONGENITAL MALFORMATION OF THE HEART—PATENT DUCTUS ARTERIOSUS—DEFECT OF VENTRICULAR SEPTUM—CYANOSIS—FACIAL ERYSIPELAS—PERICARDITIS—DEATH.

(Under the care of Dr. SIDNEY COUPLAND.)

James G., 31 years of age, a farm labourer in Hampshire, had been noticed to have had a livid appearance from his birth. He had never had rheumatic fever. When seven years of age he suffered from eczema of

the legs, and at the age of eleven from some intractable affection of the eyes for which he was treated in hospital. But he does not appear to have had any symptoms directly referable to the heart until he reached his 27th year. Up to that time he had worked steadily on the farm, and although rather dull and stupid, he was a sober and industrious man. In November, 1878, he had some swelling of the abdomen, became short of breath and suffered from slight hæmoptysis. Returning to work in April, he continued well till June, 1881, when similar symptoms recurred with swelling of the legs, and palpitation. In November, 1881, he went into Winchester Infirmary and remained there until January, 1882, when he was discharged in slightly better condition, but he found himself unable to resume work and again took to his bed.

He was admitted into the Middlesex Hospital, on July 3, 1882. He was then almost free from dropsy, had a hale appearance, and was able to walk upstairs without distress. Although of good muscular development he complained of feeling weak, and said he had pain in the abdomen and loins. The vessels of the face were markedly injected; the lips were livid, and the finger nails of a slaty bluish colour. There was a slight amount of anasarca about the ankles and feet, and also evidence of slight ascites. The heart's impulse was diffused, being most marked in the fifth interspace just below the nipple. There was a slight presystolic thrill. The cardiac dulness commenced above at the upper border of the fourth rib, extended to the nipple on the left, and to the border of the sternum on the right. On auscultation the first sound at the apex was very rough; the second sound sharp and ringing. At the base, in the third left interspace close to the sternum, a loud rasping bruit could be heard. This bruit, which was very localised, appeared to follow closely upon and partly to conceal the first sound. It was not audible at the aortic cartilage nor at the back. The pulse was of fair volume, compressible, regular, 96. The lungs were resonant, and breath sounds normal except at both posterior bases, where crepitation and occasional rhonchus were audible. The area of hepatic dulness was increased, extending from the seventh rib in the nipple line to two inches below the costal margin. The surface of the organ was readily felt. The splenic dulness was not increased. The urine was high coloured, acid, sp. gr. 1,025, containing a trace of albumen. The bowels were freely open. A perchloride of iron mixture was prescribed. He had not been in the ward three days before he was attacked with facial erysipelas. In the morning of July 8th, he complained of feeling ill; he vomited; suffered from thirst and headache; and the temperature, which had been subnormal, rose to 103°. The cyanosis now became more marked. Next morning the face, which was much flushed, was noticed to be slightly puffed on the right side. Temperature 102°, pulse 144, respiration 36. Tongue was coated, and the bowels had been open loosely three times. He had a cough, and the expectoration was rusty; basic crepitation as before. At 3 p.m. temperature 104·6°, when a dose of quinine was given; 9 p.m. temperature 104·2

July 10th.—9 a.m. temperature 100·6°, pulse 120, respiration 36. Face deeply cyanosed; the erysipelas is now marked and is spreading from the right to the left cheek. Swelling and tenderness of glands below the angle of jaw, most on the right side. Tongue dry and brown. Bowels loosely open. Towards the evening he became very weak and prostrate, and free stimulation was prescribed. At the same time the cyanosis became more and more marked, and the erysipelas continued to extend. A friction sound could be heard at the base of the heart, where the former loud musical bruit was no longer audible. The rhythm of the sounds at the apex was decidedly "cantering." Pulse 132, very small; temperature 100°.

July 11th.—Restless during the night but not delirious. Pericarditic friction very evident; erysipelas has not further extended. Temperature 99·6°, pulse 120. Urine contains no albumen; chlorides are diminished. Although the erysipelas did not continue to spread, considerable effusion occurred in the pericardium, and he became more prostrate. Death took place on the 13th.

At the *post-mortem* examination the cuticle was seen to be peeling off the face, which was puffy and œdematous. The peritonæal cavity contained about half a pint of serum. The pericardial sac containing 30 ozs. of serum, and the serous surfaces, especially about the base of the heart, were coated with shreds of lymph. The heart weighed 26 ounces; all the cavities were hypertrophied, and the auricles also notably dilated. Coagula occurred in all the chambers. The tricuspid orifice was large, and its valve incompetent. The pulmonary valves natural and competent, and the infundibulum natural. The ductus arteriosus, which had been partially laid open in removing the heart, was of large size and freely patent, admitting the tip of the little finger. At its orifice into the aorta there was some calcified atheroma beneath the lining membrane. The aortic valves were competent; the mitral also competent, but thickened along its border. A rounded aperture large enough to permit the passage of an ordinary cedar pencil occurred in the *pars membranacea* of the ventricular septum. Whether the aorta were narrowed beyond the entrance of the ductus or not, was not observed. The wall of the right ventricle at the base of the heart measured seven eighths of an inch in thickness; that of the left six eighths. The lungs were highly œdematous. The branches of the pulmonary artery within the lungs were dilated, and in many spots the intima was opaque, thick and atheromatous. The liver weighed 74 ounces, and was indurated from chronic congestion. The spleen, 12½ ounces, was also large and very hard. The kidneys were in a similar condition of cyanotic induration.

Remarks.—It is unusual, but not wholly exceptional, for the subject of such a cardiac abnormality as was here presented to attain the age that he did. Often death occurs, as in this case, from an acute intercurrent disease, against which there would naturally be a lessened capability of resistance than in people with normal circulatory mechanism. Acute fevers of any kind, and especially erysipelas, are very fatal to the subjects of cardiac disease. Had this man's life not been so cut short it seems unlikely that it would have been much prolonged. For the compensatory capacity of the heart which had sufficed to enable him to pursue the duties of life for seven and twenty years, had been failing for three years past, having reached its limit. The condition of the abdominal viscera also pointed to the long continuance of the circulatory difficulty, and the improbability of life being much longer maintained under such circumstances. The association of the pervious ductus arteriosus with an imperfection in the septum ventriculorum is not uncommon; and it is probable that the one defect depends upon the other, or that both are due to a common cause, *e.g.*, atresia of the pulmonary or aortic orifice, or contraction of the aorta. In this case there was no evidence of such a common primary change, and it is possible that the defective closure of the septum in fœtal life, may, by diverting some of the blood from the right to the left side, have aided in keeping the ductus patent. After birth, with the establishment of the pulmonary circulation, and the increased development of the left ventricle, the direction

of the flow through the ductus must be in the opposite direction to that which it takes in fœtal life. It must travel from the left side into the pulmonary artery. Hence the dilatation and disease of the intra-pulmonary branches of the latter, and the resulting embarrassment of the circulation on the systemic venous side. The aperture in the septum may have operated in the way of compensation, and for a time maintained the equilibrium between the blood pressure in the two sides; but as the heart's muscular power failed, this compensation would fail also, and there would be increased liability to over-distension of the right chambers with all its results. As to the cyanosis, although in this case a communication between the two sides of the heart did exist, it seems more probable that it was due to the lack of aëration in the lungs than to admixture of venous with arterial blood. The diagnosis of the case could not be precise; but the auscultatory signs were very suggestive of the actual condition. Congenital malformation was suggested by the history of the case; and a harsh but limited basic bruit (in the pulmonic area) is a frequent concomitant of a patent ductus. In a case in the Middlesex Hospital a few years ago (reported by Dr. Greenhow in Clin. Soc. Trans., Vol. IX., p. 152), in which the lumen of the ductus was of the size of a crow-quill, the aorta being slightly narrowed beyond, there was a marked thrill in the third and fourth interspaces, and a double bruit, viz., a harsh systolic bellows murmur followed by a humming bruit. A recent writer (Eichorst), speaking of the physical signs characterising this particular malformation, says that in it the cardiac dulness is increased to the right; the second (pulmonary) sound is accentuated, and a systolic murmur with a thrill is often met with, the murmur being conducted to the carotids. Sometimes there is bulging and dulness in the second left interspace due to dilatation of the pulmonary artery. After reference to other signs—cyanosis, dyspnœa, &c.—he says truly that they may exist from birth or first make their appearance in later life; and "that life has been maintained to nearly sixty years; but death frequently takes place early from intercurrent disease, owing to the diminished power of resistance of the organism."

Medical Times and Gazette.

SATURDAY, OCTOBER 11, 1884.

THE General Medical Council met last Tuesday, and re-elected Sir Henry Acland as their president for a third term of five years. That they were wise in so doing, those who are best acquainted with the working of the Council and the duties of the office will probably fully agree, though we must confess to not a little surprise that he should have been willing to undertake a further term of office. After a few preliminaries the first business of the day was reached in Mr. Macnamara's proposal to require of all intending students of medicine a certificate of moral character, which after being discussed at very considerable length was rejected by a large majority. This we unhesitatingly say we are glad of. Almost all who spoke for it admitted that very little reliance could be placed on such certificates, and allowed that they were frequently given on very scanty information. Indeed we think that Dr. Matthews Duncan really represented himself in quite a wrong light when he spoke of giving such certificates every day of his life, for we know of no one whose certificates are more conscientiously worded than his. But as Professor Humphry said, how are we to refuse to give such a certificate. What kind of moral obliquity would justify us in saying that a person is not of good moral character. It seems to us that Mr. Simon was nearest the truth when he said that only such offences as the criminal law takes cognisance of would justify a man's rejection on moral grounds, and if this be so, then a certificate becomes wholly unnecessary. Another point, too, seems to us of importance, though none of the speakers took it up. It was proposed by Dr. Banks that these certificates should be signed by two medical practitioners, and that certificates should not be accepted from magistrates or clergymen. To have passed this would have been a blunder of no ordinary magnitude, as it seems to us. The less medical men meddle with things that do not belong to them the better, and as it is part of their duty to certify to the professional fitness of young men as regards ability, they will do well to leave others to judge of their moral fitness.

A CONSIDERABLE amount of time was devoted both on Tuesday and Wednesday to discussing what, as it turned out on a division, a large majority disapproved of; we refer to Dr. Banks' proposal to raise the age at which men might become legally qualified to practice medicine to 23 instead of as at present 21. We fail to see any advantage in the reasons offered for the proposed change, or in Professor Struthers' suggestion to make it 22 instead of 23. There is a very good reason for fixing upon 21 as was pointed out over and over again, in that it is the age recognised by the law as that at which a man becomes responsible for his actions; and as Mr. Simon very justly urged, it is a question of fitness in a professional point of view that should be the real test and not the accident of the date of a man's birth. We do not believe that the proposal would have had the effect of really lengthening the period of study in itself; that must depend upon a re-arrangement of the subjects of the curriculum, and the only effect of the proposed alteration would, we believe, have been to discourage young men of ability from joining our ranks, and by putting off the time at which a man could become a bread winner to increase the cost of his education, and, as Dr. Storrar pointed out in a most excellent speech, to necessitate his charging higher fees afterwards to recoup himself for the additional outlay entailed.

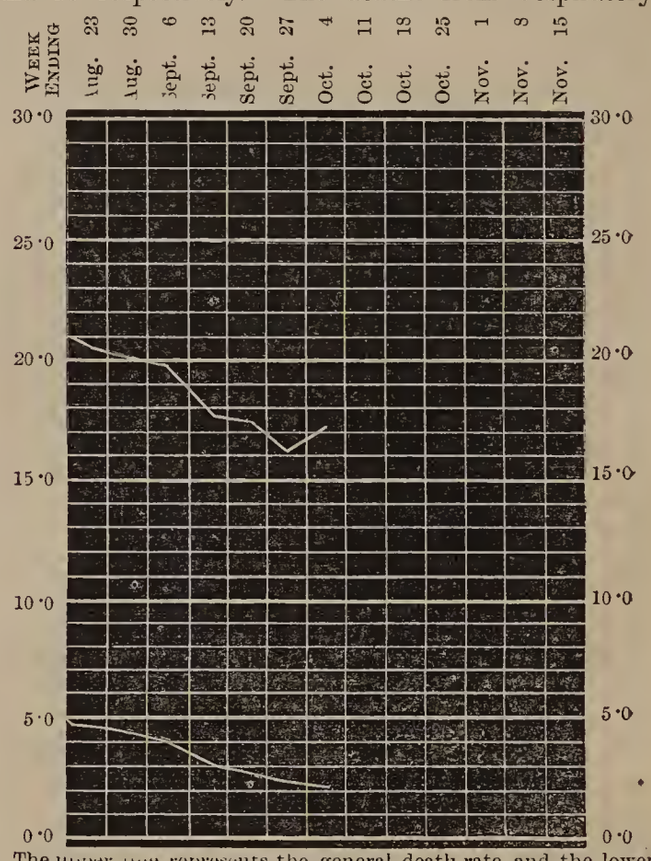
THE first half-hour of Wednesday's proceedings was (we say it with all deference to the Council) wasted. After having had a seat at that board for about ten years, Mr. (we beg pardon, PROFESSOR) Macnamara has discovered that he is not treated with that respect that he feels to be due to the exalted position that he holds as Professor of Materia Medica in the Royal College of Surgeons of Ireland, and he demanded in a formal, not to say pompous, manner that in future he shall be given his proper style and title in the printed minutes of the Council's doings. If he was in earnest, and several of the speakers evidently did not think he was, we can

only say that in our opinion Mr. Macnamara exhibited what we cannot but characterise as a piece of very bad taste, which was hardly to be expected from one with his well-known sense of humour. Even when he had learnt that in the whole history of the Council no one had ever been given the title of Professor in the minutes, he still adhered to his demand, and only consented to refer the matter to the arbitration of the President on the urgent appeal of Mr. Simon after half an hour had been spent in airing this fanciful grievance.

During the latter part of Wednesday afternoon and the whole of Thursday's sitting up to the time that we went to press, the Council was occupied with the discussion of the proposed conjoint scheme of the Royal College of Physicians of London and the Royal College of Surgeons of England. The proposal that the Council should ratify this scheme was introduced by Sir Henry Pitman, and seconded in a most lucid speech by Mr. Marshall. Dr. Quain proposed an amendment, the terms of which are given in another column. This was vigorously discussed and when we left the Council Room, at tea-time on Thursday afternoon, it had just been rejected by a very large majority, only four councillors—viz., Dr. Pyle, of the English representatives, and Dr. Aquilla Smith, Dr. Banks and Mr. Collins, of the Irish—voting with Dr. Quain. Subsequently, we hear, an amendment of Dr. Chambers', as well as two other amendments were rejected, and the sanction of the Council was given to the scheme. To-morrow the Council will probably go into Committee, to decide with closed doors what changes should be made in respect to Medical Education and Examination, in order to carry out efficiently the intentions of the Medical Act of 1858.

The Obstetrical Society re-assembled after the vacation on Wednesday last, October 8th. A long and elaborate paper by Mr. Hopkins Walters, of Reading, was read, in which was related a remarkable case in which the entire uterus was torn away by a midwife, but the patient, nevertheless, recovered. Mr. Walters illustrated his case by an exhaustive *resumé* of every similar case on record that he had been able to find. As, when cases of this kind occur, criminal proceedings often arise out of them, the summary of published experience which Mr. Walters put before the Society will greatly assist those who may have to deal with these painful cases. The paper elicited some valuable remarks on the explanation of such occurrences from Dr. Braxton Hicks, and some discussion took place on the light in which such cases should be regarded when medico-legal evidence is required concerning them. Dr. Herman, and Dr. Robert Barnes were of opinion that the rarity, difficulty and suddenness of these emergencies were such, that blame should not be hastily laid upon the medical man or midwife who should be unfortunate enough to meet with an accident of the kind, and with these speakers the writer of the paper concurred. Others on the contrary took a harsher view.

The death-rate of the metropolis rose again last week from the low figure at which it had stood in the previous week. It was, however, still only 17·2 per 1,000 and the number of deaths was 115 below the ten years' average. Nearly half of this figure, viz., 62, was due to the favourable zymotic return, the zymotic death-rate per 1,000 standing lower than it has done in any previous week in the year. The deaths from small-pox, diphtheria, and diarrhœa and dysentery were all above the average, but, on the other hand, the deaths from scarlet fever, measles, whooping cough and typhoid were all considerably below the average, to the extent namely, of 46, 8, 17, and 10 respectively. The deaths from respiratory



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past seven weeks.

diseases were 22 more than in the previous week, but were still 67 below the average. The mean death-rate of the 28 great towns was 20·1, and the mean zymotic death-rate 3·3 per 1,000. Halifax showed the highest general death-rate, viz., 31·4, while Preston, with a general death-rate of 29·4, had a zymotic death-rate of 10·0, chiefly due to the fatal prevalence of diarrhœa. The Scottish and Irish capitals had both high zymotic death-rates, viz., 4·4 and 4·9, but the general death-rate of Edinburgh was lower than that of Dublin by more than 10·0 per 1,000, viz., 16·1 as compared with 26·3. All these figures receive a new interest in the light of the very suggestive address by Dr. Grimshaw, the Registrar-General for Ireland, which we publish in full in another column.

The Congress of the Sanitary Institute of Great Britain in Dublin was brought to a successful issue on the afternoon of Friday, the 3rd instant. The President, Sir Robert Rawlinson, C.B., took the chair at the closing meeting, which was held in the new Lecture

Rooms of Trinity College. The President announced that the Council had accepted an invitation to meet next year at Leicester. He then moved a hearty vote of thanks to the Provost and Senior Fellows of Trinity College, the President and Fellows of the King and Queen's College of Physicians, the President and Council of the Royal College of Surgeons in Ireland, the Council of the Royal Dublin Society, and the Dublin Sanitary Association. The motion was carried by acclamation. Votes of thanks were also passed to the Right Hon. the Lord Mayor of Dublin, to the President and Sectional Secretaries, and to the Press. In the evening, Dr. Alfred Carpenter, Chairman of the Council of the Sanitary Institute, delivered a lecture in the Antient Concert Rooms on "Education by Proverb in Sanitary Work," at which there was a large attendance.

Dr. Carpenter's lecture did not quite square with its title, "Education by Proverb in Sanitary Work," the only utterance that he quoted as a proverb and wished to have written in letters of gold in every council-chamber in the kingdom, being this, "that the expenditure of money by the Local Authority will be repaid to them tenfold in the better health of the people." For a sanitary proverb, Mr. Maguire, who read a paper on the same day, easily carried off the palm with his Irish version of a well-known maxim, "The best way to prevent what is past, is to put a stop to it before it happens." Still Dr. Carpenter's lecture was a most eloquent plea for perseverance in sanitary work. In his praise of the Mosaic dispensation he bettered even Dr. B. W. Richardson. In the sweetening of the waters of Marah by the branches of a tree, he sees a foreshadowing of the sanitary occupation of tea-drinking. In the burning of incense he finds the germ of our modern disinfection; in the blue-ribbonism of Mahomet he traces the beginnings of the modern sanitary crusade against drink; and in the Friday fast of the Roman Church he discovers hidden a sanitary teaching of the highest moment. The rest of the lecture was of a less startling character.

Saturday was devoted to excursions to the Vartry Waterworks, at Roundwood, in the county Wicklow; to the extensive railway works of the Great Southern and Western Railway, at Inchicore; and to the far-famed and beautiful scenery of Killiney and Bray. On Saturday evening, the 4th instant, a most successful Hospital Fête took place at the Sanitary Exhibition at Ball's Bridge, Dublin. Several thousand persons were present, and as the weather was exquisite the *fête*, which was partially *al fresco*, was thoroughly enjoyable. Not the least novel and attractive item in the programme was a view of the total eclipse of the moon, which was proceeding at the time.

The new wing lately opened at St. Mary's Hospital, by H.R.H. the Princess Louise, afforded the Medical Officers and Lecturers of the hospital the opportunity of celebrating the opening of the Medical Session by an unusually large and successful *conversazioné*. About 2,000 guests visited the hospital during the evening of Thursday, the 2nd instant, and there was a very general expression of surprise and pleasure at the attractiveness of the entertainment. In the hospital the whole of the ground floor was thrown open and the rooms were excellently decorated by Messrs. Gillow. In the refreshment department there was among other things a supply of bird's-nest soup presented, on behalf of the Chinese Government, by Mr. Duncan Campbell, Commissioner for China to the International Health Exhibition. The out-patients' rooms were beautifully decorated by Mr. William Morris, with the help of wares lent by Messrs. C. B. Pare & Co., Messrs. Procter & Co., and Mr. Samuel. In the Medical School buildings which have been lately considerably enlarged, Messrs. Marshall and Snelgrove had shown considerable taste and judgment in decoration. The entrance room was decorated in an Oriental fashion and was very much admired. Some beautiful china and pottery were lent by Messrs. Doulton and by Mr. Mortlock. Quite the most attractive feature of the evening was Mr. Tayler-Smith's "Economic Electric Domestic Lighting," which was shown chiefly in the museum. The value, from a hygienic point of view, of electric lighting in habitations in the place of gas, lamps, or candles, is so great that we have thought the subject worthy of a separate article. All the decorations and exhibits that we have referred to were most liberally lent by the various firms above named. There were also exhibitions of new instruments and interesting microscopic preparations. Among the latter some cholera bacilli were to be seen by those who cared to inspect them, though one lady positively declined to look at them for fear of infection. It remains for us to add that the musical performances were quite in keeping with the rest of the entertainment.

Our Edinburgh correspondent writes:—The Anatomy-rooms in the University and Extra-mural School were opened for the winter on the 1st instant, and already a large number of men are at work. The rooms in Surgeons' Hall have undergone extensive structural modification, and are now much better adapted for their purpose. The changes in the junior teaching staff of the University are not numerous. Dr. Lockhart Gibson has resigned the senior assistantship to the Professor of Physiology. This is much to be regretted, as his departure is a distinct loss to the school. It is not satisfactory to find that one who has proved himself a capable and popular teacher, and who promised well as a physiologist, should have had so little encouragement to stay among us as he has apparently met with. Under circumstances like this, the foundation of a School of Physiology in Edinburgh seems a remote possibility. Dr. G. F. Alexander is, we believe, promoted to the vacant post. Drs. Mackay and Fraser join the staff of the Professor of Surgery. In the Extra-mural School Dr. Alexander Bruce commences a course of General Pathology; Mr. Cathcart begins to lecture on Surgery, and Mr. Macdonald Brown on Anatomy.

We understand that there is a proposal to hold a meeting of Edinburgh students at the beginning of the

session, for the consideration of the subject of note-taking in connection with the systematic lectures. Whether this leads to any immediate result or not, it is undoubtedly a wise step, for it is only by ventilating their grievance in the matter that the students can ever hope to see any change in the present absurd system. The professors show no signs of offering any remedy for the evil, and nothing short of popular agitation seems capable of meeting the case. Last winter, as the result of some pressure, a small "fasciculus," containing the gist of the lectures on the Respiratory and part of the Digestive Systems, was obtained from the Professor of Physiology. The notes were excellent so far as they went, but cover but a small portion of the course. As there is no appearance as yet of any further contribution, it is to be hoped that the projected meeting will have the effect of calling attention to the matter, so that "Fasciculus No. 2" may appear on the scene without the prolonged latent period exhibited by the second part of the same author's text-book.

Professor Cossar Ewart has sailed for the United States in order to make some investigations in connection with fishing and fishing stations. His duties at the First Professional Examination at Edinburgh are, we understand, to be performed by Dr. Ramsay H. Traquair, of the Science and Art Museum.

With reference to the attendance of medical witnesses in small debt actions, our Glasgow correspondent writes—Last week, in the Small Debt Court, Dr. Alexander Henderson Patrick was fined in the sum of two pounds for not attending the court and giving evidence in the case of a man who was injured in a ship-building yard. It was stated for the doctor that he had professional duties to attend to which prevented him from being present, but this seemed of no avail with the sheriff, for in another case, which followed immediately after, the plaintiff, who sued defendant for 12*l.* for assault, was non-suited. Dr. Matthew Martin was subpœnaed to give evidence for the plaintiff but failed to put in his appearance. The sheriff advised the plaintiff that though the case had gone against him, he should make application to the doctor for the payment of the full penalty. The extraordinary part of this state of things is, if the medical men had been present and had given their separate evidence, they would have received *no* fee for their attendance, supposing the plaintiffs had lost their case, because they were poor cases. The law in regard to medical men attending courts and giving evidence seems to stand in need of some change from its present state. We stand in need of many reforms in this city. If a suspicious death takes place, even although suspicion is strong, unless the Procurator Fiscal thinks fit no enquiry is instituted.

Our Paris Correspondent writes:—The post of Director-General of Public Assistance at Paris is vacant, in consequence of the resignation of M. Quentin. A difference of opinion with Government authorities is said to be the cause of M. Quentin's resolution. The four years during which he has held office have been marked by the steady progress of *laïcisation*, that is, by the removal of Sisters of Charity from Paris hospitals, and the substitution of lay *surveillantes* in their stead. The lay system had always prevailed in some distant establishments, such as La Salpétrière and Bicêtre, but the central hospitals had always been in the hands of some religious order (Augustines, Sœurs de Saint Vincent de Paul, &c.). The well-known temper of the present Municipal Council led to the introduction of the lay element. Various establishments passed out of religious hands, and were organised upon secular principles. St. Antoine, La Pitié, Lourraine, Cachin, Laënnec, and other establishments were successively *laïcised*. But when M. Quentin attempted to follow out the same system at Ivry, the sisters of that hospice, who appear to enjoy great influence at headquarters, were successful enough to resist the Director, through application to the Minister of the Interior, M. Waldeck Rousseau. Upon this, M. Quentin resigned.

That Sisters of Charity are in most cases diligent and well-trained nurses cannot for a moment be disputed. But in former times they unquestionably exerted a sort of tyranny which extended not only to patients, but to the medical staff itself. Guy's Hospital has recently been the scene of a similar battle between doctors and nurses or matrons, in which the medical body got the worst. In present times, however, the state of things is so different that no aggression can be anticipated from that quarter. A large number of our hospital physicians now stand up in defence of Sisters, and this, apart from any clerical proclivities, on the ground of greater competence, assiduity and economy. A Sister costs the Administration 8*l.* per annum, her services being, of course, unpaid. The salary of a *surveillante* is 24*l.* (besides other advantages), and however inadequate this remuneration may be, it represents an important sum when multiplied by the large number of persons who fill that post. Public assistance in Paris is bitterly poor. Its revenues amount to about 80,000*l.* per annum: its expenses to 900,000*l.* per annum. The deficit is made up by the Municipal Council, which, like a local Parliament, votes annually the Budget of the city. The situation of M. Quentin's successor will therefore be one of great difficulty. If, in accordance with orders from above, he refuses to *laïcise*, the Municipal Council will reject the Vote of Supplies, and Government will be obliged to interfere. No wonder that hitherto nobody has been found to accept so difficult a position, and that M. Quentin's place has not yet been filled.

The lady students of Paris are getting up a petition to be allowed to compete for the situations of *interne*, or house surgeon, in the Paris hospitals. The *internes* are annually appointed by competitive examinations, and fill their post during four years, acting in many cases as substitutes to the physicians and surgeons of the medical staff. Up to the present time these honours had been reserved to the male sex; but the lady students, with that pushing tendency which has always characterised the female element, now insist upon "equal rights." Whether a lady is apt to meet all the

emergencies of medical service in hospitals of 600 or 800 beds is a point which experience alone can decide.

Dr. Wolfe, of Glasgow, is at present in Paris, where he has been invited to come by several distinguished French oculists, who offered him cases, to show his operation for detachment of the retina, which has excited so much interest. He has already operated on several patients, and proposes to address the Academy of Medicine upon the subject.

Amongst the many interesting papers read at the meeting of the French Association for the Advancement of Science at Blois, last month, was one by M. Hayem, on the examination of the blood as an aid to diagnosis in acute disease. His idea is to watch the phenomena of coagulation under the microscope, and thus to estimate the quantity of fibrin the blood contains. After describing the apparatus he uses, he laid down certain general principles as the result of his studies. If the blood was found to coagulate without giving rise to a fibrinous reticulum, pyrexia might safely be diagnosed, probably typhoid fever; if, on the other hand, there was an increase or thickening of the fibrin of the blood, typhoid fever could be excluded. In other febrile states the fibrin was increased, and this fact served as a diagnostic point differentiating them from typhoid fever. Some inflammatory diseases, however, formed an exception to the rule, and were not accompanied by any increase in the fibrin. As an instance of such exception he mentioned typhoid pneumonia, but when pressed for an exact definition of this disease, as apart from acute pneumonia, he was obliged to admit that the matter was one of great difficulty.

Another name has been added to the list of famous workers and teachers of the past, that of Herman von Zeissl. He died in Vienna on September 23rd. A contemporary and fellow worker with Skoda, Rokitansky, and Hebra, he made for himself a reputation as a syphilographer which attracted vast numbers of students of all nations to the Great Hospital in Vienna, and his text-book on the subject enjoyed an exceptionally large circulation. Compelled by ill-health to retire from work during the last few years of his life, he carried with him into retirement the respect and affection of his colleagues, students, and patients alike. The great gathering of friends which was brought together on the occasion of his funeral, bore silent testimony to the widespread feeling of regret at his loss.

Zeissl, writes our Vienna correspondent, was born in 1817, at Vierzighuben, near Zwittau, in Moravia. After having passed through the school of his native village he was placed at the gymnasium of Leitomischl (also in Moravia), and subsequently at that of Brünn. In the year 1839 he entered the Vienna Medical Faculty, where he devoted himself with much zeal and diligence to his medical studies. In 1845 he took the degree of Doctor of Medicine, and in the subsequent year that of Surgery. After holding various resident posts in the wards of the General Hospital, he was admitted as a "secundarius of the second class," in the wards for dermatology, which were at that time under the direction of Hebra. Here he had a good opportunity of displaying his great ability, especially in the differentiation of syphilitic and non-syphilitic diseases. The great interest which Zeissl took in this special branch of dermatology induced Hebra to offer him a ward exclusively occupied by syphilitic patients in order that he might make special enquiries in this direction, and he further encouraged him in the study of the literature of the subject. In 1850 he was appointed "Privat-Docent," his inaugural address being entitled "A compendium of the pathology and therapeutics of syphilis and venereal diseases." This passed through two editions in the course of six weeks. In 1860 he received the Extraordinary Professorship, and in 1864 he published his chief work "A Manual of Constitutional Syphilis," which brought him considerable scientific reputation as the founder of the German dualistic school. In 1869 he was named director of the second ward for syphilis which had then recently been formed in the General Hospital. He filled this office up to a year ago, when he resigned it on account of bad health. Zeissl was the recipient of several distinctions. After the retirement of Sigmund he received the honour of "Regierungsrath," and when he gave up his post of director he was knighted. Besides these distinctions he possessed the Russian Stanislaus Order. Hermann Zeissl was not only an eminent scientific investigator, but also an excellent teacher, a good-hearted man and a sincere friend. Science and humanity will always remember his name with love and esteem.

Among the many pleasant recollections which all members of the late International Congress have brought back with them from Copenhagen, that of the reception and supper at the Christiansborg Palace will always hold a prominent place. The spontaneous and wholly unexpected invitation of the King and Queen, and the interest and hospitality displayed by their Majesties in person, gave to the whole entertainment an air of genuine national welcome and served at the same time to emphasise the universal feeling of the International importance of the Congress. With the recollection of that remarkable entertainment still fresh in the mind, the grim account of the destruction by fire on Friday last of the scene where it took place will have aroused feelings of something more than the complacent regret which is customary on such occasions. The building was one of the striking features of the town although not a thing of beauty in itself. Its bluff frontage to one of the most frequented canals and thoroughfares, unornamented except by four colossal bronze statues, gave an impression of solidity and strength which is often wanting in the more ornate royal residences in many continental towns. Within the palace, beauty and strength were admirably combined in the decoration of the Riddaisal, in which the King of Denmark welcomed his guests of the Medical Congress only two months ago. It is most satisfactory to learn that the valuables and pictures have been saved from the fire and it is probable that within a few years a new palace will have arisen upon

the same site, which has been devoted to royal residences since 1168. The medical profession owe a debt of gratitude to the Royal Family of Denmark and to the city of Copenhagen for their magnificent recognition of the deserts of a noble science, and will now offer to them an expression of sincere sympathy in the loss which this great disaster has entailed.

Mr. Bushby, the magistrate at Worship Street, is evidently more sensible in his opinions than parliamentary in his expression of them. A person applied to him on Tuesday with the view of achieving the destruction of a dog which had bitten him, as well as other people. The applicant said that he feared he would fall a victim to hydrophobia unless the dog were destroyed, a course which his doctor had advised. Mr. Bushby replied that his medical adviser must be a goose; and gave some very sensible advice in contravention of the said doctor's. The comparison was a not altogether unfelicitous one.

Rumour has it that a proposal is on foot for the capitalisation of the Government grants to the Dublin Hospitals, and for the founding of one or more large and central hospitals or infirmaries, a condition being that a first-class medical school shall become attached to the new hospital or hospitals. In the interest of medical science and education it is to be hoped that so desirable a project should be realised, more particularly as from their undue number and divided resources the Dublin Hospitals are at present in anything but a satisfactory state.

The lecture on the rearing of hand-fed infants, which Mr. Edmund Owen delivered at the Health Exhibition in August last, has recently been published with an introduction by Dr. Charles West. Mr. Owen's advice and directions are eminently sensible, and are expressed in a way calculated to impress the class of mothers for whom the lecture is intended. We regret to see that he has omitted to describe Dr. Frankland's method of preparing the so-called "artificial human milk," which is now made and used with success in many nurseries. Dr. West's introduction contains an eloquent plea for "suckling," and an anathema against "hand-feeding" where the mother can nurse her own child. Unfortunately, the folly and selfishness of the modern mother are too often proof against the most impassioned appeals to their sense of duty.

Medical men often witness the unwholesome and disagreeable consequences of delayed interments. Burial, which is too precipitate in France, is too long delayed in England, especially with uneducated people. It is cruel for those who ought to know better, to foster delay in the removal of the dead from the apartments of the living. Yet the following was the action of a country coroner:—A death occurred on (say) a Tuesday; the inquest was not held until Friday, on which day an eye-witness thus describes what he saw: "The most advanced state of decomposition I have ever seen. . . . The face enormously swollen; green; a bloody froth, with a considerable quantity of gas exuding from the lips; and a very powerful odour." Now, why was this inquest delayed? Why were the poor people subjected to these horrors? No reason for the delay in holding the inquest was alleged; and one cannot but think that if a medical man were thus slack in his duties he would receive small mercy. Promptness is as much a duty in country districts as in large towns, and it is for the cultured classes to set the example thereof, and not to sink into the ways of sleepy hollow.

The medical men of Exeter have been obliged to make a stand against a curious piece of injustice. It has long been the custom, when a case of lunacy was reported by the relieving officer, for the city magistrates to give him an order for the district medical officer to visit and report; or if the alleged lunatic was in the workhouse, then the order was made out for the medical officer of that institution. But of late some of the city magistrates have chosen to ignore the district medical officers, and to desire other medical men to act instead of them. These other medical men, having of course declined to act under such circumstances, have been in several instances threatened with legal proceedings to compel them to do so. Threats of this description cannot really be carried out, yet they may give considerable trouble and annoyance. With commendable unanimity, the whole profession in Exeter have resolved to stand firm in the matter, and to refuse to encroach on the emoluments of their brethren engaged in union practice. The growing tendency of local magnates to compel medical men at the point of law to do this or that, will not escape the notice of our observant readers.

The first number of the *Medical Chronicle* gives promise that the publication will be a really good *centralblatt* of medical information. Twenty-eight pages out of the one hundred and twenty are occupied by five original papers of considerable value, the list being headed by a useful essay from the pen of Dr. W. Roberts, on "Tests for albumen in the urine." The *Chronicle* consists of well-made abstracts of recent medical work, under a classified arrangement, and is especially remarkable for a due regard to the importance of the contributions chosen for abstraction. It shows no sign, so common in publications of this sort, of the choice of matter being dependent on the convenience of the writers of the abstracts; and the authors of all countries and languages receive their fair share of attention. In these points this work presents a striking contrast to any other English attempt at giving a *resumé* of contemporary medical writings, and should its future contents not belie its present fair promise, it will doubtless secure the eager patronage of all medical men, whether authors or students, who desire a really good record of medicine, and cannot help being dissatisfied with the perfunctory nature of all that is at present offered to them to supply their wants. This periodical, being almost entirely the work of Manchester men, is an important sign of the vigorous medical life in the provinces which cannot but be regarded with much satisfaction as conducive both to professional and social good.

Under the title "What is to be done in time of Cholera," Professor Tommasi-Crudeli, of Rome, in an address recently delivered before the Royal Academy of Science in Arezzo, discusses at some length the question of quarantine. Starting with the axiom, that without the introduction from abroad of individuals affected with cholera, or of cholera-infected garments, the advent of the disease is impossible in Europe, he maintains that theoretically quarantine is the best, if not the only means of warding off an epidemic. Thus in 1865 and 1866, when Italy was suffering from cholera, originally imported by way of Alexandria, the feeling of the populace being general in support of a rigorous system of surveillance, no single case occurred throughout Sicily until the arrival of troops from Naples in consequence of revolutionary disturbances in Palermo. The first reinforcements landed on the 18th of September, and on the same day some of them sickened with the disease. The epidemic spread to the city, and from the city throughout the island, and it was not till the end of 1867 that its ravages finally ceased. Yet, until this violation of the quarantine, Sicily had retained its immunity for more than a year. Practically, however, he considers that sanitary cordons are of no value, unless it be in the case of small islands or naturally isolated districts. "The Franco-Italian frontier," he says, "is certainly not one of these exceptions. The smugglers alone are sufficient to render the system a failure. For if they ordinarily show but little fear of the rifles of the custom-house officers, it is hardly likely that they will be deterred by the lesser punishment which threatens the violation of the *cordon sanitaire*." The result is, that people in easy circumstances, who travel by rail or carriage, are kept out, while the poorer classes, who are much more likely to import the disease, pass on foot through the cordon with comparative ease. Putting on one side the immense expense and trouble entailed, the check on commerce, and the impoverishment of the lower classes which must naturally result, Dr. Crudeli regards the cordons with their accompanying lazarettos as something worse than needless. The latter, he says, become true foci of cholera infection. Travellers crowded together in them, under not too sanitary conditions, become infected, and while the disease is still in the period of incubation they are released, only to develop it on their arrival at their destination. Our Indian possessions have given us an experience of cholera second to that of no other nation, and our best authorities agree with Dr. Crudeli as to the inutility of quarantine, except in special instances. That an epidemic of cholera may be at least delayed, if not entirely kept off, by the protection of the sea-board of islands is possible, but frontier quarantine is, to use the professor's words, at once expensive and ridiculous.

