**PORTABLE BUILDINGS.**—*G. J. Calvert, York, and C. L. Light, Parliament-street, London.* Dated 22nd March, 1860.—The patentees first form foundation shoes, consisting of a screw having a gaining thread, or thread of variable angle, cast or wrought upon it, and above the screw a sole-plate or loose plate, which supports either an iron standard or a socket, and one or more pockets for receiving the horizontal beams and upright posts or standards of the building. They prefer to commence the thread at the point of the screw, where they make it very narrow, and to increase the breadth of it, and increase also the

angle which it makes with the axis of the screw as it rises from the point towards the sole or base plate, the greatest diameter of the screw being equal to two-thirds of the diameter of the base plate. The principal standards are supported directly by the screwed foundation shoes, and the intermediate standards are tenoned into mortises formed in horizontal beams, which extend from one foundation shoe to the next, and which are held at either end by the pockets before mentioned. Framed panels form the wall, and are dropped down from above between the standards, being held in position by tongues or fillets of hard wood or other suitable material. These framed panels are formed hollow, and are composed, by preference (although not necessarily) of Bielefeld's fibrous slab, which secures the interior of the building from extremities of temperature. The edges of the fibrous panels are received in rabbets formed in the wooden framing of the panel. The roofing is composed of grooved rafters, the grooves of which hold canvassed slabs of the aforesaid fibrous material, or a roofing of any other suitable material. The whole of the fibrous slabs are waterproofed with a suitable composition. Buildings constructed in the aforesaid manner are said to be exceedingly light and portable, and easily put together without the aid of skilled labour. The invention also consists in the employment of a gaining screw for fencing posts, gate-posts, and other purposes.

#### VENTILATION OF HOUSES.

SIR,—The importance of ventilation is now so generally understood, that those portions of your paper which relate to the supply of fresh air to houses, and the removal of impure air, are among the most interesting.

Arnott's valves were a very valuable discovery; but the objection to them is the frequent escape of smoke and dirt from the chimney. These drawbacks have caused many to discontinue the use of them. In new houses this nuisance can be avoided by building up a shaft or flue expressly intended for the escape of air only, by the side of the chimney flues. I don't know how often this is done, but it ought to be made compulsory in all new houses.

What is the best remedy in houses already built, and not provided with such flues? At present, the only plan which occurs to me is an opening in the centre of the ceiling, which might be concealed by an ornament, and air-bricks in the walls, allowing the air from the room to pass between the floors into the open air. Will this be attended with an inconvenient down-draught of cold air from without, which in a low room might prove unpleasant?

I shall be glad to see some remarks on this subject from one of your experienced contributors.

SALUS.

#### Books Received.

*All Round the World: an illustrated Record of Voyages, Travels, and Adventures, in all Parts of the Globe.* Edited by W. F. Ainsworth, F.R.G.S., &c. London: Marsh, Fleet-street. This new series promises well to form an entertaining and valuable work. It will not merely constitute a record of the experiences of a single voyager, traveller, or adventurer, but a compilation from all that is most interesting and curious in the narratives, already written, of the experiences of many voyagers, travellers, and adventurers, in all parts of the globe, selected and collated by an accomplished editor, Mr. W. F. Ainsworth, the well-known traveller. The work, it would appear, will be plentifully illustrated. The first part is devoted chiefly to the Holy Land. At the close of it, a section is begun on "Sicily as it is."

#### VARIORUM.

THE *Quarterly Review*, for October, contains several articles of considerable importance and interest. One of these is on "Competitive Examinations;" another on our "Iron Sides and Wooden Walls;" and a third, under the title of "Deaconesses," relates to the question of female employment. The article on "Competitive Examinations" is by no means favourable to this mode of appointment to offices in the civil service; and certainly a strong memory, or even a good education, does not necessarily imply the possession of temperance, justice, diligence, and all the public virtues. We should be inclined even to go a little farther, and to maintain that learning is the lowest and most superficial of the three great faculties—learning, talent, and genius—into which

Coleridge and others have, with pretty fair accuracy and comprehensiveness, divided the intellectual or scientific aspect of the threefold mind—scientific, sentient, and potential. A capability of responding with ready tact and memory to the questions of the examiners, therefore, can disclose but a very small clink of the "light within." Nevertheless the system has its advantages, rightly administered, and opens the door to unaided ability. The author of the article on our "Iron Sides and Wooden Walls" maintains the superiority of iron ships for the navy, and states that these only are capable of withstanding the vibration caused by the screw, which shakes wooden ships, he says, to pieces. There is one important point which ought not to be lost sight of, however: that is, the suddenness with which iron ships founder and sink: carefully constructed, and as carefully kept, compartments might do much to obviate this disadvantage. There are also articles of varied interest in the *Edinburgh Review*. "The Churches of the Holy Land" is an especially interesting and able one, in which the writer resists Mr. Ferguson's ingenious theory on the subject of the Holy Sepulchre, the history of which is practically in itself the history of the churches of the Holy Land. In reference to this perplexed question, there is one collateral point which ought, we think, to be well considered; namely, the fact that caves, rocky crypts, or cells, beneath temples were a feature in some Gentile religions: there were round temples, too, with such sacred caves beneath them; in which, moreover, as in most if not all others, mysteries of death and resurrection were enacted. Even the Mexican Aborigines, according to Mackey's Lexicon [article, "American Mysteries"], had a temple with cavernous excavations beneath, in which mysteries of "regeneration" through "the path of death" were practised; one horrible feature of which consisted in throwing down, into the presence of the aspirant to initiation, a sacrificed human victim still in the agonies of death, from the high altar of the temple into the cavern under the altar. Indeed, the Gentile rites in general comprised manifestations of death, real or simulated, with funeral rites and lamentations, followed up by resurrective representations and rejoicings. And that there are strictly Gentile, as well as Mahomedan, elements in the question at issue in respect to the Church of the Holy Sepulchre, which ought to be taken into account by all who discuss this question, there can be no doubt. Thus Eusebius, in his "Life of Constantine" states, in general terms, that wicked men had choked the holy sepulchre or cave with earth, covered it with a high mound afterwards paved, and built upon it a tomb for dead souls, in the shape of a temple of Aphrodité. Socrates also speaks of the Aphrodité over the sepulchre, and Dion Cassius attributes to Hadrian a temple of Jupiter built on the site of the Jewish temple itself. We merely wish here to indicate to others the point referred to—not to draw any inference from it on either side of the argument, far less to discuss its bearings on the whole question.—The number of deaths arising from the burning of ladies' dresses, especially since they became literally "swells" with steel hoops and crinolines, is really lamentable. The Registrar-General, writing on this subject in March last, says—"The fires of Smithfield, and the Suttee fires of India, have been extinguished; but the fires of our own hearths destroy hundreds, and deform thousands, of English women and children annually. Assuredly some remedy may be found. Why are combustible dresses carelessly worn? Eight persons should not be burnt to death in seven days (in London alone). Such deaths can scarcely be considered inevitable accidents." Her Majesty, it may be remembered, referred this subject, in November, 1858, to Professor Graham, the chemist, and Master of the Mint; and he appointed Messrs. Versmann & Oppenheim, to investigate the subject experimentally. The result was, the discovery of two chemical agents suitable as blaze-proofers, if we may so call them, for the combustible fabrics used for women's attire. One of these agents is sulphate of ammonia, which is now used in the manufacturing process of woven fabrics that require no ironing, such as book muslins, tarlatans, net and lace curtains, &c. The other is tungstate of soda, which is sold for domestic use under the name of "the ladies' preserver." Information as to the mode of using this useful agent can be had from a tract now before us, titled "Description of the Ladies' Life Preserver," &c., and issued by Messrs. Briggs & Co., at 20, Great Peter-street, Westminster.—A pamphlet titled "The Iron-band Gun, and its Applicability to various Military Field Purposes;"

by Sergeant-major John Jones, Royal Engineers (Fordham, Chatham, printer), gives an account of an article which appears to be of singular and varied use in military operations. The tedious multiplication of the basket-like gabions at the Crimea will be remembered. By the use of iron-band instead of wicker or bamboo, two men can now, it seems, make a gabion in less than five minutes; whereas the wicker gabion takes three men three hours. The bands are prepared with buttons and slots, and they are capable of being converted into suspension bridges, hospital beds, ambulance litters, network for military obstacles, and field stabling and butting. They are also light and portable, and can be packed in small compass, and must constitute a most important element in future field practice.—"Development of Christian Architecture in Italy," by Sebastian Okely, A.M. (Longman & Co.), is before us for early notice. We have also received G. Barclay's "Monograms," "The Wit and Wisdom of the Rev. Sidney Smith" (Longman & Co.); "The Progressive Screw as a Propeller in Navigation," by Julian John Révy, C.E. (Weale, Holborn); Stanford's "London Guide" (Charing-cross); "The Proceedings of the Liverpool Architectural and Archaeological Society," 1858, 1859; Fairbairn's "Crests of the Families of Great Britain and Ireland," edited by Joseph Maclaren (T. C. Jack, Edinburgh); "Observations on the Niagara Railway Suspension Bridge," by P. W. Barlow, F.R.S. (Weale); Longman's superb edition of Moore's "Lalla Rookh," with sixty-nine illustrations by John Tenniel, 1861; and some others.

Miscellanea.

**BUILDERS' BENEVOLENT INSTITUTION.**—The 13th anniversary dinner of this association took place at the London Tavern, Bishopsgate-street, on Thursday evening, as announced; Mr. George Plucknett, the president of the year, in the chair. The attendance was good, and the dinner passed off very satisfactorily: we shall report next week.