"Dr. Klein," the public is informed by a newspaper telegram from Calcutta, "does not believe in Dr. Koch's bacillus. Dr. Klein has proved its harmlessness by swallowing a microbe himself." After this satisfactory announcement the further statement that "Dr. Klein is coming to Calcutta for the purpose of further investigation" seems an indication of wastefully superfluous energy, unless these investigations are to determine whether this edible microbe, presumably indigenous in Hindoostan, can be made available for supplementing the admittedly scanty fare of the native labourer. But, having caught, cultivated, and cooked our microbe, we are tempted to ask whether he should be swallowed whole, "or how?" Truly the little knowledge which our lay contemporaries occasionally serve up for the delectation of their readers is sometimes presented in a form more mirth-provoking than dangerous.

A recent number of the *Boston Medical Journal* publishes the following "Medical Fable:"—Once upon a time a poor but humane physician was travelling along a road which led by a dark forest, when he saw by the wayside a sick and miserable dog which had lain down to die. Moved with pity, he got down from his carriage, picked up the poor animal tenderly, and gave it some food and drink. Suddenly the dog vanished, and he saw standing before him a beautiful fairy. "You have saved me from a miserable doom by your compassion," she said. "Command now anything you wish, and it shall be yours." The astonished physician replied. "I am a poor man, I should like to be rich." The fairy waved her wand and extended to him a piece of paper and a bottle filled with a dark-coloured fluid. "Here," she said, "is a prescription for an Infallible Compound Hair Restorer. It will never fail, and it has been endorsed by all the leading clergymen on both Continents. The world is yours! Do you wish more?" "I am a quiet man," replied the doctor, "and little known. I should like to be famous." "You shall be more; you shall be immortal." Waving her wand again, she presented to him a small, dark, and curiously shaped instrument. "See," she exclaimed, "it is a new and 'Unquestionably Perfect Pessary.' It radically restores every malposition. Your name is blown into the side. Generations of suffering women and successful doctors will read, and bless you. I have tried it myself," she added, blushing a little, and vanished.

FORBIDDING THE BANNS.

Most of our readers will be glad to hear that the arrangement made between the Royal College of Physicians and the Royal College of Surgeons for the appointment of a conjoint examining board received the formal sanction of the General Medical Council on Thursday, and has thus been placed in a fair way towards realisation. Before the scheme came on for discussion in the Council, it seems to have been generally taken for granted that it was impossible that there could be any just cause or impediment why the proposed union of the Colleges, in respect of their diploma-granting powers should not be consummated. The evils attending a multiplicity of licensing bodies are so obvious and so undisputed that an arrangement which practically rolls two of the most important of them into one has been accepted as a boon, we may almost say without enquiry, by the Fellows of the Colleges concerned as well as by the medical press.

**

The Fellows of the Colleges were no doubt justified in assuming that their respective Councils, who are nothing if not conservative, would enter upon no arrangement which would be detrimental to the prestige or the privileges of the institutions under their charge ; while the organs of medical opinion, not excepting the *Lancet*, are too radically inclined not to welcome any change which appears in the guise of a reform. The proposed union, however, loose as it was intended to be, has not been allowed to be completed without a protest. Dr. Quain—who, if he were in the House of Lords, as some of us would wish to see him, would no doubt find his place on the cross-benches—has seen grave reasons to dissent from the views of his late colleagues on the Council of the College in Pall Mall, and besides actively opposing the scheme in the Medical Council, has published a vigorous protest against it. This protest appears in the form of a letter addressed to the Fellows, and its author is at pains to show (1) That the course of education and the examinations required to be undergone by candidates for the College Licence form a sufficient guarantee of fitness to practise physic in its widest sense as defined by law and precedent, viz., Medicine, Surgery, and Midwifery. (2) That the licence is in itself a full and legal qualification to practise all the above branches, and that as the College is not only authorised but required by law to examine the candidate in Surgery, it would be unjust and illegal to compel every candidate for the diploma to pay an additional fee of more than twenty guineas for another diploma which he does not desire to have. (3) That the proposed change would be injurious to the interests alike of the public, and of the profession, and also of the College, the authorities of which are bound by duty and honour to hand down unimpaired to their successors the great privileges which their predecessors have handed down to them. Theoretically, no doubt, Dr. Quain has conclusively proved his theses, and on the point as to whether the College may legally refuse the request of a candidate to be examined by it in Surgery, as it proposes to do, we think that his arguments demand the most serious consideration before the scheme is allowed to be carried into effect. We are as confident as he is that a body of honour, integrity, and dignity like the College of Physicians will not "knowingly adopt and pursue an illegal course, waiting until the action of the law is called upon to check it," and we cannot believe that the College has gone into the present scheme without first obtaining an opinion from counsel that it might legally do so.

When, however, we come to look upon matters from a practical point of view, we cannot believe that the effects of the proposed change are likely to be so serious as Dr. Quain depicts. It may be quite true that the Licence of the College is a complete diploma, giving its possessor the right to practice Surgery as well as Medicine and Midwifery, and we will grant Dr. Quain that the College is competent to carry out an examination in Surgery. But it is a plain fact that the vast majority of London students are not content with the Physicians' Licence alone, but, as a matter of course, take the Membership of the College of Surgeons in addition. Mr. Marshall, in the course of his able speech in the Council on Wednesday, showed that of the first 2,450 names on the medical register, there were 153 Licentiates of the Royal College of Physicians, only six of whom had no other qualification, while as many as 139 had taken the M.R.C.S. Dr. Quain subsequently admitted that the same is true of the rest of the 1,700 practitioners who hold the licence, 93 per cent. of them also holding the College of Surgeons' diploma. It is true that the yearly number of licences granted is steadily and even rapidly increasing, but it is difficult to imagine, and, in our opinion, unwise to desire, that the College of Physicians should ever be able to compete with the College of Surgeons in regard to the popularity of its licence as a surgical qualification. It may be taken for granted that ninety-nine out of every hundred successful candidates for the licence will, for years to come as they do now, take the Membership of the College of Surgeons as well, and the arrangements of the College of Physicians must necessarily be mainly guided by the interests of the ninety-nine, rather than by the interests of the one. No doubt if the scheme comes to anything a way can be found by which the interests of the latter will be as well served as they are now. But it seems to us that if the College believes that the ninety-nine can be examined with greater efficiency and economy by means of its arrangement with the College of Surgeons, it is bound to enter into it. The interests of the students ought to be the first consideration. The Colleges exist for them, and not they for the Colleges, so that if the conjoint arrangement should render it possible to considerably reduce the fee for the double diploma, as, of course, in time, it will do, this advantage of itself should be regarded as an ample set-off against any such sentimental disadvantages as loss of prestige or privileges on the part of the Colleges.

Dr. Quain has dwelt eloquently and ably on the privileges that his College will lose by the proposed scheme, but he has said nothing as to what it will gain. To an impartial observer, however, it must be evident that its gains are likely to far exceed its losses. The College of Surgeons, it must be remembered, also renounces its independent privilege of giving a qualification, and as it at present awards every year nearly two diplomas for every one awarded by the College of Physicians, it is obvious that it will lose much more by the scheme than the latter College. The practical effect will no doubt be that many more students will be driven to take the licence of the College of Physicians than take it at present.

Dr. Quain points out that the College of Surgeons cannot give a complete diploma, and in his speech he compared its arrangement with the College of Physicians to the diplomacy of the fox which had lost its tail. But coming again to matters of fact we discover that the practitioners practising with the M.R.C.S. alone are more than twenty times as numerous as those practising with the L.R.C.P. alone. Having taken the trouble to go through the first two letters in the Medical Register, we find 126 names with the former diploma alone, and only five with the latter diploma alone; and we have no reason to suppose that the same proportion does not obtain throughout the rest of the letters of the alphabet.

It is clear then that the gain to the College of Physicians from the proposed scheme is likely to be much greater than that of the College of Surgeons. We fully agree with Dr. Quain that "the close association of the whole profession with the College of Physicians should be encouraged," but we think that the conjoint scheme is much better calculated to secure that end by the inducement it will offer to students to join the College, than the policy that Dr. Quain advocates.

For our own part we should like to see the Colleges bound together in a much more intimate union than that which they contemplate. We see no reason why they should not give up their separate existence, and be merged in a Royal College of Physic with one President, one Council, and one local habitation. The progress of science is daily lessening the space that once separated Surgery from Medicine, and even were it otherwise they could never be so diverse from each other as are the branches of learning that find room enough to grow up side by side under the shelter of a single university. It would not be an ill-assorted marriage. The College of Physicians has lineage, the College of Surgeons has, or will have, wealth. Together they could be much more useful and influential in the State, in the profession, and in the field of science than they can ever hope to be separate. Let us ask, would any one have ever talked of a Medical Bill, or if a bill had been thought necessary would any talking have availed to defeat it, if an English College of Physic had declared for or against it? In the present temper of our leaders, however, such considerations are, we suppose, purely visionary.

THE PROGRESS OF THE OVER-PRESSURE QUESTION.

In a former article on Dr. Crichton Browne's report to the Education Department on Over-pressure in Elementary Schools and the officially-inspired memorandum by Mr. Fitch which accompanied it, we credited the latter gentleman with scoring a dialectic victory, though we endorsed all that was essential in Dr. Browne's conclusions, and considered that he had amply made out an important case for further enquiry. It will be evident now to any fair-minded person who reads Dr. Browne's letter to the *Times*, of the 8th inst., that the victory such as it was of the Inspector of Schools was very cheaply won. It is easy to be trenchant and superficially logical when we can assume and arrange our data to support what is apparently an inference, but really a foregone conclusion; and that this has been Mr. Fitch's method is clearly shown by Dr. Browne's letter, which is at once a complete vindication of himself, and a crushing reply to every important charge made by his opponent. It is needless to repeat and refute again the gratuitous and somewhat absurd attack made by Mr. Fitch on Dr. Browne's personal fitness for undertaking the investigation entrusted to him by Mr. Mundella; while the "deficient preciseness," to say the very least, of most of the Inspector's statements, most certainly disqualify him for reflecting on Dr. Browne's knowledge of the nature of scientific evidence.

It now appears that, contrary to Mr. Fitch's contention that the schools visited by Dr. Browne were all in one district, the report was based on enquiries instituted over a very wide area, comprising eleven schools scattered over North, South, East, and West London; and further, that Mr. Fitch accompanied Dr. Browne on his visits to only *three* of these, remaining one hour-and-a-half, one hour, and ten minutes, respectively, at each school; Dr. Browne's visits, on the other hand, being all of five or six hours' duration. These facts are enough in themselves to take the sting out of Mr. Fitch's criticism of Dr. Browne's method of enquiry, and to deprive of all its previously apparent force the grave assertion that Dr. Browne's report contained not a line which deserved the name of proof. The remarks, indeed, made by Dr. Browne on this point in his recent letter to the *Times* more than justify our former opinion that his methods of enquiry were not deserving of being stigmatised as slipshod, either from a medical or logical point of view; and had we not been irresistibly led to believe from Mr. Fitch's own words that he had been present at the major part of Dr. Browne's examinations, it would have been impossible to give even a modicum of real weight to any statement whatever in the official memorandum. Dr. Browne has now made it quite clear that his conclusions rested on a far greater array of facts than appeared to be the case from the statements contained in his opponent's official gloss. There is one more point in Dr. Browne's reply to Mr. Fitch, which, though of subordinate importance as regards the main subject, is yet of some gravity, and imperatively demands an explanation from Mr. Fitch. The question has to be answered how it was that Mr. Fitch believed Dr. Browne to be merely a "private enquirer," when the President of the Education Department stated in the House of Commons as long ago as February 19th, that he had invited Dr. Browne to visit some of the public elementary schools in London in company with one of Her Majesty's Inspectors (that inspector being Mr. Fitch), and to favour him with an opinion of their work from a sanitary point of view.

It is now more than ever clear from this controversy that further investigation should be made by the Government on this matter, and should any corroboration of this contention be asked for it may be found in the great consensus of medical opinion shown in the correspondence on over-pressure which has recently appeared in our columns. The letters we have received on this subject are certainly free from bias, representing for the most part the impressions received directly from experience, and by no means conclusions drawn from facts observed with any preconceived object of enquiry. The seven physicians who have addressed themselves directly to the question at issue, all of them on the active staffs of our hospitals for children, are of opinion that cases of chorea in its various degrees, frequent headaches, and disturbed sleep, are often to be attributed to overwork at school; and it must undoubtedly be inferred, though it may not be possible with the data at present at command to demonstrate conclusively the evidence of fatal or permanent effects of over-schooling, that the evils resulting therefrom are of sufficient magnitude and frequency

to arrest the attention of those who administer the Education Code. It is infinitely probable that long-continued disorder of the literally impressionable nervous system of children will have a far reaching and prejudicial effect on the ultimate development of the mind, and permanently damage the delicate structures which it is the avowed object of national education to keep in good working order.

REVIEWS AND NOTICES OF BOOKS.

GUIDES TO MEDICINAL THERAPEUTICS.[1]

THERE is no department of medical study in which the student and practitioner stand more in need of a trustworthy guide than in that of Materia Medica and Therapeutics. It is a more difficult country to find one's way in than the most trackless of jungles, for the luckless strangers who enter therein find themselves at once surrounded and importuned by a thousand self-constituted authorities, shouting themselves hoarse and pointing each in a different direction, like hotel touts at a French railway station. One shouts the praises of this drug and this mode of treatment, another gives him the lie direct and vociferates in favour of that drug, a third politely whispers that both are charlatans and presents his own specific, and so on through all the thousand and one substances, animal, vegetable and mineral, that have been pressed upon a suffering humanity and a long-suffering profession. To the guide who can keep his head amidst all this turmoil, who can push aside the pretensions of this and that specific-monger, and safely show the way through the labyrinth of drug-literature, the student and practitioner have every reason to be grateful. Such a guide should be a man of words few and to the purpose, a man of decision who knows his own mind and can inspire confidence in his clients, a man who has read much, thought much and doubted much, and lastly, a man of culture and science, in the best sense of those words.

Dr. Mitchell Bruce, the first author on our list, has most if not all of these qualifications, and the handbook which he has produced, may be safely recommended to all who wish to have the main facts of materia medica and therapeutics presented to them in a concise and orderly manner. His book is a small one, but in the subject of which it treats, the size of a work bears no relation, except perhaps an inverse one, to the amount of labour spent upon it. The first two parts, comprising an account of the materia medica, have been arranged with much skill, and with the synoptical tables attached to them, will no doubt be found by the student to have many of the advantages of a *memoria technica*, without its disadvantages. The facts of materia medica are so diverse and unconnected that it is only by bringing into prominence the few natural links between them that the student can hope to impress them upon his memory. The action and uses of each drug are given with brevity and with just that amount of authority that the student needs. There is a refreshing absence of the "reputed to be an emmenagogue," "some evidence of its value as an expectorant," and similar doubtful sayings which sorely bewildered the present writer in his student days. It is however on the third part, that dealing with General Therapeutics, that the value and we hope the reputation of the book will mainly depend. It contains the best summary of our knowledge of rational treatment that we have met. It bears signs here and there of a little confusion of thought, and it is perhaps more strictly classified than the subject will bear. But the student who reads and digests it will not fail to gain from it a clear idea of the powers and mode of action, as well as of the limitations, of the drug-cure.

The volume which bears the name of Dr. Binz is the first of three parts in which the distinguished Professor of Pharmacology in the University of Bonn promises to publish his lectures as they are delivered to his students. It was a happy thought to determine to produce a thoroughly readable book on the action and uses of medicines, which should bear very much the same relation to the text-books on materia medica and therapeutics that a good clinical lecture bears to a systematic treatise on the practice of medicine. After a short introductory chapter, the author begins with the subject of anæsthetics, and in a pleasant demonstrative style reviews the action and uses of ether, chloroform, and nitrous oxide gas, touching lightly from time to time on various historical, chemical, and physiological points connected with this group of therapeutic agents. The narcotics are next fully discussed; and here occasion is taken to introduce the subject of poisoning by opium and chloral. Nothing better than this arrangement could be desired in a volume such as the present, for the professional and practical reader can best appreciate the indications for the treatment of poisoning after a thorough discussion of the physiological action of the toxic substance. We question, however, the advantage to the student of pharmacology of having the subject of poisons mixed up with the subject of medicinal remedies, notwithstanding the fact that το φάρμακον signifies both "poison" and "medicine," as Professor Binz is careful to remind us. Iodine, iodoform, and iodide of potassium are, of course, very thoroughly treated, including Binz's own theory of the manner in which the iodides come to act upon the cells as free iodine. Naturally, his theory of the sedative action of the halogen compounds (chloroform, iodoform, chloral, bromides) on the brain is also laid before the reader, but the amount of discussion which this involves is surely somewhat excessive for the ordinary student. This remark brings us to estimate the special use of these lectures. In their present form they will prove of the greatest value to lecturers on therapeutics and possibly to advanced students, but hardly to the rank and file of a materia medica class. Many of the experiments are described in such a way that they could be easily repeated, either in the lecture room or

[1] Materia Medica and Therapeutics, an introduction to the rational treatment of Disease, by J. MITCHELL BRUCE, M.A. Aber., M.D. Lond. London: Cassell and Co., 1884.

Vorlesungen über Pharmakologie, für Aerzte und Studirende, von Dr. C. BINZ, Ord. Professor, &c. Bonn. 1. Abtheilung. Berlin: 1884. A. Hirschwald.

The National Dispensatory, by ALFRED STILLÉ, M.D., LL.D., and JOHN M. MAISCH, Phar.D. Third Edition. London: J. and A. Churchill.

A Practical Treatise on Materia Medica and Therapeutics, by ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor in Philadelphia. Fifth Edition. New York: D. Appleton and Co., 1884.

in the private laboratory. We have not considered it necessary in this notice to refer to statements of facts by an authority of the rank of Professor Binz. But we must call in question one point. It is said on page 242 that atropia diminishes the intra-ocular pressure. This may still be the common view, but it is fraught with so much danger, through the indiscriminate use of atropia to which it has led, that it is high time it were renounced as being incorrect. When freely applied, atropia even increases the tension of the eyeball.

Stillé and Maisch's *magnum opus*—a volume of nearly 1,800 closely printed large octavo pages—has just reached its third edition. It is considerably larger than previous editions; eighty additional pages having been required merely to give the fruits of recent clinical research. Besides this many additions have been made to the pharmaceutical portion, and an idea of the labour involved in preparing the new edition may be gained from the fact that the general index contains over 3,700 more references than that of the second edition. It is scarcely possible to imagine a more complete compendium of materia medica than the Dispensatory. The paragraphs describing the medical uses of the different drugs are not always entirely satisfactory, and we have in more than one instance found important facts, or at any rate beliefs, omitted. But altogether it is a wonderful compilation, and no author of a smaller manual can afford to ignore it.

A book which has gone through five editions in the course of a few years does not demand a lengthened notice. Dr. Bartholow's work is probably in the hands of many of our readers, and is no doubt valued by them for being thoroughly practical in character, whilst giving succinctly and clearly the physiological action of the drugs which are recommended for use. The prescriptions embodied in the text must be specially useful to the busy practitioner. But in the strength of this book is to be found its weakness. The therapeutical applications of medicines which it teaches are confident in the extreme. In these days, when it is seriously proposed by some authorities to reduce the contents of the British Pharmacopœia to "half-a-dozen really useful articles," it would do therapeutical sceptics a great deal of good to read a few pages of Dr. Bartholow's book; but to ensure conviction on their part we should have to pull them up very shortly, otherwise they might again begin to doubt and to say that all disease appeared to be amenable to medicinal treatment, that "everything seemed to be a cure for everything." Professor Bartholow is too sanguine a therapeutist. Still, this frame of mind is, in the view of the present writer, infinitely to be preferred to that studied disbelief in drugs which too often begins in ignorance and ends in utter carelessness and disaster.

Manual of the Dissection of the Human Body; by Luther Holden. Fifth Edition. Edited by John Langton, Lecturer on Anatomy, St. Bartholomew's Hospital, &c., &c. London: J. & A. Churchill. Pp. 879.—Among the many new books which generally appear at the opening of the medical schools each year, there are none of greater importance than works on anatomy, for they are chiefly intended for and used by the men who are commencing their studies. It is thus highly essential that they should be made to assume as pleasant an aspect as their subject matter will permit. Anatomy is a difficult subject, and for beginners, who are least able to see for themselves the great importance of it, requires a special gift in the writer to invest it with such interest as will draw them on to its study almost in spite of themselves. In our opinion, there are only two really *interesting* works on anatomy, Hilton's "Rest and Pain," and the book before us, "Holden's Dissector." In contrasting this present edition with, say, the second, we find very considerable additions, emendations, and alterations, besides a large number of new woodcuts. There are upwards of 250 additional pages of print, perhaps a doubtful improvement from the purely student's point of view; nevertheless, we are bound to say that the book has grown in scientific as well as practical value *pari passu* with its increasing size; and whatever it was formerly, it is now, under its present editor, not merely a guide for freshmen, but suited to and intended for members of the profession who may wish to refresh their anatomical knowledge. Throughout it is embellished with diagrams and drawings from the subject, which bespeak much artistic power for their original author, Mr. Holden, and which greatly help the student in his work. The text is written in that easy flowing style which gives such a charm and practical value to all Mr. Holden's works, and clothes dry anatomical facts with the living impress which makes them acceptable and fixes them on the memory. If there are any points on which we should feel tempted to offer criticism, it would be on the *instructions* for dissecting some of the parts. Never very long, in some instances these instructions are very short; nor is the importance of carefully noting how a given part is or has been dissected sufficiently insisted upon. In other words, the majority of students would hardly answer a college dissection question satisfactorily from such instructions as are here given. Doubtless the supervision and help of demonstrators will remedy this defect; but we think the book would be still more valuable than it is if it contained a little more instruction in this respect. Students should ever bear in mind that the chief object of dissection is to learn how the body is constructed, rather than the length, breadth, or depth of any particular part. These points will be found in the systematic treatises on anatomy. In a Dissector we chiefly look for the plan on which a part is constructed, and for instruction as to how these parts may be displayed and studied in their actual and relative positions to each other, and to the whole part. The subject is systematically treated from the head to the feet, with chapters on special organs. The style throughout is clear; the descriptions accurate, but brief; and the information up to actual date. The book is admirably published, and we do not doubt that it will fully maintain its reputation.

THE INTERNATIONAL MEDICAL CONGRESS.

International Collective Investigation of Disease.

At the general meeting of the International Medical Congress, on August 14th, it was resolved:—"That the Secretary be instructed to prepare a statement as to the objects of the Committee, for translation and publication in the journals of the various countries represented." Dr. Isambard Owen, the Secretary-General, has accordingly drawn up the following statement:—

The main objects which the Committee seeks to attain through the Collective Investigation of Disease are to widen the basis of Medical Science, to gather and store the mass of information that at present goes to waste, to verify or correct existing opinions, to discover laws where now only irregularity is perceived, to amplify our knowledge of rare affections, and to ascertain such points as the geographical distribution of diseases and their modifications in different districts. It will be its endeavour to place clearly before the

whole profession the limits and defects of existing knowledge, as well as to stimulate observation, and to give it a definite direction. It will be a not unimportant incidental result of its work should it tend, as is hoped, to the better training of the members of the profession in habits of scientific and practical observation, and in systematic methods of recording the facts which they observe.

The age in which we live has seen enormous advances in the sciences on which the fabric of Medicine rests, such as Chemistry and other branches of Physics, Physiology, and Pathology. Each of these has taken giant strides. It must be admitted, however, that purely medical knowledge has scarcely made proportionate progress. It cannot be expected that it should do so, as it deals with the aberrations of the most complex of organisms, is of all sciences the most difficult, and demands the greatest patience and the largest accumulation of data.

Hitherto the advancement of Medical Science has been brought about mainly by individual effort. The value of such work in the past we in no way underrate, nor do we desire to lessen the amount of it in the future; but in Medical Science there is much that defies interpretation from individual experience, and many problems so far-reaching in an ever-widening field, with elements so manifold, that no single man, however gifted and long-lived, can hope to bring the whole within his range. The need, therefore, in Medicine, of that combination and concentration of individual work which is adopted in many other branches of science and in commerce, and to which increasing facilities of intercommunication have given so much impulse and so much strength, cannot be questioned. Indeed, it may be said that, resting on individual research alone, medical knowledge can be advanced but slowly and with difficulty. Future progress to any great extent must be the work, not of units acting disconnectedly, but of the collected force of many acting as one. For many to act as one, organisation is needed; that organisation it is the purpose of our Committee to supply.

Disease is many-sided; and we wish to include in our organisation those who see it from every side. All, therefore, whether hospital physicians, family and school attendants, specialists, medical officers of the Army and Navy, and of workhouses and asylums, will be asked to contribute their quota of observation to the common fund.

In England and in Germany organisations for this purpose already exist, through which good work has been accomplished; and a volume entitled the *Collective Investigation Record*, containing tabulated returns, with reports upon them and other matter, is published annually by the British Medical Association. France and Austria are alive to the importance of the new method. In Scandinavia and in the United States the foundations of associations have been laid. Denmark, Russia, and Switzerland are setting their hands to the task. To unite these several associations by an international organisation for the study of various problems, and to induce the formation of similar combinations elsewhere, is felt to be a work peculiarly befitting an International Congress. Our Committee is enjoined by the Congress at Copenhagen to endeavour to carry out this work, and, in compliance with that injunction, it invites the co-operation of all who have at heart the promotion of Medical science and practice.

The following is the proposed method. A subject having been selected, a person or persons of acknowledged authority will be asked to write a memorandum, in the form of a short essay, upon it. The memorandum will succinctly give the present state of our knowledge. It will also point out the directions in which further research may best be made; and, with this view, will suggest a few simple and definite questions upon the subject selected. The questions will relate to matters of fact, to be elicited by observation of cases, rather than to matters of opinion.

The contemplated organisation will, it is hoped, in time enable the Committee to ask and collect answers to these questions from the profession at large wherever scientific medicine is studied or practised. It will be a further duty to examine, arrange, tabulate, and deduce results from the mass of observations thus collected, due credit being given to each contributor for the information he has furnished; and reports on the results of the several investigations will be laid before the International Congress at its next meeting at Washington.

Section of Diseases of Children.

Monday, August 11th.

The Educational Value of Policlinics for the Treatment of Diseases of Children.

In a paper on this subject Dr. Rauchfuss (St. Petersburg) maintained that not the least of the benefits that resulted from policlinics was the diffusion throughout the community, and especially among the poor and the ignorant, of a knowledge of hygiene. If ignorant mothers could only be impressed with the importance of observing at least the elementary rules of hygiene, a vast amount of good would be accomplished. Prevention was better than cure.

The Pathology and Treatment of Cholera Infantum.

Dr. A. Baginsky (Berlin) then read a communication on this disease, which, he said, was to be reckoned, in Berlin at least, as the chief cause of death in infants. The number of cases of the disease in any given summer was in direct proportion to the height of the temperature of the air, but seemed to be only indirectly dependent upon the height of the temperature of the ground, the lowering of the level of the ground water, or the degree of moisture of the atmosphere. The quality of the nourishment and the degree of care which the child received, as well as the situation of the dwelling, were very important factors of the ætiology. Teething had no direct influence on the disease. As regards pathology, the different forms of summer diarrhœa of infants might be divided into—(1) Primary dyspeptic catarrh; (2) Genuine cholera infantum (cholera nostras); (3) Follicular disease of the intestinal tract; (4) Secondary dyspeptic catarrh; and (5) Intestinal atrophy. All these processes were as links in a chain, and might pass one into the other. *Post-mortem* examinations proved the correctness of this statement. Micro-organisms were found in the walls of the intestines, and were perhaps not unconcerned in the causation of the disease. The therapeutic management varied according to the form of the disease with which we had to deal.

Professor Hirschsprung (Copenhagen) then read a paper summing up the result of observations on hæmoglobinuria during the first year of life, and gave a demonstration of this condition.

Dr. H. Rehn (Frankfort-on-the-Main) followed with a paper on so-called acute rickets, in which he attempted to answer the question whether the experiences of later years have enabled us to determine the position of the affection known as acute rachitis. Most of the papers elicited more or less discussion from those present.

On Tuesday, August 12th, the members of the Section, together with those of the Section on Hygiene and State Medicine, made an excursion to the Asylum for Young Girls at the Château Jaegerspris, near Copenhagen.

Joint Meeting with the Section of Hygiene and State Medicine.

Thursday, August 14th.

The Treatment of Chronic Diseases of Children at Sea-Coast Hospitals.

Dr. Schepelern (Refsnaes) read a paper on this subject, in which he advanced the proposition that sea-side sanitaria ought to be kept open the entire year, winter as well as summer. He then spoke of the good results following a winter course of treatment, dwelling more especially upon the value of hydrotherapy in this connection. Among the diseases of childhood in which great benefit may be derived by a course of treatment at sea-side sanitaria, the author spoke more particularly of the scrofulous affections. One point upon which he dwelt at some length was the value of an increase in weight as evidence of the favourable progress towards recovery in scrofula.

Dr. Englested (Copenhagen) read a second paper on the same subject. His views did not differ substantially from those of the preceding speaker.

Croup.

At the afternoon session Dr. Rauchfuss (St. Petersburg) read a paper in which he argued the question as to how far croup can be considered, from a clinical point of view, as a well-defined morbid entity.

In the discussion which followed Professor Virchow and others took part.

Friday, August 15th.

Antiseptic Treatment of Wounds in Childhood.

Dr. Ruppreciit (Dresden) thought the best disinfectant was a one-third per cent. solution of salicylic acid, or for very septic wounds, a four to eight per cent. solution of chloride of zinc. One of the poorest materials for use in operations on children was carbolic acid. The general admissibility of corrosive sublimate solution (1 to 1,000) in childhood was, he thought, questionable. For certain wounds iodoform in small quantities is indispensable. The best material for dressing was gauze impregnated with salicylic acid (five to ten per cent.), or corrosive sublimate (1 part per 1,000), while carbolised gauze was objectionable. Wood-wool cushions are of advantage for certain wounds. Dry dressings are best for fresh, as well as for large suppurating wounds, but for small suppurating wounds moist dressings are more suitable. In these, however, neither carbolic acid nor corrosive sublimate should ever be used. In order to prevent soiling of the dressings with urine he favoured covering them with a water-proof cloth, the edges of the dressings being smeared with grease. Other methods of avoiding irritation from the urine were vertical suspension of the child, frequent changing of the dressings or the permanent bath. In concluding, the author pointed out the special indications for the employment of one or the other mode of treatment of wounds occurring in children.

Professor Jacobi (New York) then presented a communication on primary sarcoma of the kidney in the new-born and in the young.

Prophylactic Treatment of Ophthalmo-Blennorrhœa Neonatorum.

Dr. Sophus Meyer (Copenhagen) read a paper in which he pointed out that ophthalmia neonatorum is an essentially dangerous affection, and that measures of prophylaxis are therefore of especial importance. We do not yet know with certainty the cause of the disease, and we ought to encourage all investigations tending to elucidate this matter. Among the measures employed of late years, that of Credé may be considered the best. It is certainly a very satisfactory one, as since its introduction into lying-in institutions the malady has almost disappeared. Credé's method is not dangerous, and can be employed by midwives just as well as by physicians. The speaker concluded by urging upon his hearers the necessity of inducing midwives generally to make a constant use of the method in every case.

Intestinal Invagination.

A paper on this subject by Professors Hirschsprung (Copenhagen) and Ribbing (Lund) was read. The condition was treated of as it occurs in children, and some remarks were made upon its comparative frequency in different countries. The authors endeavoured to show that the great difference in this respect, as shown by the statistics of the several countries mentioned, was rather apparent than real.

Professor Faye (Stockholm) followed with some remarks on the treatment of scoliosis.

Joint Session with the Section of Hygiene and State Medicine.

Saturday, August 16th.

Normal Increase of Weight in Advanced Childhood.

Two interesting papers on this subject were read by Mr. Malling-Hansen (Copenhagen) and Dr. Vahl (Jaegerspris.) The observations were made upon girls, from four to fifteen years of age, inmates of the Jaegerspris Asylum. The children were weighed in April and October of each year, from 1874 to 1883. It was found that the normal weight of girls at this age increases in regular progression from thirty-two and a half to ninety-eight and a half pounds (16·25 to 49·25 kilos). Up to the end of the fourteenth year the annual increment is eleven per cent. of the weight of the previous year, but after this time the rate of increase falls off somewhat. The increase during the six warmer months is greater than in the six colder months, in the proportion of four to three.

Tubercular Meningitis of Early Infancy.

In a paper with this title Professor Medin (Stockholm) maintained that tuberculosis is frequent in the new-born, occurring sometimes in very severe epidemics, but tubercular meningitis is rare. Even epidemic cerebro-spinal meningitis is of more common occurrence in young infants. The author then spoke of the influence of age and sex, and of the seasons, and pointed out the differences in the symptoms and course of the disease as it occurs in young infants and in children of a more advanced age. Tuberculosis of the meninges may occur, he said, without producing meningitis, and in such cases there are no symptoms by which the condition can be recognised. The paper was illustrated with a number of charts.

Professor Prévost then read a communication from Professor d'Espine (Geneva), who was absent, on a rapidly curable form of infantile spinal paralysis. At the conclusion of this paper addresses were made to the Section by the presidents, Professor Rauchfuss (St. Petersburg), in French; Professor Jacobi (New York), in English; and Professor Hirschsprung (Copenhagen), in German.

Section of Military Medicine.

On the Use of Antiseptics in War.

Professor Esmarch (Kiel) opened an important discussion on this subject with a paper, the full title of which was: "Antiseptics in war, considered generally and especially in regard to the use of efficient and simple dressings, which, on account of their small bulk, are most suitable for field practice." In the course of his remarks he laid down the following propositions: (1) We are bound in humanity, in war as well as peace, to give the wounded the protection and the benefit of antiseptic treatment. (2) In order to satisfy this obligation (*a*) all military surgeons should be thoroughly familiar with the principles of the antiseptic treatment, and practised in its employment; (*b*) their subordinates, hospital attendants, and bearers should be instructed in the principles of antiseptics and versed in their application; (*c*) field hospitals, permanent hospitals, field-waggons, bandage-cases, and the pockets of hospital attendants should be sufficiently supplied with antiseptic bandages; (*d*) In war, every soldier should carry a bandage, to be used in case of necessity as a provisional antiseptic dressing. (3) All dressing material should be packed so as to take up as little space as possible, and the bandages of different sizes should be so arranged that they can be got at without loss of time. (4) Hitherto, corrosive sublimate has proved the most efficient antiseptic, and it is therefore the best substance to use to impregnate the dressings. (5) The best material for dressings is gauze (Verbandmull) which may be used both for compresses and bandages. (6) The best complete dressing will therefore be a gauze bandage impregnated with a sublimate solution (1 per 1,000), the volume of which may be considerably lessened by compression. (7) Of this sublimated gauze, pieces of varying length and breadth may be prepared so as to be adapted for every kind of wound. (8) To disinfect the hands and instruments, a solution of carbolic acid is indispensable. It must be taken on to the field in measured quantities. Carbolic spray, protective silk, and macintosh may be dispensed with in field practice. A substitute for the last-named may be eventually found in varnished paper. (9) Sublimate must form a part of the equipment in order that the various dressing materials (gauze, cotton-wool, lint, moss, sawdust, &c.) may be impregnated

with it, and the dressers, &c., must be instructed in the methods of using it. (10) Iodoform is only applicable to certain varieties of wound, and in antiseptic power is not to be compared with sublimate. (11) Instead of sponges, which could not be used at the dressing stations, sublimated wool should be employed and destroyed after use. (12) Where strict antiseptic treatment is not possible, as *e.g.*, at the dressing stations, no wounds except those attended with dangerous hæmorrhage should be examined by fingers or instruments which have not been rendered aseptic. (13) Extraction of bullets should not be undertaken without antiseptic precautions. (14) Hence at the dressing stations all that is to be undertaken is—(*a*) to apply provisional dressing, *i.e.*, to freely cover fresh wounds with antiseptic material; (*b*) to give support to wounded parts; (*c*) to transport the wounded as quickly as possible to a place where they can be dressed antiseptically. (15) At the field hospital, only those provisional dressings are to be examined in which it is absolutely necessary (fever, pain, hæmorrhage, soaking through of secretion from the wound). (16) Each examination is to be conducted with strict antiseptic precautions, the wound being properly opened up, drained, disinfected (chloride of zinc, sublimate, iodoform) and finally covered with an antiseptic bandage. (17) All that the bearers have to do is to carry the wounded as carefully as possible to the nearest dressing station. (18) The dressings which the soldier carries with him are only to be used in cases where surgical aid is not at hand or where the supply of dressings falls short. These soldiers' dressings consist at present of two sublimate compresses, one sublimate bandage with safety pin, a three-cornered handkerchief, the whole enclosed in a piece of waterproof.

Professor Neudörfer (Vienna), in a paper on the same subject, said that antiseptic treatment was especially important in war. Wounds were infected by the hands of the surgeon or dresser and never by the projectile. There was therefore on the field of battle no need to trouble about slight wounds, and wounds of the upper extremity. All the severely wounded should be removed to the dressing station as quickly as possible. There was no need to hurry about putting on the dressings, as the oxygen of the air had no unfavourable effect on the secretions of the wound. Salicylic acid in powder should be the first application to the wound. In gunshot fractures extension only need be applied.

Sir Wm. MacCormac agreed with Professor Esmarch's propositions. As the conditions were not the same in the field as in hospital, the first principle of treatment ought to be *not to injure*. A strict organisation of the medical staff and of the field hospitals was indispensable. For dressing material he recommended cotton-wool impregnated with sublimate, salicylic acid, or iodoform. He also recommended that the wounded should be removed as speedily as possible to the hospital, where they could receive strict antiseptic dressing.