**AN ITALIAN EXHIBITION.**—A letter from Turin says:—"Florence is making preparation for a grand exhibition, which is to take place next summer, and which is to bear the name of the 'Italian Exhibition.' Florence gives 100,000*l.*; the Provincial Council of Florence 30,000*l.*; Milan, 20,000*l.*; Leghorn, 10,000*l.*; and Pisa, 7,000*l.*"

**THE STREET TRAMWAY PROJECT.**—Further proposals have been made to the Westminster district authorities. Mr. Train has made application to them to be allowed to extend his tramways to various streets under their jurisdiction, such as Oxford street, Regent-street, Piccadilly, Coventry-street, and Pall-mall. Mr. H. Greaves applied to be allowed to submit his plan for combining tramways with gas and other pipes, the pipes to form the sleepers under the rail or train. His gas-pipe sleepers are patented, and form, he says, one continuous structure, so that gas could not escape, and each would bear 30 or 40 tons weight. By laying such pipes, he urged, the breaking up of streets would be obviated, as also the contamination of the subsoil by gas escape. Both projects were referred to the Works Committee of the district for consideration. Mr. Train has also applied to the City Sewers Commission for permission to construct railways in some of the principal thoroughfares in the City. It was resolved that he should be invited to appear before the court, and answer questions as to his project. It is said that a gentleman in Manchester has taken out letters patent, for a plan of what he terms a "perambulating railway." The projector proposes to lay down his line perfectly level with the roadway, each rail not exceeding 3 inches in width; and in the centre he places a grooved rail in which is to run what he terms the perambulator, which is simply a wheel 9 inches in diameter, centred in a bar hinged to the fore axle of the vehicle, and spurred to it on both sides, so that when the wheel revolves in the groove the axle is always at right angles to the rails. This bar is suspended from the splinter bar by a strong elastic band, which holds the wheel about 4 or 5 inches clear of the road; and an upright rod, passing through the footboard, and acting on the perambulator, enables the driver, when he has fully adjusted his vehicle upon the rails, to depress, by the action of his foot, the wheel into the groove of the centre rail, and to retain it in position as long as he wishes to remain on the metals. It is stated that the patentee has obtained permission of the trustees of the Pendleton road, Manchester, to lay down such a length of line as will suffice to test its efficiency and utility.

**THE GLASS TRADE AT SUNDERLAND.**—The various glass and bottle manufactories at Sunderland, says the *Gateshead Observer*, are now in full operation, and several of the proprietors are extending their works. Messrs. J. Hartley & Co. amongst others are now building two additional cones for the manufacture of sheet glass.

**A NEW PLAN FOR THE IMPROVEMENT OF THE PORT OF BRISTOL.**—Mr. Masters, of Bristol, architect, has prepared plans which have been submitted to the members of the Town Council, as offering a means of meeting the desideratum of Port Improvement. Mr. Masters's design is to make, at the "horse-shoe" bend in the river, between Semallies and the Powder-house, a new and much straighter channel, and the curve, comprising the present course of the stream, which would be taken off, he would make the site of new docks, of considerable area, with the addition of a railway running to Bristol.

**EXCAVATING TUNNELS.**—Mr. Gilbert, Coleorton, has invented an apparatus to excavate sewers, tunnels, &c., and at the same time to allow the building of the required number of rings of brick-work, without the aid of timber to prevent the slip from above, no more ground being displaced than is necessary, these being done as well in running sand or new ground as in solid firm ground, and effected in the following manner, as described by him:—I propose employing a cutting shield, of the form of the upper part of the tunnel or sewer, and supporting it by suitable framing, upon which are powerful screw-jacks, hydraulic presses, or other suitable power for the purpose of driving said shield forward. The shield travels over rollers on the top of the frame, and can be made to travel in a straight line, rise, fall, or turn a course by means of such rollers. The bearing prop or framing at the back of the brickwork may be formed in the shape of an X; the lower part thereof serving as an entrance passage to a wagon-road, where such is required for clearing away dirt, or other purposes.

**BATHS AND WASH-HOUSES FOR THE CITY OF LONDON.**—The corporation has not one such institution under the shelter of its wings, and therein it lags behind the age in its ministrations to the poor domiciled in the City. It will be in vain to ignore the necessity for such institutions on the ground of decreasing population and the growth of banks and warehouses, because some large districts are wholly occupied with residents of the artisan and labouring classes. These are put to severe shifts if they have any desire to maintain their health and personal decency at a fair station: the wives have no grass-plots whereon to bleach their linen: kitchens and wash-houses are, to a great extent, converted into dwelling-rooms; and, though soap may be cheap and water plentiful, the day's wash has either to be done on the roof of the house, or on the pavement of the narrow street, while the clothes-lines are hung from window to window as decorations to the public way.—*City Press*.