Dr. Michaelis (Innsbruck) thought that the question whether the soldier should carry a dressing in his knapsack need not be discussed, as it had already been settled in practice in the affirmative. As a rule those wounded early in an engagement were well cared for, but there was always a lack of surgeons at the point where the decisive struggle took place. It was therefore necessary to remove the wounded to the dressing stations as quickly as possible.

Professor Mosetig v. Moorhof (Vienna) contended that the application of a provisional dressing in the field only caused loss of time. If a wound could not be thoroughly dressed, it had better remain undressed. He did not recommend that the combatants should carry dressings, for a large quantity of such got lost, besides which the wounded man could not dress himself, and his comrade might not do it. It would be much better to furnish the medical staff with a sufficiency of the dressings. Amongst antiseptic substances, powders could only be used for a first dressing, solutions being unattainable for want of water, and as, of the dry substances boracic acid was too weak, and salicylic acid too irritating, there only remained iodoform, which acted as an antiseptic in minute quantities, did not ball together like salicylic acid, and did not necessitate a covering bandage. He recommended iodoform most strongly. Unfortunately its odour was not to be removed or covered, but considering the other prominent advantages of the substance, this defect must be disregarded.

Dr. Lommer (Magdeburg) said that in Prussia the question of antiseptic or no antiseptic was no longer debated, a decision having been long since arrived at in favour of antiseptics. In the first line strict antiseptic treatment was very difficult from want of dressing materials and insufficiency of medical staff; he therefore recommended the use of iodoform-charpie. In the field and other hospitals sublimate could alone be used, partly because only small quantities of it were required, and partly because it was necessary, on account of the formation of the army, that a single antiseptic should be used throughout. He fully agreed with previous speakers that it was necessary in time of peace to train the subordinates of the medical staff in the use of simple antiseptic dressings.

The discussion closed with remarks from Dr. Ziegel (Stettin).

GENERAL MEDICAL COUNCIL.

Thirty-seventh Session.

First Day—Tuesday, October 7th, 1884.

President's Address.

The President on taking the chair delivered the following address:—In conformity with the instructions of the Council, I have summoned the present meeting at the first convenient day after the Long Vacation. The Council will remember that the second period of five years, for which they had elected the present President, ended on July 18, but that, since it might be undesirable to meet at that particular date, in view of the Medical Bill then before Parliament, it was agreed that I should continue in office in order that I might call the Council together at the time most suitable either for the winding-up of its arrangements under the Act of 1858, or for the further discharge of its responsible duties under that Act. This accordingly has been now done for the latter purpose. The Bill, on which so much labour and care has been expended, was withdrawn by the Prime Minister at the close of the Session, after it had passed the House of Lords, but not before 185 amendments, in 13 folio pages of more or less importance, some being in duplicate and triplicate, had been put on the notice paper of the House of Commons. The Council, therefore, meets now, without delay, both for the election of a President, and for the grave purpose of considering the situation in which the medical education of Great Britain and of the colonies is once more placed by causes in large measure unconnected with it. It is not my intention, under these circumstances, to make any elaborate address before retiring from the high office in which you have twice been pleased to place me. It would not, indeed, be strictly in order to do so, even if it were expedient. But I crave your indulgence while I say a very few words on the position in which, as the guardian of medical education in this country, the Council seems now to be placed. Government Bills, conferring fresh powers and imposing new duties on the Council, and this year reconstituting the Council, and assigning new and important functions to medical boards, have been four times passed through the House of Lords in the last twelve years, and have been four times withdrawn by the Government in the House of Commons without full discussion in that House. Into the causes of this abiding misfortune I will not enter, but I ask your leave to record that this failure has not been dependent on the action of the Medical Council. It is true that the work of the Council has been affected by an unusual, perhaps unprecedented, state of things. It has been hampered in its action, both from without and from within, by the sense that the powers and duties assigned by the Act of 1858 might shortly be modified or transferred. The

Council, though anxious to act to the full extent of its powers, was aware that its recommendations and its conclusions were, pending the new legislation, of late years made at a disadvantage. It cannot fail to be asked, What then is now the duty of the Council? Is it to wait for further attempts at legislation? or is it to continue to develop the work which lies before it, and, with the varied experiences it possesses, to act as though no legislation and no change were impending? It would ill become me to-day to attempt to answer these grave questions. The Council will give its own reply by its actions. But I venture to hazard the statement, that three short clauses, to which no serious person could object, would, if passed into law, shortly relieve the teachers and students of modern medicine in this country of almost all their present educational uncertainties:

The *first*, directing the Council not to admit to the *Register*, after a given date, any person who had not passed examinations, satisfactory to the Council, in Medicine, Surgery, and Midwifery.

The *second*, empowering the Council to appoint, in such manner as it deemed expedient, one or more Assessors to every Examining Board, whatever be their number now or hereafter.

The *third*, making it clear that the Council can, under Clauses 18, 19, and 20 of the Medical Act, enquire into the modes of teaching by the schools, as well as into those of examining by the Licensing Bodies.

But I might go further and say that, at the present crisis, it probably is in the power of the existing Licensing Bodies and Schools, by a combined effort, to give practical effect to these several propositions without legislation, and to secure thereby peace to themselves, and in great measure to obtain more completely the confidence of the public at large. I trust that I have not in these few words transgressed the bounds which you would wish me, at the close of ten years as your President, to set to these remarks. I do not presume to forecast the future. Of the past I know that the work which I have had the honour of sharing with you at this table for twenty-six years since the establishment of the Council has been work of the deepest interest, and often of great difficulty. During the last ten years it has been such as to produce in me sentiments of profound gratitude and to give confidence that the Council, as the guardian of Medical Education in Great Britain, will deal with the present crisis alike in the spirit of patriotism and in the temper of scientific progress on which modern medicine so largely depends. Whatever may be the case elsewhere, there is no question that within the walls of this Council there can be now only one aim, viz., how to unite in using and regulating, for educational purposes, and in the best attainable way, the many forces which bear on the study of all problems connected with the prevention and treatment of disease, both personal and national. These are forces which are ever moulding anew the character of the true student for the common good of mankind. They ever need for their study and their guidance fresh thought, and new exertion. I now leave the chair, in which you have twice done me the high honour of placing me, that you may discharge the duty under the Act of electing a President.

The PRESIDENT having vacated the chair and left the room, Sir HENRY PITMAN, Chairman of the Business Committee, took the chair. Mr. MARSHALL proposed and Dr. HUMPHRY seconded, that the President's address be entered upon the minutes. This having been agreed to, the strangers were ordered to retire, in order that the Council might choose their new President in private.

Election of President.

At the expiry of about half-an-hour they were re-admitted, and learnt that Sir Henry Acland had been re-elected for five years. The following were elected members of the Business Committee, viz., Sir Henry Pitman, Dr. Haldane, and Dr. Aquilla Smith.

Returns from the Army and Naval Medical Departments.

The returns from the Director-General of the Army and the Director-General of the Navy were next acknowledged, a good deal of time being taken up by various criticisms.

The Rev. Dr. HAUGHTON pointed out some errors in the order of precedence, which he thought of some importance, and it was decided that Mr. Miller should rectify this.

Dr. AQUILLA SMITH drew attention to the fact, that the Director-General of the Army did not append any remarks to his table, and that the remarks on the other table were not sufficiently full. He did not, however, wish to propose any formal resolution with regard to this matter.

Mr. TEALE rose to draw attention to one fact in connection with these lists, and it was with reference to the numbers who passed as compared with those who were qualified, but for whom there was no room. He noticed that of the English candidates a large proportion were successful, but that only a very small proportion of the Irish were: thus, out of twelve candidates from an examining body, only one was successful, the other eleven being reported as qualified; and in another instance, one out of ten was successful, the other nine likewise being reported qualified. He thought that the matter was sufficiently remarkable to be worth drawing attention to.

Mr. MACNAMARA, with some vigour, gave as the reason for this failure of the Irish candidates, that they were not sufficiently up in what he was pleased to call the "straight tips" of the examinations; and he was now advising his pupils to come over to London before going up for these examinations, in order that they might make themselves familiar with these tips from the best coaches.

Mr. MARSHALL referred to the fact, that these 44 candidates possessed between them 89 licences, and he thought it would be interesting if they knew which men had failed.

After some remarks from Dr. HERON WATSON, the motion to receive the reports was carried.

Prof. STRUTHERS then moved a resolution, that they should ask for a similar return from the Indian Department of the men who entered the Indian Medical Service. This was agreed to, as likewise a proposal of the Rev. Dr. HAUGHTON'S, that they should apply to Netley and Haslar for a similar return of the final results.

This, having been seconded by Dr. BANKS, was also agreed to.

Results of Preliminary Examinations.

Sir HENRY PITMAN then moved that a communication from the College of Preceptors should be received, referring to the results of the preliminary examination, from which it appeared that out of the total number of candidates more than half had failed to pass the examination; a result which he regarded as at once important and disheartening.

Dr. STORRAR, in seconding the motion, said that his impression was that the fault lay entirely with the candidates. He said that there was a great tendency, at the present day, for young men to go up for an examination and take their chance of passing. Formerly to be rejected at an examination was regarded as of the nature of a disgrace, but that opinion did not seem to prevail now, and candidates came up again and again for examinations, without being in the least prepared for them.

The Rev. Dr. HAUGHTON said that, as an honorary fellow of the College of Preceptors, he ought not to stand up to praise them, but he wished to add his testimony to the way in which that body did their work, and he was convinced that the cause of the large percentage of failures was that the candidates were totally ignorant of what was expected from them. He did not consider a large percentage of rejections as any test of the examination being a good one; in fact, he thought that the reverse was the case. He noticed with much regret that only four candidates were described as having passed in mechanics. It was to be assumed that no more had gone in for the examination, but it was to be regretted that such a poor return should be obtained after all the stress they had laid upon mechanics as a subject of preliminary education.

The motion was carried.

Sir HENRY PITMAN then moved a resolution that the other bodies mentioned in the Medical Act as conducting an examination in preliminary education be requested to furnish the Council with a return as to the number of those who had passed, and the subjects of examination. He said

that there were no fewer than 56 bodies whose examinations were recognised, and the College of Preceptors was the only one who sent in any return. He thought that it might be found that some of the bodies had not so high a proportion of rejections, though as the subjects of examination were the same, the results ought not to be very different. He did not know whether any useful information would be gained by such a return, but he thought that there would certainly be some information of interest to be got out of it.

Mr. MARSHALL seconded the motion.

Mr. MACNAMARA thought that the idea was a very useful one, and he was in a position to furnish the Council at once with the results at his own corporation, the College of Surgeons in Ireland.

Dr. AQUILLA SMITH suggested, that all whose examinations were recognised should be asked for a return.

The Rev. Dr. HAUGHTON said that they ought to ask for the papers that were set, as well as for the standard adopted in the examination, which would be found much better guides than a mere list of the numbers rejected. The scheme as at present proposed was impossible, as in Dublin, at any rate, the University had no means of knowing who amongst the candidates were medical students, as distinct from law or the church. He thought that possibly the University might be willing to institute a separate examination, but he was not in a position to state anything positively on their behalf.

The PRESIDENT pointed out that some of the speakers had dealt with a wider question than was included in the motion before them; he noticed that there were two resolutions which proposed to deal with the whole subject of preliminary education, and he suggested that the further discussion on this matter should be postponed until those resolutions were under consideration. The motion was then by leave withdrawn.

Certificates of Moral Character.

Mr. MACNAMARA then brought forward a motion to the effect that students before being registered must produce a certificate of good moral character, signed by a clergyman, a magistrate, or a medical practitioner. He said that this was the rule in the case of the Irish bar, and he thought it ought to be adopted for medical students. He had excluded the schoolmasters from the list of those whose certificates they would accept, as he had learnt that their certificates were worthless. His scheme was not perfect he knew, but nothing was perfect, and it was the best that had suggested itself to his mind. This proposal it was in the power of the Council to enforce if they chose to do so. His next resolution, making the same proposal with regard to students up for their final examination, they could not enforce; they could only recommend it to the various examining bodies, and therefore he had kept it separate. The College of Physicians of Ireland already required a certificate of good moral character from candidates for the diploma, and he hoped that before long the College of Surgeons in Ireland would do the same. The matter had been brought under his notice by the case of a student who had passed half of his final examination, and had just been convicted for stealing, and there was no power by which, so far as he (Mr. Macnamara) knew, this young man could be prevented from receiving his diploma on moral grounds. Had he already been a qualified practitioner, they could have very easily dealt with him.

Dr. BANKS spoke of the way in which this scheme had been found to be perfectly satisfactory at the College of Physicians in Ireland, and he would be happy to second Mr. Macnamara's motion, subject to certain alterations. He had no opinion of clergymen, and would not place any reliance upon their certificates or upon those of magistrates, and if Mr. Macnamara would substitute for them the words "two registered practitioners," he would support his motion.

The Rev. Dr. HAUGHTON could not allow such a statement to pass; they ought not to offer such an insult to the clergy as to decline to receive their certificates. For his own part he was not afraid to say that the lowest in the ranks of the clergy were far higher than the lowest in the ranks of the medical profession.

Dr. QUAIN suggested that the certificate should be issued in more general terms, to the effect that a candidate shall produce a certificate of good moral character which shall be satisfactory to the Registrar. Subsequently, at the suggestion of Mr. Simon, the words were added, "under the direction of the Branch Council."

Mr. SIMON said that a resolution such as this contained much that all would sympathise with, but it ought to be made very general. For his part he did not believe it could be of any use. What, he would ask, were the evidences of disqualifying immoralities? Every man was assumed to be of good moral character until the contrary was shown. They would not be able to get hold of anything but what the criminal law took notice of. A man might be required to make a declaration, and then if this was afterwards found out to be untrue, he could be prosecuted for making a false declaration. Whilst entirely sympathising with the object with which this resolution had been brought forward, he would strongly object to adding anything more to the "dreadful certificate system" as he called it. Under cover of certificates an immense quantity of false statements were made, and this would be an utterly unnecessary certificate.

Dr. LYONS said, that whilst fully sympathising with the intention of the proposer of this resolution, he could not but feel that the subject was very complicated and full of difficulties. It had worked well at the College of Physicians as he knew from personal experience, but there the numbers were very small, and every man was personally known to the Fellows. He referred to the great injustice that might be done by refusing a certificate, and instanced a riot that had taken place some years previously in Dublin, when a theatre had been wrecked, on which occasion two of the most prominent rioters were students, one of whom afterwards became a bishop, and the other a judge. They were all accustomed to sign these certificates without knowing really very much about a man, and he did not think that this rule could be rigidly worked, and he doubted if it would be of much use if it were. He would suggest as an amendment that the certificates should be from two persons of character, one who had known the student at the commencement of his student career, and the other a person who had known him at the end. After some further remarks he moved that the resolution be referred to a small committee. This was seconded by Dr. PYLE.

Dr. AQUILLA SMITH did not see that they would be in a better position to decide on this question in a week's time than they were then. He thought the proposal was utterly impracticable and could not be worked, and it was quite open to doubt whether it would be useful or not. He entirely agreed with Mr. Simon.

PROFESSOR HUMPHRY said that it was most undesirable that the Council should pass a resolution likely to be inefficient. This one could not have any real effect. It would scarcely be possible to conceive of any ground on which such a certificate could be refused to any lad of the age in question. How, he asked, could a general practitioner possibly refuse to give such a certificate to the son of a patient? The certificate could not be of the least value.

Dr. MATTHEWS DUNCAN said he should support Mr. Macnamara. He thought that the fact that a certificate had to be obtained would exercise an influence amongst the students themselves. He was under the impression that formerly a certificate had been required by the College of Surgeons in Edinburgh. The only objection that had been raised was that the certificate would be worthless. All certificates might be said to be imperfect. In all the schools and colleges, a man was required to be of good moral character, or he was not allowed to remain there. Modern history and Euclid, he said, were all very well in their way, but it would be far better to test a man as to moral character than in these subjects.

Mr. MACNAMARA could not accept the amendment. He believed that the knowledge that he had to obtain a certificate would be an incentive to the student to abstain from bad practices. As to objections that had been raised, he thought that the Irish benchers would not retain it if they did not find that it worked well.

The amendment was then put and lost by an immense majority.

The original motion was then put and lost by a considerable majority.

Mr. Macnamara then, by leave, withdrew his motion relative to the certificate before the final examination.

Age as a Qualification for Practice.

Dr. Banks then proposed that the Council should recommend the licensing bodies not to confer a right to practise upon any man until he had attained the age of 23. He commenced by saying that the present regulation was frequently evaded. For most men there was not time for them to have received a good education by the time they had reached the age of 21. A man now became qualified just at the age when he ought to be commencing his professional studies. He quoted a list of the periods of study required upon the Continent, from which it appeared that, with the exception of Germany, all the countries required a longer period of studentship than our own. In Sweden, which required the longest of all, the profession stood upon a higher platform, so to speak, than elsewhere. It would be said that he would debar poor men from the profession; he did not think so, but poor parents should put their sons into a trade, and not into a profession. A very young man might be so situated that people had no choice but to employ him or do without a doctor. This did not apply to the bar, for people were never obliged to employ a junior counsel. Billroth had expressed himself very strongly in favour of raising the age to 25.

Dr. Aquilla Smith seconded the motion.

The Rev. Dr. Haughton supported the motion. He thought that at present the limit was too young, considering the grave responsibilities and delicate position in which a medical man often found himself, and he referred to the Hippocratic oath to show the nature of those responsibilities. The lowest age in the Church was 23. He thought that very little injustice would be done, especially as the public services were open to candidates up to the age of 27. The length of the curriculum would have to be taken into consideration. This resolution would facilitate the giving of more time to the preliminary subjects.

Mr. Simon said that the analogy of the custom in the different churches was a false one. There one had to do simply with the spiritual welfare of those entrusted to the man, here it was a question of a man's earning his livelihood. The meaning of 21 was that that was the age at which legal responsibilities could be undertaken. Whether the man knew his business was for the examiners to decide. He quite agreed that it was doubtful whether the amount required could be done in the time. It was the curriculum that should be extended rather; if a man could pass the preliminary examination it mattered not what his age was. Possibly, an average man would not pass until he was 22. Further than that they could not go; there might be many men competent at the age of 21 and it would be a great injustice to prevent a man from earning his bread if competent.

Dr. Lyons said that this proposal should not be allowed to affect those who had already commenced their studies. The question carried with it various financial considerations for the parents and guardians. He suggested a four years' limit of notice, and thought that 1888 might be named as the date when the scheme should come into operation. It involved another very important consideration, viz., that a large number of men would entertain the idea of an Arts degree first, but it would nearly double the cost of education. He thought that the proposal would lead to a higher education, and raise the social status of the profession.

Dr. Matthews Duncan would have supported the proposal cordially if it had been a recommendation, but it was compulsory, and though he sympathised with the spirit of it, he could not agree to so sweeping a change. They ought to have the deliberate opinions of the licensing bodies upon it. At present none of them required more than 21 years of age, and the Council ought to wait for some expression from them.

Professor Struthers said that this question was one of the greatest importance. He would be quite prepared to support the resolution if 22 was fixed instead of 23. In no country, he said, was the curriculum longer than four years, and Dr. Banks had included the preliminary education in his statistics. He would suggest that a return be obtained from the various licensing bodies. If the age were 22, the lads would either spend a year longer at school or they would go out as assistants for a year at the end of their student period, which would be of great advantage to them.

At this point the discussion was adjourned until the next day.

Dr. Quain asked for an expression of opinion from the members as to the effect of the changes that they had endeavoured to introduce into the ventilation of the Council room, and Dr. Fergus said he thought that the room had been very much improved; they had got rid of the dry rot which formerly had been so objectionable.

Second Day.—Wednesday, October 8th.

A Question of Title.

The minutes of the previous meeting having been read, Mr. Macnamara rose to object to their being confirmed, on the ground that he was incorrectly described, in that, being a professor, he was called "Mr." throughout; and he moved an amendment, substituting the prefix "Professor" to his name wherever it occurred in the minutes, instead of "Mr." He said that he had written to the secretary on the subject, and had received a reply to which he felt bound to take exception, on account of the use in it of an expression about persons "who adopt the title of Professor." He was a Professor of Materia Medica in the Royal College of Surgeons of Ireland, which had a royal charter, and he read extracts from the charter to prove that his office was designated a professorship.

The President said that this was part of a general question, which had hitherto been always left to the discretion of the Chairman of Business, and he regretted that it should be brought before the Council.

The Rev. Dr. Haughton seconded the motion, and he did so because he had had on a former occasion to make a somewhat similar application on his own behalf.

Sir Henry Pitman claimed the right to say a few words, as his discretion had been somewhat called in question in the matter. The secretary had referred Professor Macnamara's original letter to him, and he, supposing it to be some recently acquired title, had directed the answer to be sent of which the speaker had complained. Professor Macnamara had been for ten years a member of that Council, and had never before claimed this title, and he gave no sort of reason in his letter, and it was therefore only natural to suppose that it had only recently been obtained. As a matter of fact, there was no precedent on the point, for the prefix of Professor had never been used in their minutes since the foundation of the Council. If Professor Macnamara was really serious in the request he was making, the whole question would have to be gone into, and he ultimately drafted an amendment, proposing to refer the matter to a committee.

Dr. Matthews Duncan seconded the amendment.

Dr. Lyons asked under what Act of Parliament the royal charter of the College of Surgeons in Ireland had been confirmed, as until it had been so confirmed none of its provisions were valid. He regretted that this question had been brought up at all, but as it had, he did not think it could be shelved, and he would therefore approve of its being referred to a committee.

Mr. Macnamara would not submit to a committee; he had a right to the title of Professor, and he would not permit a committee to question that right. It was nothnig to him that others had a right to the title but did not claim it.

Dr. Lyons rose again to correct an assertion of Mr. Macnamara's. The Medical Act did not in any way convey the power by implication that Mr. Macnamara wished to make out that it did, and there was nothing in that Act which could be taken as confirming the legality of the charter in question.

Mr. Simon regretted exceedingly that this question should ever have been brought up, and he suggested that the motion should now be withdrawn, and that the President

should be requested to decide on the point, and that Mr. Macnamara should abide by his decision. At the same time he reminded Mr. Macnamara that in the original document, announcing his election to the Council, he had not been described as Professor.

This course having been agreed to, the minutes were confirmed.

Order of Business.

The PRESIDENT then asked the permission of the Council to make a short statement. He had been unable to say anything on the previous day, as any remarks from him at such a time would have been most unsuitable; but since then he had considered what would probably be the best course of business to adopt, and he had a few suggestions to offer. The work they had before them he described as complicated and tangled. They had to consider whether they should wait for further legislation and fresh powers, or whether they should go on attempting to do what they were originally appointed to do, but what for the last ten years they had found increasingly difficult. For more than ten years Parliament had been endeavouring to remedy the present state of affairs and had failed. But their powers remained intact, and the Council was just as responsible now as in 1858. The great question was what could the Council do with its present powers in regard to general medical education throughout the country, and what could it not do? He would put on the minutes for the next day the following resolutions which he had drawn up with the aid of the Chairman of Business, and if the Council saw fit they would resolve themselves into a Committee of the whole Council, and proceed to discuss them, strangers being absent, as he thought that would conduce to shorten the speeches:—

"(*a*) That the Council consider in Committee what are the most important changes, if any, in respect to Medical Education and Examination, which should be made for efficiently carrying out the intention of the Medical Act (1858).

"(*b*) That the several changes, if any, be classed into (A) those which can be effected by the action of the Medical Council, the several Medical Bodies, and the recognised Medical Schools; and (B) those, if any, which may require, for carrying them into effect, an alteration of the law.

"(*c*) That the Council suggests to the Representatives of the several Licensing Bodies here specified to use all due effort to obtain the consent of their respective Institutions to such *Resolutions* on the aforesaid subjects as are agreed to by the Council at its present meeting, with a view of immediately carrying out those which can be effected without alteration of the law, and for their observations on the importance and desirability of those which cannot."

After some remarks from Dr. QUAIN about the Divisional Boards, the Rev. Dr. HAUGHTON asked if he would be in time to bring forward other resolutions besides those he had already given notice of, and was assured that he would have plenty of time.

Dr. LYONS asked if it was intended to sweep away all the motions at present on the paper.

Dr. HUMPHRY did not see how any consultation about what they ought to do could help matters, and he said it with the utmost respect. Their powers were most clearly defined in the Medical Act, and it seemed to him that legislation having failed, they ought to go on without reference to any future legislation. A discussion could be of no real use, but if they used their powers they might do a vast amount of good.

Mr. MACNAMARA thought that the President's proposal would simplify matters very much.

The PRESIDENT said that he had not often had occasion to make a statement of that kind, and he was very sorry that he should have alarmed Dr. Humphry, but he had really suggested nothing new, his proposals had related only to the order of business. The practical object that he had in view, would, he thought, bring forward every motion that had been put on the paper. The motion would appear on the minutes in the morning.

The discussion on Dr. Banks' motion was then resumed.

Dr. HALDANE thought that it would be very unfair if a man was able to pass his examination at the age of 21, to prevent him from doing so on the score of his youth. It was a conventional age at which a man assumed all his ordinary responsibilities. In this respect he saw no reason why medicine should differ from almost every other body. He agreed with Mr. Simon that the question was one for the examiners. As to the higher qualifications, it did not apply in the Universities; a man always took an Arts degree first, and the question of his age need not be considered, he would be sure to be much over 21. In most instances men were 22 or 23 before becoming qualified, but there were exceptions. On the subject of poor men entering the profession, he altogether objected to the idea of preventing them. Many of the most brilliant men the profession had produced had commenced as very poor students. Also the need of men to practice in poor districts must not be forgotten. It had been said that the proposed alteration would promote diligence; he believed it would have just an opposite effect. The tendency on the part of all students was to postpone work. To delay the age at which he could enter the profession would simply give the student so much more time to waste.

Mr. MARSHALL said that this subject had often been discussed at the College of Surgeons, and that he was very anxious to prolong the period of the curriculum, but not by altering the limit of age. At his own college he had found that two-fifths did not pass until they were 22 years old. Most of them obtained a medical qualification first. Except as a means of prolonging the curriculum he did not approve of this motion.

Dr. STORRAR said that there were many practical difficulties in the way of the present proposal. They must remember that they had to meet the wants of the public in this matter. There were it might be said three classes amongst the public. (1) Those who were rich enough to retain distinguished men whenever they wanted medical advice. (2) Those who were moderately rich, and were content with a rough and ready, or rather he would say with a ready practitioner, who knew his work well, and who knew when to call in the advice of a consultant. (3) Those who could not afford to pay anything like so much, and they formed a very large class. They must remember that men practising in the lower parts of London, and in many of the large towns, had to do a great deal of work for very little return; there were many men who could never reach an income of 400*l.* a year. Their patients could not afford to pay for an expensively educated man. At the University of London he would be a very remarkable man who could obtain his degree by the age of 21. He instanced the case of a young man who went up to Edinburgh and obtained his licence to practise at the age of 21, and who then took an appointment where he saved a little money and was now reading up for his degree at the University of London. If the present proposal had been in force this man would not have been able to do this, for he would not have been able to support himself during those two years. If the age was extended the career would become more expensive; they would therefore charge the patients more, and these would, in consequence, fall into the hands of unlicensed practitioners. In spite of all ambition to raise the status of the profession they must recognise that in a matter of this kind the public would have its own way. Fifty years ago the College of Surgeons had 22 as the limit, and they had lowered it, doubtless for some very good reason, though he did not know what it was. Prior to 1815 the College of Physicians had been requested to give a licence to practise, but they had always refused, he supposed because they wanted none but highly educated men to practise the healing art. The Apothecaries' Society had started a qualification to practise in consequence of this refusal, and he thought that the country was under a debt of gratitude to that society for their action between 1815 and the passing of the Medical Act in 1858. If they raised the standard above a practicable point the men would be above the means of the public, who would then pass into the hands of the unlicensed practitioners. He thought there always must be, so to speak, a staff corps in the profession and a commonalty.

Dr. SCOTT ORR said that the question was really one of lengthening the curriculum, rather than of altering a fixed age. Practically the age was already extended for the low

class men who could not get through in the time, and for the high class men who liked to devote more time to their work, but it was the middle class men who wanted to be restrained. He quite approved of the idea of fixing 22 years as the age.

Dr. HUMPHRY did not think it would be wise to limit the minimum age. It would tell most injuriously on the most intelligent and ablest students. He had had a large experience, and the younger students were often the best prepared. It had been said that this scheme would improve the status of the profession; it seemed to him that it would have the opposite effect. Supposing that a man had two sons, the one sharp and industrious, the other dull and idle, which would he be likely to send into a profession where he would not be able to earn his own living till the age of 23? There could be very little doubt that it would not be the one who was intelligent and industrious; he would look to his making something by the time he was 21. The proposal would be, he believed, prejudicial, and it would be much better he thought that it should be left to the various licensing bodies to take the initiative.

Dr. BANKS said in reply to the various speakers that he had not contemplated that this scheme should come into operation at once. As regarded France he admitted that he had overlooked the fact that the first two years of the six were spent in non-professional study, but the figures he had given in regard to the other countries he would guarantee the accuracy of, as they were taken from Billroth's work on the subject. Many of these countries were poorer than Ireland or Scotland. He knew that ignorant boys got into the profession, on his plan they would have time to learn. His motion might be regarded as piloting the way for the extension of the curriculum. The Universities did not come into his contemplation at all. He said that he had not overlooked the wants of the rank and file. His object had been in a great measure obtained by the discussion that had taken place. The full question of the curriculum would perhaps come up later. He was quite willing to accept 22 instead of 23.

Mr. SIMON objected most decidedly to the proposal. He was against the principle of an age test at all, but was a strong believer in the principle of an examination test. He thought that the curriculum was unduly short, and he thought that this question was of much less importance than the much larger question of the curriculum and the arrangements of the curriculum, which he suggested should be postponed for consideration at the next session of Council, and that in the meantime the various representatives could confer with the licensing bodies and obtain their feeling on the matter.

The question was then put that the age be altered from 23 to 22 in the resolution and lost by 9 to 11. The original motion was then put and lost by a large majority.

The English Conjoint Scheme.

Sir HENRY PITMAN then brought forward his motion that the Council should sanction the scheme of the Royal College of Physicians of London and the Royal College of Surgeons of England to co-operate under the direction of the Council. The scheme had, he said, been printed upon last year's minutes, and the present one was identical with that in every essential detail. The words in the notice, "under the direction of the Council," had been inserted because they appeared in the resolution with regard to the Scottish conjoint scheme which had been passed at their last session. He could not conceive of any reason why the Council should refuse its sanction to the scheme, seeing that 14 years previously they had expressed the opinion that the bodies should co-operate. The Council had it in its power to grant the sanction at once, and he could see no reasonable objection to it on the part of the Council. As to whether it was in the interests of the bodies themselves was a matter that did not concern the Council. Similar proposals were, he understood, being considered in Ireland. He would press for a settlement of this question at once. Last year the matter had been postponed because the duration of the time of notice of a former scheme had not expired, that reason however no longer existed.

Mr. MARSHALL seconded the motion, and said that he would refer somewhat to detail, not that the Council had any right to object to a scheme on the ground of detail. Last year no discussion had taken place on the details of Scottish scheme. He believed that the details would prove interesting. There was nothing that would interfere with any future bill. Their scheme did not profess to cover the whole ground of medical reform, or the whole ground covered by the conjoint scheme. That had failed, and had not been revived; their scheme was both realisable and viable. There was perfect harmony between the two colleges, who were prepared at once to act upon it. As regarded the curriculum, it was founded upon the lines of the conjoint scheme, and on that of the two colleges. It was an advantage to the student that he should only have one course of study to obtain a double qualification to practise. Both in the matter of simplification and consolidation it was an improvement upon the present state of affairs. They had also improved on the old conjoint scheme, students would have fewer lectures to attend, and there would be three examinations instead of two, as at present at the College of Surgeons. He believed that students liked a first examination. Then, a student would not be required to take up all the subjects at once, but might take them up in three parts for his final, and might divide them in the other examinations. This would prolong the period which the student gave to his studies, without making any special alteration or regulation as to age. All their changes tended to relieve the student from personal anxiety, and make him less distrustful of himself. As to the value of the licence of the College of Physicians, he granted that it was complete in itself, but he had some figures to give, which he thought would be interesting. Out of the first 2,450 names on the register, 153 held the licence of the College of Physicians. Of these, only six were contented with it; two of these, however, were Canadians, and might have diplomas there as well, the other four were comparatively young men, who very likely intended to take some surgical qualification. Out of the remaining 147, two held the licence of the Society of Apothecaries, all the rest had some surgical qualification, 139 the M.R.C.S. These facts were most satisfactory, and showed that the scheme was both desirable and practical, and it did not infringe on any existing lines or tendencies. As to the question of fees, they would remain the same as at present, 21 guineas to the College of Surgeons, and fifteen guineas to the College of Physicians. They might have raised them but he thought that that was out of the question. If they had lowered them they would have been accused of bidding for candidates, and of coming into competition with other licensing bodies. It would moreover, he pointed out, be an injustice to the already existing licentiates. Under the new scheme, if twenty-four candidates presented themselves for examination, and all passed the whole series of examinations, the cost would be greater than it was under the existing *régime*, chiefly owing to the first additional examination. But the numbers would gradually diminish, so that there would be fewer to be examined at the final examination, and consequently fewer fees would have to be paid to examiners. As to what their funds might be in the future they would not speculate, they must not count their chickens; at present they had not the funds which would justify them in reducing the fees, but if at any future time they should be in a better financial position, they could always re-open the question of fees.

Dr. QUAIN said that this scheme had originated with the College of Physicians. The only effect of it would be to create a new examining board, as each college could, as before, grant its diplomas to anyone who had obtained the other qualification elsewhere. The Scottish question was totally different, as the Board of Management was differently constituted. The Scottish bodies had combined; the present proposal was for co-operation, not combination. Each college would appoint their own examiners, and each would pay their own men; there would be no common fund. The Scotch had previously to their scheme no Board that could give a complete examination, but this was not true of England. The present favourable position of the College of Physicians was entirely owing to the exertions of the late Dr. Todd and himself. They had decided to do away with the Extra-Licentiates and institute the new order of Licentiates, and in spite of much opposi-

tion they had succeeded. He reminded the Council that the word Physic, as used in Henry VIII's charter, included Surgery. Why should they give up the single Examining Board they had now got? The College of Physicians had only assented to the scheme under the belief that they were going to form a grand national board, and had not intended to assent to such an arrangement as that now proposed. He said that 93 per cent. of their Licentiates also took the M.R.C.S., but what was more remarkable was that 30 per cent. took the L.S.A. in addition. Why should men be compelled to go to the College of Surgeons? He could see no reason for it. If they sanctioned a partial or incomplete board it would be a great mistake, and he concluded by moving an amendment to the effect that while they approved of the College of Surgeons undertaking not to give their diploma to anyone not fully qualified, they could not sanction an arrangement by which the College of Physicians would become a partially qualifying body.

Dr. Pyle briefly seconded the amendment.

Mr. Macnamara rose to explain why he must have his say on this subject, though he had agreed to the Scotch scheme without making a speech. [The distinguished professor's memory is somewhat at fault here, for he certainly did take the opportunity of making some observations (not much to the point, we admit) when the Scottish scheme was brought forward last session.—Rep. *M.T.*] The reason for this was that the Scottish scheme took in all the corporations, whereas the present scheme did not, the Apothecaries' Society being left out. He thought that the mode in which the examinations were to be conducted, as detailed by Mr. Marshall, could not be improved upon. Dr. Quain had said that they were going to make a new scheme. [Here Dr. Quain interposed to disclaim having made any such assertion.] Referring to the Licence of the College of Physicians, he was surprised that the Local Government Board should have accepted it as complete; it would not be so regarded in Ireland, and was not accepted for the public services. If the Apothecaries' Society had been included he would have voted for sanctioning the present scheme.

Mr. Teale said that when he first read the present scheme, he did so with much disappointment. It fell short of the original conjoint scheme. The Council, however, ought not to refuse its sanction to it except for very strong reasons. His feelings had become modified towards the scheme since his first impressions. The step proposed in it was one in the right direction, it would help to determine the curriculum, both for the teachers and students. The system of three examinations, with fees payable for each, would virtually commit the student to go on with his examinations, as he would have already paid part of the expense of his diploma. The man who possessed this diploma would possess a very valuable qualification, the best that he could possibly have, and for his part he should certainly now support the scheme. It was a co-operation and not a combination, but this was partly owing to the nature of the two bodies. For the College of Surgeons the question of finances was a grave one. He was disappointed when he heard that the full double fee was to be charged, and he thought that it would be desirable if possible to reduce this. As regarded the first examination, it would depend upon how it was carried out whether it was a benefit or a burden. Were the students to be brought up from the country for it, or would the examination be conducted by examiners sent down to the different schools? This was a very serious matter. Another examination in London would entail serious additional expense to the student, and if the percentage of rejections was as large as in the later examinations the expense would be greater still. He also asked whether it would be possible that in all the examinations the paper work could be done at the schools and the candidate only come up to London for his *viva voce*. In this way a student would only have to stay a night in town instead of a week, and the expense would thus be considerably reduced. The examiners, too, by having fewer men to examine would be saved labour, for he would suppose that a man who was rejected for certain on his paper work would not be brought up to London for nothing. It would probably be said that the numbers rejected on the paper work alone were so small that it was not worth while to stop them from coming up for *viva voce*; he believed at present the proportion was about 5 per cent. He would suggest that the number might be largely increased with great advantage if the paper work were made a little more extensive. All the medical centres in the provinces were growing, and the question would be certain to arise in the future.

Mr. Simon said that the position of the College of Physicians differed somewhat from that represented by Dr. Quain. He had always had a doubt, and he had expressed it, as to their right to give a double qualification. Physic truly did include surgery, but for 300 years the College had taken no notice of it, and then asserted a right to give a qualification in surgery. It was quite true that the Act of Henry VIII. stated that the members were entitled to practise surgery, but that was a different thing from their giving a licence to practise surgery. Had the College of Physicians a legal right to refuse to examine a man who had not a registrable qualification? The point had come up before the College of Surgeons as to whether they could so refuse, and after conflicting legal advice in the matter, they had got a special Act of Parliament which empowered them so to refuse. If the College of Physicians had not got that power it seemed to him to be an insuperable difficulty in the way of the present scheme for co-operation.

At this point the Council adjourned.

Third Day.—Thursday, October 9th, 1884.