**THE POLYTECHNIC INSTITUTION, REGENT-STREET.**—This well-known institution is about to make a fresh start for popular support under new managers. The building has undergone a renovation, and will shortly be open to the public. The entrance-hall has been rendered fire-proof, and additional means of ingress and egress provided. The lighting and ventilation, it is said, will be accomplished in a new manner, and a cheerful style of decoration has been adopted throughout the interior. The institution is not to be diverted from the laudable purposes for which it was originally established. Although the various alterations are not yet completed, they were sufficiently advanced last week to enable Mr. C. Dresser, the lecturer on botany at the South Kensington Museum, to deliver the introductory lecture to the course of study in that interesting science.

**DURHAM AND TYNE BRIDGE TRAMWAY ROAD.** The following tenders for the improvement of the road at Chester Dene have been sent in, according to the *Gateshead Observer*:—

John Kellett, builder, Crook .....	£4,637	0	0
William Graham, John Macnaught, & Matthew Howey Wells, contractors, Birtley .....	4,628	16	1
J. W. Bulmer, contractor, Sherburn House, Durham .....	3,951	0	0
Foster & Lawton, contractors, North Biddick Hall .....	3,800	0	0
Joseph Nicholson & Co., contractors, Sunderland .....	3,723	0	0
Edward & Charles Drier, builders, Bishop Auckland .....	3,700	5	10
Eden & Dickenson, contractors, Gateshead .....	3,374	15	3½
Harrison Hodgson, contractor, Durham .....	2,695	10	0

The committee have recommended for acceptance the tender of Mr. Harrison Hodgson.

**PNEUMATIC DESPATCH COMPANY.**—At a recent meeting of shareholders of the Pneumatic Despatch Company, held at Westminster, the chairman, Capt. Huish, in the course of the proceedings, said they were continuing experiments, not to ascertain the power of propulsion by exhaustion, but to ascertain the means by which they could produce a revenue at the lowest possible cost. The experiments had shown most satisfactory results, and would be completed in about a fortnight, when a tabulated statement would be furnished by the engineers to the board. The engineers had already informed him that, by the use of the fan, which was a most elaborate thing, but very economical, they could obtain a speed of thirty or forty miles at a very inexpensive cost. Until they received the report they would not do anything, but he believed it would be of such a nature as would justify the directors in commencing operations. The first pipe would be laid from St. Martin's-le-Grand to Bloomsbury for post-office purposes.

**WORCESTER DIOCESAN ARCHITECTURAL SOCIETY.**—The annual meeting of this society has been held in the Lecture-room of the Natural History Society, at Worcester. The chair was taken by the Hon. Frederick Lygon, M.P. Mr. J. S. Walker, hon. secretary, read the seventh annual report. The committee expressed their regret that there had not been so many members added to the society as during former years, and that, on account of his removal to London, Mr. Theodore Galton had resigned his position as one of the honorary secretaries of the societies. They stated that the annual volumes of reports and papers published by the six associated societies had been distributed amongst the members. Under the head of "New Buildings and Restorations," a lengthy and critical account was given in the report of work done to religious and educational buildings in the district. The Rev. R. Cattley, the treasurer, read the financial statement. He said a large sum was due for arrears, chiefly from members residing at a considerable distance from the city. He recommended that as the addition of members was scarcely so great as the withdrawals, through removal and other causes, efforts should be made to induce persons to join the society. The Rev. H. G. Pepys read a paper by the Rev. E. Trollope, on Monastic Gatehouses and Walls, the author of the treatise being unable to attend. On the day after the meeting, the members proceeded on their annual excursion to visit and inspect some of the churches in the diocese. The churches selected for that purpose this year were Stoke Prior, Bromsgrove, Headless Cross, Redditch, and Beoley, but the last was not visited.

**SCIENCE AND ART DEPARTMENT PRIZES AT GLASGOW.**—The Queen's honorary prizes awarded to the students of the chemistry class lately formed in connection with the Science and Art Department, in the Secular School, Carlton-place, Glasgow, were distributed recently on commencing the second course of instruction. Mr. James McClelland presided. A large number of persons interested in the institution were present. The chairman stated that at the metropolitan examinations Mr. Mayer had succeeded in gaining a certificate in chemistry, after being severely examined by Professor Hoffman during two days; and that he was the only candidate from the north of the border. Mr. Mayer then established, with the sanction of the Department and the promoters of the school, a special class for the study of chemistry, apart from the regular school studies. Six out of twelve of the students of this class had gained Queen's prizes, nine of the twelve having previously passed their examination. The chairman then said that these prizes would be distributed after the delivery of an introductory lecture by Mr. Mayer. The lecturer then proceeded to show that the study of abstract scientific truths is essential to industrial progress, as had been beautifully demonstrated by what might be regarded as the crowning event of Sir Humphrey Davy's career as an eminent student of science,—the invention of the safety lamp. This invention was not a mere lucky hit, but the result of the strictest scientific induction; and the instrument itself had been of incalculable service in the preservation of human life,—what the inventor desired it to be. To prove his position, the lecturer performed a variety of instructive experiments, showing how explosions of fire-damp are caused in coal mines, and how they may be prevented by the use of the safety lamp. The descent of a miniature coal mine with a Davy lamp, into an inflammable gaseous mixture, without causing an explosion, was exhibited.

**THE NEW HORTICULTURAL GARDENS, SOUTH KENSINGTON.**—The works are making rapid progress, and the boundary line of the gardens is shown on all sides by the rising arcades. The arches of the north arcades on the west side are nearly all turned. The north arcades are in Portland stone, with a rusticated red-brick pilaster, which is placed between small Doric stone columns. The foundations of the conservatory, which is on the north level, are now laid. The moulded brick pillars on the middle level are several feet above the ground, on both sides, and the brick piers on the south, or lower level, are nearly at their full height. It is expected that the new council-room for the Horticultural Society will be ready to be occupied in a few weeks. The pavement and heating apparatus are now in execution. The ornamental front of this structure, towards Exhibition-road, is not yet commenced. All the heavy earthworks and various levels of the gardens will be completed, it is said, next week, when the planting will begin. The Horticultural Society have announced that their first flower-show is to take place next May, when the arcades will be sufficiently completed.

**CHAPEL OF ST. APOLLINE, GUERNSEY.**—The chapel of St. Apolline is situated in the west of Guernsey, close by the sea-coast, and is of great antiquity. Mr. Dally, in his "Guide" to the Channel Islands, remarks that it is the only one standing of the many similar ecclesiastical structures in use prior to the erection of the parish churches. The interior consists of a plain chamber, about 27 feet long by 14 feet 9 inches wide. The chapel has two segmental doorways and three small openings; while it is covered with a pointed and ponderous vaulted roof. The sides of the roof and walls are adorned with fresco paintings; several figures of saints being visible on the north wall and one, a bishop, on the east wall. Nothing is known of the date when the building was erected, but it is considered to be the oldest in Guernsey. Some suppose it to have been erected in the middle of the tenth century, by the monks, who, it is reported, arrived in the island at that time. There is now in the possession of a gentleman in the island a silver-gilt chalice belonging to this chapel, round which are the words "Sancte Paulæ ora pro nobis," from which it may be inferred that the name of St. Apolline,—unknown to fame,—is substituted for that of St. Paul. But this chapel is in a very unsatisfactory state of preservation, for we regret to say it is used as a barn. Certainly such an edifice, which is, perhaps, the oldest we have standing, ought not to be allowed to fall to decay. It has been proposed to repair this chapel, and thus render it fit for public worship, small as it is, there being no church close to it.—M.

TENDERS

For repairs and laying 2,200 feet of 3-inch rubbed York paving, at the Butchers' Charitable Institution, Walham-green; Mr. Henry McCalla, architect:—  
 London Building Company.....£310 0 0  
 Bingham, Brothers..... 230 0 0  
 Porter..... 295 0 0  
 Bishop..... 215 19 0  
 Bryan..... 150 0 0

Tenders for alterations to No. 18, Store-street, Bedford-square. Mr. P. F. Holdsworth, architect. Quantities supplied by Messrs. Laisdown:—  
 Wicks.....£915 0 0  
 Battenbury..... 892 0 0  
 Keyes & Head..... 887 0 0  
 Jeffs..... 722 0 0  
 Tyler..... 775 0 0  
 Harvey..... 750 0 0

For new school, &c., Northampton; for Mr. Wainwright, Mr. E. F. Law, architect:—  
 Smith.....£280 0 0  
 Roberts..... 374 10 0  
 Jreson..... 365 0 0  
 Cosford (accepted)..... 359 0 0

For erecting a farm-house on the Branches-park Estate, Covingham, Suffolk; Messrs. Benest & Newson, Norwich, architects. Quantities supplied by Mr. E. E. Benest:—  
 Westley & Arber.....£1,200 0 0  
 Brooke & Wiseman..... 1,199 0 0  
 Lacey..... 965 0 0

For erecting bay window and making alterations to a house in St. Giles's-street, Norwich; for Mr. John Goddards, Norwich, architect. Quantities supplied by Mr. E. E. Benest:—  
 Ling.....£400 18 0  
 Brooke & Wiseman..... 381 12 0  
 Lacey..... 364 0 0  
 Moore..... 362 0 0  
 Spiaks & Burrell..... 359 0 0  
 Browne & Bailey..... 338 16 0  
 Bead..... 345 0 0  
 Chapman..... 309 11 5  
 Plummer & Bloom..... 281 0 0

For alterations and additions to the baths and wash-houses belonging to St. James's parish; Mr. Chas. Lee, architect:—  
 Myers.....£1,690 0 0  
 Patrick..... 4,547 0 0  
 McLennan & Bird..... 4,260 0 0  
 Adamson & Son..... 4,248 0 0  
 Humphreys & Lister..... 4,226 0 0  
 Walker..... 4,222 0 0  
 Palmer..... 3,826 0 0

For finishing two arcades, for Mr. R. Hallett; at Inck-burst-hill, Woodford; Mr. J. H. Rowley, architect:—  
 Masters.....£983 0 0  
 Humphrey..... 980 0 0  
 Cushing..... 973 0 0  
 Davey..... 893 0 0

For a house at Stoke Newington; Mr. Brooks, architect. Quantities supplied by Mr. J. Clever:—  
 Glenn.....£1,060 0 0  
 Hocken..... 1,010 0 0  
 Henshaw..... 992 0 0

VOL. XVIII.—No. 926.