The English Conjoint Scheme (continued).

Mr. Collins could not vote for giving sanction to this scheme. A tripartite board and not a dual control was the real kind of reform that was requisite in the United Kingdom. What he hoped for was a conjoint scheme of education and examination by the three corporations in the United Kingdom. The universities had declined to take a part, and this he much regretted. In both England and Ireland it was the Apothecaries' Societies that were in the way. The Scottish corporations had arranged a satisfactory union, and he still hoped almost against hope that a tripartite union might be effected. Some thought that the Apothecaries' Societies were no longer required to take part in medical education and examination. The objection was not valid, but if it were, then it was equally valid in the case of the other corporations. The Society of Apothecaries of England could not be ignored. As Dr. Storrar had said, it had been very valuable in the past, and more than half the practitioners in England held its licence. This was a most important fact, and the Society could not be overlooked. Referring to the Apothecaries' Hall in Ireland, he admitted its connection with a drug establishment; and he submitted that that had proved a wise arrangement. As to its professional status and the opposition to it of the College of Physicians in Ireland, they must remember that that opposition was no new thing, it had been going on for the past thirty years. Their position had repeatedly been under the notice of the Legislature in Ireland, and their status and rights had always been maintained. More recently a decision, very much in their favour, had been obtained from Earl Kimberley and Sir Robert Peel. All this had largely increased and improved their professional status. He thought that it was high time now that all the bodies should come to some wise and harmonious resolution. The scheme before them on the whole was excellent in regard to the examinations, except that the first examination was incomplete, as intended for general practitioners. He regretted that the fees were not to be reduced, and thought that they ought to be made to approximate more to those of the Scottish bodies. It was desirable that the standard of fees should be made as uniform as possible throughout the Kingdom. The system of visitors would tend to equalize the examinations. He objected to the present scheme, because he believed it would hinder a larger and better scheme.

Dr. Matthews Duncan had doubted whether the College of Physicians had the power to refuse to give a licence to a man not possessing a surgical qualification, and had said they ought not to proceed until they had information on

this point, but when the Scottish scheme had been brought forward no such observations had been made, and the position was not different. [Dr. Quain here rose to a point of order, as the speaker was not confining himself to the amendment, but the president ruled that he might proceed.] It was not, he said, for the Council to find objection to a scheme of which they otherwise approved. As to the action of the College of Surgeons in obtaining an Act of Parliament, it had not decided the question at all; there was no doubt that now they could refuse to give the single qualification, but the original question as to their power to refuse or not before, was left unsettled.

Dr. STORRAR not being connected with either corporation, had decided to support the scheme. He did not dispute the merits of either body of Apothecaries, and had a scheme of tripartite union come forward he would have been prepared to consider it favourably. They had not made arrangements which included the Society of Apothecaries, but that would not justify the Council in refusing to sanction the scheme. That would be preposterous. Dr. Quain had opposed it vigorously, and had his arguments been addressed to the College of Physicians, they would have been entirely in place, but they were worth nothing in the Council Chamber. The object of the scheme was to put a stop to inconvenient competition; they did not want both to be giving a separate qualification. In Scotland the College of Surgeons had always given a qualification in Medicine, but that had not been in the way of an amalgamation. The Faculty of Physicians and Surgeons of Glasgow, a surgical body, had united with the College of Surgeons of Edinburgh. Mr. Simon's objection was one for the College of Physicians to deal with, not for them. He did not think it was very likely that a candidate would ever apply for a *mandamus* to compel the College to examine him. The University of London had been very willing to join in the conjoint scheme, but the co-operation of the Universities was not essential. There was no likelihood of another Medical Bill, and it was their duty to go forward; they could do all that was wanted. No young man in the future would be without a double qualification.

Dr. QUAIN asked Dr. Storrar to state why the University of London had obtained an Act of Parliament, and stated that it was because their charter did not permit them to refuse to examine a man for their degrees.

Dr. STORRAR replied that they had got the Act of Parliament because they had been requested to do so.

Sir HENRY PITMAN rose to speak to the amendment. He said that it asked them to declare a certain thing to be right in the case of the College of Surgeons and wrong in the case of the College of Physicians. Was that, he asked, equal justice, was it right in principle? He could not see how the scheme would make the licence of the College of Physicians a partial qualification, it could not alter the value of the licence, the power of which would remain the same. If they agreed to the amendment they would be stating what was untrue. As to the additional expense mentioned, that would be exactly the same, but this was no part of the business of the Council and no reason for withholding their sanction. The last reason—the inconvenience to the student, he characterised as childish. What was the inconvenience if the candidate had to go to the College of Surgeons to be examined in surgery instead of to Pall Mall; he was not required to do anything more than at present.

The Rev. Dr. HAUGHTON asked if the College of Physicians was under any pressure, if not, how could the Council object? The College would not abdicate any function, but merely asked a highly competent body to conduct a part of the examinations. He should vote against the amendment.

Dr. HERON WATSON considered that the scheme was within the lines of the Medical Act, and that the two bodies were perfectly within their rights. The Council had no right to refuse its sanction unless there was something behind the scenes; he could not think that there was so in this case. Dr. Quain's opposition was not supported by any petition from the College of Physicians, and nothing ought to be allowed to interrupt them in a plain duty.

Dr. STRUTHERS said he had taken part in the formation of the original conjoint scheme in Scotland. He thought that Dr. Quain was wrong, all his objections applied with more force to the original conjoint scheme, to which Dr. Quain had been so much attached. No new qualification was added, it was quite true that each retained its single qualification, the Scottish scheme did the same. A University man would only want to take the one or the other diploma. Each College should absolutely refuse to take a student for the one examination. There was one new thing in the scheme of which he approved, and that was the subdivision of the examinations, allowing a man to pass in one subject when rejected in another, or to take up one only.

Dr. HUMPHRY referred to one point in Dr. Quain's remarks indicating that there would be additional boards of examiners. The opposite would really be the case; there would be one board, and not two, and there would be a diminution in the number of examinations by three. A man who already possessed a qualification would be examined under the direction of this single board. He regarded the scheme as essentially and fundamentally good.

Dr. LYONS, after a historical retrospect, regretted that these two bodies had not shown more of a bold, generous and confiding spirit, but had exhibited so much coldness and caution. He regarded the scheme as tentative and halting. The action of the two bodies was not courageous and trusty. Had the bodies left out in the cold been included, a perpetual cause of dissension would have been avoided. It had been said that the present state of affairs was likely to last a long time; that only made matters worse. Was this a wise scheme? The Legislature has endeavoured to fuse all bodies. They could not hope to meet the full confidence of the Legislature unless they had a comprehensive scheme. He would like to see it reconsidered that they might accommodate themselves to the pressing needs of the State. He could not see that the joint body affected the State at all. They were bound up with the Society of Apothecaries and the problem would not be solved until a joint agreement was arrived at in which that body shared to a reasonable extent. The State looked to the Council to deal with the need for qualified men in the poor districts at present supplied only by unqualified men. This scheme did not go far enough, and an attempt ought to be made by it to raise the Society of Apothecaries in science and knowledge, and it was the duty of the Council to turn their attention to that subject.

Dr. QUAIN said that virtually there would be separate boards for half-qualified men. He wished to know what would be done with doubly-qualified men from Scotland. It seemed to him that the College would be in union with all the other examining bodies. He had used the word sham in the sense of a hollow thing, not a pretence. The union was not and could not be real. The College of Physicians had approved of it, but they knew less about it then. He did not believe they would approve of it now. Dr. Struthers had evidently failed to understand the conjoint scheme. He repeated his statement that the College licence would be henceforth a partial qualification. The College had for four years worked well on the lines of the old conjoint scheme. The expense and inconvenience were, he admitted, minor considerations. He wished to record his protest against the scheme.

The amendment was lost by a large majority.

Three further amendments were proposed and successively rejected, and in the end the proposition of Sir Henry Pitman was put to the Council and carried, the English Conjoint Scheme thus receiving the sanction which is necessary before it can come into operation.

GENERAL CORRESPONDENCE.

OVER-PRESSURE IN ELEMENTARY SCHOOLS.

[To the Editor of the Medical Times.]

SIR,—I have read with great interest the letters in your columns on the above subject, and I venture to trespass on your space, because I happen to have had excellent

opportunities of forming an opinion on the matter, inasmuch as for a considerable period I was Resident at the Hospital for Children, Great Ormond Street, where it was part of my duty to admit all out-patients, passing them on to the physician or surgeon after briefly interrogating them as to their complaints. I should like to record one of many examples which have passed under notice. Amongst the patients for admission, one morning, was a delicate looking boy, about 10 years of age, whose mother told me that he was very poorly, suffering from constant headache. On asking if she could think of any cause, she at once replied that she "thought his lessons were too hard for him." I enquired of the boy what he had to do at school, whereupon he drew from his pocket a Euclid, saying that he could not learn the Fifth Proposition! From my own observation I should say that headache and disturbed sleep are the commonest troubles in children made to overwork at their books, and I have noticed in many, sudden "flushing" of the face; a child sitting at rest, and apparently without any cause, suddenly becomes suffused with redness which, after remaining a few seconds, passes off; in these children headache is constantly present.

I firmly believe that there is too much brain-forcing in elementary schools, at least amongst the poor; for one ought to remember the circumstances amidst which the children of the latter have to learn the tasks for the morrow, and it is possible that the same children who now suffer would fare otherwise were they carefully looked after at home.

Now, the answer to such an opinion as I have expressed, for it is nothing but an opinion, by Mr. Fitch, or anyone taking his view of the matter, is, naturally enough, that in such an important enquiry we must deal with facts and not opinions. But as it is almost impossible to obtain statistics which would be of value in such an investigation, beset, as must be obvious to anyone giving it a thought, with so many difficulties, I maintain that opinions expressed by those who have had great experience in children's hospitals, such as by the gentlemen who have already written to you, are entitled to the highest consideration. And it is to be hoped that those in authority may read the letters you have published, and that, in due time, the whole system of elementary education may be re-organised. Should this be the case, the public will owe you a debt of gratitude for taking up this matter which is really of national importance.

I am, Sir, yours &c.,
R. A. GIBBONS,
Physician to the Grosvenor Hospital
for Women and Children.

[To the Editor of the Medical Times.]

SIR,—In the correspondence on the subject of Over-pressure in Elementary Schools, to which your columns have been lately opened, nothing has interested me more than the indications of a causative connection between educational overwork and the development of choreic symptoms in school-children. So far as this may or may not be true in the case of elementary schools, my own observations have been too limited to allow of my expressing a personal opinion. But cases of this kind have from time to time come under my notice, and, in so far as they seem to illustrate one of the evil results of "over-pressure" in young scholars surrounded with more than average care and comfort, they may have some bearing upon the question as to how far similar results are likely to attend the application of over-pressure to the less capable and more poorly-nourished nervous system of the average Board School learner. One of the first of these cases was that of a young lady, greatly devoted to the study of music. There was a neurotic history on the father's side; no cardiac or rheumatic affection. After some weeks of hard work, which involved the copying of a good deal of music, she developed slight chorea, in the form of facial contortions, almost entirely limited to the muscles affecting the right angle of the mouth. Cure was complete at the end of three weeks, with rest and change of scene. Since then I have noted several cases in which more or less tremor of the facial muscles, and especially of those concerned in the movements of the angle of the mouth, have supervened sometimes during the preparation for, but generally in the course of or just subsequent to, examination. In the great majority of these cases the jactitation was unilateral, and in all such instances right-sided. All the patients were right-handed, and their work had, for the time being, involved an unusual amount of writing—most of it against time—in addition to a general increase of the subjects and the time of study. I have not seen a case of such symptoms developing in a left-handed school boy or girl. Only one of these cases developed general choreic movements, and that but to a slight extent; he soon recovered. The others either quickly got well, or at all events returned to school at the end of the holidays quite free from any sign of the affection. An adult is now under observation in whom, after prolonged periods of writing for some days together, there developes a slight paresis of the lip muscles of the right side, leading to temporarily altered articulation, and a slight dribbling of saliva. Bearing in mind the contiguity of the cortical centres for the movements of the hand and wrist and for those of the angle of the mouth respectively (and the spread of nervous energy from one to the other is well seen on watching the face of anyone using a screwdriver forcibly, or striving to turn a key in a rusty lock), is it too far-fetched to suppose that excessive motion of the hand and arm, as, *e.g.*, in the prolonged and hurried writing of examination papers, should lead to irritation of neighbouring motor centres *in a young and developing brain which has been at once irritated and exhausted by previous and prolonged overwork?* The hand and arm do not always escape; there may be fumbling with the dress, or purposeless twitching of the fingers; but sometimes the limb seems unaffected, as though its centres were more stable, or too exhausted. There appears a close analogy between ordinary chorea and those cured or curable cases of so-called locomotor ataxia; possibly they are homologous, *i.e.*, both are dependent upon *congestion* of the nerve-centres respectively involved. A congested tissue is being poisoned by the products of its own metabolism, causing first increase of irritability, and finally torpor. Given a brain in the requisite stage of congestion, the centres for facial movement would most readily be stimulated with reflex activity, seeing that the face presents so large an exposed and unprotected surface, with such a rich nervous and vascular supply, and with so many and so large sensitive areæ in direct connection with it. On this view, some form of facial chorea would naturally be among the earliest symptoms of an "over-pressed" brain; the simply work-worried child wearing its intermittent frown—a chorea of the brow-knitting muscles; the child that has written much and painfully showing twitching of its mouth, as well as of hand and fingers possibly. All this, of course, would be noted only in the earliest stages of any case which subsequently ran on into general chorea. Others, with much

wider experience than mine can claim to be, may perhaps be able to disprove the notion; but so far, I am tempted to believe that choreoid affection of some facial muscles is frequently the earliest indication of educational over-pressure amongst school children up to about the age of puberty, at all events.

Instances of insomnia and of somnambulism traceable to over-work have occasionally come under notice, and much more frequently cases of persistent headache, and of general nervous breakdown, towards the end of a long term's work. All these cases, however, are relatively very few in comparison with the total number of scholars under observation. But I am convinced that in the best of schools this proportion would be very much greater were it not for the vigilance generally exercised in detecting the earlier symptoms of malaise, &c., and the promptitude with which such cases are at once set apart for medical inspection, and, if necessary, for treatment, safeguards which are, as yet, unfortunately lacking in the School Board system.

I am, Sir, yours, &c.,

October 6th, 1884. CHAS. EDWD. SHELLY.

INVENTIONS AND IMPROVEMENTS.

ELECTRIC LIGHTING IN OUR DWELLINGS.

Notwithstanding the increase in the use of electric lighting in streets and public buildings during the past few years, hitherto we have been practically unable to obtain it in our dwelling houses. Where the wealthy owners of large mansions have overcome the difficulties of its introduction, they have at least had to incur an expense that would be prohibitive to the general public. The supply of electric lighting upon an extensive system, in a similar manner to the supply of gas, is at present impracticable. Even when there happens to be no difficulty in conducting wires from distant dynamos, the cost of the supply must, under the old system, be very large. There is at present no known means for measuring the amount of electricity consumed by individual customers of the suppliers, and consequently a charge has to be made for every lamp fitted in a house. To overcome this and other difficulties, Mr. Tayler-Smith has devised a system which must commend itself to every practical man. Acting upon the principle that every room in a house can seldom, if ever, be required to be fully lighted at one time, he has invented and patented moveable brackets, so that a limited number of lamps can be used in various places. By unhooking a lamp from one wall, it can be removed to the opposite wall or to another room, or to any place, in fact, which has been previously arranged to receive it. Consequently, all the lamps can be placed in one or in two rooms, if the brackets have been suitably arranged, and thus the supply of electricity sufficient for the limited number of lamps in the householder's possession can never be exceeded. By means of a variety of arrangements in the position of lamps a great economy of light is effected. An electrolabra can be easily moved from one room to another. A lamp from the wall can be connected with the table lamp. A moveable light supplied by a cord which runs upon a winch seems to us a very clever invention. A lamp which can be placed in any position over a bed is a most convenient apparatus for use in performing surgical operations, and there is even an arrangement by means of which an invalid can have a small disc, which he can place under his pillow, and by a movement light up his room in a moment. These inventions are shown at the Health Exhibition, and Mr. Tayler-Smith demonstrated their use at the *conversazioné* at St. Mary's Hospital on the 2nd instant. Then again the use of accumulators effects an immense saving. If the engine used is producing more electricity than the lamps are consuming, the superabundance passes into the electrical store room, and is kept for future use; thus not only economising the electricity, but preventing the injury to the wires which might otherwise take place. When the engine is stopped the accumulators afford means of providing temporary light in the night or at other times. Whether we consider this subject in regard to safety, health, or economy, it is equally worthy of attention. No fire, no harm of any kind seems likely to occur from it, the atmosphere is not deteriorated, and the furniture is not spoilt. But it may well be asked how will this system compare as regards cost with our present means of lighting, and here we must rely upon Mr. Tayler-Smith's own statements. It would seem that after a first installation the cost is little if at all in excess of gas to supply the same lighting, whereas there is a distinct saving in respect to cleanliness. There are many other interesting points in connection with this subject which we have no room to discuss, but we sincerely trust that before long electric lighting will become general in the dwelling-houses of all large towns, and especially in London where our breathing space is so rapidly being used up by extensive building. The practical difficulties have, as we have seen, been overcome. It only remains for the public to fully realise the value of good light and pure atmosphere to make economic domestic electric lighting not a dream but an accomplished fact.

INDIA-RUBBER BAGS FOR SUPPORT AND FIXATION OF THE HEAD IN DISEASE OF THE UPPER PART OF THE SPINE.

This invention has already been described by Dr. Wm. Jas. Fleming, of the Glasgow Royal Infirmary, in a recent number of the *Glasgow Medical Journal*, and the following account of it is extracted from his paper on the subject:—The arrangement consists of two sets of three fusiform india-rubber bags connected by a narrow flexible but non-elastic material, and having at the free ends flaps by which they can be laced together. In each set the bags are internally in communication with each other, and from the lowest depends an india-rubber tube with a stop cock to which the nozzle of an ordinary small blower fits. A size suitable to the particular case having been selected, it is, while collapsed, laced rather loosely round the neck. On inflation, the lower bag rests upon the root of the neck, the

clavicle and the muscles of the shoulders, while the upper bag moulds itself along the posterior portion of the jaw, the mastoid process, and the skull back to the occipital

region; the front of the apparatus, where it is laced, is on inflation rather withdrawn from the neck, so that no pressure on the trachea is produced. In practice I find it best in the majority of cases to adjust a piece of poroplastic round the neck like a wide turn-down collar, as shown in the diagram, and allow the lowest bag to bear upon this rather than the skin. If great lifting power is desired, the lateral expansion of the bags may be checked by a net or light bandage, but from their construction the chief expansion is in a vertical direction, so that the net is rarely necessary; indeed, it is generally easy to lift more forcibly than the patient can tolerate, but the wearers very soon come to manage the distension for themselves, carrying it just to the point from which they derive the greatest advantage. In some experiments which I made by placing the bags round a glass cylinder, over which a broad ring just slipped, I was able to raise over eight pounds through a distance of more than an inch; no doubt greater pressure could have been obtained, but the fear of bursting the bags prevented me from carrying the inflation further. By this means, then, I claim that we have the power of taking a large part of the weight of the head off the portion of the vertebral column above its connection with the shoulder girdle, and to a great extent of fixing the head. The apparatus is light, can be worn either in the upright or recumbent position, and when covered with a scarf is scarcely perceptible. No inconvenience has been complained of by the wearers except that in one case the heat was objected to, but this I hope at least to mitigate by fluting the inner surface. That the whole weight of the head can be borne by the apparatus I do not consider probable, but neither can this be attained by the jurymast, and we know how even the support of the hand in those cases, slight as this must be, gives relief. The apparatus is made by Messrs. Hilliard, of Glasgow.

LIQUOR CINCHONÆ (PAUL).

Messrs. Savory and Moore have recently brought under our notice a new Liquor Cinchonæ, specially prepared by a process elaborated by Dr. Paul, who will superintend the manufacture of the preparation, analysing and guaranteeing the contents of each bottle. Dr. Paul is well known as an expert in the art of cinchona bark assaying, and has had an exceptional experience of the best methods of extracting the alkaloids from the bark, so that any preparation which bears his name starts with a good character. The new Liquor Cinchonæ professes to contain the whole of the medicinal constituents of the best selected bark in their natural proportions and state of combination. One fluid ounce contains 24 grains of alkaloid and represents an ounce of bark of the best quality. The Liquor Cinchonæ is thus greatly superior to the liquid extract of the Pharmacopœia, prepared by a process which does not profess to exhaust all the active principles of the bark, and it deserves a fair trial at the hands of the profession.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, October 2nd, 1884:—

Thomas Matthews Angior, 39, Oriel Road, Bootle, Liverpool; Herbert William Brighouse, 98, Fortess Road, N.W.; Thomas Hindle Sykes, 50, Houghton Street, Southport; Edward Eggington Thompson, The Square, Tenbury; William Sidney Ridout Woodforde, Oakbank, Spencer's Wood, Reading.

Also on September 25th—

Philip Robert William Santi, 4, Doughty Street, W.C.

The following gentlemen also on the same day passed their Primary Professional Examination.

Harry Gravely, University College Hospital; Archibald Thomas, Middlesex Hospital.

The German-Speaking University in Prague.—Professor Christopher Aeby, of Bern, has recently been appointed Professor of Anatomy in this University.

University of Berlin.—A splendid legacy has just been left to the University, the late Countess Bose, of Cassel, having bequeathed to that institution the sum of 39,000*l.* for the benefit of poor students of medicine.

St. Mary's Hospital Medical School.—Mr. R. T. Graveley and Mr. F. Lewis, divided the Scholarship in Natural Science of one hundred guineas, open to such students of Epsom College as are sons of medical men.

A Physician-President.—Don Raphael Zaldivar, now on a tour in France, Italy and Spain, who is a much employed physician, has recently been elected for the third time President of the Republic of San Salvador.

Measles at Aberdeen.—A serious epidemic of measles is raging at Aberdeen, and as many as 1,000 children were on Monday reported as absent from the Board Schools from this cause alone.

The Epidemic at Kidderminster.—The outbreak of fresh cases of fever at Kidderminster still continues, and the only satisfactory feature is that they are much milder in character than the preceding ones. The number of deaths from typhoid fever registered in the borough up to Tuesday was 52. There is an increasing number of convalescents, and some are being sent away to convalescent homes.

The Vienna General Hospital.—On the occasion of the celebration of the 100th anniversary of the *Wiener Allgemeinen Krankenhaus*, with which he is so intimately connected, Herr Joseph Leiter, the celebrated Vienna surgical instrument maker, announced his intention of supplying artificial legs to the extent of 500 florins per annum, to patients who had undergone amputation.

Sanitary Assurance Association.—The Council of this Association has resolved to present to the Free Public Libraries of the country, copies of Mr. Mark H. Judge's "Sanitary Arrangements of Dwelling Houses, Notes in connection with the Sanitary Exhibits at the International Health Exhibition," recently published by the Sanitary Assurance Association, of which Mr. Judge is the Surveyor.

A New and Voluminous Author.—A contemporary states that "Jahrbuch" reports the treatment of 43 cases of diphtheria with turpentine. Dr. Jahrbuch had excellent results. We are reminded of the freshman who inquired at the library for the works of "Ibid."

The Cholera in France in 1884.—The ravages of the present epidemic have been much more considerable than is generally supposed. The *Lyon Médical* (October 5th), states that a statistical enumeration shows that from the 17th of June to the 15th September there have been about 5,000 deaths distributed over 200 communes, which supposes at least from 10 to 12,000 cases of the disease. Seventeen departments have been successively invaded.

Army Medical Department.—The undermentioned officers have been granted a step of honorary rank on retirement:—To be Surgeon-General—Deputy Surgeon-General J. J. Clarke, M.D., of the Bengal Army. To be Deputy Surgeons-General—Brigade-Surgeon W. Watson, M.D., of the Bengal Army; and Brigade-Surgeon T. Mathew, of the Bengal Army. To be Brigade-Surgeon—Surgeon-Major F. Odevaine, of the Bengal Army.

Non-Communication of Leprosy in California.—The *Pacific Medical and Surgical Journal* states: "Since the foundation of the State of California, 35 years ago, Chinese immigration has gone on, with the occasional introduction of cases of leprosy, and in all those years, occupying more than a third of a century, only one doubtful case of leprosy has been found to prove the risk of the disease extending to the white population. The subject has more than once been considered by the State Board of Health, and not a solitary instance has been reported to it from any part of the State." It is interesting to compare this statement with the history of it in the Sandwich Islands, where the disease has spread so disastrously.

Charitable Bequests.—Mr. William James Patterson, late of Carlton Crescent, Southampton, has bequeathed 5,000*l.*, free of duty, to the executive body of the Royal

South Hants Infirmary, to be called "the Patterson Chaplain Fund," upon trusts for investment, the income to be appropriated as a stipend for a chaplain, who is to be a member of the established Episcopal Church of England, and a graduate of one of the Universities of Oxford or Cambridge; 1,000*l.* to the Royal South Hants Infirmary for its general purposes; 500*l.* to the Southampton Dispensary; 250*l.* to the Royal Hospital for Incurables, Putney; and the National Hospital for the Paralysed and Epileptic, Queen's Square, Bloomsbury.

Fifeshire Medical Association.—The annual meeting of this association was held last week in the class-room of Professor Pettigrew, United College, St. Andrews. There were representatives present from all parts of the county. Dr. Archibald, the president, delivered an address, in which he reviewed the history of St. Andrews generally, and the University particularly. He gave it as his opinion that that Faculty should be strengthened by the addition of a Chair of Botany, and that the whole should be used as the basis of a Science Faculty. Dr. Dow, Dunfermline, was appointed president for the ensuing year; Dr. Macdonald, Cupar, vice-president and treasurer; Dr. Douglas, Cupar, secretary; and Drs. Archibald, St. Andrews, and Whitelaw, Cupar, members of Council. Dr. Hunter Mackenzie, Edinburgh, gave a demonstration of the tubercle bacillus, and exhibited specimens under the microscope. The members afterwards dined together at the Cross Keys Hotel.

The Board of Control of Lunatic Asylums in Ireland.—The Lord Lieutenant, by the advice of the Privy Council, has re-constituted the Board of Commissioners for General Control of Asylums for the Lunatic Poor in Ireland. His Excellency has appointed Major-General H. R. Sankey, R.E., C.B., Chairman of the Commissioners of Public Works in Ireland; John Nugent, Esq., M.D., Inspector of Lunatic Asylums in Ireland; George W. Hatchell, Esq. M.D., Inspector of Lunatic Asylums in Ireland; William R. Le Fanu, Esq., Commissioner of Public Works in Ireland; and Samuel Ussher Roberts, Esq., Commissioner of Public Works in Ireland, to be Commissioners for General Control and Correspondence, and for the Superintending and Directing the Erection, Establishment and Regulation of Asylums for the Lunatic Poor in Ireland.

Egypt.—Surgeon-General J. Irvine, of the Army Medical Department, having returned to Egypt and resumed duty as Principal Medical Officer of the Army of Occupation in that country, Deputy Surgeon-General Fox, who has been holding that position, has returned to Alexandria from Cairo, and taken over the post of Principal Medical Officer of the Alexandria Garrison. The four lady nurses who have been selected to proceed to Egypt for service with the Army Medical Department in the Nile Expedition sailed in the steamship *Cameo* from Woolwich Arsenal on Wednesday. They will be distributed among the hospitals which are now being established at Wady Halfa and other stations on the Nile, and although they are few in proportion to the number of male nurses who will have to be employed, they will undoubtedly have an influence for good such as only the gentler sex can exercise in the sick chamber. In all the military hospitals at home these devoted women work side by side with the soldier orderlies of the Hospital Corps, and many of them have seen active service abroad, as shown by the ribands they wear for the last campaign in Egypt, together, in many instances, with the Royal Order of the Red Cross. A medical officer will accompany them to Egypt, probably Surgeon-Major F. A. Davy, M.D., who has been for some time at the Auxiliary Hospital, Woolwich; and special arrangements have been made for their comfort on board ship.

Sanitary Undertakings in the Provinces. — Considerable activity prevails in many of the provincial towns and districts in remedying defective water supplies and drainage. Improvements in water works have been or are being carried out at Nottingham, where a new reservoir holding 1,500,000 gallons has just been completed at Mapperley Plains; at Torquay, where a second storage reservoir is in progress at Kenwick, so that there will be a total of 300,000,000 gallons of soft pure water always on hand, or a constant supply for the whole district sufficient to last ten months; at Launceston, where a storage reservoir of 2,000,000 gallons is to be built at Trethorne; at Frodsham, where a recent boring has produced a daily supply of 12,480 gallons at a depth of 22 feet, this supply to be increased to 30,000 gallons; at Stratford-on-Avon, where 14,000*l.* is being spent upon water mains (11 miles) and a new reservoir; at Peebles, where an outlay of 6,000*l.* is undertaken to supply the town from the Manor Springs; at Market Harborough, where it is proposed to spend 19,000*l.* in bringing water at the rate of 20 gallons per head per day from a stream near Husbands Bosworth; at the village of Mevagissey, in Cornwall, where a reservoir is being built to hold 342,000 gallons; and at Petersfield, where 5,800*l.* is to be spent on combined water and sewerage works. An extensive scheme is under consideration for the drainage of Rochester, Chatham, Strood, and Gillingham, at an outlay of 90,000*l.* Frome is about to spend 15,000*l.* in sewage works. Cleckheaton, near Bradford, is about to deal with its sewage by means of chemicals, and other plans are being carried out at Howden, in Yorkshire, at a cost of 3,000*l.* Presteign, in Radnorshire, and King's Lynn, in Norfolk.

Society for the Study and Cure of Inebriety.—A meeting of this society was held in the large room of the Medical Society on the 7th instant. The President, Dr. Norman Kerr, who was in the chair, exhibited specimens of the South African kola nut, *sterculia acuminata*, said to have the property of preventing intoxication. Containing a considerable proportion of caffeine, with a lesser amount of theobromine and tannin, it was a stimulant and tonic. Dr. Alfred Carpenter read a paper on the Study and Cure of Inebriety, with special reference to the recent *Times'* article, contending that, to the query "Is the study of inebriety needful?" the answer must be Yes, and the results of this study must be made known, as dense ignorance widely prevails on the subject. The author insisted on the physical and disease aspect of inebriety, which was often caused by nervous shock, as from sudden loss of property, grief, &c. The worst effects were seen in the children of young drunkards. Pains and penalties were no cure. If dipsomania should be punished, why not dyspepsia? Total abstinence was an essential to cure. Mr. Oakey Hall described American legislation for the inebriate.

Communication of Rabies to the Fœtus.—The *Revue de Thérapeutique*, for September 15th, gives an account of an experiment performed at the Veterinary School, at Alfort, towards determining whether rabies may be communicated by the mother to the fœtus and consequently without lesion of any kind. Two bitches about to bring forth were bitten by a mad dog. It is not stated how long the period of incubation was, but six hours after the symptoms of the disease had manifested themselves with great violence the puppies were born. The mothers suckled and licked them with tenderness. The paroxysms came on again with redoubled violence from time to time, but whenever the little ones whined, the mothers seemed to forget their sufferings and again began licking and soothing them in a state of complete calmness. They died within a few minutes of each other twelve hours after the symptoms had become urgent. The pups were carefully washed and sponged, and fed with milk; but in spite of every care they all died in a few days. The reporter asks whether these pups were infected through the milk of the mothers, or did there take place a cutaneous absorption of the virus deposited during the lickings which they were subjected to. Cases of poisoning from the licking of a mad dog have several times occurred when no excoriation existed.

Female Hospital Internes.—His "inexorable logic" drives a Frenchman into many absurdities, and surely to attempt to allow women to become internes is one of them. Not so, says the *Progrès Medical;* you admit her as a candidate for the diploma, and if successful she is entitled to all the logical consequences that ensue. Many years ago that journal counselled her to seek some other profession more suited to her physiological organisation, but did not for a moment dispute her right of pursuing

that of medicine. This once admitted there is no post she may not fill. "If it suited the fancy of our doctresses to compete for the *agrégation*, what regulation is there that prevents them, and where is the obstacle to their filling a chair in the Faculty? Nor is there any law that we know of which would prevent a gallant minister from creating a chair for a doctoress who had rendered herself famous by the brilliancy of her work in any specialty." So also in the *Assistance Publique*. Female students long since obtained permission to act as externes, whose duties they have satisfactorily fulfilled, and they now demand the power of contesting the *internat*, which would eventually open to them the highest posts in the hospitals. Although this claim is backed up by the *Conseil de Surveillance* yet the *Administration de l'Assistance Publique* looks upon it as rather a serious matter, and hesitates to follow up its former approval of the appointment of externes. By the aid of the present liberal Préfet de la Seine and Ministre de l'Instruction Publique, however, the *Progrès* believes that this body will have to pursue the logical sequence of its former resolution.

Glasgow Health Report.—The Health Officer's report states that there have been 482 deaths registered during the past fortnight as against 483 for the preceding fortnight. The number of deaths from pulmonary disease was 94, against 108. There has not been such a low death-rate from pulmonary diseases since August 1882. The number of deaths from fever was 26, of which number enteric fever caused 25 deaths, and one undefined. Of these the following shows the place where they died and their milk supply:—

	Infected Dairy.	Other Dairies.
In Western Infirmary	1	..
„ Royal Infirmary	3	..
„ Belvidere	10	5
At Home	2	4
	16	9

Since the 18th September there have been added to the Western Infirmary group nine new cases (one nurse, one cook, the son of the lodge-keeper and six patients). Belvidere group, twenty new cases (three nurses, two cleaners, and fifteen patients). Royal Infirmary group, ten cases (two nurses, two under-servants, and six patients), most of whom have been attacked after they had been dismissed from the infirmary. Some contributory evidence has been obtained of the activity of the specific infection conveyed by the milk of the agent who supplied these institutions. In the north quarter of the city he has a branch establishment situated in an isolated block of dwelling-houses, in which there are 235 families, of whom 128 were customers of this dairy. Contemporaneous with the outbreak in the hospitals, there were fourteen cases of enteric fever among the 128 families who obtained their milk from this dairy. The City Poor-house is supplied by this agent, and two patients, an adult and a child, suffered from enteric fever. Dr. Robertson, the Medical Officer, says he has never known any inmate contracting this disease in the poor-house until now. At present there are in the fever hospital 232 cases of scarlet fever, 175 cases of enteric fever, 5 of typhus fever, 45 of measles, 10 of whooping-cough; in all 467 cases as compared with 409 in the previous fortnight.

The Greely Arctic Expedition.—The *Philadelphia Medical News*, for September 8th, inserts the highly interesting official report of Dr. Edward Green, surgeon of the U.S.S. *Thetis*, of the Greely Relief Squadron, in which he furnishes the detailed medical history of the unfortunate expedition, and of the physical and mental condition of the rescued survivors. This is far too long for our pages, but we may transcribe the judicious editorial comments which it has called forth.—"The results of this expedition differ in one important point from former ones—but a single case of scorbutus occurred. The advance in our knowledge of the purpose subserved by the various kinds of aliment, permits the construction of dietaries adapted to the various exigencies of life. Given a route of the proposed exploration, the isotheral and isochimenal temperatures, and the kind and quantity of work to be done, a diet table can be formed which will be exactly adapted to the conditions present, so that the body will be maintained at its maximum of efficiency. That the aliment furnished to the Greely Expedition served its purpose is shown in the fact that the party was in good condition when it reached its permanent quarters. The solitary case of scurvy would not have occurred, probably, if the other circumstances had been propitious in the affected individual. Another lesson is the very small amount of food which may suffice to keep the human machine in a state of efficiency. Compared with some other historical examples, the food allowed each member of the party at Cape Sabine was liberal; it was in the aggregate nearly 15 ozs. At the siege of Paris the daily rations was at one time reduced to 10 ozs. of bread and 1 oz of meat. The rations allowed the United States' soldiers in the Andersonville prison was 5 ozs. of bacon and 20 ozs. of unbolted corn-meal, which was not equal, in points of material available for nutrition, to that given the Greely party. In view of the small amount of aliment allowed at the outset, and subsequently greatly lessened, an attempt was made to assimilate their lives to that of a hybernating animal. This, we believe, was unwise. Although the amount of food and the low temperature precluded active exercise, they would have done better to accommodate themselves, as nearly as possible, to the conditions of health in normal surroundings. A hybernating animal has a store of fat laid up for consumption during the period of repose. The accumulating carbonic acid lessens the activity of the nervous centres, and induces a comatose state, during which all the functions are inactive. Such a state of things is impossible to man, and the attempt to accommodate themselves to such abnormal conditions only produced a pathological state and accelerated waste. The air space allowed them was entirely inadequate, and the enforced lack of attention to personal cleanliness prevented excretions by the skin. Hence animal heat was not properly developed, and the food taken was not efficiently utilised, either to promote nutrition or to maintain the body temperature. Suitably placed as to their hygienic surroundings, and the functions sufficiently exercised, the amount of food allowed at Cape Sabine, at the beginning of their stay there, might have been much lessened, and yet have proved sufficient. In the procees of slow starvation the beneficent results greatly lessen the terrors of the situation. At a certain point the desire for food ceases until the stomach is roused from its functional torpor by the introduction of some aliment. In those cases of voluntary fasting, with the details of which the public is now and then regaled, it is probable that the experimenter experiences but little the pangs of unsatisfied appetite after the first few days of torture. Such was the experience of the Greely party. The other beneficent experience of the starving, is the pleasing delirium in which feasting on sumptuous viands is indulged; in such a mode does nature offer compensation in this dire extremity. But the delirium may take other forms. In the struggle for existence, when only the animal instinct remains, and men living in the state of animals lose the distinctive qualities of the civilised state, it is not surprising that mere savage feelings sway them entirely, and hence the delirium, if not occupied with the pleasing illusions of feasting, may take the form of an aggressive animality.

Professor Von Bergmann's Surgical Clinic.—A correspondent of the *Canada Medical Journal* gives the following particulars of the clinic of Von Bergmann, the successor of Langenbeck at Berlin. The operating theatre is large and well-ventilated, the porcelain floor, tables, and woodwork being scrubbed, and the rest of the room, seats, &c., swept and sprinkled with carbolic acid every morning. Once a week also every part of the theatre is thoroughly scrubbed and disinfected. Carbolic spray (two per cent.) plays on it for at least two hours every morning, during which all patients who can be brought in have their dressings changed there. The operating tables (for there are often three and even four in requisition) are covered with sheets of rubber a third of an inch thick, which project beyond the edges, so that the patient never comes in contact with the wood; and after each operation, the rubber is thoroughly washed with sublimate solution (1 to 1,000).