The Central Park, New York.

HE Prince of Wales, during his recent stay in New York city, the commercial capital of the United States, after visiting the New York University, the Astor Library, the Women's Library, and some other public buildings (it was on the 12th of last month), went to the Central Park, and assisted at the transplanting of an English oak and an American elm. Long may they flourish side by side, vigorous and sturdy mentees of the pleasant visit paid by England, and the hospitable and warm hearted reception accorded by America.

Considerable progress has been made with the Central Park. Our readers may remember that,

in 1858, thirty-three plans for forming the proposed new park were submitted in competition, and four premiums, consisting of 4000, 2000, 1500, and 1000, were awarded. The successful design was presented by Messrs. F. L. Olmsted and Calvert Vaux, and the works were at once commenced by the Commissioners having the matter in charge, Mr. Olmsted,—the author, among other works, of "Walks and Talks of an American Farmer in England,"—being appointed to the chief position and the resident charge of the work; and Mr. Vaux, some of whose designs have been illustrated in former numbers of the *Builder*, acting as consulting architect.

The plan which has been followed is, with a few modifications and additions, the same to which the first premium was awarded. The cost of land taken for the park, with the extensions in contemplation, will be rather more than 1,000,000. The expenditure at present made on it amounts to about 500,000, and the total sum authorized to be expended is about 800,000.

When the architects sent in their designs they pointed out that, up to that time, in planning public works for the city of New York, in no instance had adequate allowance been made for its increasing population and hitherto; not even in the case of the Croton aqueduct, otherwise so well considered. The City Hall, the best architectural work in the State, and built to last for centuries, does not at this time afford facilities for one-third of the business for which it was intended. The present Post-office, expensively fitted up a dozen years ago, no longer answers its purpose. The Custom-house, expressly designed for permanence, and constructed to that end at enormous expense, less than twenty years ago, is not half large enough to accommodate the present commerce of the city. The explanation of this apparently bad calculation is mainly given with the fact that, at every census since that of 1800, the city's rate of increase has been found to be overrunning the rate previously established. In the allotment of land for the new park it was determined that this mistake should not be made.

The park is about two miles and a half long, and half a mile wide, bounded on the sides by straight parallel "avenues," and at the ends

by streets crossing these at right angles. It is now enclosed by a rough, dry stone wall, 4 feet 6 inches high, in which there are gates at convenient intervals. The area enclosed is about seven hundred and sixty-eight acres, of which one hundred and thirty-six acres are occupied by the reservoirs of the Croton aqueduct, whence the city is supplied with water. Measures are in progress for adding a space of seventy-five acres, which will make the length of the park 13,516 feet, and its area eight hundred and forty-three acres.

The old reservoir covers thirty acres, and stands upon high ground in the centre of the park. The enhancement is faced exteriorly with dressed stone, and, except where obscured by the recent improvements, forms a conspicuous object in the view from nearly all points in the southern half of the park. The new reservoir, when completed, will cover one hundred and six acres; but these are too much elevated for the water within them to form a part of the landscapes.

The park is practically divided by the reservoirs into two portions, the northern or upper park containing 160 acres; the lower park, containing 331 acres; and the connecting ground, lying on both sides of the reservoirs, 135 acres. It will be further subdivided by four thoroughfares (a very necessary consideration, one crossing it between the reservoirs, one at each end of them, and the remaining one near the middle of the lower park. These thoroughfares are to be so constructed, by means of tunnels and other contrivances, as not to interrupt the landscape, or practically effect any division of the park. Roads and walks will cross them in such a manner that, when the trees and shrubbery by their side are somewhat grown, they will not be seen by the casual observer. They will be noticeable from no part of the park, except at their extremities, where they unite with the exterior streets, at a higher grade than the surface of the park; appearing as causeways, a few hundred feet in length, terminating upon a hill-side. The park not being directly accessible from these covered ways, it will be unnecessary to close them at night, when the public are shut out from the park itself. They will furnish the means of direct transit across the park for business purposes, without causing inconvenience to its visitors. Two of these roads are now nearly completed, and one already in use.

To clear the site it was necessary to knock down many wretched hovels. During the autumn of 1857 three hundred dwellings were removed or demolished by the Commissioners of the Central Park, together with several factories and numerous "swill-milk" and hog-feeding establishments. Large tracts, partially covered with stagnant water, were superficially drained, and 10,000 cart-loads of loose stones taken from the surface and conveyed to the borders of the park, furnishing materials for the construction, during the winter, of the present enclosing wall.

Even after the removal of the buildings, and the drainage of the pools, the lower park still presented a confused and unsightly appearance. Parts were rocky and parts a bog. With the exception of portions of the two swampy valleys and the two ten-acre tracts above mentioned, and about three acres on Sixty-sixth street, near Sixth avenue, there was not an acre in which the great underlying ledge of gneiss rock did not, in some form, thrust itself above the surface. Probably not a square rod could be found throughout which a crow-bar could be thrust its length into the ground without encountering rock.

The designers desired that the park should, as far as practicable, present to the eye a charming rural landscape, such as, unless produced by art, is never found within the limits of a large town; always remembering, however, that facilities and inducements for recreation and exercise are to be provided for a concourse of people, and that the object of the scenery to be created is only to further the attainment of this end in the most complete and satisfactory manner. No kind of sport is to be permitted which would be inconsistent with the general

method of amusement, and no species of exercise which must be enjoyed only by a single class in the community to the diminution of the enjoyment of others.

Casual observers have been apt to think the selection of the site an unfortunate one, its general ruggedness being rather forbidding than expressive either of dignity or grace. But this was due very much to the absence of soil and foliage. As these are supplied, the quality of picturesqueness becomes agreeably prominent. Grass and shrubbery can be formed anywhere; but rocks, and those salient forms of earth-surface which are only found in nature where rock exists, can never be imitated on a large scale with perfect success. Although, therefore, it will require a heavy expenditure to make the park complete, a good artistic effect may be looked for.

In one part is a broad hill-side, broken by ledges of rock and strewn with boulders. This, which is to be called the Ramble, furnishes an interesting picture viewed from almost any point, but particularly so from the end of the mall. On the descent from this to the pond an ornamental stone terrace is under construction. This, the principal architectural feature of the park, is shown, as if complete, in our view.\* At the highest and most remote part of the bill, as seen from this terrace, a small tower will be erected; and this will be the vista-point of the avenue of the mall. Looking northward from the terrace it will be the only artificial structure in sight (the reservoir being "planted out" and the rising ground on the right and left shutting off the city). The whole breadth of the park will be brought into this landscape, the foreground of which will be enriched with architectural decorations and a fountain; the middle distance, composed of rocks, with evergreens and dark shrubs interspersed among them, reflected in the pond; and the distance extended into intricate obscurity by carefully planting shrubs of lighter and more indistinct foliage among and above the gray rocks of the background.

The sunken and tunnelled street thoroughfares across the park were planned to remove what would otherwise have been a ceaseless annoyance. Extending the application of the same expedient, several miles of gravelled walks have been laid out, carried by arched passages under the drives when necessary, by means of which all parts of the lower Park may be traversed on foot, without encountering a single carriage or horseman. The rides are everywhere in like manner made independent of the drives, but horsemen can enter the carriage-roads if they choose.

It is intended to introduce an arboretum, in which, within a space of about sixty acres, will be arranged in as natural a manner as possible, consistently with convenience for study, specimens of every tree and shrub which can be grown upon the site in the open air. The hill-side and valley between the fifth avenue and the east drive of the upper park arc reserved for this purpose.

When the commissioners made their last report, at the beginning of the year, about 18,000 trees and shrubs had been planted; 3½ miles of road had been made; 5 miles were in progress; 7½ miles of paths were completed; 10½ miles of drains had been laid down; 10 bridges were finished, and 8 were progressing. Of one of the bridges—that over an arm of the lake near the Ramble—we give a view from a photograph, showing the character of the ground with which the architects have had to work.

It is provided by law that bequests may be made to the city for the improvement and ornamentation of the Central Park, or for the establishment or maintenance of museums, zoological gardens, &c., upon prescribed conditions.

The commission have already granted permission to place within the park a monumental statue, in marble or bronze, of the late Commodore Matthew C. Perry, the gift of one of its members. The commissioners say, "To its intimate commercial relations with all parts of the Union, the city owes its unprecedented advance, wealth, and population. It is fit that

\* See page 745.

the virtues of heroes and statesmen, whose fame is the common heritage of the country, should, in this crowning work of its metropolis, find appropriate commemoration."

It is interesting to observe the eagerness that exists in the public mind for the establishment, within the Central Park, of institutions that will afford the means of popular cultivation and innocent recreation. Observatories, museums of natural history, zoological and botanical gardens, and galleries of art, find offers of substantial aid for their foundation; and though the board doubt the propriety of appropriating the moneys placed at their disposal for these or any kindred purposes, they deem it right to aid by all means in inducing the foundation of them by others.