The patient is always completely stripped and covered with clean sheets, and a blanket if needed; and these, whether soiled or not, are sent at once to the wash-house. Carbolic acid (two per cent.) and sublimate (1 per 1,000) are used indifferently as disinfectants, a strength of five per cent. of the former being sometimes employed for washing the intestines during abdominal section, &c. Iodoform is used in powder when the wound is situated in a cavity, as in the nose, mouth, or vagina; and a five per cent. ointment is kept at hand to anoint the fingers before digital examination. A ten per cent. solution in sulphuric ether is also used to wash out the wound in resections and for tampons. Spray is not always employed, but is so most regularly during intra-peritonæal operations. For dressing, sublimate gauze and wadding or wool form 99 per cent. of what is used, and iodoform gauze, &c., the rest. The sublimated gauze, made in the hospital, is beautifully soft and light, and perfectly dry. Tampons of iodoform gauze, rolled up in different sizes and tied, are used to pack cavities or wounds not expected to heal at once, being first dipped in the ether solution. Protective is not applied, the outermost dressing usually consisting of several layers of sublimated gauze, with a very thin rubber tissue between the two outer layers. The bandages are of sublimated gauze, charged with a little starch, and dipped in water before applying; they hold the dressings splendidly. Plaster bandages are also used very freely; and the limbs are nearly always steadied by strips of felt, gutta percha, or light splints of wood or of perforated zinc. During an operation, all engaged are clad in clean white-duck overcoats reaching nearly to the ankles, and having the sleeves short, so that the forearms are always bare. If at all soiled they are changed before the next operation. Everyone washes their hands with soap and a nail-brush, dipping them in carbolic or sublimate solution before and frequently during the operation, the patient's body near the site of the operation being also washed with the same. The instruments lie in carbolic, and are washed in pure water instantly after using. No sponges are used except to guard viscera against injury, &c.; but small pieces of dry gauze are very freely used instead, so that the floor after a bloody operation is covered with them. Irrigation is employed to a surprising extent. In the room above the theatre are two large tanks full of the solutions, with which are connected rubber tubes supplied with ingenious nozzles. There are also at hand large cans, like enormous tea-pots, to flood the wound and table whenever it seems desirable, which is very often. Carbolised catgut is generally used for ligatures and sutures; but in many cases Chinese silk is preferred for the latter, and sometimes, as where great force has to be used, for the former. The drainage tubes are of extraordinary large size, the advantage of which is doubtful. "A word or two about instruments. Bergmann uses several which are seldom thought of at home. Three kinds of retractors are in use—sharp treble hooks, short broad-beaked blunt, and broad long-hooked-beaked blunt retractors. These are *always* used, the first and second assistants applying them as soon as the skin is incised, keeping the wound well open. In many cases the sharp hooks suffice; but in some, as in resection of the hip, ligature of the subclavian, &c., when a very deep wound is made, the last-named are very useful. Single hooks of various sizes, both blunt and sharp, are also much used. To me it seems that these retractors are very useful, keeping the wound well open down to the bottom, and allowing an uninterrupted view of the knife. They also keep important and delicate structures well out of harm's way. The artery-forceps used are those of Langenbeck, much like those known to us as torsion forceps. They are used in large numbers, as no vessels are tied until the end of the operation, except in abdominal section, when great pains are taken to arrest *all* bleeding vessels before opening the peritonæum. In resections and operations on bone, very strong knives of many different shapes are used, and recourse is very frequently had to chisel, gouge, or sharp spoon. All these, and all instruments, as far as possible, are made of one piece of steel, the handles being plated in nickel, and they can thus be made aseptic with the greatest ease. Bergmann also uses the chain-saw very commonly and the sharp spoon—this latter indeed is scarcely ever out of his hands. In his operation on bone he takes the greatest pains to remove every fragment that seems at all suspicious; and also, with scissors and forceps, cuts away all the thickened and infiltrated tissue always found about diseased bones and joints. The enormous wounds made are tightly stuffed with iodoform tampons, and heal in a really surprising manner . . . . In conclusion, let me say that the expense of carrying out this system must be enormous; but in this happy land the hospitals, &c., are all Government institutions, and have practically *carte blanche*, and the director (in this case Ernest von Bergmann) is an absolute sovereign in his own institution."

APPOINTMENTS.

Benton, Samuel, M.R.C.S. Eng., M.R.C.S. & L.M. Lond.—Medical Officer to the Buckingham Palace Road Workhouse, St. George's Union.

Creagh, William, L.R.C.S. and L.M. Ire., L.A.C. Lond.—Medical Officer to Lullington and Rosliston District, Burton-upon-Trent Union.

Cripps, C. Couper, M.B., M.S. Durh., M.R.C.S.—House Physician to the Hospital for Women, Soho, *vice* Felix Winrace, M.D., resigned.

Deming, C. Ernest, L.K.Q.C.P.I., L.R.C.S.I.—Senior Assistant Medical Officer to the Salop and Montgomery County Asylum, Shrewsbury, *vice* W. H. Racker, M.D., resigned.

Gibson, Charles John, M.B. and M.C. Edin.—Medical Officer to the Stone District, and the Workhouse of the Stone Union.

Harmer, Sidney Frederic, B.A.—Demonstrator of Comparative Anatomy in the University of Cambridge.

Harvey, Frederick George, M.R.C.S. Eng., L.R.C.P. and L.M. Edin.—Medical Officer to Acton Burnel District, Atcham Union, *vice* Mr. John Glover, resigned.

Ingoldsby, Frederick, M.R.C.S. Eng., and L.R.C.P. Edin.—Assistant Medical Officer and Dispenser to the Workhouse Infirmary, Fulham Union.

Johnson, Samuel Ebenezer, L.R.C.S. Edin., and L.S.A. Lond.—Medical Officer to Balsall Heath District, King's Norton Union, *vice* Mr. Richard Farnham, resigned.

VACANCIES.

Aberystwith Infirmary.—House Surgeon. (*For particulars see Advertisement.*)

Bristol General Hospital.—House Surgeon. Salary, £120 per annum, with board, washing and residence in the house. Candidates must be Members of the College of Surgeons of London, Edinburgh, Glasgow or Dublin, and also Licentiates of the Apothecaries' Company of London or Dublin, or some other recognised medical qualification and must produce testimonials of good moral character and ability and must send certificate of registration. Applications to be sent to the Secretary, on or before October 27th.

Central London Sick Asylum District.—Assistant Medical Officer and Dispenser. (*For particulars see Advertisement.*)

Charing Cross Hospital, Strand, W.C.—Assistant Physician. Also, Anæsthetist. (*For particulars see Advertisement.*)

Cuckfield Union.—Medical Officer to the Fourth District, *vice* Mr. W. E. Porter, resigned. Area, 13,598 acres. Population, 4,793. Salary, £95 per annum.

Hull Borough Asylum.—Assistant Medical Officer. (*For particulars see Advertisement.*)

Mile End Old Town Hamlet.—Assistant Medical Officer to the Infirmary, *vice* Mr. Henry Beattie, resigned. Salary, £100 per annum, with board and lodging.

North Shields and Tynemouth Dispensary.—House Surgeon and Dispenser. Salary, £130 per annum, with house, coals, water and lighting. Candidates must be legally qualified. Private practice prohibited. For further information apply to the House Secretaries, to whom applications with testimonials are to be sent before October 15th.

Swansea Hospital.—Resident Medical Officer. Salary, £100 per annum, with board, furnished apartments, &c. Candidates must be registered in Medicine and Surgery. Applications and testimonials to be sent to the Secretary, on or before October 28.

The Kilburn, Maida Vale, and St. John's Wood General Dispensary.—Resident Medical Officer. Salary, £100 per annum, with furnished rooms, coals, gas, and attendance. Candidates must be doubly qualified. Applications and testimonials to be sent to T. W. Dobson, Esq., Hon. Sec., at the Dispensary, 13, Kilburn Park Road, N.W., on or before October 15th.

DEATHS.

Brewer, Thomas, M.R.C.S., of New North Road, Huddersfield, on September 29th, aged 44.

Duncan, P. C., M.D., at 51, Great Marlborough Street, W., on October 7th.

Jowett, Joseph, Surgeon-Major (retired), at 12, Cedars Road, Beckenham, on October 3rd, aged 69.

NOTES, QUERIES, AND REPLIES.

"*Bizarre.*"—It is our rule never to give such information as you require.

COMMUNICATIONS RECEIVED—

Dr. Quain, London; Dr. Donkin, London; Mr. A. Wynter Blyth, London; Dr. Isambard Owen, London; Dr. Clifford Beale, London; Dr. Shelly, Hertford; Mr. Noble Smith, London; The Secretary of the Apothecaries' Society, London; The Sanitary Commissioner for the Punjab, Lahore; Mr. E. W. Richardson, jun., London; The Registrar-General, London; Mr. D. Fraser, Paisley; Dr. Norman Kerr, London; Dr. R. A. Gibbons, London; Our Vienna Correspondent; Our Dublin Correspondent; Our Glasgow Correspondent; Our Edinburgh Correspondent; The Secretary of the International Health Exhibition, London; Dr. E. Symes, Thompson, London; The Dean of the St. Mary's Hospital Medical School, London; "Bizarre"; The Secretary of the Devonshire Hospital, Buxton; The Secretary of the London Society for the Abolition of Compulsory Vaccination; Mr. B. Lampe, London; The Secretary of the Medical, Pharmaceutical, etc., Exhibition, London.

BOOKS RECEIVED—

The Boy's Own Paper, Vol. 6—The Girl's Own Paper, Vol. 5—Notes on Materia Medica aud Pharmacy, by Fredk. T. Roberts, M.D.—Handbook of Diseases of the Eye, by Henry R. Swanzy, A.M., M.B.—Étude sur Les Cystites, par le Docteur F. Leprévost—Système Nerveux Vaso-Moteur, par A. Dastre et J. P. Morat—Dissection of the Human Body, by Luther Holden—The Ophthalmoscope, by Ole B. Bull, M.D.—Half-Yearly Report of the Port of London Sanitary Committee, ending June 30th, 1884—Report of the Quekett Microscopical Club—Lectures on Cataract, by R. Brudenell Carter, F.R.C.S.—On the Development of Physiological Chemistry, &c., by Professor Felix Hoppe-Seyler—Micro-Organisms and Disease, by E. Klein, M.D., F.R.S.—Report on the Sanitary Condition of the Borough of Birkenhead for the year 1883—Archivio di Ortopedea—The Sweet Story of Old, by Hesba Stretton.

APPOINTMENTS FOR THE WEEK.

Friday, October 10 (*this day*).

Operations at St. George's (ophthalmic operations), 1¼ p.m.; Guy's 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Clinical Society of London.—Dr. Haddon, "On certain Nerve Symptoms in Rheumatic Affections;" Mr. Croft, "Cases of Preputial Calculi;" Dr. Crocker, "On a Case of Urticaria Pigmentosa or Xanthelasmoidea;" Dr. Finlay, "On a Case of Perforation of the Vermiform Appendix;" Mr. Golding Bird, "On a Case of Dislocation of the Patella."

Saturday, October 11.

Operations at King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

Monday, October 13.

Operations at the Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopædic, 2 p.m.

Tuesday, October 14.

Operations at Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic 2 p.m.; Royal Sonth London Ophthalmic 3 p.m.; St. Mark's Hospital, 9 a.m.

Wednesday, October 15.

Operations at Middlesex, 1 p.m.; St. Mary's, 1¼ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopædic, Great Portland Street, 10 a.m.

Thursday, October 16.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.

THE CAUSATION OF LABOUR.

By C. E. SHELLY, M.B., Cantab.

Since the time when it became necessary to relinquish the convenient and labour-saving assumption that the fœtus—finding itself "cabined, cribbed, confined" and determined on cutting the Gordian knot of its mysterious trammels by a practical *solvitur ambulando*—made its way into the world of its own free will and by the exercise of its unaided muscular energy, obstetric writers have sought and seen many and various explanations of, and causes for, the occurrence of parturition at term. Though Denman was content with the sententious aphorism that, the needful preparations having been accomplished, "Labour takes place by the command of God," others were not satisfied without endeavouring to investigate more minutely the *modus operandi*; and if—regarding their results with that advantage of mental perspective which the lapse of time confers on him—the observer of to-day is enabled to descry how the importance of individual discoveries and deductions was often over-rated, and a part thus made more or less to do duty for the whole; he must also acknowledge his indebtedness to them, not merely for ascertained and isolated facts, but for a whole array of correlated discoveries, which he may indeed now arrange in something of their due order and association, and to each of which he may hope to assign its proper place. That the theory propounded by an investigator has subsequently been disproved, does not invalidate the facts on which it was (mistakenly) founded—any more than the fall of a house negatives the material existence of the earth—nor does it diminish their right to be regarded as links in the chain of causes which have, we may feel assured, an arrangement orderly and definite although not yet mapped out, or realised as such by us.

In explanation of the production of labour in the parturient female, theories have been proposed which made the process dependent upon:—(1) The uterus having reached its limit of distension; (2) The so-called obliteration of the cervix and its consequent inability any longer to oppose the contractions of the body of the organ; (3) Irritation of the nerves of the cervix uteri by the complete dilatation of its sphincter fibres; (4) The irritating presence of a large amount of venous blood in the susceptible uterine tissues; (5) The partial and progressive separation between the decidua and the uterine wall which takes place during the later period of pregnancy; (6) A stimulus derived from ovarian excitement; while others, in despair of finding any more satisfactory solution of the problem, are fain simply to refer it to; (7) A *natural law*, similar to that which causes the shedding of ripe fruit. If we examine some of these theories more in detail, it will be found that, while no single one of them

affords in itself an entirely sufficient explanation, the various facts upon which they severally depend may be collectively so arranged as to afford in the aggregate a satisfactory working hypothesis.

Theory No. 7—if theory it can be called—seems at first sight to shelve the whole question of cause, and to entrench its advocates behind a stolid generality; yet it really contains a great physiological truth, for the very definite and special process by which the falling of ripe fruit—and of deciduous leaves—is provided for, is strictly analogous to the equally definite series of anatomical changes upon which Sir James Simpson founded the hypothesis which has been distinguished above as (5), and to which it will be necessary to allude again hereafter.

To say that labour commences when the uterus has reached its limit of distension is not to explain how distension begets expulsive action; nor does it meet the cases of expulsive uterine effort occurring in the early months of normal gestation, or in extra-uterine fœtation; or those instances—as, *e.g.*, of twin-pregnancy—in which the gravid uterus sometimes attains a much larger bulk than is usual in the same individual; or, again, why labour should follow rupture of the membranes with escape of liquor amnii and consequent diminution in the volume of the uterine contents. And yet, having regard to the influence produced by the mere bulk of their contents upon the contractile action of the walls of other hollow viscera, such as the bowels, the stomach, and the chambers of the heart, we are not justified in denying that the womb is in any degree stimulated to contraction by the pressure exerted by its contents, especially as the uterine nerves undergo, during pregnancy, a progressive development both in size and in irritability. Still, this cause cannot be regarded as, in itself, sufficient to account for the phenomena of parturition taking place with such regularity, with such comparative punctuality, and with such force; and while not without a certain value, it must be classed as quite a subsidiary factor in the process.

The second theory is open to various objections; but it conspicuously fails to account for the occasional setting in of labour during the early months of utero-gestation, and while the cervix is still rigid and unyielding. On the other hand, the advocates of the third theory, which has been ably expounded by Dubois, hold that in the complete obliteration of the cervix its fibres attain their highest physiological development. This part alone of the uterine parietes appears to possess a direct nervous communication with the cerebro-spinal system by means of twigs derived from the sacral plexus; the other (motor) uterine nerves being derived from the sympathetic. It is assumed that irritation of the nerve fibrils in the distended and susceptible cervix induces a reflex action, whereby contraction of the whole organ ensues; and this assumption establishes a tempting analogy between the expulsive cycle of the uterus and that of other hollow organs, such as the bladder and the rectum, and best affords the further explanation required by the distension theory. Its importance cannot be considered as altogether disproved; and we ought probably to recognise that uterine action may be evoked, or at least augmented, in this way and under certain conditions; although it cannot be accepted as the all-sufficient cause of the on-coming of labour since it fails to account for the occurrence of uterine contractions in cases of either abortion or of extra-uterine pregnancy.

The ingenious theory which was mentioned in the fourth place, is founded upon certain experiments performed by Brown-Séquard; who ligatured the trachea of pregnant animals after having previously destroyed the lower portion of the spinal cord. The uterus immediately began to contract, but the contractions ceased on relaxing the ligature, to be resumed as soon as it was again tightened. These phenomena were explained as being occasioned by the contact of venous blood with the preternaturally irritable muscular fibres. The earliest uterine contractions were thus connected with the large size of the uterine "sinuses" which ensures the presence within the substance of the uterine wall of a large quantity of venous blood; and hence, "so soon as the muscular fibre reaches, at the termination of pregnancy, its highest point both of irritability and of development, it becomes for the first time excited to contraction. The immediate result of this is to empty, in a great measure, the sinuses of blood, but so soon as the rhythmical relaxation occurs, the venous blood once more gains access to the irritable fibres, and anew excites them to contraction."

It is obvious that it would be to the advantage of the fœtus (if of viable age) that its expulsion should coincide with the incidence of any cause which had already operated so as to render the maternal blood unfitted for its further nutrition. But this theory fails to explain why expulsion of the ovum should take place in the earlier months of pregnancy, or why it should be excited by rupture of the membranes. Although it has been shown that the passage of venous blood through the capillaries of a muscle—whether of the striated or unstriated kind—induces its immediate contraction; and although the experiments of Dr. Bennett Dowler[1] (who observed the phenomena of independent contractility in the muscles of amputated limbs) and others prove that the influence of the central nervous system is not essential; it must not be forgotten that "however thoroughly we may destroy the lower half of the spinal cord, there still remains —in the connections which subsist between the sympathetic system and the upper part of the cord—a possible, though circuitous route, through which the important influence of the cord may still, although more feebly, be exercised upon the uterus (Leishman).

While it is difficult to admit in this theory of Brown-Séquard the one efficient explanation of the occurrence of uterine action, the cause to which he has drawn attention can scarcely be without some influence; under certain conditions it probably exerts an important influence; and the violent expiratory efforts and voluntary straining which occur during the second stage of labour may possibly act not merely directly by producing pressure upon the abdominal contents, but may also tend indirectly to augment the uterine contraction by inducing—as they sometimes obviously do—a condition of partial and temporary asphyxia which reacts upon the uterine fibres, after the fashion indicated above. Moreover, since the stimulus to contraction in such cases depends on the deficiency of oxygen rather than on the presence of carbonic acid,[2] we may here find a partial explanation of the tendency to abortion exhibited in the course of profound anæmia and of certain febrile diseases.

The theory which occupies the fifth place on our list was first enunciated by Simpson, and has been elaborated into something very definite by Dr. Karl Schroeder.[3] According to this view, "the influence of the sympathetic in the expulsion of the ovum is called forth by the irritation which the ovum exerts upon the terminations of the nerves on the inner surface of the uterus; by reflex action that irritation is transformed into motor activity. Only towards the end of the tenth month" of gestation does this irritation begin to be

[1] Experimental Researches on the Post-mortem Contractility of the Muscles.

exerted, "because, only then—through fatty degeneration of the decidua—does the ovum become a foreign body in the uterus. This fatty degeneration of the peripheral layers of the ovum causes a separation between the ovum and the uterus, which the resulting contractions complete."

There is very much to be said in favour of this theory; and we must attribute to the causes which it specifies a considerable share, as will be shown hereafter, in the production of labour at term. But it fails to explain why labour should occur just at that period of gestation which is so constantly the tenth multiple of a catamenial epoch—reckoned from the menstruation immediately preceding conception; or to explain satisfactorily why an apparently healthy ovum should be aborted; or why expulsive uterine action should take place in cases of extra-uterine pregnancy; and for these reasons it cannot be accepted as the one conclusive theory of the causation of labour, to the exclusion of all others.

The sixth theory is that propounded by Dr. Tyler Smith,[4] who maintained that "ovarian excitement is the law of parturition in all its forms of ova expulsion." He argues that the exciting cause of labour is due to the recurrence of the periodical excitement of the ovary, acting by reflexion on the uterus; this excitement continuing to recur at monthly intervals throughout the entire period of gestation, and culminating at the eleventh recurrence, so as then to induce the parturient effect. To this it has been objected that (1) No satisfactory reasons are given for the cause of the ovarian excitement, or why the excitement which occurs at one particular period should be more successful in inducing expulsion than is that which occurs during any one of the preceding months of gestation; (2) The period of gestation, although commonly a multiple of the menstrual period, is by no means constantly so; (3) Parturient efforts take place in the uterus despite the previous removal of the lower part of the spinal cord. (With reference to this objection, see the remarks already quoted *antea* from Leishman); (4) The removal of the ovaries in the later period of gestation does not oppose any check to the parturient action.[5] And to these might be added—(5); that such an explanation would apparently fail to apply in the case of those animals for instance in which the period of ovarian excitement—as evidenced by the phenomena of "heat"—appears but once a year.

This theory has, however, won the support of many writers on the subject, several of whom are at least willing "to admit that it is probable that a presiding influence springs from the ovary at the period of the natural menstrual molimen," while they do not care to "commit themselves to the opinion that this is the sole cause" of the induction of uterine action. The present writer, coinciding in this cautious acceptance of so much of Dr. Tyler Smith's views, would yet go somewhat further; and it will be the object of the concluding portion of this paper to endeavour to show that this theory, somewhat modified and extended, and correlated with certain of those other hypotheses which have been already briefly considered, affords a scientific and consistent explanation of the occurrence of parturition.

A careful consideration of the phenomena attending ovulation, gestation, and labour, combined with a review of the facts revealed by the physiological investigation of these conditions as they occur, not in women only, but in all known female animals, leads to the conclusion that the expulsive action of the gravid uterus, occurring normally at the termination of pregnancy, cannot be referred to any one of the causes which have been enumerated, singly; but, rather, that it is a result of the joint action of several causes which, individually, take very various shares in its production; that some of these causes are operative, in a degree, more or less throughout the fruitful period of the individual's life, whilst others are of shorter duration, and are, usually, only evoked at different stages of the period of gestation; but that, once established, they each and all act and react on one another, so as to intensify the manifestations of their joint operation, until they culminate in a result which necessarily entails on all of them a period of less exalted vigour, while securing for the majority a time of complete, if only temporary, rest.

In other words, labour at term is the outcome of a physiological conspiracy, an *émeute* which is the result of several forces, of which some are always in activity, more or less, whilst others are incidentally roused and added during the progress of the events immediately preceding; the original exciting cause of the movement, and that which, in the vast majority of cases, determines the punctual incidence of the final catastrophe, being the nervous influence which springs *primarily* from the ovaries.

It will be necessary to examine the nature and method of this influence in some detail. It is admitted that, in all vertebrate animals at least, the maturation and discharge of ova from the ovary is a periodical phenomenon; although we are still in ignorance as to why the period of each recurrence should be some multiple of a week since the previous ovulation. In the human female it occurs during the childbearing period of life, and unless kept in abeyance by pregnancy or by lactation, at intervals of, usually, four weeks; and is produced, according to Pflüger, thus:—The slow continuous enlargement of the Graafian follicles causes a constant irritation of the terminations of the nerves embedded in the rigid stroma of the ovary; this irritation is at first too slight to beget an immediate reflex action; but at intervals—which are, practically, in consequence of the mode in which the producing causes act, periodical—the sum of these irritations becomes so great as to induce a reflex nervous response, which takes the form of a considerable arterial congestion of the genital organs. This suddenly increased afflux of blood produces a double effect; not only is that Graafian follicle whose development is most advanced (usually) ruptured by the increased intra-follicular pressure, but from the vessels of the congested mucous membrane hæmorrhage may take place upon the free surface of the uterus. The escape of the ovum from its follicle and the menstrual flow are both consequences of one and the same cause, viz., the pressure which the growing follicle exerts upon the terminations of the nerves contained in the ovarian stroma. It is, therefore, this pressure which causes the periodical reflex action—congestion of the genital organs.[6] In most mammals this congestion shows itself in tumefaction of the parts, with a mucous discharge of a catarrhal nature; in several this fluid becomes more or less blood-stained—especially towards the termination of the *œstrus*, when the mucous membrane of the uterus itself undergoes partial exfoliation; and in some, a considerable discharge of little else than pure blood takes place. The labours of Buffon, Cuvier, Burdach, Darwin, Ehrenberg, Raciborski, Laycock, and numerous other investigators abundantly prove that, although often disguised by various accidental and other circumstances, this congestive action tends to recur, in the unimpregnated females of the higher animals, with great regularity at intervals of two, three, four, five, or more weeks, according to the par-

[4] "Parturition, and the Principles and Practice of Obstetrics," 1849.

[6] Cf. Schroeder *op. cit.*, p. 10.

ticular species concerned; and that both its intensity and the regularity of its recurrence are specially favoured by those conditions of regular and sufficient feeding, warmth, and care, to which the women and domesticated animals of civilised countries are exposed.

That the uterus is, in virtue of its muscular and nervous endowments, an organ possessed—even in its unimpregnated state — of contractile power, is a proposition which will readily be admitted; indeed, we should expect no less, seeing that the uterus is, in all animals which possess it, but a specialised portion of one or both Fallopian tubes, and that it is by means of the peristaltic contraction of these canals that the ovum accomplishes a considerable portion of its journey after escaping from the ovisac. This contractile power will be augmented rather than lessened by the active congestion which attends the menstrual *nisus*; and the blood and mucus coincidently effused within its cavity, and acting as a foreign body, supplies just such a stimulus as is required to evoke contractile and expulsive action; a stimulus which must be all the more intense because, for a part of the time at least, it is acting upon a sensitive surface partially denuded of its protecting epithelium. This expulsive action of the uterus is not, usually, a noticeable feature of menstruation (although even the flow of a normal catamenia from the os uteri is somewhat remittent in character, and "the soft condition of the uterus is alternated with contraction"), because, as a rule, the blood easily drains away from the uterus almost as quickly as it is effused, and does not accumulate within the cavity in sufficient quantity to cause marked contraction of the organ. But if there be any obstacle to free escape of the blood poured out into the womb, as by marked narrowing or occlusion of the cervical canal, or by an imperforate hymen, it is well known that strong uterine contractions do occur during menstruation, evidenced by the acute and cramp-like pains which distinguish one variety of dysmenorrhœa; and this condition may result in a distension and hypertrophy of the uterus and a dilation of the Fallopian tubes analogous to the conditions with which surgeons are familiar as resulting from the obstruction caused by an enlarged prostate or an urethral stricture. Like results follow similar causes in the lower animals, and have sometimes even given rise to the impression that the beast in question was either in labour, or about to abort;[7] and recently, in the case of a patient suffering from an acute menorrhagia, the immediate effect of plugging the cervical canal was to replace a profuse but painless hæmorrhage by paroxysms of acute and expulsive uterine pain. There can be no doubt, then, that the combined effect of uterine congestion, and the effusion of blood, &c. (acting as an irritating foreign body) within the uterus, is to produce expulsive uterine action; moreover, since the primary cause acts periodically, so will the ultimate effect be periodically manifested. And hence there would arise, in time, *a tendency*, intensified by transmission and inheritance, *to periodical congestion, periodical hæmorrhage, and periodical contractions on the part of the uterus;* in support of which we might adduce those not uncommon cases of scanty or absent menstrual flow, in which, although a patulous cervical canal offers no obstruction, and in some of which, even, no blood is effused, the cramp-like hypogastric paroxysmal pains distinctive of sharp uterine contraction, occur nevertheless at the usual monthly period. Moreover, this periodical uterine action, once *the habit* was established, would retain its tendency to periodical recurrence, even though that which was its original cause, the growth of Graafian follicles, evoking reflex action, should cease or fall into abeyance. And here we find an explanation of the *periodic* uterine congestion (and contractile action) which occurs even in females whose ovaries have been removed (subsequently to the age of puberty), as well as that which is constantly noticed during pregnancy and lactation.

Symptoms of "heat" are frequently observed to occur in the domestic animals at the usual periodic intervals, even throughout the continuance of gestation; and still more frequently during lactation. And although women usually cease to menstruate whilst pregnant or suckling, this is not invariably the case; and there exist, besides, other evidences of the persistence of the rule of periodical congestion of the genital system, accompanied with the usual tendency to uterine contraction at such times; this latter being especially borne out by the well recognised fact that abortion is particularly likely to occur at those dates which represent what would be (but for the pregnancy) a menstrual period.

We are therefore justified in asserting that the normal process of ovulation (which begets, as we have seen, congestion of the whole generative apparatus) leads to effusion of fluid (mucus or blood, or both) within the uterine cavity; that this effused blood, acting as a foreign body, induces uterine contraction, and that there thus arises *a habit of* (or, at least, *a tendency to*) *periodical contraction and expulsive efforts on the part of the uterus at intervals corresponding to the catamenial periods.* We have seen, further, that not only does this *habit* of periodical uterine action persist throughout gestation; but that it receives, even during that period, the intensifying stimulus of some recurrent monthly ovarian excitement, which (in many cases at all events) appears to be not entirely quiescent.[8]

During a normal pregnancy, however, this active congestion of the generative tract leads to no effusion of blood on the free uterine surface, because (1) the blood easily finds its way from the strictly maternal to the fœtal structures. (We might, consequently, expect to find the placental and funic bruits specially marked at what would (but for the pregnancy) be catamenial periods; and such observations as the writer has had opportunity of making on this point, appear to corroborate this idea). This additional volume of blood, therefore, not being effused, does not act as a foreign body. And (2) so long as the fœtal and maternal structures continue in full vital and anatomical union, the ovum itself does not act as a foreign body. So that no additional element likely to beget reflex expulsive action comes into play. During the progress of gestation, however, other forces are called into activity. The muscular tissue of the uterus itself undergoes an enormous hypertrophy, as do also its nervous elements, and the concurrent observations of Brown-Séquard, Kehrer, and Obernier, show that the *irritability* of the uterine nerves increases in accordance with the advance of pregnancy. The distension of the uterus and the stretching of its wall, which is effected in the latter weeks by the growth of the ovum, must further tend to exalt this irritability, and thus to make reflex expulsive action more easily provoked. At the same time, the dilatation of the cervix (which means, according to one view already noticed, its highest physiological development, and makes it fully susceptible to external impressions) becomes complete; while the fœtus, driven against the internal os, partly in virtue of its own growth and the action of gravitation, and partly by incipient uterine contraction, tends to exercise that pressure-

[8] *E.g.* Ova have been found to be discharged from the ovary of the mare during pregnancy, by Franck; and ripe follicles noticed in the ovary of a three months pregnant woman, by Lawson Tait.

stimulus which the cervical nerve-endings are now disposed to appreciate.

Most important of all, however, amongst these ancillary stimuli, is that gradual relaxation of the anatomical connections between the ovum and the uterus which immediately precedes birth, and in which Simpson recognised the determining cause of parturition. Schroeder (*op. cit.*, p. 57), who regards the sacral nerves as being probably inhibitory, writes, "the influence of the sympathetic in the expulsion of the ovum is called forth by the irritation which the ovum exerts upon the termination of the nerves on the inner surface of the uterus; by reflex action that irritation is transformed into motor activity. Only towards the end of the tenth month does this irritation begin to be exerted, because only then, through fatty degeneration of the decidua, does the ovum become a foreign body in the uterus." The reason why this fatty degeneration should commence only in the latter weeks of pregnancy may possibly be due to the then distended condition of the uterus, and the consequent interference with the continued circulation and nutrition of the expanded mucous layers. "The organic connection which previously existed between ovum and uterus," now undergoes a process of solution by the degeneration of the intervening cellular tissue. "At all places where the degeneration has reached a certain stage, the terminations of the nerves are irritated." Gradually this continuous irritation accumulates, until—about the end of the tenth month of utero-gestation—it reaches a certain sum whose incidence then coincides with a (mensual) period of recurrent uterine contraction; at the same time the other stimuli which were lately enumerated have attained increased activity; and, thus reinforced, the first uterine contractions of this (tenth) period are more forcible than any which occurred during the preceding months of pregnancy. Owing to these contractions, "the uterine wall is partially removed from the ovum, and this separation (intensifying the action of the ovum as a foreign body) becomes a new source of irritation to the uterine nerve-fibres, and provokes, after an interval, fresh uterine contraction. The reflex action, manifested as labour-pains, becomes more and more powerful, producing further separation, and increasing the force of the train of phenomena just mentioned; until, finally, the expulsive energy thus begotten suffices to ensure the complete separation of the ovum, except at its placental attachment, and so birth of the child at about the 280th day; ultimately, and in the same way, follow separation and extrusion of the placenta.

Thus we have an explanation of the occurrence of labour at or about the end of the tenth month of utero-gestation, or, more strictly, at the time corresponding to the tenth catamenial period subsequent to conception. A distinct tendency to uterine contraction occurs at periodic intervals throughout a normal pregnancy; but only at the tenth recurrence are the uterine tissues so developed, and only then have the other stimuli become simultaneously so potent, as to make possible the occurrence of really forcible contraction; and only then are the anatomical and physiological relations between uterus and ovum such as to favour further separation between them, and thus ensure the recurrence of fresh and still more powerful contractions.

Thus far as regards a normal pregnancy carried on "to term." Let us now briefly examine to what extent such an explanation will apply to the different forms of premature expulsion of the ovum.

It is admitted that abortion and miscarriage occur almost invariably at a period[9] corresponding to a menstrual epoch. Admitting that there exists a tendency to (and probably, in some degree, an actual) uterine contraction at each recurrent catamenial period, it is not difficult to comprehend that an abnormality in the process of gestation, such as a partial separation of the ovum from the uterus due to external violence, to disease or degeneration of the fœto-maternal connections, or to injury or disease of the uterine tissue itself, should afford just the additional stimulus requisite to convert a potential uterine activity into actual contractions, contractions which, themselves furthering the separation of the ovum and thus causing it to act still more as a foreign body, would ensure the persistence and increased force of the expulsive action. The death of the embryo owing to interstitial disease or specific blood poisoning, as by syphilis, may produce similar action. In other cases, in which no definite lesion either of fœtal or maternal structures appears accountable, the cause may be found in a special nervous sensitiveness which permits an impression, transmitted with unusual force by some other channel and originating, *e.g.*, in the breast, the stomach, the vagina, the ovaries, or the intestine, to act as the additional stimulus required. The expulsive action which follows the introduction of a foreign body, as an elastic catheter for example, between the membranes and the uterine wall, is thus also easily explained; especially as this manœuvre is most successful, and is, indeed, for that reason, usually practised at what would be a menstrual period. Similarly, rupture of the membranes, followed by escape of fluid and consequent shrinkage of the bulk of the uterus owing to its natural tonicity, ensures some separation of the anatomical connections between ovum and womb; it also brings the (more or less sensitive) uterine wall into more direct contact with the firm and irregular outline of the child, and the latter can hardly be without its effect in inducing reflex contraction. It is possible that violent fœtal movements may even be occasionally instrumental in determining or in accelerating the on-coming of labour; and it has been noted that the presence of a large amount of liquor amnii, which tends to minimise the action now under consideration, is a frequent accompaniment of prolonged gestation. That causes (such as external violence, use of instruments, &c.) which would almost certainly provoke labour at the termination of the period of normal pregnancy, should nevertheless so frequently fail to do so in the earlier months, is probably due to the fact, already noted, that the irritability of the uterine nerves progressively increases with the advance of pregnancy; and this, while helping to explain the regular setting in of labour, will also serve to account for the not infrequent retardation of the pains in cases where the separation of the ovum has been premature.

In cases of extra-uterine gestation the uterus itself does not usually undergo, to any marked extent, the development—anatomical and physiological—which attends a normal pregnancy. Especially when the pregnancy is ovarian, abdominal, or truly tubal, the increase in bulk of the uterus and the formation of a decidua follow but in a slight degree, and the process usually soon subsides. The rupture of a tubal or of an ovarian fœtal cyst seems to be determined mainly by the amount of distension which it has sustained, combined with accidental causes, such as straining or external violence, and is not usually correlated with true and distinct uterine contraction. Yet it is not astonishing that the irritation produced in the generative nervous circuit, at the site of the extra-uterine implantation of the ovum, should be able to evoke reflex contractile action; this is more noticeable in cases of abdominal pregnancy which are prolonged to the eighth and ninth month, and especially so in cases of interstitial or utero-tubal gestation, in which, from its

[9] "Taking a large number of cases of abortion as a basis of calculation, I find that it much more frequently happens at what would otherwise be a catamenial period." MEADOWS' "Manual of Midwifery."

*

immediate proximity to the site of the vital processes concerned, uterine development and irritability are much more directly implicated.

In connection with this subject generally, we should not overlook the fact that, when once, from whatever cause or combination of causes, there had been established in the females of the human species, the habit of parturition at or about the termination of the tenth month of pregnancy, this *habit* would be intensified and fixed by inheritance and transmission through successive generations; and that thence there would arise a *law* of exceptionally powerful uterine contractions occurring at this particular epoch of gestation.

It does not appear a fatal objection to this theory that the date of delivery but seldom corresponds exactly to the 280th day of gestation; indeed, all things considered, it would be somewhat remarkable if this were the case; and for the following reasons. The period which intervenes between the commencement of successive catamenia is not in all women exactly 28 days. Putting aside the occasional abnormalities of "regular" menstruation every 2, 3, or 6 weeks, it varies in most cases from about 26 to 33 days; and often, in the same woman, varies at different times by two or three days, without her "regularity" being in any other way impeached. Amongst less civilised people the menstrual flow is apt to occur at even longer and less certain intervals. Again, the duration of the flow varies considerably in different cases, and even in the same individual upon different occasions. Brierre de Boismont thus states its duration in days, the number of days thus occupied being arranged in order of frequency:—8, 3, 4, 2, 5, 1, 6, 10, 7. When the catamenial nisus occurs during pregnancy, we do not know what effect the altered conditions of the uterine circulation may produce upon the *duration* of the period, nor how far (if at all) a possible lessening of its duration would induce an earlier recurrence of the period next in succession.

There can be no doubt, however, as to the generally tetra-hebdomadal character of the ovarian *nisus* in the human female; and, allowing for the slight variations in time, due to one or more of the causes just alluded to, we find no difficulty in the usual onset of parturition at some time between the 270th and the 290th day; bearing in mind also, that the prime factor in the process (the habit of recurrent uterine congestion and contraction) requires for its effectual display the co-operation of other causes which (owing to the *modus operandi* of their evolution) can exert an active and simultaneous effect only at that period of pregnancy which practically corresponds to this particular date. Observations upon the lower animals corroborate the idea that the date of parturition corresponds to a period of ovarian excitement; thus, *e.g.*, it is asserted that mares will breed readily if put to the horse within a few days of their foal's birth.

Finally, we may briefly summarise our conclusions thus, dividing the causes of labour into (1) the *Primary*, which is the habit of periodic (mensual) uterine contraction; (2) the *Obcidental* (*i.e.*, causes which, being accessory, arise naturally in the course of, and are necessarily evoked by, the progress of the pregnancy itself); and (3) the *Accidental*, which include *e.g.*, external violence, toxic agents, instrumental interference, emotional effects, and the like.

1. Ovulation begets periodical *congestion* of the generative organs. (*a*)

2. *a* produces rupture of vessels on the uterine surface, giving rise to *effusion of blood*. (*b*)

3. Effused blood, &c., acting as a foreign body, tends to produce reflex *uterine contractions*. (*c*) (This expulsive action is not usually noticeable in ordinary menstruation for reasons previously given).

4. *a*, *b*, and *c*, thus induce *habit of* periodic contraction and expulsive effort on the part of the uterus, at intervals corresponding to the catamenial periods. (*d*)

5. During pregnancy this *habit* (*d*) continues in force; but, owing to the character of the fœto-maternal relations, no additional element likely to beget strong reflex expulsive action comes into play, until towards the 40th week. (*e*)

6. Towards the end of the tenth month of gestation there occurs (owing to the pressure consequent on distension) *fatty degeneration of the connections between ovum and uterus*. (*f*)

7. In consequence of *f*, there arises a *further stimulus* to contractile action by local *irritation of* the uterine nerve-endings. (*g*)

8. Hence, when the tendency to mensual uterine contraction recurs for the tenth time, it is reinforced by the stimulus *g*; as well as by the other stimuli which are by this time also more or less effective. Whence ensue, at this period, more vigorous contractions, leading to *further separation between ovum and uterus*. (*h*)

9. *h* increases the irritation of *g*; thus leading again to recurrence of *h*, and so to a constant repetition of this train of phenomena, until the expulsive force thus roused suffices to ensure complete separation of the ovum and its subsequent extrusion.

10. The mere *habit* (even apart from the persistence of its original exciting cause) of recurrent (mensual) uterine activity, as well as the resulting tendency to expulsion of the ovum at the tenth mensual period of gestation, would become gradually fixed, and so exalted into *physiologieal laws*, by transmission and inheritance through numerous successive generations.

While this view of the subject, thus imperfectly sketched, can hardly fail to increase the interest with which we regard the problem of the causation of labour, it has also a practical value by bringing before us the numerous array of factors engaged in producing that result, and by showing how the normal progress of pregnancy may be jeopardised by the too early or too vigorous incidence of any one or more of them. It claims also to afford an explanation of the process in harmony with the great laws of correlation and of continuity whose operations are so widely evidenced throughout the world.

[Note.—Pflüger's explanation of the origin, rise, and operation of the ovarian nisus is not universally accepted; notably, Mr. Lawson Tait holds the Fallopian tubes responsible for the occurrence of the phenomena of menstruation. The position taken up in the preceding paper is not invalidated by regarding the tubes as the chief exponents of a recurrent condition which most observers are still disposed to connect in some way with the processes of ovulation; the element of *periodicity*, however originated and maintained, still remains as the prime factor in the chain of operations which have been here considered.]

PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.
President of the Epidemiological Society of London.

(Continued from page 429.)

Bronchocele

Is more or less prevalent chiefly along the sub-Himalayan ranges, from Assam, in the east, to Ladak, in the west. Solitary cases are not unfrequently met with in Lower Bengal. My own experience in that part of India confirms that of Mr. H. M. Greenhow, who wrote—"I have not seen a case of goitre among Europeans in India." In 1881 one European soldier's

wife was admitted for goitre in all India. In her the disease probably originated, as it did in Ann Boleyn, at home.

In a report on the Medical Topography of Tirhoot,[39] Kennetli Mackinnon observes that "European adults are very seldom attacked with goitre, children very frequently, but infants never." The Editor of the journal remarks in a footnote, "a child who arrived in Calcutta about 12 years since still has it as much as ever."

A late head of the Bengal Medical Department, Mr. John M'Clelland, who paid great attention to the subject of Indian goitre in its relation to locality and soil, denied[40] that the neighbourhood of Indian mountains is influential in the production of bronchocele. He said—"The districts from Rungpore to Goruckpore extend along the borders of the Tarai, and this last extends along the foot of the Nepaul mountains ; and so, from an association of ideas, the goitre has been here generally supposed to bear some immediate local connection with the mountains. But such is not the case, for it is found in open cultivated districts of the plains sixty miles from the mountains. In other places it may extend much closer to them, but never so as to" [lead us to] "suppose that it can be due to their influence merely as hills."

So Kenneth Mackinnon asked—"Why is goitre confined to mountainous valleys or plains lying in the vicinity of great mountainous chains? I make the latter observation because the disease is as common, I believe, in the villages of Tirhoot, lying hundreds of miles from the Himalaya, as in any part of the world."

In Indian localities, where goitre is most prevalent, it affects the lower animals. Mr. McClelland says that, in these districts, dogs and cats are often affected with goitre. Dr. Coates says that in the Chumparun District, goats and sheep, dogs and horses suffer from the disease.

Mr. Bramley, the first Principal of the Calcutta Medical College, wrote that, in Nepaul,—"on one occasion a goat brought forth a kid with a goitre as large as its head. Puppies of a month old, bred from English dogs, are very frequently affected by it, as are also lambs."[41]

Writing in 1883,[42] Dr. Archibald Campbell said that "congenital goitre is not known in Nepaul to occur among the human race." Mr. McClelland wrote (page 107) that there is no authentic instance of congenital goitre, *i.e.*, in a child. Mr. Bramley, however, observed[43] that children are sometimes born with goitre. Mr. Baillie Fraser made the same observation in his work on the Himalayas. Mr. Greenhow confirms this from his own observation. He met many persons who had suffered from the disease from their birth.

In 1867 Dr. Colles received at the Calcutta Medical College Museum a "bronchocele from a newly born infant," contributed by Mr. G. D. McReddie, civil surgeon, Hurdui, Oudh.[44] It appears very desirable that a full examination of the entire system of muscles of respiration should be made in one or two of these still-born children.

With regard to goats and sheep, Dr. Campbell found from many observations "(1) Goats and sheep brought from the North-Western Provinces of India, where goitre is unknown (?) to Nepaul and Tirhoot, where it is very common, produce goitred young, though they were pregnant previous to arriving in the infected districts.

"(2) A goat or sheep unaffected, and in perfect health, produces in Nepaul goitred offspring.

"(3) A female parent having the disease scarcely ever produces other than diseased young ones.

"(4) Of 23 lambs and kids born with bronchocele all died within a few minutes after birth, with the exception of a lamb in which 'one gland only was enlarged ;' when it was six weeks old the disease had vanished.

"(5) The tumours in the offspring of goitred parents are invariably larger than in that of healthy ones.

"(6) The death of the affected young ones does not depend on the size of the goitre."

The vulgar say "the creatures die because they cannot suck." "Possibly they could not," remarked Dr. Campbell, "but they are very rarely allowed to try. The common course being this—the creature is born, is feeble and *unable to raise its head*, gasps half-a-dozen times for breath, and dies."

He found that "the muscles arising from the sternum to be inserted into the os hyoides and thyroid cartilages are nearly obliterated by the pressure of the tumours." A further examination of these remarkable cases, by comparative anatomists, is a desideratum. Such enquiry should also include a full investigation of the condition of the cranial bones of cretins and goitred animals.

Speaking of goitre as observed in Kemaon, Mr. McClelland thinks that the tumour does not always originate in the thyroid gland, and states that, in a third of the cases which he saw, it appeared to commence with a fulness of the base of the neck, on one or both sides over the middle of the clavicle. Thence the swellings ascend, and, in a longer or shorter time, reach the situation of the thyroid gland, when both tumours unite. I do not find that any other observer has noticed this ; but Dr. Hilton Fagge held that when the thyroid is absent in cretins, fatty tumours will almost invariably be found in the posterior triangles of the neck.

With regard to the *Prevalence* and *Localisation* of bronchocele in India, the returns for 1881 show 59 admissions for bronchocele in the Sepoy force of the Bengal army, none among the native troops of the Madras and Bombay Presidencies. Among the prisoners there were only 2 cases in Bengal and 7 in Madras.[45] Mr. John Leslie[46] saw a good many cases at Gowhattee, in Assam, but in none was the enlargement of the gland very great.

In a tour which I made throughout Assam, in 1865, I saw nothing of goitre, except at one very small village on the plain country between Tezpore and Nowgong. I was surprised to see that nearly the whole of a large crowd of young children who ran out to see my elephant, had goitre.

Dr Mouat says[47] that "in the districts about *Motiharee, Segowlee, Bethiah, Bhagolia, and on to Goruckpore*, indeed all along the line of the Terai, goitre is so prevalent that it can scarcely be an over-estimate to state that, in many localities, one individual in ten is afflicted. Dr. Coates has stated that, 90 to 100 cases of goitre resorted daily to the *Chumparun* dispensary when he was civil surgeon. Writing in 1859, Dr. John Brown[48] observed that in the valley of *Nepaul* (where Dr. Campbell made his observations on goats and sheep, cited above) and its vicinity, goitre prevailed to a large extent. (See Cretinism). Dr. D. Wright

observed,[49] in the same locality, that the disease which supplies most patients to the dispensary is goitre. "The door is, in fact, often besieged by crowds of applicants for "*gullê-ka-dawa*" (medicine for the throat). "Goitre is most common among the women, but is also pretty frequently met with in males, and in certain districts of the valley, where it is most abundant, the very dogs are affected by it." My friend Mr. Greenhow's observations on goitre[50] were confined to the Trans-Gogra portion of *Oude*, and more especially to the neighbourhood of *Secrora*. At that station he easily brought together 300 cases; and from his careful examination of these, he draws many inferences which will be found of great value by all who may investigate the subject of bronchocele. He notes that "at Hissampore, a village on the Surjoo, about 12 miles distant from Secrora, dogs and other animals are affected with it."

My friend Dr. Cayley observed[51] that he had travelled through the greater part of Ladak, and had seen very few goitres, and those very small ones; and he saw no cretins, and hardly an idiot; although, in the Lower Himalayan ranges, as at Kangra, Kullu, and about Simla, goitre is very prevalent, and cretins not uncommon.

It is stated in the "Madras Topographical Reports"[52] that, in the highlands both of Siam and Ava, bronchocele is frequent, but the enlarged gland does not attain any great size, nor is it attended by cretinism.

Dr. Waring states, in his "Medical Notes on the Burmese," that, amongst some of the tribes of Karens, in the interior from Mergui, bronchocele is very common, but is confined to small communities inhabiting certain districts.

A full report upon the morbid anatomy of Indian goitres, in man and animals, would be a very desirable addition to pathology.

A great deal has been written by McClelland,[53] Professor Liston, Greenhow, and other Indian observers, with regard to the *Geology of the localities in which* goitre prevails. The whole of the interesting results deserve to be carefully weighed by those who may desire to investigate this important subject particularly in the localities themselves. McClelland and Liston are agreed in the following observations upon localities in the Goruckpore district: "Goitre or *geega*, as it is called, is very prevalent where the soil is white, damp, and sandy; such lands being called *bhat*, as not requiring irrigation for the dry weather crops. It is unknown in *bangar* lands, where the soil is reddish, sandy, and dry, so as to require irrigation in the dry weather. There is, however, no remarkable difference of level in the two kinds of land generally. All the villages on the *bhat* lands are not equally affected; the inhabitants of some being quite exempt, while the inhabitants of others are affected to the extent of 10 per cent. of their population; women being more subject to the disease than men." Professor Liston observed that the *bhat* is a soil retentive of moisture, that a very notable proportion of it is calcareous matter. "The *bangar* country," he says, "is more congenial to the human constitution, and to horses and dogs than *bhat* lands are. The inhabitants are better grown, stronger, fairer, handsomer, and the children more playful in the former than in the latter."

I read, in Mr. Pugin Thornton's article "Goitre," in Quain's Dictionary, that "In the Indian Punjaub, where goitre affects 60 per cent. of the population "[?]", 59 grains of lime have been found in a gallon of water, 10 grains being an undesirable proportion." (Professor Frankland.)

The *Treatment* of goitre by the inunction of biniodide of mercury ointment, which I believe originated in India, met with so much success there, and has for so long a time been noticed in the medical literature of Europe, that it appears surprising that we should have heard so much of late years of the very serious operation of thyroidectomy.

Writing in 1857, Dr. Mouat stated that, in 1854–55, Captain Cunningham, second in command 12th Irregular Cavalry, began to employ the biniodide ointment. I do not find it mentioned who suggested this plan of treatment to Captain Cunningham. He appears to have been speedily satisfied of the efficacy of this treatment, as we are told, in Dr. Mouat's paper cited above, that, in the first winter, he must have treated some 25,000 cases of goitre, having seen as many as 500 at his house in one day. Dr. Mouat considered that, in about three years, not less than 60,000 persons had been treated.

The observations made by Dr. Coates in 1881, already cited, are the latest on this subject that I have seen. He said that the whole of his very numerous cases at Chumparun were treated with an ointment composed of biniodide of mercury ʒ ix. to lbs. iij. of lard. His experience was that one-third recovered completely, in one third the size of the tumour was reduced, and in one third no change took place. He considered it of importance to expose the part to the full rays of the sun during and after the application of the ointment.

I had an opportunity of witnessing that issue which is threatened in cases of unchecked bronchocele. An old native woman was brought into my ward in a very low state. She was attacked with symptoms of suffocation and died unrelieved, as there was no room to allow us to open trachea or larynx, and as it was clear that she could not have survived an attempt to remove the tumour. I found that the air-passage was surrounded and pressed upon by the tumour as it would be if grasped in front by the palm of the hand and embraced behind by the thumb and fingers joined, save that the tumour was bulkier posteriorly.

(*To be continued.*)

A CASE OF DETACHMENT OF THE RETINA WITH GLAUCOMATOUS EXCAVATION OF THE OPTIC NERVE CURED BY WOLFE'S OPERATION.

By Dr. HENRI CAMPART.

Madame B., aged 57, came to the Clinique Nationale Ophthalmologique des Quinze Vingt, July 12th, 1884. She stated that in the previous April she had frequently noticed shadows floating before her right eye. Every object that she looked at attentively appeared to her surrounded by coloured rings, especially if the objects were in a bright light. She had never been myopic, and three months' previously the sight of her right eye was quite as good as that of her left.

About two months' ago the patient on getting up one morning found that the sight of the right eye had become considerably impaired, and that in a very rapid manner. Objects appeared to her curved, and she could not distinguish their lower half. The eye gave her no pain. She felt as usual a sense of weariness on using the eyes, but there was no spontaneous pain. Dr. Galezowski, when consulted some days later as to this anomaly of vision, found a detachment of the retina of the right eye. He ordered cold compresses to the eye, a blister and leeches to the right temple, and a collyrium of sulphate of eserine (·05 centigrammes to 10 grammes of distilled water). Having received no

benefit from this treatment, the patient presented herself at the Quinze Vingt on the date above-mentioned. She was a stout plethoric woman, and stated she had long suffered from asthma, attacks of which occurred several times a-week. Her occupation was that of a laundress, and she had evidently been much overworked. Dr. Fieuzal diagnosed the case as detachment of the retina of the right eye, with glaucomatous excavation of the optic nerve. Visual acuteness: Right eye, she could count the fingers at 58 inches' distance. Left eye, V=$\frac{2}{3}$ of Wecker's types.

Treatment.—A solution of sulphate of atropine (1 in 200) was dropped into the right eye, and sulphate of eserine into the left. Iodide of potassium was also prescribed, to be taken before each meal. The sight was gradually getting worse, she could see no type, and she could distinguish only the lower half of objects held before her. It was then proposed to her that she should undergo an operation; she assented, and the operation was fixed for Oct. 7th, 1884.

With the authority of Dr. Fieuzal, chief physician to the hospital, an anæsthetic was given, and Dr. Wolfe performed paracentesis of the sclerotic. The lids were kept widely open and fixed by means of a blepharostat, and a small opening having been made in the conjunctiva, the sclerotic was punctured on its outer side, between and posterior to the insertion of the external and inferior rectus. A brownish limpid fluid escaped from the wound. When it had ceased flowing, the instrument was removed, and without any sutures having been introduced in the conjunctival wound, the eye was closed, and an agglutinative dressing applied to keep it so. The patient was ordered absolute rest; she took every morning a glass of aperient water which gave her two motions daily.

On October 10th the dressing was removed, and as soon as she opened her eye, the patient was astonished at the result of the operation. She could count the fingers, could see the whole length of them, and distinguish between two different coins of the same colour.

On October 12th the dressing was again removed, and it was found that progress continued to be made. The patient could read at a distance of two metres $\frac{1}{3}$ of Wecker's types with the eye that had been operated on, and she could easily tell the time on a watch.

REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

EAST LONDON HOSPITAL FOR CHILDREN.

SUPPURATION IN MEDIASTINAL GLANDS, OPENING EXTERNALLY — LOCULATED EMPYEMA—AUTOPSY.

(Under the care of Dr. EUSTACE SMITH.)

(For these notes we are indebted to Mr. OWEN LANKESTER.)

GEORGE C., aged 18 months, was admitted into the hospital on July 7th. There was no history of phthisis in his family. The child had appeared pretty healthy up to the commencement of his present illness, three months ago. During this period the child has wasted. He has been sick after his food, and has not enjoyed it for some time past. He sweats at night; occasionally he has had twitchings in his face, but no general convulsions. There is no œdema of his feet or legs. The urine has a sp. gr. 1,020, and does not contain albumen.

July 11th.—Dr. Smith dictated the following note: The jugular veins are very full, and the superficial veins in front of the chest and abdomen are more visible than usual. The percussion note is high pitched over the upper part of the sternum. There is a venous hum on ausculting this part with the head thrown back. There is complete dulness over the lower half of the right back, with great resistance, as far back as the posterior axillary line; the respiration is high pitched and bronchial with large clicks on inspiration. The intercostal spaces sink in deeply on both sides; the spine is quite straight. The heart's apex is behind the fifth rib, inside the nipple line. There is a spasmodic cough, and the breathing is short. There is no retraction of the base of the chest in inspiration; no lividity of face. The eyelids and the lips are not congested.

July 18th.—The following note was made: The child coughs very little and not at all spasmodically. The fulness of the jugular veins continues. The percussion note is very high pitched over the upper half of the right front to the distance of one finger's breadth beyond the edge of the sternum, but respiratory sounds are normal. There is the same dulness over the lower half of the right back, where respiration is high pitched and blowing; there is no increase of vocal resonance. The intercostal spaces deepen on inspiration on the two sides alike. There is no difference in the respiratory movements of the right and left chest; the face is not livid, breathing is not short. The child is taking food well.

July 22nd.—The percussion note is tubular, with very great resistance over the lower half of the right back reaching to the posterior axillary line; all over resonance is somewhat impaired. Over the dull area the respiratory sounds are harsh, and accompanied with coarse bubbling rhonchi on inspiration as well as expiration. The vocal resonance is increased. The face is pale, and there is some lividity of the nose and mouth. In the second interspace, just to the right of the sternum, there is a slight swelling, and also a small globular fluctuating swelling in the episternal notch. A puncture was made, but nothing was evacuated; hence they were considered as softened and enlarged glands.

July 25th.—The above-mentioned swellings having been poulticed discharged a little pus. The superficial veins still much distended. The dulness at the right base posteriorly remains much as when last noted; respiration is very loud and harsh, with large bubbling rhonchus, and some increase of vocal resonance. There is faint vocal fremitus on both sides. The right side appears to move rather less than the left; the intercostal spaces sink in equally.

July 29th.—There is now a soft fluctuating swelling in the first intercostal space to the right of the sternum Dulness over the whole right back; respiration very loud and bronchial with fine, rather metallic, clicking sounds on inspiration. Vocal fremitus is increased.

August 7th.—The dulness over the right back is absolute below a transverse line drawn from the angle of the scapula.

August 19th.—The abscess in the episternal notch has much enlarged. Both it and the lower one discharge slightly, but continuously; they are dressed with iodoform. The child gets thinner and weaker, and refuses food. An exploratory syringe was put in in four places over the dull area, but without striking pus.

August 22nd.—The physical signs have remained about the same. The patient, having gradually become exhausted, died in the evening.

Autopsy.—The openings in chest wall were found to communicate with enlarged, tubercular, suppurating mediastinal glands. The right pleura was adherent to the ribs all over. The right lung was adherent to sternum above and in front; it was also adherent to

ribs behind. At the right base behind, where dulness was absolute, there was a loculated empyema. The right lung itself was quite solid, and full of tubercular material. Pleuræ much thickened. Small masses of tubercle were disseminated throughout the left lung. The heart and pericardium were normal. The spleen, intestines, mesenteric glands, and peritonæum were full of tubercle; the intestines were studded with patches of tubercular ulceration. Liver and kidneys natural.

Remarks.—(By Dr. Eustace Smith.) In this case the child's illness appears to have begun with an attack of pleurisy. The acute tuberculosis and suppuration of glands seem to have followed as a consequence of the purulent collection in the chest. It will be observed that the child did not come of a consumptive family. Some authorities hold that a tubercular predisposition is essential to the development of tuberculosis, but cases such as the above seem to indicate that if this be the rule, it is at any rate a rule not without its exceptions. The practical inference to be drawn is that purulent matter should not be allowed to remain in the body a day after its presence has been ascertained. In this child, although the physical signs pointed to fluid in the chest, exploratory punctures failed to give evidence of its presence. In many cases where this disappointment is met with the failure is due to thickness of the pus, and its admixture with flakes and strings of jelly-like lymph.

PURULENT PERICARDITIS AND EMPYEMA —AUTOPSY.

(Under the care of Dr. EUSTACE SMITH.)

Frank P., aged 2 years 5 months, was admitted into the hospital on September 2nd. The child's family history is fairly good, there is no special hereditary tendency to disease.

Previous History.—The child has never had any previous illness, and has always appeared strong and hearty.

Present Illness.—For the past six weeks his mother says he has been languid, refusing to play, and has lost his appetite and is getting thinner. He has been feverish also and has sweated a good deal, especially at night. He has a frequent cough, but no expectoration.

On Admission, the child is pale and his face looks puffy, but there is no œdema; his temperature is found to be normal, but his respirations are 48, and his pulse 140; the pulse is regular in rhythm but not in force. The ribs are rather beaded; the epiphyses at the wrist are large, but the fontanelle is quite closed, and his legs are straight. He does not appear to be thirsty. The urine is acid; its density is 1·030, and it contains no albumen. On percussing the chest, there is some increased resistance at the right base behind, which is dull; this does not extend into the axillary region; elsewhere percussion appears normal, as do the breath sounds. The heart's apex beats in the fifth interspace, a quarter of an inch within the nipple line; the sounds are healthy. The liver edge is three fingers' breadth below the margin of the ribs; the margin is sharp; substance firm, and appears to be rather tender when pressed. The spleen is normal. The whole abdomen is more tender than normal, but it is not distended or tense.

September 4th.—The boy has by this time become much worse; his temperature is now 102° F., his respirations 43, and his pulse, which is very full, 43. He looks ill and complains of thirst.

September 9th.—There is dulness, with increased resistance, over the right back from the spine of the scapula downwards, extending also into the lower axillary region. The respiration over this area is blowing in character, and accompanied with coarse bubbling rhonchus. Vocal resonance is bronchophonic. Over the lower half of the left chest, front, back and axillary regions, respiration is bronchial with some rhonchus. Stomach is distended, and gives metallic resonance to laryngeal sounds. The temperature has remained high, varying from 101° to 102° F.

September 12th.—The legs and feet are very œdematous; no urine can be obtained; it is all passed under him into bed. Percussion resonance is now much impaired over the whole of both backs, chiefly however at the bases; respiration is high pitched and blowing on both sides with occasional clicks and rhonchus. There is complete dulness over the whole left front; this dulness passes just a little beyond the middle line. Respiration is very high pitched, and bronchial in character. There is superficial crackling at the base. There is no dulness over the right front. The heart sounds are weak. There is no pericardial friction. The apex beat is behind the fifth rib in the nipple line, and very feeble. The liver is as last noted. The abdomen is rather more distended, with some increase of tension on the right side. The child has a distressed expression; he is very pale; the œdema of legs and feet is still present. The temperature remains high.

September 14th.—He died this morning.

Autopsy.—On opening the chest, the pleura on both sides were found adherent to the chest wall. Both lungs were congested and there was some slight consolidation at the base of the right. There was a loculated empyema on the left side occupying the left front from below as high as the transverse nipple line. The pericardium contained about half a pint of pus; its interior, and the corresponding surface of the heart were rough and shaggy; heart otherwise normal. A small patch of lymph was found in the abdomen on the right side. The kidneys appeared normal. The liver was large and fatty.

Remarks.—(By Dr. Eustace Smith.) Purulent inflammation of the pericardium is not a very uncommon disease in the child. In this instance the chief interest arises from the age of the patient, who was little over two years old. In most of the cases of purulent pericarditis in young persons which have come under my notice the pericardial lesion has been secondary to a pleurisy. When the suppurative process begins around the heart the child looks haggard and pale. He has irregular fever, and often complains of discomfort in the chest. The pericardial friction disappears early, but the præcordial dulness persists. After a time œdema of the legs is noticed, and the end is then not far off.

In the present case the physical signs arising from the inflammation in the pericardium were masked by the presence of pus in the left pleura; but œdema without albuminuria is a rare consequence of empyema in the child, while it is a constant symptom when the purulent collection occupies the pericardium. Its presence, therefore, in any case of empyema should at once direct attention to the heart. It will be noted that extension of the inflammation was taking place to the peritonæum, and that a limited peritonitis had been set up. This, if the life of the child had been prolonged, would, no doubt, have become more generalised. In early life, when inflammation extends from the chest to the abdomen, the symptoms induced by the complication are often curiously insignificant and few. In this case the child made no complaint of pain nor did he show any sign of uneasiness when pressure was made upon the abdomen. The only symptoms of the peritonæal lesion were the slight swelling of the belly and the appreciable increase of tension of the parieties over the site of the inflammation.

Medical Times and Gazette.

SATURDAY, OCTOBER 18, 1884.

THE General Medical Council finished its Session on Thursday, after sitting for nine days. The business done may be summed up very briefly. The Council sanctioned the proposed co-operation of the two English Royal Colleges; it referred the subject of professional examinations to the Branch Councils, to consider and report thereon; and it drew up a new scheme of preliminary examination. It will probably meet again shortly after Easter. The President in his valedictory remarks foreshadowed the possibility of the Council's having in future two sessions in every year. He expressed his surprise that amidst all the criticisms upon their conduct, which were no doubt so salutary for them, it had never been pointed out that they were practically *in absentiâ* for eleven months in the year. If the President had put himself in a medical journalist's place, and realised what the meeting of the Council means to him—the strain on space and effort that it involves, without any very obvious advantage or return—he would have seen good reason to fear that the luckless journalist who should propose a second Session of Council would have been drummed out of his regiment in disgrace.

THE closing portion of the discussion on the question of the co-operation of the Colleges of Physicians and Surgeons took place so near our time of going to press last week that we were unable to do more than make the bare announcement of the fact that the sanction of the Council had been given to the scheme. Some analysis of the voting on the several amendments will probably prove of interest to our readers. On Dr. Quain's amendment 13 were against, 5 for, and 6 did not vote. Dr. Lyons' amendment that the scheme be referred back with a view to the Society of Apothecaries being included was rejected by 16 to 4, 4 abstaining from voting. And the motion itself was carried by 14 voting for, and none against it, 10 refusing to vote. Whilst believing that a step in the right direction has been taken by the union of the two corporations, it is impossible to close our eyes to the fact that these bodies must get further powers than those at present given them by their charters if the scheme is not to be practically set at naught. As we understand the matter, it is quite conceivable that a candidate who has presented himself for the final examination, and been rejected in Surgery, but passed in the other subjects, may at a subsequent period present himself at the College of Physicians armed with a licence in Surgery obtained elsewhere in the United Kingdom, and demand that their licence in Medicine be no longer withheld from him. Or the same thing might apply to a man who had passed the surgical portion of the examination, but failed in Medicine. The examination will never take the high position which it is fully entitled to until the two Colleges resolve to recognise the examinations of no outside body at all. We believe that they are quite strong enough to do this, and when they have done it, and not till then, shall we be able to reap the full benefit of the very important step which has received the imprimatur of the Council.

LAST week it was our unpleasant duty to complain that Professor Macnamara had been unnecessarily taking up the valuable time of the Council with an imaginary grievance, and we regret that we should have again to make the same charge. On Friday last nearly an hour was consumed in discussing what one of his fellow countrymen very justly described as a storm in a teapot, in respect of an incident which English ideas of etiquette would certainly never have allowed to come up at all. Professor Macnamara had resigned his seat on the Pharmacopœia Committee chiefly, as we understand it, because he could not get his own way, and prevail upon the rest of the Committee to adjourn at 6 o'clock on the occasion of a special meeting. There were other reasons. A pet preparation of his had been treated with scant courtesy by one of the Editors of the Pharmacopœia, and refused admission on what the Professor considered insufficient grounds. This part of his complaint was completely answered, it seems to us, in the fact that he had not availed himself of the opportunity afforded him of giving due notice of any suggestions. As to the other part of his grievance, for most people it would have been enough that a majority were in favour of finishing the discussion at the one sitting and avoiding the necessity of an adjournment, and they would have remained with a good grace or have asked permission to withdraw, and trusted their colleagues to do any business that remained in a proper and loyal spirit.

SELDOM, we believe, has the Council entered upon a more misguided or mischievous course than it did on Monday, when it undertook to resolve itself into a Committee of the whole Council to consider the subject of preliminary education. The members who before had been most eloquent on the subject of supervising the professional examinations by means of experts, were now most strongly convinced of the superior fitness of the Council, as compared with anybody else, to deal with the subject of preliminary education. And so they went into Committee, and at the end of the first four hours they had succeeded in agreeing that so far as English was concerned they would leave matters as they stand. At this point Mr. Simon considered that they had accomplished a great deal, Sir Henry Pitman avowing that they had done nothing. Both are in some degree right, they had done a good deal in that they had left well alone, and had not done any harm, and they had done nothing inasmuch as they were exactly in the same state as if they had not discussed the matter at all. What possible good can result from such a discussion as this? Are the Council prepared to enforce their recommendations? Supposing that they had decided that dictation should form a definite part of the preliminary examination, do they suppose that they could have got any of the general educational bodies to insert it into their list of subjects required, if it was not already there? Fancy

dictation being asked for in Smalls at Oxford or the Little-Go at Cambridge. The thing is preposterous. If the Council are really of opinion that the standard of their preliminary examination is too low at present, as they certainly seem to agree, by all means let it be raised, but surely the way is to strike out from the list of bodies those whose examinations are not up to what they consider ought to be the standard. If dictation is really necessary would it not be as well to have an ante-preliminary examination in which the alphabet and the multiplication table up to six times six formed the *pièces de résistance ?*

One of the most senseless things done this session was the insisting on Wednesday that Prof. Humphry should put his motion as to leaving out the optional subjects. The feeling of the members on the subject had been amply expressed in the course of the preceding debate, by the references to Greek and modern languages, and Prof. Humphry, recognising this feeling, made a most laudable attempt to save the time of the Council by not proposing it. The opposition with which this suggestion of his was met showed the sort of spirit that actuates many of the Council, for no fresh arguments were used in favour of the optional subjects beyond those already adduced, in deference to which Prof. Humphry had suggested the course which he was not allowed to follow. We do not quarrel with the President for his ruling—under the circumstances he could not have done otherwise—but forty-five minutes were frittered away for reasons best known to the majority, certainly not even for airing their own views on the subject.

The decision of the Council on Thursday not to make any exception in favour of the Universities in respect of elementary mechanics was another piece of absurdity. Nothing can be more futile than for a body to pass resolutions they cannot enforce, and for four and twenty doctors, however distinguished in their own line, to presume to dictate to the Universities on a matter of general education can have but one effect, viz., to bring their own body into ridicule. Earlier in the afternoon they completely upset the work of the two previous days in respect of raising the standard of preliminary education, by resolving that candidates should not be required to pass in all the subjects at once. This showed that they did not understand the objects of a preliminary examination, the main object, very clearly set forth by Dr. Heron Watson, being to find out what sort of an education a boy has received, and what sort of use he has made of it. Where is the hardship of asking a boy to be examined in Latin a few months after he has shown a competent knowledge of it? If he knows any Latin at all a few months would not make any difference to him.

A wet evening induced very few members of the Ophthalmological Society to attend the first meeting this Session on Thursday sen'night. The bill of fare provided, though small, was good of its kind, and merited a larger audience. Mr. Nettleship and Professor Fuchs, of Liège, contributed cases of impaired vision, due apparently to the vapour of bisulphide of carbon, and the subject was so new and so important that the President nominated a small Committee to see if anything further could be ascertained in respect of it. Dr. Brailey contributed three cases of detachment of the retina treated in different ways, in which he seemed to have had unusually good results with tapping. Mr. Adams Frost read an account of two cases of night-blindness, and Mr. Arthur Benson detailed the results of his trials of cocaine, the new local anæsthetic of the cornea. Neither he nor those who joined in the debate have found reason to put much faith in it.

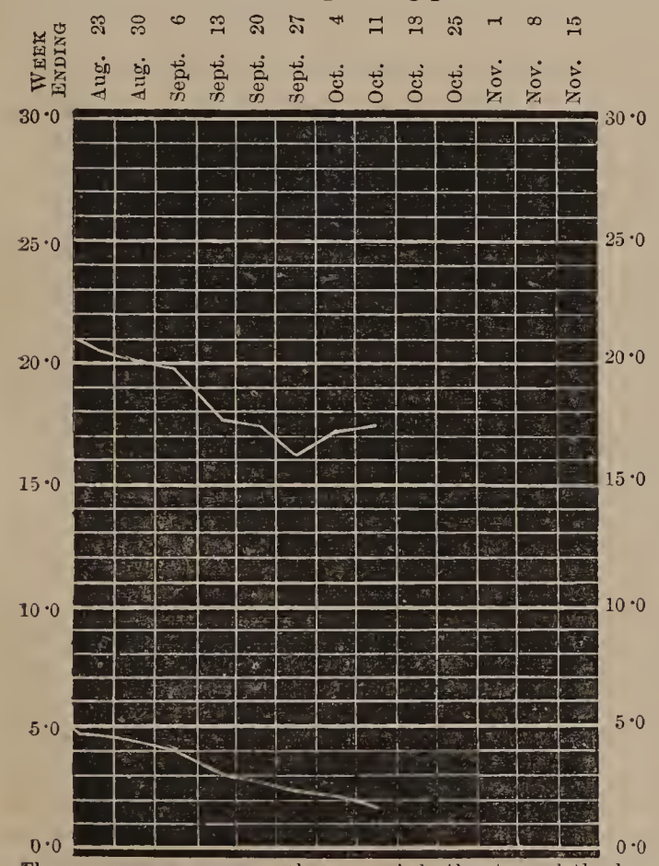
The Clinical Society entered upon a new Session on Friday, October 10th, a very fair attendance of members being present at the first meeting. A slight innovation in the course of proceeding, suggested by the President at one of the last meetings in the summer, was tried for the first time and received general approval. It consisted in the serving of tea and coffee before instead of after the meeting. The change is very appropriately made during the presidency of Sir Andrew Clark, who strongly holds that the consumption of these decoctions at bedtime is a most unphysiological proceeding, whereas their effect when taken before the meetings is eminently beneficial to the vigour of debate owing to the wakefulness which they so frequently induce. An interesting paper by Dr. Hadden upon certain nerve symptoms in rheumatic affections was followed by a rather weak discussion on the subject of the nerve influences in chronic joint disease. A great deal has of late been ventured upon in this direction, and a feeling evidently prevails that more observation and study are necessary before so obscure a condition can be fairly understood or explained. A paper communicated by Mr. Croft on preputial calculi, and an interesting account of a case of urticaria pigmentosa, by Dr. Crocker, failed to elicit any discussion.

An important practical question, however, was raised by Dr. Mahomed, with respect to the early treatment of peri-typhlitis. In commenting upon a case related by Dr. Finlay, he stated that he had long thought that an operation might be performed for removal of concretions in the vermiform appendix, which were generally found to be the cause of ulceration in that region. In one such case his success had been complete, but only one case had as yet been attempted. The idea was very favourably received by many surgeons present, notably by Mr. Bryant who, we believe, will shortly bring forward the whole subject in a more elaborate form in his series of Harveian Lectures.

The session of the Liverpool Medical Institution was opened, on the 9th instant, by an address from the President (Dr. Gee), "On the History of the Liverpool Medical Institution since 1864." He sketched in an able manner the most interesting features of its history from its foundation in 1779 till 1864, and then gave more in detail the social and developmental history of the society from 1864 up to the present time.

In conclusion, Dr. Gee generously offered a donation of 100*l.* to the society upon the same terms as the first president of the institution, Dr. Dawson, who gave a similar donation. His offer was received with much appreciation by the members who were present in large numbers. During the evening Mr. Paul showed, by means of the oxy-hydrogen lantern, a number of micro-photographs of diatoms, &c. Dr. Barron showed several beautiful frozen sections of the human body, and a series of vertebræ, much enlarged and carved in oak for demonstrative purposes. Dr. Briggs showed ovaries mounted in glycerine jelly. Several instrument makers showed a select collection of instruments.

The most noticeable fact in connection with the Registrar-General's last weekly return of the health of the 28 great English towns, is the extremely low zymotic death-rate, especially in London, where it only amounted to 1·7 per 1,000. The general death-rate in London was 17·5, and the deaths were 184 below the average. It is to be hoped that we shall have a series of low returns before the winter comes as a set off against the comparatively high death-rate of last quarter, which was 20·9 per 1,000 as compared with 20·5, 18·6 and 18·8 in the corresponding periods of the three



The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eight weeks.

preceding years. The deaths from the zymotic diseases in London last week numbered 145, or 94 below the average. Small-pox and measles caused 9 each, scarlet fever and diphtheria 16 each, whooping cough 11, enteric fever 26 and diarrhœa 57, only four of which occurred between the ages of 5 and 60. The small-pox epidemic still decreases; 68 new cases were admitted into hospital last week as against 129 and 106 in the two previous weeks. The deaths from scarlet fever were as many as 62 below the average. The returns from Scotland were not very favourable. The general death-rate of the eight chief towns was 22·8 and the zymotic rate 5·0 per 1,000. Glasgow had a zymotic rate of 7·2, which was only exceeded amongst the English towns at Preston, which had a rate of 7·3.

On Monday the Duke of Northumberland laid the foundation stone of the new Infirmary for Diseases of the Eye, at Newcastle. The institution dates from seventy years back, and the old premises had naturally long out-grown the demands upon them, patients having to be constantly turned away. The committee wisely determined to build an entirely new hospital, and the plans show that they have determined to spare no expense to make their new building a solid and well arranged structure. Funds of course are wanting, but in such a wealthy part of the country there should be no difficulty in collecting them. At the luncheon which preceded the ceremony of laying the stone, the Duke of Northumberland made a sensible speech, and Dr. Jeaffreson in responding took the opportunity of championing specialism in general and his own special hospital in particular. Some of his remarks were very *àpropos*. We have only space to quote a few sentences: "Some years ago he attempted to make an estimate of the proportion of eye disease cases to the general population, and he came to the conclusion that not less than one in ten suffered some ocular defect. This estimate, though it might seem high, he was inclined to think was below the mark. Defects requiring correction by proper glasses, when neglected or overlooked, gave rise to the most anomalous symptoms. This matter was one of considerable importance in these days of compulsory education, when children were taught to use their heads almost before they could use their legs. He had known children who were thought to be stupid and idle, and had been much injured physically and morally by punishment, who after all, were only struggling with difficulties arising from some ocular defect. The popular idea of putting off the use of spectacles as long as possible was an erroneous one; and many thousands of eyes were lost, or, if not lost, had deformities developed in them by acting on this idea. It would be well if some form of examination were made compulsory at all public and Board schools, and it would be to the advantage of the community if this examination were carried further than the eyesight, and a complete but brief medical sheet were kept for each child."

I informed you last week, writes our Paris correspondent, that Dr. Wolfe had come to Paris, at the request of several distinguished oculists, for the purpose of demonstrating his method for the treatment of detachment of the retina. He has thoroughly established the success of his operation in restoring sight in cases of total blindness from this hitherto incurable disease, and has shown that the posterior hemisphere of the eye can now be brought within the range of operative interference. The operation has already been adopted by several ophthalmologists in

Paris, and we shall probably hear of it in future, not as a novelty, but as a permanent advance in ocular surgery.

Paris, where popular feeling has seized and expanded the cholera reports from Toulon and Marseilles with all the vividness and exaggeration of the reflector in a Thompson's telegraphic receiving instrument, has been somewhat emphatically advised as to the necessity of setting its own house in hygienic order. The imperfections of a quarantine system are powerful for evil in direct proportion to the sanitary imperfection or otherwise of the district which it is designed to protect. Whether cholera be a disease which originates *de novo*, or whether it march like the "army-worm" *pari passu* with those changes of climate and temperature which are severally necessary to the successive stages of its development, or whether it be imported in the form of sprouting microbes attached to the persons of travellers or to their baggage, and even to disinfectants (for a consignment of chloride of lime is said to have been "fumigated" at one quarantine station), foul dwellings, dirty habits, and foul water are the conditions which above all others invite its appearance.

At the risk of startling them into panic, Dr. Daremberg has done his fellow-citizens good service in directing attention to the sources of the water supply of the suburban localities of St. Denis, St. Ouen, Aubervilliers, Clichy, and Levallois, and of a part of the 18th Arrondissement of Paris (Montmartre). The water is drawn from the most infected part of the Seine, below the mouth of the great sewer which pours into the river a large portion of the impurities of the city. The analysis of this water exhibits the presence of a proportion of 0·002 per cent. of organic matter, while good drinking water only contains 0·0001 per cent., and water just fit for culinary purposes, 0·0003 per cent. The source of the pollution being too well known, it may be admitted that each inhabitant of the above-mentioned localities drinks about *one cubic centimetre* of fæcal matter in the space of a week. This state of things goes far to account for the habitual prevalence of typhoid fever in Paris, and is a standing danger in time of cholera.

In reply to Dr. Daremburg's statement, Professor Gautier, in the name of the *Conseil d'Hygiène*, makes the following remarks: The water supply of Paris is divided into two distinct classes; 1st, public services, namely, watering the streets, supplying manufactories and bathing establishments. The water for these purposes is derived from the Canal de l'Ourcy, a tolerably impure source, since the canal is the main artery of navigation to the port of La Villette, on the outskirts of Paris, which ranks third among all the ports of France, after Marseilles and Le Havre. 2nd, private services, namely, water distributed in houses for home purposes. This is derived from the two small rivers, La Dhuis, and La Vanne, both of which are remarkably pure. Each inhabitant of Paris receives 220 litres of water daily, being about 450 pints. The litre is nearly equivalent to two pints and one-third.

It is proposed, as soon as possible, to supply the suburban localities above-named with water drawn from the Seine above Paris, which, of course, is much preferable to water drawn from that river below the great sewer at Asnières. Still, as Dr. Rochard observes, the Seine above Paris is already polluted by the dejections of a population of eighty thousand souls. These sanitary problems which affect in so large a degree the welfare of the city, cannot be satisfactorily solved without enormous expense. Our forefathers were less exacting, and in many respects less well provided for; but they had the advantage of drinking clean water, for at the beginning of the present century the Seine was a pure stream, while it is now polluted, not only by the excreta of three millions of souls, but also by the residues of a multitude of manufactories, which do more to injure the river than all the impurities evolved from the human body.

We are glad to see that the British visitors at the recent Copenhagen Conference have not forgotten or neglected the *convénances*. The following address to the King of Denmark, condoling with him on the destruction of his palace, has been drawn up and signed by 64 of his late guests. Every effort, we hear, has been made to make the list of signatures complete.

To His Majesty Christian IX., King of Denmark.

May it please your Majesty—We the undersigned English, Scottish, and Irish members of the International Medical Congress lately held in Copenhagen, desire very respectfully, to offer to your Majesty the expression of our profound regret at the destruction of the grand and beautiful palace of Christiansborg. We very gratefully remember the honour conferred on us in that palace, where we were received and entertained with splendid and graceful hospitality by your Majesty and the Members of your Royal Family. The recollection of that reception and of all the proofs of welcome which were shown to us in the city of Copenhagen, impels us to offer, and to hope that your Majesty will graciously accept, this assurance of our sorrow for the loss which your Majesty and Denmark have sustained.

Had any more evidence been wanting, after the *Times'* letter of last week, to show up in the fullest light the unfairness of Mr. Fitch's attack on Dr. Crichton Browne, it must be admitted now that it is supplied in full measure. Dr. Browne, in a second letter to the *Times* of the 13th instant, goes into some detail in vindicating his method of enquiry from the charge of carelessness and fallacy. The important point he makes, that the sum of morning, afternoon, and evening headaches constantly corresponded with the sum-total of headaches *previously* counted, is surely by itself clear enough to convince even Mr. Fitch that he has been very unwise in so lightly contemning Dr. Browne's powers of observation and reasoning. Scarcely less important, as showing that the enquiries did not lead to haphazard results, are the facts alleged by Dr. Browne, (1) that the proportion of headaches increases *pari passu* with the standards; and (2) that it is always higher among girls than boys. After reading, indeed, the whole of Dr. Browne's letters, we

must sincerely commiserate Mr. Fitch for the harrowing process he is undergoing. Not only has Dr. Browne conquered him by argument wherever demonstrative argument is possible, but he has shown, moreover, that when statement is opposed to statement in the two reports, the doctor has more evidence in reserve than the inspector. Mr. Fitch will find it hard to make nothing of Dr. Browne's reiterated assertion, not unattended by good evidence, of the frequency of home-lessons, and "keeping in," and of the considerable raising in late years of the standard of proficiency required by the Code.

Although we now must yield the palm to Dr. Browne whenever he and Mr. Fitch have crossed swords in this controversy, we cannot endorse Dr. Browne's opinion that there is as yet any strong case made out for a connection between the requirements of the Education Code and increased fatality from nervous diseases. Dr. Browne's case is good enough without this contention, which would at any rate be very difficult to prove for years to come. The complexity of causes of "nervous disease" is overwhelming, and the solution of the question will not be effected by the method of agreement alone. Besides, before any scientific, and much more any practical, application can be made of such statistics as those of Dr. Rabagliati, it would be necessary to give, in the first place, a good working meaning to the term "nervous disease;" and in the second to have some little reason for supposing that even a majority of cases in children returned under that heading by practitioners all over the country were correctly diagnosed. And a still further source of fallacy in the conclusion of Dr. Rabagliati that "the working of the Education Act is a main part of the cause of the proportional increase of the mortality from nervous diseases at school ages," is the very great probability that many more such affections, considering the rapidly advancing knowledge of the subject, are recognised and described now than formerly. But this point, the only one which we think Dr. Browne might have omitted, or but incidentally touched upon in his report, has not been seriously attacked by Mr. Fitch. He has apparently, with studied fool-hardiness, rushed headlong on when defeat was almost certain, trusting only, for a possible victory, to throwing an unmeasurable quantity of the dust of inaccurate statements into the eyes of the judges of the combat. But the dust seems to have been already wiped away.

In a leading article on this over-pressure question, which is evidently written by one not biassed in favour of Dr. Crichton Browne, the *Scotsman* nevertheless admits that "it is desirable that the over-pressure question should be settled as speedily as possible, in the one way or the other. If it really exists, it must be doing serious harm to those who are its victims. If it does not exist—or does not exist to the extent that is alleged—harm is being done in other ways. The whole educational world is unsettled. Many nervous people are kept in a state of apprehension. Efforts for the improvement and the further extension of education are retarded from a timid feeling that the advance may mean an increase of injury to the rising generation. On all these grounds it is of the utmost importance that the cry of over-pressure should be put down, either by putting down the thing if it be found to exist, or by showing the hollowness and impertinence of the cry if the thing be non-existent." The only way to secure this object is, as we have pointed out, by the appointment of a special commission of enquiry into the subject. It is very doubtful, however, whether we shall get it.

On the question of Educational Over-pressure Dr. Dyce Duckworth writes to us—"I have no definite experience to set forth on the question of over-pressure in elementary schools, but I have a very strong opinion on the matter. I believe it to be a most vicious and unwholesome practice to force schooling and mental training on young children of all classes. Each case really demands a separate determination as to what is fit and proper. I think the present Procrustean, un-English, 'steam-roller' efforts at uniformity in education, at any age, to be thoroughly bad, and especially so in the case of ill-housed and poorly dieted children. Most children require a good home and a good mother's training only till they are *six* years old, and afterwards very gentle education up to eight or nine years of age. The School Board training, I think, is far in excess of the requirements and proper demands on the ratepayers' pockets, and the results, so far, are not satisfactory in the shape of right-minded, contented, and virtuous lads and girls. Too much is attempted for the majority. The system of premiums to successful teachers is simply pernicious to the last degree. I infinitely prefer the work done in the National Church Schools under the old system, and only wish it was co-extensive with the numbers that it ought to deal with."

The Chancellorship of the Glasgow University having become vacant through the death of the Duke of Buccleuch, there is much speculation as to who is likely to be appointed as his successor. The names of the Earl of Stair and the Earl of Rosebery have been mentioned, and both of these noblemen possess qualifications which might fairly recommend them to the Members of the Council of the University with whom the decision lies. The former, it is reported, has already given his consent to be nominated for the post. The Duke of Argyll has been suggested as a most eligible chancellor, and admirably fitted to adorn the office, but there is unfortunately an obstacle in the way, viz., the Duke is at the present time Chancellor of the University of St. Andrew's. It is difficult to see why there should be any objection to the Marquis of Bute, unless it be on the score of religion, but it is well known that the Marquis would in no way exert any influence which he may possess in that direction in the University.

Dr. Russell Reynolds will deliver the annual Harveian Oration at the Royal College of Physicians on Saturday, the 18th inst., at 4 o'clock.

It will perhaps be a kindness to those practitioners who during the past year have favoured us with intelligence of their change of address, as well as to others, if we call their attention to the advertisement of the Medical Registrar, which appears in another column. It is excusable, if, in the turmoil of moving, men forget to include the Medical Registrar amongst the friends and clients to whom they decide to notify their change of quarters; but the Registrar has a way of not forgetting such omission, and the consequences may turn out serious.

Last week Mr. Sampson Gamgee, on resigning the presidency of a local debating society, delivered an address on the relations of the working classes to medical charities of Birmingham. He was able to show that since 1867 the yearly contributions by the working classes to these charities has risen from 500*l.* to nearly 10,000*l.*, which is more than one-fifth of the total expenditure of the institutions concerned. Of this sum considerably more than one-half was collected in connection with Hospital Saturday, while close upon 2,000*l.* was directly contributed in the form of registration or admission fees. Some of the smaller special hospitals received from the working classes more than their total expenditure. The one unfavourable consideration in connection with this subject is that a large proportion of these contributions must have been drawn from funds which previously were used to pay for the attendance of local practitioners. Since 1867 the hospital population, as Mr. Gamgee terms it, has risen from 66,671 to 144,750, or one-third of the population of Birmingham. This is not a subject for congratulation, for it is not fair to the medical profession that such a large proportion of the population should obtain medical advice without the advisers being a penny the richer for it. We are glad to see that this blot on the present system is fully realised by Mr Gamgee, who strongly advocates the necessity for revising the present system of hospital administration, "which inadequately provides for the public health, works great injustice to many distinguished junior members of the medical profession, and is rapidly spreading the canker of a demoralising pauperism through this vast community." The justice of making some payment to the medical officers of hospitals thus largely subsidised by the patients is also recognised by the *Birmingham Daily Gazette*, which, in commenting on Mr. Gamgee's paper, says: "The serious question of the gratuitous labour of medical men and where it is to end must sooner or later be faced. If all—or nearly all—the recipients of the charities contribute to their sustenance then medical services should be remunerated." The subject is one which is evidently coming on for solution, and we shall not be surprised if it is dealt with and settled in the go-ahead cities of the North long before we are ready to consider it in London.

The *Lancet* has had the good fortune to discover a new picture by Rembrandt, entitled "Vesalius at his Dissections." This painting had previously been claimed as his own production by a modern painter, E. Hamman, and hitherto the world has been blind enough to accept it as his. Now that the *Lancet*, however, has discovered its real authorship, the picture galleries and picture-lovers of Europe will no doubt at once enter into a keen competition for its possession. Jesting apart, we have seldom seen so many errors compressed into so few lines as in the *Lancet's* notice of the two German lithographs, the publication of which we noticed a few weeks ago. In the first place, the picture of Vesalius is of course not by Rembrandt. Vesalius died in 1564, forty-three years before Rembrandt was born, and the great artist was too true a Dutchman to paint a man out of his inner consciousness. In the second place the anatomist whom Rembrandt has immortalised in "The Anatomy Lesson" was named Tulpius, and not Talpius; and in the third place, the lithographs fortunately are not of the same size as the pictures. A reproduction of the same size as Rembrandt's celebrated picture at the Hague would inconveniently crowd the wall space in most consulting-rooms.

It appears that for several years we have had a poet of high rank in our profession without knowing it. Until the *Spectator* noticed it on Saturday last, we believe that no English Journal had called attention to the epic of *Dreizehn Linden*, a poem by a German physician which is said to be the most important contribution made to the poetical literature of Germany since the days of Heine. Its author, Dr. F. W. Weber, now a septuagenarian, practised, and for aught we know still practices, at Lippspringe, a little health resort in the north-west of Germany, sheltered by the Teutoberg forest, and recommended mainly for consumption and scrofula. Dr. Weber appears not to have suffered from his *entourage*. His is no sickly epic, but a robust and healthy poem dealing with the struggles of Franks and Saxons in the years that followed the death of Charlemagne. We ought to be proud of this *confrère* of ours. The medical profession has not produced many authors of the first literary rank. From the time of Sir Thomas Browne till now we only recall two whose works are likely to live by their literary charm alone—the two Olivers, Goldsmith and Wendell Holmes. We cannot honestly claim Keats, and we have a doubt as to whether we have a right to Goldsmith. The great writers seem to come from less definite and laborious professions than that of Medicine, the serious prosecution of which tends to make one think lightly of literary power as such.

A correspondence of considerable interest has lately been taking place between Dr. Smyth, of Islington, and the Holborn Board of Guardians relative to the removal of fever cases. It appears that Dr. Smyth had a child under his care suffering from scarlet fever, and that he recommended the mother to apply to the relieving officer for an order for the removal of her child, and that she had told him her request had been refused, on the ground that the father of the child must apply in person. The relieving officer, on being asked for an explanation, stoutly denied that such an application had ever been made to him or refused. It was the rule, he said, that the head of the house must

apply for relief in person, but this rule did not apply to fever cases, and no order for a fever case had ever been refused on that ground. After so complete a denial of the charge, of course there is nothing more to be said ; but it would be well if there was a distinct understanding that an order would be immediately granted to anyone on the production of a properly filled-up medical certificate to the effect that in a certain house there was a case of infectious disease.

The Berlin correspondent of the *Wiener Medicinische Zeitung*, continuing his account of the Schweninger affair, states that after the Berlin Medical Faculty had protested against Dr. Schweninger's appointment as Extraordinary Professor of Dermatology, the official *Norddeutsche Allgemeine Zeitung* gave what is regarded as an explanation of the occurrence, namely, that it was quite within the province of the Minister of Education to make the appointment without any consultation with the Faculty. This formal right, however, had never been disputed, but only the questionable mode of its exercise in the present case. For, not only had Dr. Schweninger not exhibited any proficiency in this branch of medical science, but he had not come to Berlin with a very good character. If he had enquired, the Minister would have learned that he had been already denied admission to the Munich Faculty because he had been condemned by the law courts to several months imprisonment, which he was only prevented undergoing by means of a royal pardon. Since then he has succeeded in becoming a fashionable physician in Berlin, and after his successful treatment of Prince Bismarck and his son, his rehabilitation was commenced by giving him the order of the Red Eagle, and nominating him to the *Reichgesundheitsamt*, preparatory to the bestowal of the professorship which has made such a stir. Dr. Levin, a great friend of Count William Bismarck, Professor of Syphilitic Diseases in the Faculty, who also held the Chair of Dermatology "provisionally" for twenty years, now found that his increasing practice compelled him to resign this, and Dr. Schweninger was forthwith appointed to it.

To all who have watched the development of pædiatric studies in Italy, the sad intelligence of the death of Professor Luigi Somma, of Naples, the founder and director of the recently established periodical entitled *Archivio di Patologia Infantele*, and devoted to the study of children's diseases, will cause sincere regret and sympathy. He died of cholera on the 19th of September.

At a recent meeting of the Metropolitan Board Teachers' Association, which consists of 2,078 head and assistant masters and mistresses employed in 320 London Board Schools, it was resolved unanimously : "That the Metropolitan Board Teachers' Association endorses generally the report of Dr. Crichton Browne on over-pressure and worry in schools, and further thanks him for his report."

There are always two sides to every question, however simple it may seem to be, and there appears to be one aspect of the great question connected with the amalgamation of the Colleges of Physicians and Surgeons which is in danger of being overlooked ; at any rate it has as yet received but very scant attention at the hands of the Council. It is this—Have we got an examination at present which is so arranged that the man who can pass it is safe to practise and no more ? In other words, is this new Examining Board going to establish a minimum which, if a man cannot attain to, he is to be regarded as not having sufficient knowledge to practise ? If that is the case then it follows either that the examination as hitherto conducted by the College of Physicians for its licence, so far as medicine is concerned at any rate, has been unnecessarily high, or that the standard in medicine adopted by the Apothecaries' Society has been dangerously low. We are not now speaking of the examination in the three essential subjects, but we want to make it quite clear that if the examination at the College of Physicians as conducted in the past is to be accepted as the minimum of safe knowledge in medicine, then the Council will be wanting in their duty to the public if they do not at once announce that the examination at the Society of Apothecaries does not afford a sufficient guarantee of trustworthiness to practise.

What we must have is a minimum standard in the three essential subjects of medicine, surgery, and midwifery, and we do not believe that the new board about to be established will give us that. The men who are turned out under the new qualification will, we doubt not, be on the whole a well educated and highly qualified body of men, fit to undertake any class of family practice, but they will have spent a considerable amount of time and money upon their education, for the majority will doubtless avail themselves of the subdivision of the examinations to take them piecemeal, and so the curriculum in a large number of instances will be lengthened in comparison with what it is at present. But these will not be the sort of men who will, by the superiority of their advice and treatment, drive the unlicensed practitioner or herbalist out of the field, for the simple reason that they will never come into competition with him. It will not be worth a man's while who has gone through the decidedly expensive education that most will go through to obtain the double qualification, to practise amongst those who cannot afford to pay such fees as would be likely to afford a fair return for the outlay incurred.

It is a duty that the College of Physicians and College of Surgeons owe to their licentiates and graduates that they shall not lower the standard of examination. Mr. Marshall told us that one of the reasons for not lowering the fees was that it would be unfair to those who had already paid the higher fees for the same qualification ; this is just as applicable in the case of examinations as in the case of fees. It seems therefore tolerably clear that the new qualification will not represent the lowest standard of professional education, and a considerable number of men

will want something cheaper and easier if they are to be able to earn a living for themselves as registered practitioners. If the majority of those who practise amongst the poor in this country are in future to carry on their practices on the strength of qualifications not obtained out of England, it is certain that we must have something more approaching the examinations in other parts of the United Kingdom, as regards easiness and cheapness, than what the new board is apparently going to offer.

We have only received returns from two of the medical schools at present as to the fresh entries. At St. Bartholomew's there are 125 regular students and 13 for special courses, not including those entered for preliminary scientific or matriculation classes At the London Hospital there are 83 full students and 46 special students. We understand that the entries at Guy's, King's and Westminster are not at present as numerous as could be expected or wished by those connected with those Institutions.

The Sub-Committee appointed by the Association of Fellows of the Royal College of Surgeons to prepare a draft-scheme of reform has concluded its labours. The report is, we believe, to be presented to the General Committee some time next week for discussion and approval. It will then be submitted to a General Meeting of the Association, and afterwards to the Fellows and Members of the College, who will be invited to assist in carrying out the objects of the Association. The scheme is likely to embrace not only college administration, but also the question of the relation of members of the Corporation to the College, and matters concerning the examinations and diplomas.

Only a small College met in Pall Mall, on Thursday evening, to hear Sir Henry Pitman report that the General Medical Council had sanctioned the co-operation of the Royal College of Physicians and Surgeons. Dr. Quain reiterated the objections he had already expressed at the Council meeting, but he was completely out-voted, and Sir Henry Pitman, Dr. Ord, and Dr. Norman Moore were appointed visitors to represent the College on the Conjoint Board.

THE FUTURE OF THE ROYAL COLLEGES.

During the past twelve months it has been the fate of the Royal Colleges of Physicians and Surgeons to attract a good deal of attention. Important questions have come before the College of Physicians on which the decision of the Council was looked forward to with great interest and with an amount of anxiety which the event proved to be perfectly justified. Questions too have been raised with respect to the College of Surgeons which cannot yet be regarded as having received a definite settlement. We are still in the dark as to what action the Council will take on the grave constitutional questions which have been recently raised, and we have very little information as to what use they will make of the grand opportunities presented by the wealth which is destined to them. On the latter point all will agree with Mr. Marshall that the time has not yet come for the College to count its chickens, but it is to the interest of the profession, for whom in this matter the College ought to look upon itself as in some sort trustee, that the chickens shall be well brought up and disposed of to the best advantage. Many weeks ago we pointed out that the one important duty which this new possession of wealth would impose upon the College would be the foundation of an institute of pathology. We take no credit to ourselves for priority of discovery, for it is a fact perfectly obvious to everyone and we are glad to see it taken up by no less an authority than Dr. Wilks, who, as for many years an Examiner in Medicine at the College, may be expected to have some influence with its executive. The organisation of a pathological laboratory has already been initiated on a small scale at the Health Exhibition, and it is not, we believe, beyond the bounds of possibility that this undertaking will be endowed to a certain extent out of the profits of the Exhibition and continued as a permanency under the control of its present efficient head. If this be so, we see no reason why the infant should not in due time be bodily transferred to Lincoln's Inn Fields to feed and fatten on the College chickens as they are hatched. No words are needed to set forth the enormous benefit which such an institute would have upon the success of scientific research in this country, and we are glad to think that the opportunity has come to the College at a time when wise and unselfish counsels are likely to make themselves heard. It may be taken for granted that the influence of Sir James Paget, Sir Spencer Wells, and Mr. Marshall —all of them endowed with the imaginative power needed to rise to a great occasion—will be cast in favour of devoting some of the new fund to that form of pure research which has hitherto been so inadequately endowed in this country. We may point out that the influence of such a course would be no less beneficial to the College than to Science, making it realise that it has a wider and airier field open to it than that of a mere examining body, and a greater claim upon the respect and loyalty of its members than that involved in its having opened to them the portals of practice, and freed them from the claims of the jury box.

The disposal of its wealth when it falls to it will, however, be an easy task compared with the solution of the difficult problems which the College has taken upon itself in entering upon the arrangement with the College of Physicians, which has just received the sanction of the Medical Council. It is easier to discern what will be the logical outcome of that arrangement, than to believe that the College will find the courage to follow it thither. We have pointed out some of the difficulties elsewhere, but may here reiterate that we see no means of escaping from the *impasse* but for the two Colleges to boldly break their way out of it by deciding that they will for no purpose recognize any examinations but their own. This decision once taken, we should at length have the real national "examining board," which Sir Henry Acland painted in such glowing

colours when he recommended the scheme to the College of Physicians in the summer. The double diploma of the Colleges would then become almost the only viable diploma in the country. It would be taken as a matter of course, like the German State Diploma, by everyone who wished to practise Medicine, whatever University Degree he might possess, and if it were only found possible to grant with it the title of doctor, an end would be put at one stroke to some real and many imaginary grievances, as well as to a fertile subject of discussion in the medical journals.

Two objections will be raised to such an innovation: first, that the diploma would be too difficult, and secondly, that it would be too dear, for the lower order of medical students. The first objection would, we hope, be met by improvements in medical education, and by the gradual entry into the profession of men of a higher average capacity than at present. It could also be met by the Society of Apothecaries obtaining powers to examine in surgery, and thus to give a licence which would represent a complete and fair test of efficiency though it would not carry with it the rank or prestige of the diploma of the Colleges. As to the second objection, we trust that the course of events will present an easy solution. In the first place, though it may have been quite right for the College of Surgeons with its large financial responsibilities to refuse to lower its fees, until it is actually proved that examination by co-operation is cheaper than an examination with doubled parts, we hope that no long time will elapse before the Colleges find themselves able to considerably reduce the aggregate fee. In the second place, some portion of the new endowment of the College of Surgeons will no doubt be devoted to the maintenance of the library and museum, and will thus enable it to remit the fines on candidates for its diplomas by which those valuable institutions are at present mainly supported. And in the third place, as Mr. Teale has recently pointed out, the College will probably find it advisable to make considerable changes in the plan of its examinations, which might be rendered much less expensive without becoming in any way less efficient. At present the examinations press very hardly on the important body of provincial students, and with the increase in the number of tests contemplated by the new scheme, the burden will be still more severely felt. The provincial student, in order to obtain his double diploma, will have to come up to London certainly three, and more often probably four or five times before he passes his final examination; and each time he will have to stay several days in town. We have nothing but praise for the policy of dividing the examinations into as many steps as possible, but unless some considerable change is made in the manner of conducting them, such division will be absolutely intolerable to the students in the distant provincial schools, and will certainly tend to divert them towards the more considerate and kindly Colleges of Scotland and Ireland.

The plan suggested by Mr. Teale would meet many difficulties, and it has this to recommend it, that it has been adopted and found to work well by such an expert in examining as the University of London. It would consist in considerably extending the written examination, both in scope and severity, and by holding it in various provincial centres, as well as at head-quarters. At present the College of Surgeons only plucks about five per cent. of the candidates on the written part of its examination, whereas it plucks something between thirty and fifty per cent. on their *vivâ voce*. The unfortunate students who form the difference between five per cent. and fifty, and whom it would no doubt be easy enough to dismiss at once if more stress were laid upon the paper, have now to kick their heels for days in town, drowning their anxiety perhaps in dissipation until the time comes for the pronouncement of their inevitable doom. If the written part, at any rate in the earlier examinations, were held at the chief provincial schools, this danger and expense would, at least to a great degree, be avoided. It is a serious matter affecting an important and constantly increasing body of men, and if the College is to keep its place as a national institution, it must sooner or later make some such arrangement as Mr. Teale suggests. For our part we see no reason why the *vivâ voce* examinations should not also be held in the provinces. The provincial universities find it possible to get London men to go down to examine their students, while it is surely not altogether inconceivable that some of the anatomical and surgical talent of the provinces might be used to supplement the ordinary examiners of the College. It would of course mean renouncing for a certain number of students the unrivalled opportunities of examination afforded by the College Museum, but it would greatly encourage the formation of provincial museums, if the College refused to examine at any school which had not provided itself with proper preparations. We have said enough, we think, to show that one of our Royal Colleges, at any rate, is at a great turning-point in its career. It has been relieved of the shadow of impending legislation which has long paralysed it, for it may be safely predicted that it will be many years before a Minister of the Crown again touches the thorny subject of medical legislation. Meanwhile the College has a fair and open field before it. It will depend on the policy adopted by it during the next ten years whether it shall fall back into a mere licensing corporation, to be superseded as a matter of necessity by a State examining board when the Government of the day awakens to its defects, or shall blossom out into a great national institution, disposing of its large revenues for the welfare of science and humanity, and hand in hand with its elder consort, the College of Physicians, passing down through the coming generations as the twin mother of all who follow the calling of Medicine in this country.

Glasgow Medico-Chirurgical Society.—At the first meeting of the Medico-Chirurgical Society of Glasgow, held in the Faculty Hall on the 3rd inst., the following gentlemen were elected office-bearers for the present session:—President—Dr. G. H. B. Macleod. Vice-President—Dr. Hugh Thomson, Dr. David Taylor, Paisley. Council—Dr. Maclean, Dr. J. C. Woodburn, Dr. Wm. Whitelaw, Kirkintilloch, Dr. W. A. Wilson, Greenock; Dr. R. Cowan, Dr. J. A. Lothian, Dr. Wm. Patrick, Dr. M. Thomas. Secretaries—Dr. W. L. Reid, Dr. J. W. Anderson. Treasurer—Dr. Hugh Thomson.

GENERAL MEDICAL COUNCIL.

FOURTH DAY.—FRIDAY, OCTOBER 10TH.

Report of the Pharmacopœia Committee—Mr. Macnamara's Resignation of his seat on it.

THE first business of the day after the minutes had been read was to receive the report of the Pharmacopœia Committee, in which it was mentioned that the edition of the present Pharmacopœia was exhausted, and that considerable progress had been made with the new edition. The report concluded by mentioning that Mr. Macnamara had sent in his resignation as a member of the Committee.

Mr. MACNAMARA then asked permission to make a statement. After some general observations he spoke of the immense importance of their not using an empirical chemical notation in the new Pharmacopœia, and said he was glad to understand that the newest notation was likely to be adopted. He complained that his suggestions to the Committee had not been treated with sufficient respect, especially in the matter of the nitrate of copper which he declared of his own knowledge to be a most important salt, but which had been refused on the ground that it was difficult to prepare, and deliquescent. He knew quite well the mode of preparation, and was prepared to advise that full directions should be given with regard to it. He knew too perfectly well that it was deliquescent, but that was not a reason for rejecting it; there were lots of salts as deliquescent, if not more so, already in the Pharmacopœia. His complaint was that when he wrote and made these suggestions, he was told by Professor Attfield that his suggestions must come through the Council. (Dr. Quain explained that the word Committee had evidently been meant, but Professor Macnamara refused to see it in this light. Council was the word written and not Committee). He also referred to the extra meeting which had been held in London, and complained that when he had left the meeting because he declined to sit after six o'clock, the Committee had taken the opportunity to pass several resolutions in his absence on which he was very anxious to have made some observations. So that HE the Professor of Materia Medica in the Royal College of Surgeons of Ireland, and the author of a book on the subject, which had reached a seventh edition, found himself in the position of being on the Committee but not allowed to have any part in the production of the new edition of the Pharmacopœia. He had therefore felt it to be his duty to resign his seat on the Committee.

Dr. QUAIN said that he really felt sad at heart that such a disturbance should have been made. He had really taken infinite pains to give satisfaction to everyone. All the teaching authorities and others engaged on the subject had been requested to supply the Committee with information, and the only body that had not sent them anything was the Royal College of Surgeons in Ireland. (Mr. Macnamara here interposed that they had sent a great deal—they had sent him). Mr. Macnamara had complained that they would not adjourn until the next day, but he, Dr. Quain, knew that they had no right to go on for another day on account of the expense. As it was, the sitting on that one day had cost about 40*l.* more than he had estimated it would, and at 6 p.m. only about ten minutes were required to finish the business in hand, but Mr. Macnamara would not stay, and spent nearly ten minutes in saying so. They had also met the next day for a short time. If Mr. Macnamara had sent in his suggestions beforehand they would have been able to give them a full consideration. He concluded by reading the minutes of the meeting in question.

Dr. AQUILLA SMITH had felt with Mr. Macnamara that they ought not to be called upon to sit after six o'clock, and had left the room with him. After that the Committee had got through an amount of business in ten minutes which at their previous rate of progress would have taken thirty-eight. He considered that they had scamped the business. Dr. Quain had imputed that they had wanted to be paid for the next day's sitting, but for that there was no foundation. As to the expense, he contended that there was ample authority for paying them for extra sittings.

Sir HENRY PITMAN gave his impression as to the close of the meeting which substantially was the same as that of Dr. Quain.

The REGISTRAR explained that the letter which Mr. Macnamara had received inviting him to the next day's meeting was purely unofficial.

The Rev. Dr. HAUGHTON regretted exceedingly what he could not but consider a trifling misunderstanding, and especially that it should have been made public. Turning to the report of the Committee he supposed that Professor Redwood meant "new chemical elements" by the words "new substances," and he suggested some verbal alterations in the wording of the report. As to the chemical notation they should take the newest and best, but it would not be final. He thought that they ought to take the opinion of some professional chemist on the subject.

Mr. COLLINS said he had a reputation for being a peace-maker, and he thought that all this disturbance was based on a mistake. He had been treated he said with the greatest respect and courtesy by Dr. Quain, and he considered that the fact that there were no funds was sufficient reason for their not holding a second meeting. He had retired from the meeting for private reasons, but was quite satisfied with what had been done in his absence.

Mr. MACNAMARA explained that he had said at the time that it was quite immaterial to him whether he was paid or not for the second day's sitting, but he objected to being required to sit after six o'clock.

Dr. QUAIN asked permission to quote from the resolution to which reference had been made to show that they had not the power to spend more money. The resolution was so worded that Dr. Quain had obtained permission for an extra meeting, he stating that the probable expense of such meeting would be about 70*l.*, whereas as a matter of fact it had cost nearly 120*l.* Under these circumstances he was not justified in spending any more.

The PRESIDENT regretted this incident very much, and he could testify from his own personal knowledge to the extreme pains that Dr. Quain had taken to avoid this difficulty, and under all the circumstances he hoped that Mr. Macnamara would withdraw his resignation and allow the report to be received without the reference to it. Mr. Macnamara having assented, the motion was agreed to.

Qualifications for Registration.

Professor HUMPHRY said that he had three resolutions on the notice paper of some importance. The first of these as ultimately modified was: "That in the opinion of the Council no person should be granted a degree, diploma or licence to practise, registrable under the Medical Act, unless he has proved his competency in Medicine, Surgery and Midwifery by passing examinations in those subjects at one or more of the licensing bodies. And that this resolution be communicated to the several licensing bodies with an expression of the hope of the Council that each licensing body will use its best endeavours to give effect to it." The Council, he said, was now entering on a free breathing condition, and he felt that it ought to take active steps to carry out to the best of its ability and power those views which had met with general acceptance. The President in his address on Monday had mentioned certain points that they ought to keep in view, one of which was that no person should get on to the Register unless he could produce a certificate of his competency in Medicine, Surgery and Midwifery. This had long been recommended by the Council to the licensing bodies, all the Bills introduced into the Legislature had contained it as an essential proviso, and it should be the first point to which they should direct their attention and upon which they should insist. He thought that they ought again to send to the licensing bodies a resolution on the subject. There were a considerable number of men on the Register who had passed only in part, and such men were still getting registered. They ought to put a stop to this, and with the co-operation of the licensing bodies they could do so without the aid of a Bill. Unless a person had passed an examination in all these three subjects he had not the requisite knowledge. This opinion was so universally expressed that he could not

but think that bodies which had not already acted upon it would see their way to doing so in the future. He would for the present leave it to them.

The Rev. Dr. HAUGHTON in seconding the amendment did not think it touched the evil completely. The Universities of Cambridge and Dublin had already adopted the same practice, and others also were following. In Dublin a man was allowed to be rejected in one subject. Professor Humphry had underrated the importance of the principle. He was so afraid of the resolution not being carried out that they ought to go further. He did not want it to go forth to the public that the Council approved of the way a man could get put on to the Register. He referred to cases where an otherwise well informed student was ignorant on the subject of fever. Dr. Humphry's proposal should be made compulsory on the licensing bodies, but the Council, though it had the power, had not the moral courage to compel them. They must do something more than pass mere resolutions.

Dr. BANKS said that the motion had his cordial sympathy but he thought that compulsion would be necessary. In the new Royal University he had insisted that six months midwifery should be required before a man came up for his medical degree. There was no subject upon which so much ignorance prevailed. Many men otherwise well educated were utterly and entirely ignorant of it, and had never seen a case. It was to the discredit of the Council that many men had been allowed to pass from their student days with no knowledge on a special subject like this.

Dr. STORRAR would give his hearty support to the motion, but he saw a difficulty in the way. The Apothecaries' Society had no power by their charter to examine in Surgery, how could they refuse to examine a man, and when he had got his licence he could be put on the Register. It seemed to him that there were only two ways out of the difficulty. Either the Society of Apothecaries would become effete, or they would be embraced by the other two bodies. He supported the motion because every expression of opinion was valuable, but it was very difficult to see how it could be brought to bear.

Professor STRUTHERS instanced the way in which the scheme had been found to work in Scotland. He contended that they had the power to insist, and thought the motion far too weak and behind the age. He would require not recommend that under Clause 20 of the Act, the examinations should be satisfactory to the Council.

Mr. SIMON thought that Dr. Struthers had misunderstood the clause. The appeal to the Privy Council was where proper examinations were not held in accordance with the Act, and as long as this was the case, deplorable though it might be, they could not interfere. He agreed with the spirit of the motion, but they must not shut their eyes to the difficulties. He thought that the Society of Apothecaries would immediately appoint a surgical examiner, and saw nothing in their Act to lead him to suppose that they could not do so. They could not prevent a Licentiate of the Apothecaries' Society being registered, and if any question was raised against that society for appointing an Examiner in Surgery, they could reply that Medicine included Surgery, and they could also point to the resolution of the Council that they ought to do so, and that without it the examination would be incomplete.

Mr. TEALE thought that if a man was prevented from getting on to the Register with only a single qualification, it would be a very important step. In Scotland this had already been secured, and also in England, except in the case of the Society of Apothecaries. It was not for the Council to decide points of law; either the Society could examine in Surgery, or keep their licence in suspense. He did not agree with Mr. Simon as to the interpretation to be put upon Clause 20 of the Act, and thought that this resolution ought to be forwarded to each licensing body with a request that it would report to the Council in March 1885 what regulations were in force to secure this result.

Dr. AQUILLA SMITH expressed a decided opinion that they could not do what they were attempting to do, and that an Act of Parliament would have to be obtained before they could refuse to receive on the Register the present qualification of the Apothecaries' Society.

Mr. COLLINS, after referring to his expressed views on this subject on a former occasion, said that in the case of his own body, the number of cases of midwifery required had been reduced from 30 to 20 in order to be in accord with others. As to surgery, one of the Clauses of the Conjoint Scheme had given much latitude to their recommendation, and they had since acted upon it as far as they could. Did Professor Humphry, he would ask, expect them or the College of Physicians to give as full an examination as the College of Surgeons in surgery? Their examination was regarded as important in Ireland as including a good deal of pharmacy. Their men were not intended or expected to practise large operations but only to be able to discriminate between cases, and to perform the minor operations. They had not the appliances and ought not to be required to examine in the higher branches. This question showed once more the importance and common sense of the tripartite scheme which he had advocated on the previous day. They, *i.e.*, the Apothecaries' Hall of Ireland, were ready to join in this for the benefit of the public.

Dr. LYONS said that this motion was admirably devised and with the best end in view, but it was trying to accomplish what was not possible, viz., to coerce all men entering the profession to qualify themselves in almost every conceivable branch of medical knowledge. Such a thing was neither desirable nor practicable. They were going against tradition, and running counter to modern feeling in regard to the division of labour quite unnecessarily. All who entered on a special branch of the profession should show special evidence of their fitness to practise it, but it was not possible to mould all men in one rigid and unyielding mould. A very considerable number of men would be deterred from a profession in which they had to pay attention to that which was repugnant to them and which they never intended to practise. After speaking of the important subject of women in labour he said that he would require of all men who intended to practise midwifery, full and satisfactory evidence of their education in this subject, and they should be tested both by hospital work and by examination. But why should some four or five thousand men be made to study midwifery when they never intended to practise it, and would give it up the moment they were qualified? What good public object would be attained by this course? He would make it penal for any man to practise midwifery who did not possess a special licence to practise it. This would answer the requirements of the public, and save men from learning what they never intended practise. They ought to pause before passing this resolution and apportion their aims to the necessities of the case. Besides midwifery there were at least two other very important subjects. One was connected with the army, viz., ophthalmia, and the other was lunacy. Legislation of a stringent character on this matter was impending, and he characterised the recent alleged case of feigned lunacy as a discredit to the profession. A more ludicrous, painful or humiliating case had never been before the public than one recently in the law courts. Such cases ought not to be possible or practicable, and the way in which the alleged lunatic got out of the asylum was almost the worst part of the case. He thought they were in danger of travelling too fast; if they enforced midwifery in a short time they would have to enforce lunacy, and many men he believed were incapable of mastering it. Each man should be tested and fully examined in that branch which he wished to practise, and in no other. Under this scheme there would be great danger of favouring a man who was good in some subjects but weak in others, and they must remember that every exception made weakened the rule. If they enforced one subject they would have to enforce others, and there was no saying where it would all end.

Mr. COLLINS seconded the amendment of Dr. Lyons, to the effect that it should be made penal to practise midwifery without a licence.

Dr. QUAIN would not admit that the fact that a man should feign lunacy and thus get admission into an asylum, threw any discredit on the profession. As to the recommendation they were asked to pass, he called attention to a very similar resolution they had passed in 1869, and

thought that the Council ought not to show any disrespect for its former resolutions by acting as if they had not been passed.

Mr. Simon suggested that they should refer to the former resolution and emphasize it.

Mr. Macnamara did not see that the passing another resolution was of any use, nothing weakened them more than passing resolutions which were not carried out. He agreed with Mr. Simon in his interpretation of Clause 20. In the event of a body being reported to the Privy Council, they would say that they only undertook to examine in medicine or surgery as the case might be, and they would be able to prove that in the one branch their examination was satisfactory. He was aware that to make recommendations when they had not the power to enforce them was lowering. His own College had endeavoured to carry out all the recommendations of the General Medical Council. He considered that all these recommendations were futile, they must obtain complete power over the Register. Speaking of midwifery he said that all the troubles that he had ever heard of arose out of cases of midwifery.

Dr. Fergus called attention to a resolution passed in 1880, which was almost identical with the one then under consideration. He considered that the whole discussion had been absolutely idle and futile.

Dr. Matthews Duncan objected to reference to the resolutions of former Councils, as implying a degree of continuity which they did not possess. The Council was a totally different body now from what it was in 1869, only four of the then members were still on the Council. Another objection was that the state of medical reform was not in the same condition. They were now disposed to consider how they could enforce their resolutions. The Council would not be deficient in respect to its own resolutions by not making any reference to them.

Dr. Banks thought with regard to Dr. Lyons' observations that very few young men had made up their minds what branch they were going to follow, and often a man did not pursue the bent of his first inclinations. Mental disease he considered very important, and the Royal University of Ireland insisted upon a knowledge of it.

Dr. Pettigrew said that every man ought to be duly examined in all the three branches; he need not practise them all, but he ought to know them. This scheme would work well, as was shown by the experience of Scotland.

The amendment was then put and lost.

Mr. Simon suggested a verbal alteration, introducing the words, "at the present juncture," to connect the resolution with the former ones on this subject.

The Rev. Dr. Haughton objected to their going back to the old resolution, which mentioned ten subjects. What they wanted to do was to insist on a competent knowledge of Medicine, Surgery, and Midwifery. These three were matters of life and death, and ought to be kept separate from the rest, which in comparison were of minor importance.

After some observations from the President and Dr. Quain to the effect that the former resolution was still in effect, inasmuch as it was daily given away in a printed copy of regulations, Mr. Marshall observed that the former resolution was a sort of general direction to each body to examine in all subjects. His own corporation had got out of the difficulty by obtaining power to withhold its diploma until the candidate had passed in all the subjects. All that a half qualifying body had to do was to wait. Certain bodies might not have this power. They could, however, take steps to obtain it.

Professor Humphry said that he had given very considerable and very serious thought to this resolution, and it was satisfactory to find that the Council had come back substantially to what he had suggested. He knew of the former resolutions on the subject, but it was their duty to press this matter in a definite, separate, and distinct form. It was not desirable to issue threats. Each licensing body would become conscious of its deficiencies, and would seriously and carefully consider what steps it could take to remedy the defects. The Apothecaries' Society might get over it, they might require their candidates to pass the examination at the College of Surgeons, or if they could not do so, it would be worth their while to obtain an Act enabling them to do so, if they wished to exist.

The motion was then put, 21 voting for, 1 against, and 2 not voting.

Mr. Marshall then moved that the qualification of M.R.C.S. be removed from the name of George Washington Evans in the Register. The name had been removed from the Roll of the College of Surgeons on what he considered ample grounds, and if necessary he could give the facts. The erasure was ordered without discussion. It was stated that his case was now under the consideration of the Faculty of Physicians and Surgeons of Glasgow, of which body he was a licentiate, and that his name would probably shortly be removed.

Dr. Heron Watson made a similar application with regard to the qualification of L.R.C.S.E. of Thomas Robert Horton, which was likewise agreed to, and it was stated that the College of Physicians of Edinburgh had the case under consideration, and that before long doubtless his name would be removed from the list of licentiates of that body also.

A communication was then read from the Irish Branch Council respecting the enforcing of hospital attendance on students.

The Council then adjourned.

Fifth Day.—Saturday, October 11th.

Returns Respecting the Preliminary Examinations.

Sir Henry Pitman moved that the Council should ask for certain information from all the bodies whose certificate they accepted in regard to the preliminary examination, such information to comprise the following points, viz.:—The percentage of highest marks, the percentage of pass marks, the number of candidates at the examination in question, and the copies of the examination papers set. He said that as regarded the professional examinations they already had such information on the first three heads, and they were now asking for the same information from those connected with the general education. It had been suggested to his mind that they ought to apply for such returns, by the return recently communicated from the College of Preceptors, the only one received from the bodies whose certificate they accepted for the preliminary examination, which showed that 75 per cent. of the candidates were rejected. This showed a considerable amount of strictness in their examinations and they had no means of judging as to other bodies in that respect, they accepted their certificates without a word of enquiry. He thought that it was the duty of the Council to exercise some sort of supervision over these examining bodies, though not by visitation. Probably some who had been rejected at the College of Preceptors got through elsewhere afterwards.

The Rev. Dr. Haughton referred to the great amount of information they had derived from the lists they had received from the foreign and colonial examining bodies. He spoke of the list of passed and plucked as a function of many variables, it showed the preparedness of the candidates.

Dr. Aquilla Smith moved that a return should be asked for of the subjects in which the candidates had failed; this would make the information complete, without it the rest would be of little value.

Sir Henry Pitman saw no objection to the proposal. The College of Preceptors already furnished that information.

Some rather desultory conversation then ensued on various points connected with the motion. Professor Haughton pointed out that the Universities examined a man as to general knowledge and without any reference to the Council, though it so happened that all the subjects they insisted upon were included in the general examination. He thought they certainly ought to make the request so that the return should deal with the past year and not give them only the results after all these questions about it had been made. Mr. Macnamara was of opinion that they certainly ought to be told in what subjects the candidates

had failed, and his own corporation would be quite prepared to give that information. Professor HUMPHRY raised a question as to the meaning of certain parts of the wording of the resolution, and this led to a general conversation on the part of the members, which lasted over ten minutes before the debate could be said to have been resumed. Dr. STORRAR pointed out that they ought to ask for the numbers of those who had passed and those who had not passed, as men often went in for an examination and came out without being rejected and without passing because they withdrew. Ultimately the motion as amended was carried.

Dr. PETTIGREW moved and Dr. WATSON seconded the following amendment as they pointed out that it was desirable that the system of marking from which these averages were to be obtained should be as uniform as possible :—"That the several bodies referred to in the foregoing clause be requested to give the results of their examinations in question (whether written or oral), by means of percentages." This was agreed to.

A Question of Duty.—Branch Council or Executive Committee.

Dr. STORRAR rose to move an alteration in one of the Standing Orders, viz., the substitution of the words Branch Council for Executive Committee in a certain passage. The matter referred to an old rule which provided that questions relating to certain of the Indian services should come before the Executive Committee. Two such cases had lately arisen, and had been referred to the Branch Council by the Executive Committee, who had referred them back to the Executive Committee again. This was a most round-about way of doing business, and might be very expensive. As much business as possible should be given to the Branch Council on the score of economy. Another disadvantage of the present system was that it postponed decision on a matter that ought to be adjudicated upon without delay. The English Branch Council had very little to do so far as he knew; one year, he thought, it did not meet at all.

Professor STRUTHERS seconded the motion.

Mr. SIMON admitted the circuitousness of the present transaction, but said that harmony of action must be secured. There were three Branch Councils, but there was only one Executive Committee. The cases in point ought never to have come before the Executive Committee. If the Branch Council were satisfied that there was a case for the Executive Committee, it would refer it to them. The clause in question had been inoperative for a very long time, but he thought that when such cases did arise they ought to be decided by a single central authority.

Dr. QUAIN explained how the mistake had crept into the regulations which permitted of a doubt on the subject, and Dr. Storrar consented to alter his motion, as he saw the danger of collision between the different Branch Councils.

Visitation of Examinations.

Professor HUMPHRY proposed that the visitation of examinations be resumed, suggesting that four visitors should be appointed in England, two in Scotland, and two in Ireland. He said that the power of visiting was most important, effective, and beneficial. The influence thus exerted had been very great, not so much by the reports, excellent though they had been, or by the resolutions thereon, but by the influence of the visitors on the examiners, and by their communicating the impressions they had derived to their own bodies after their return. It was a quiet, unseen, yet most important influence. Almost all the bodies had been influenced and improved. Bodies were often unconscious of this influence; it produced very little credit, as was known, and was almost always passed over in silence. It should be more continuous and efficient; there should not be outbursts of visitation, a sort of bombardment with due notice. It had not been regarded as an attack; the visitors had everywhere been received with open arms. They all had the information before them as to the previous results. Occasional outbursts had their evils; the people were forewarned. Then, too, the visitation caused a certain amount of disturbance and nervousness at examination, especially among the candidates, who always knew when they were coming. The evil associated with visitations would be lessened if they were more continuous; people would get accustomed to them. Then the report should be much shorter. They would soon be able to judge whether the examination on the three points was satisfactory. He would leave all details to the Executive Committee, and he considered that no expense should be spared in promoting so grand and important a work as that of improving the examinations, but at the same time he did not think that the examinations need be so very expensive.

Dr. QUAIN thought that no objection could possibly be raised on the score of expense, they could not put their funds to a more proper use. The resolution should be in as general terms as possible, and certain of the standing orders with which it would clash would have to be suspended.

Professor STRUTHERS laid great stress upon the importance of distinguishing between expert and general visitors. The President in his address had said something about their sending assessors to every examination, but that they had already the power to do. The Branch Councils also had the power. After referring to the coadjutor system advocated by Sir Lyon Playfair in the House of Commons, he expressed the opinion that the number of visitors suggested by Professor Humphry, viz., eight, would not be nearly sufficient.

Dr. PETTIGREW said that if the visitors were to be efficient they should be experts. No mistakes ought to be made in their reports. One locality might be taken one year and another at another.

The Rev. Dr. HAUGHTON asked whether they were to visit the preliminary examinations or only the final.

Mr. SIMON said he thought that was a mere question of detail. The essential thing was that the Council should instruct the Executive Committee to resume the visitations, and conduct them from year to year. The terms of the resolution should be made quite general.

Dr. BANKS thought that the visitations had been productive of a vast amount of good, and he hoped there would be no difficulty in getting men as able as their predecessors to undertake them.

Dr. HERON WATSON referred to the good effects of the visitations. He would not say, however, that the visitations should be from year to year, but from examination to examination. As to the expense, they had not made sufficient use of their income in this direction formerly. He quite agreed as to the good effect of the visitors on their own bodies. The visitations ought to be so carried out that they could assure the public that the examinations were conducted satisfactorily.

The PRESIDENT referred to the very large power that the Council had in their hands in the right they possessed of visiting any examination in virtue of their seat on the Council. Were they justified in not using that power more than had been done in the past.

Mr. TEALE, referring to the report which had been alluded to, reminded the Council that the object of the visitors on that occasion had been to see something of all the examinations of the corporations at the same time, so as to afford a comparative statement, and they had been unable to pay any long visit to any of the examinations, owing to the difficulty of getting from one place to the other in time. The new visitations would be for an entirely different object. Formerly many of the licensing bodies were much below the standard, but that was no longer the case. They would now require experts as visitors to judge of special subjects. These visitors would form a body to keep the Council in touch with modern education, and assist the Council in framing regulations as regarded the curriculum. It would aid them in revising that curriculum and subtracting from it much that was useless.

Dr. LYONS thought that the Council would be guilty of a dereliction of duty if it did not proceed with a system of visitation. The same system was adopted in the public services. He approved of the principle of the resolution, but would rather it had been left in the definite form in which it had been proposed.

The motion was carried.

On the motion of Dr. QUAIN certain of the Standing Orders relating to this subject which would have interfered

with the free action of the Executive Committee were ordered to be suspended.

A complaint respecting certain registered dentists was then received, and it was resolved that the Council do not see fit to take any action in the matter.

A communication was read from the Preston Medico-Ethical Society and ordered to be laid on the table.

A communication was read from the Irish Branch Council, respecting the Amendment of the Medical Act of 1858, and ordered to be entered upon the minutes.

The Council then adjourned.

Sixth Day.—Monday, October 13th.

Professional Education and Examination.

Mr. Simon moved a resolution to the effect that the Branch Councils should be requested to reconsider the present regulations for the professional examinations and confer with the licensing bodies and communicate to the President before the end of January next any amendments they might have to suggest. He said he moved this almost as a matter of routine. After so many years it was a matter of necessity that they would require some revision. There would be several points it would be well to discuss, on which he could form no opinion at present until he had heard what the licensing bodies thought. He wished to look at the whole systematically. Dr. Banks's resolution had touched on the question of the length of the curriculum. From what had already been said, it was essential that that should be discussed, but not until after they had had an opportunity of discussing the matter with the various licensing bodies.

Dr. Banks seconded the motion; it was comprehensive and complete. His own motion had been brought forward mainly with a view to lengthen the curriculum.

Mr. Marshall was in favour of the resolution; it did not bind the Council to any definite line, and could not fail to produce a beneficial result.

Professor Struthers approved of the resolution; he would like to see the Branch Councils have something to do. It seemed to him that in accordance with Clause 6 of the Act they had this power, and were virtually divisional boards. He thought that January was too soon for the reports to be sent in to the President.

Dr. Lyons referred to the last sentence of Clause 6, to the effect that the President was a member of every Branch Council, and he thought that if the President would exercise that power it would be followed by very important results. He hoped that the Branch Councils would have more life. Fresh duties were about to be imposed upon them and activity infused into them, he had no doubt with great profit and advantage.

The Rev. Dr. Haughton was sure that all his fellow countrymen would welcome the President at their Branch Council meetings.

Dr. Haldane said that hitherto all requests of this sort to the licensing bodies had come direct from the Council, and he thought that in a matter of such importance this should still be the case. It would come with much greater effect.

Mr. Teale thought the motion an exceedingly good one. It suggested a much more intimate consultation between the Branch Council and the licensing bodies than had existed. They would have a quiet discussion on the matter beforehand. Medical education in England and Scotland was taking a new departure at the present juncture. The Council had been adding to their recommendations and the time had now come for reconsideration. It had been said that hygiene, ophthalmology and mental disease ought to come in to the curriculum, some advocating hygiene at once. He was not of that opinion. Ought they not to cut out or seriously limit some of the subjects? If the time was not extended they could not add to the curriculum. Some subjects he considered were dealt with in unnecessary detail in the examinations, and he instanced materia medica and more especially pharmacy. Another important point was the fact that they turned out men nowadays who could pass very good examinations but who were very bad assistants.

Dr. Pettigrew thought that there was a necessity for the Branch Councils to do this work and not throw it on to the Council. Centralisation was bad and should be avoided as much as possible. The work would be better done by the Branch Councils.

Sir Henry Pitman said that the motion was imperfect and he should have been very glad if the mover had included preliminary as well as professional examinations in it. He knew that they were quite distinct and separate, but he feared that if they once began to discuss preliminary education the sitting would last a long time. He suggested that the subject should be dealt with by the Committee and framed in a form fit for the Council, when they had received the reports from the Branch Councils.

Mr. Simon entirely agreed in the idea of giving a larger share of activity to the Branch Councils; that would be in accordance with the spirit of recent attempts at legislation, and they ought to develop the Branch Councils. He expressed his approval of the idea of the President being omnipresent at the meetings of the Branch Councils. He was quite willing that a copy of the resolution, if it was passed, should be forwarded to the various licensing bodies. He thought that the vigour of the Branch Councils ought to enable them to do the work necessary by the end of January, and was sure that the Executive Committee would require at least two months to go through those reports.

The President said that he should regard this motion, if carried, as one of the most important resolutions of the Council since its foundation. This was the latest phase, carrying out the spirit of the most important recommendations of the Royal Commission. As to the work being done by the Branch Councils this might appear to some a retrograde step, but it was not so in reality. There were divers bodies of different opinions and interests, he used the word advisedly, and the difficulties were enormously increased by discussion there. It was absolutely essential that some arrangement should be arrived at by which these matters should come before them in a state of preparation, and the loss of common time which now happened be put an end to. The resolutions would come in future before the Council in a form in which they could be discussed. This would be accomplished if this motion were agreed to. Speaking of the differences between the schools, differences of nationalities, of prejudices and of interests, he said that neither the public nor the Council appeared to appreciate these differences, and until they were understood no real solution of the difficulty would be arrived at. This was a better procedure than he had sketched out in his address when he had said that the Council must seriously consider what they were going to do. Possibly when these reports were presented they would also have the reports of the new visitors before them. As to the remarks about the President being on the Branch Councils, he had about ten years ago presided at a Branch Council meeting in Scotland by invitation when he happened to be in the neighbourhood, and he had four times been in Ireland at the time of the meeting of the Branch Council, but had not been invited to join. If ever summoned to a special meeting, if he thought any useful purpose would be served by his presence he should feel it his duty to go. The Council he considered were entering on a new phase, though not an entirely new one, and he considered the present resolution a most important one.

The motion was then carried.

Mr. Simon then moved that it be an instruction to the Executive Committee to prepare for the next meeting a statement of the reports which would be handed over to them by the President. This raised a good deal of opposition, some objecting on the ground of unnecessary expense, others not trusting the Executive Committee to deal with the reports, so that Mr. Simon withdrew his motion and the more readily as by the Standing Orders the matter would anyhow pass through the hands of the Executive Committee.

Mr. Simon then moved, and Dr. Haldane seconded, that a copy of the resolution be sent to each of the licensing bodies.

Preliminary Examinations.

Sir HENRY PITMAN then moved that the Council should resolve itself into a Committee of the whole Council to enter fully into the consideration of the subject of preliminary education. He had hoped that this would have been included in the former motion, and would thus have been rendered unnecessary. He brought the subject up in consequence of a resolution of the Council at the past session, when it was observed that if the Bill then before the Parliament became law, the consideration of the subject would devolve upon another body, but if not it would be their duty to lose no time in entering upon it. There was another reason. At the examination of the College of Preceptors already referred to, only four had passed in mechanics out of a total of 274 candidates, though all were not necessarily medical students. This seemed to afford matter for investigation. Then again they had received from the Cambridge University some representation on the subject of a higher examination which they did not recognise, whilst a lower one was recognised, but it had not been taken into consideration at their last sitting.

Dr. AQUILLA SMITH seconded the motion.

The Rev. Dr. HAUGHTON thought that the cause of elementary education would be better served if the matter came through the Branch Councils. If they did this they would gain time, he believed. The Council had made the recommendations without a sufficient knowledge of the working of the bodies who conducted the examinations in elementary education.

Professor STRUTHERS thought that it was for the Council to lay down the lines upon which the elementary instruction should be constructed.

Mr. TEALE supported the proposal of Dr. Haughton. The Council would obtain information through the Branch Councils of what the various examining bodies were doing. On this subject as on the professional examination question they wanted the aid of expert advice.

Mr. MACNAMARA held that this examination was altogether on a different footing from the professional examinations. They ought to discuss it; they had distinctly promised to do so, and not to do it now would be only postponing the evil day. They knew more about it than the experts, and would look at the matter from a professional standpoint. They ought to proceed to the work and not shirk it. As Mr. Simon had said, they could not deal both with preliminary and professional education in one session.

Dr. PETTIGREW thought it would be a great mistake to defer this subject; it was the very one for which the Council had been summoned, and the Branch Councils were not so competent to deal with it as they were.

The Rev. Dr. HAUGHTON withdrew his amendment.

The motion was then put, and 16 voted in favour of it.

The strangers were then ordered to withdraw, when a letter read by Dr. Fergus was referred to the solicitor to the Council, and on their re-admission the Council were still sitting in Committee.

Professor HUMPHRY brought forward his motion with a view to lessen the area, and at the same time improve the quality of the examination. He thought that in the present system of work there was not enough of mental training, and too much of mental cramming. The defect was not in the acquiring of facts, but in showing that they comprehended those facts. Candidates could answer questions as to facts, but could not give reasons, and if asked a simple rider to a question they almost invariably broke down. The mental training and cultivation were not of the requisite kind; more time was required; indeed time was the most important element. He had excluded some subjects in order to diminish the amount of the work. They ought to select those subjects best fitted to prepare the mind. It might be said that he had reduced the area without improving the quality, but a slight improvement in quality was equivalent to a large diminution in area. What they wanted was that a little thought should be required; the difficulty was not so much to get up a large number of subjects as to go more deeply into a few.

Mr. SIMON thought that the best plan would be that they should rescind the subjects they wished to discard in the order in which they occurred in the regulations.

The Rev. Dr. HAUGHTON thought that the optional subjects ought to be rescinded.

Professor HUMPHRY went on to say that he had chosen Latin to represent language because he thought none was so well calculated to give a knowledge of systematic grammar; it was taught in all schools and would be useful to the student in his after career. As to a specific book being chosen, he admitted that it was an evil; it was wrong in principle and encouraged cramming, but in the present state of school education it seemed to him unavoidable. Unseen passages, as they were called, would be a far better way of testing a man's knowledge, but to adopt it would, he had been assured, exclude a large number of men from the medical profession, and he had therefore suggested passages from a specified author or unseen passages or both. A good man might not happen to have read the particular book set, and he therefore ought to have the opportunity of translating at sight. Ultimately he hoped that the unseen would supersede the other, and would gladly have had it alone.

Mr. TEALE seconded the motion.

Dr. MATTHEWS DUNCAN could not see how the quality of the examination was improved by this if the man could not do a piece of unseen Latin. This was a matter of detail and all details should be left to the examiners; in fact they were always over-ridden by the examiners, and an examination was just as hard or as easy as an examiner liked to make it.

Mr. SIMON said that it was most undesirable to give an easier and a harder alternative. There should be no option in the matter, their object was to fix upon a minimum.

Dr. STORRAR referred to the fact that in 1859, the Council had at his suggestion resolved that it was inexpedient to set up a standard in arts of its own, but that it should rely on those bodies which superintended general education. It seemed to him that the effect of this resolution would be to set up a standard in arts lower than that of any other body, and if they did this, who would conduct their examination, as the proposition had long ago laid down that these preliminary examinations were not to be conducted by a medical body.

The Rev. Dr. HAUGHTON said that nobody had a greater respect for the dead languages than he had. He would wish every student to be familiar with Latin, and the minimum he would accept would be translation from a prose and verse author specified, and from an easy unseen passage, and also the translation into Latin of an easy English passage. If anything less than this were proposed, he would rather see Latin out of the curriculum altogether.

Dr. HALDANE seconded Dr. Haughton's amendment, and thought that the proposal of Professor Humphry would not test a man's knowledge of Latin. At present the secondary education throughout the country was very bad, and as a rule the knowledge of Latin was extremely bad.

Dr. CHAMBERS could not accept the high standard that Dr. Haughton had set up of being able to read Cicero in old age with pleasure, as by any means the minimum that ought to be aimed at. Latin strengthened and improved the mind, it was on account of the grammar that it was especially useful. It taught people to be logical and that was one of the objects of language, and Latin was the best of all for this purpose. Even a very little was useful. A specified author marked the distance to which the examination would go. To translate English into Latin was not of much importance, it was requiring a very high degree of knowledge, too high he believed. He would not accept Cæsar as the minimum.

Professor HUMPHRY said he had been charged with lowering the examination, but the great majority of men went up to the College of Preceptors, and they did not ask for unseen Latin, nor did the Junior Local Examinations of Oxford and Cambridge. He would accept Professor Haughton's amendment as to prose and verse, and unseen passages as well, but not as to the rendering English into Latin. He would be satisfied with Cæsar done well.

Sir HENRY PITMAN said that they were now proposing to raise the standard, a dangerous experiment, seeing the

large proportion who were rejected under the existing examinations. They must remember that they drew the majority of their men not from the Universities, but from the middle class schools. They must be careful in raising the Latin, as they would have to raise all the other subjects in corresponding degree. He thought that the former scheme included all that was requisite in the matter of Latin.

Mr. Simon said that on those subjects on which they insisted they ought to have a fair knowledge. They were trying to narrow the area, and increase the requirements; he would insist on three subjects, viz., Latin, elementary mathematics, and elementary mechanics, and would dismiss all the optional subjects, such as geography and English history, nor would he require a separate examination in English.

Dr. Lyons saw great difficulty in dealing with this subject. They were discussing details when they had had no opportunity of discussing the principle. He did not quite understand where they were; were they discussing this question finally, because he could not assent tacitly to exclude Greek; he believed a certain knowledge of Greek to be of great importance. He would move, if necessary, as an amendment, that Greek be given a recognised place in the curriculum.

Professor Struthers considered that they were altogether going on a wrong tack; they ought first to have had a discussion on the general principle.

Professor Humphry asked leave to withdraw his original motion, and substitute one declaring that the examination should comprise Latin, elementary mathematics, and elementary mechanics.

Dr. Storrar said that if those subjects alone were going to be proposed he should certainly oppose the motion. Why should they admit at a lower standard? The College of Preceptors and the Universities were much more likely to understand the capacities of students. The candidates came up for examination exceedingly unprepared. They were now bidding down their examination when they had been trying to raise it ever since 1858.

Dr. Lyons strongly objected to a new motion being substituted when they had spent so much time in discussing the former one.

Dr. Pettigrew said he had understood they were to have had a discussion on preliminary education. As to Latin, what they wanted was variety. Was it the best training? He hoped they would not strike out the optional languages, by all means let them keep Latin, but not to the exclusion of other languages.

Mr. Marshall said that this was a new proposal, it abandoned the principle of the former motion. The first was exclusive, this was to comprise. They were said to be raising the standard of the examinations, he could not see it himself.

Mr. Macnamara said he could not see the necessity for this resolution which was already practically on their minutes.

After some further conversation the Council resumed without any report being sent up from the Committee.

Seventh Day.—Tuesday, October 14th.

Preliminary Examinations (continued).

After the reading of the minutes the Council went into Committee to continue the consideration of Dr. Humphry's propositions with regard to preliminary education.

Dr. Humphry obtained leave to substitute a different series of resolutions for those which had been put down in the programme, and he proposed to consider the present subjects of preliminary examination *seriatim*, moving certain modifications of the present requirements in connection with each. With regard to the first, viz., English language, including grammar and composition, he moved a resolution to the effect that this subject as such should form no part of the preliminary examination, but that the candidate should be required to answer the questions (*i.e.*, in other subjects, especially Latin) in such a manner as to satisfy the examiners that he had an adequate knowledge of English grammar and orthography. He said that this was the method adopted both at Oxford and Cambridge of testing a candidate's knowledge of the English language, and he thought it was perhaps the best test. In large schools it was held that a knowledge of Latin as a language was applicable to English. He was anxious to improve the preliminary examination by lessening its area, and he thought that by raising the standard in Latin they would at the same time secure a more thorough knowledge of English.

The resolution was briefly seconded by Mr. Simon.

Dr. Storrar said that he would deeply regret the exclusion of English as a special subject. He could not agree with Dr. Humphry that English was not a special subject of study in grammar schools. In the so-called modern schools where Greek was left out, the greatest attention was paid to the teaching of English. In some of the best and most recently established schools the boys were trained in the logical analysis of their language, and in paraphrasing plays of Shakespeare and books of Milton. In fact it had been discovered that of all subjects English was the most important factor in education, whatever might be the profession for which the pupil was destined. Dr. Storrar then went on to say that if the Council determined on a list of their own of the subjects of preliminary examinations, they would have to see that the examining bodies followed out their requirements. But they could hardly dictate to such bodies as Oxford and Cambridge, whose examinations, though requiring a higher standard in some subjects, might not include all the subjects insisted on by the Council. Their attention ought to be directed to the residuum of students who had not passed good preliminary examinations, and of such, subjects might be required which were not necessarily required by the Universities. He thought that preliminary examinations should be conducted by bodies independent of the Council and the licensing corporations, and he hoped that Dr. Humphry was not going to apply the sponge to all the preliminary examinations as they at present existed.

Dr. Humphry stated that that was not his intention.

Mr. Macnamara thought English one of the most important subjects of the curriculum. It was important that the members of a learned profession should show that they had some knowledge of their own language when answering invitations to dinner or otherwise corresponding with the public.

Mr. Teale said that they were discussing what language they should base preliminary education upon, Latin or English. He felt that the area of subjects at present required was far too large, and they ought to try and reduce it in such a way as to secure a thoroughly good training in a limited number of subjects.

Mr. Simon said that what was wanted of the student was a good practical young man's knowledge of English, and the question was, could that knowledge be better tested by an abstract examination or by the practical test of his being able to spell his words and construct his sentences correctly? To him it seemed that the latter was quite sufficient for their purpose.

Dr. Matthews Duncan agreed with Mr. Simon and Mr. Teale, feeling that in testing the student's knowledge of philology, examination in one language, and that Latin, was abundantly sufficient.

Dr. Pettigrew thought that Latin was rather overdone, too much time was spent upon it. He would like to see more importance attached to modern languages. After all, it was language that made the grammar, and not the converse.

Dr. Haldane said that every student ought to have a practical knowledge of the English language. A candidate ought to be required to write from dictation, and also to write a short piece of English composition.

Dr. Banks said that English was lamentably neglected in their schools and throughout Ireland. It had been said to him by an Edinburgh examiner once that they sent over smart clever fellows, but lamentably deficient in spelling.

Dr. Heron Watson would regret the motion being accepted. The examination was not so much to test the knowledge of the candidate as to see whether he had had a

liberal education, such as would fit him for the medical profession. He considered the study of the dead languages most important. At the present day the knowledge of the English language possessed by the boy educated at a good school was less than that of one who had been to an inferior school. He thought the former recommendation much better than the present one suggested by Professor Humphry.

The Rev. Dr. HAUGHTON spoke of the English grammar as being exquisite, but it was not studied enough. An examination in English without composition was miserably deficient. A man ought to know his own language, and English was the finest language ever spoken.

Sir HENRY PITMAN said that the Council were in great danger of falling into an error. They were proposing to dictate to the examining bodies such as the Universities and the College of Preceptors. They were assuming that these bodies did not know how to conduct an examination. They might require grammar and spelling, but to go into details of how it was to be done was almost an insult. The Council were putting themselves in a very false position.

Mr. MACNAMARA said that he thought they were already dictating to them.

Professor HUMPHRY said that his idea had been that the student was to obtain a better knowledge of English by a deeper and more careful insight into one language—Latin. He would require an additional knowledge of Latin to that already required. English was not a good subject for an examination. A better knowledge of Latin would ensure a better knowledge of English. Those who had the best knowledge of Latin were the best English scholars. Dictation was hardly the kind of thing to put men to; it only tested spelling, and so much depended upon the examiners.

Dr. HERON WATSON could see no incompatibility between their having a higher examination in English as well as in Latin.

Dr. QUAIN observed that if they did not examine in English the teachers would give up teaching it.

Professor STRUTHERS observed that some one had said that the Council had failed in their preliminary examinations; he did not think so, and he held that the work done in this matter was one of the great merits of the Council. He was in favour of a rise all round. He referred to Germany and France to show how much in advance their requirements were of those in this country, but he would not admit that either of these nations was superior to the English in intellectual ability. The professional bodies ought not to hold special examinations for medical students. He held that students were very unfairly rejected; if he did badly in one subject, say Latin, no matter how well he had done in mathematics, a man would be rejected. This he considered very unfair. The English language, including grammar, was the most important subject of all, and if he could only have one subject he should certainly choose it.

Mr. MARSHALL asked whether it was the duty of the Council or of the General Educational Bodies to settle this question. They ought not to take upon themselves to join in settling it. They should keep their minds fixed on what was essential, then on the useful, and lastly on the ornamental. He would like to see a preliminary examination in scientific subjects introduced, and would then strike out elementary mechanics from its present place and put it in that examination. The preliminary examination would then consist of the elements of education and nothing else, viz., language and mathematics. The scientific examination which would follow would deal with physics, mechanics, and chemistry, and after that would come the more strictly professional subjects. He was a stout advocate for retaining English as a distinct subject. The work of the Anglo-Saxon philologists during the past twenty years had made English a great deal easier than it formerly was, and a thorough knowledge of English would fit a man better for the profession than a knowledge of Latin. The proposal before them was inadequate as a test in English, and he objected to an examiner being called upon to perform a double function. No man ought to be called upon to examine except in his own subject. He would therefore be in favour of leaving matters as they stood.

The PRESIDENT, after referring to a conversation he had had with the late Dr. Parkes, bearing on the uneducated state of the profession, observed that the English language had in the last twenty years acquired a new shape, it had become one of the greatest of languages. He could testify to the general desire there was on the part of the Council to improve the general knowledge of the language, though they were not quite agreed as to how this would be best brought about. They ought to be careful to do nothing that would disparage the study of the English language and the great English writers. Their object was to increase the standard of general education, and the great question was whether this resolution would have that effect.

The motion was then put to the vote when there were seven for it and sixteen against it, one not voting. It was therefore lost.

Strangers were then ordered to withdraw.

Dr. HERON WATSON brought the case of a practitioner in Scotland before the Committee, and it was decided that the Executive Committee should take steps to bring the case before the Council at their next meeting.