They propose to establish a system of licenses for franchises and privileges, that will yield a revenue to the park without in any respect obstructing or taxing its free enjoyment in all departments. Licenses for refreshment-rooms; for light and proper public vehicles to run on the park; for perambulators, or Bath-chairs, for invalids, to be allowed on the walks; and for boats on the lake, are all to be made to yield a revenue, and relieve the city of a part of the annual cost of maintaining the park.

In their report the commissioners give the following statement of the size of the most celebrated European parks:—

	Acres.
"London—All parks in and near London, including gardens, squares, and parade-grounds .....	6,000
Ditto. Hyde Park .....	380
" Kensington .....	227
" St. James's Park .....	87
" Green .....	56
" Regent's .....	572
Windsor—Great Park .....	3,500
" Little .....	900
Richmond .....	2,250
Dublin—Phoenix .....	2,000
Gardens at Versailles, about .....	3,000
Paris—Bois de Boulogne .....	2,158
Berlin—Tiergarten, about .....	200
Munich—Englischer garden, about ..	500
Vienna—Prater .....	1,500
Magdeburg—Park and garden .....	120
Birkenhead-park, near Liverpool .....	180

The central lake was completed in December last, with the exception of a small amount of work at the extreme northern point, and the water entering from the natural sources of supply was shut in by closing the gate at the dam. The arrangement of this lake is for a summer depth of 7 feet, and a winter depth (for the greater security of persons frequenting it for skating) of 4 feet.

The area covered by the summer level of the water is 20 acres, and by the winter level, 17 acres.

All the inlets for the drainage into the lake likely to bring impurities or turbid water are provided with filters.

Mr. W. H. Grant, we may add, is the superintending engineer; Mr. G. E. Waring the draining engineer.

Some dissatisfaction has been expressed in respect of the time occupied and the largeness of the works contemplated; and, even on this side of the Atlantic, we have received a letter of complaints on the subject. The New Yorkers, however, may console themselves with the reflection that it is much better to do a thing well than quickly. A noble park worthy of their handsome city is not to be produced now-a-days out of a stony tract by rubbing a lamp.

The New Yorkers are very fond of designating New York as the "Empire City;" and they may justly consider it such; since, in the vastness of population, the amount of money capital, the number of public and private institutions for learning and benevolence, the elegance of its buildings, interest in art and literature, display in private munificence, as well as its vice and virtues, it exceeds all the other cities in the states.

It is also the seat and centre of commercial and financial matters. Its railways extend in every direction, communicating with all parts of the Union, even to distances of thousands of miles, and its shipping extends to all parts of the world. Thus its citizens may justly be

proud, especially since, but a little more than a century ago, it was a wilderness trodden by the Indian.

Entering its harbour from the ocean, we pass Staten Island on the left, Long Island on the right, over a bay of some twelve miles in extent, and approach Castle Garden, the lowest extremity of the city. From this point, the Hudson river extends along the west side, while the East River separates it from Long Island and the ocean, and bounds the east side of the city. In each of these rivers, for nearly two miles along the city, the spars of the shipping rise like a leafless forest, including all kinds of craft, from the noble merchant ship, the ocean and river steamer, to the small ferry-boat and fishing-smack. Brooklyn, on the East River, and Jersey City on the Hudson River side, are opposite to this part of New York, and are small cities in themselves, although in all their business relations they are connected with New York.

Castle Garden is now beginning to assume some historical importance, from having been a fortification in its earlier days, and having done service in the defence of the city, and latterly, being the place of reception for visitors of note, closing up a long series of them with the last illustrious arrival—the Prince of Wales.

Leaving Castle Garden, the chief thoroughfare is Broadway—the Regent-street of New York. But how it should have acquired its reputation as a broad way is not now evident, since it is not so wide as Oxford-street. But we suspect the early Dutchmen who planned it thought it wondrously wide, since all the adjoining streets are very narrow. Half a mile from Castle Garden, passing out of Broadway, is Wall-street, the street of banks and banking-houses, and the centre of money speculations for America. This street is adorned by the Custom-house, a good example of Doric architecture, built with white marble; and the Merchants' Exchange, a large building of blue granite. Situated in Broadway, and facing Wall-street, is Trinity Church, a specimen of Gothic. Some half mile more and we reach the City Hall, and the little plot of ground around it, designated as the City Hall Park.

From this point we find a succession of spacious stores or warehouses; some built with white marble, others with red sandstone, but vying with each other for architectural display and convenience of interior arrangements. The vast St. Nicholas Hotel, of white marble, rises from amidst these shops; and near it is the Metropolitan Hotel, of red sandstone. Nearly a mile beyond, and we reach Fourteenth-street and Union-square—a fashionable neighbourhood,—and the Opera-house, just a little out of Broadway. Here, too, a bronze statue of Washington is placed. Numerous buildings devoted to various business purposes, a few churches, theatres, public picture galleries, fill up the remainder of this crowded and busy street. Dwelling-houses, various public buildings, and shops of lesser importance, occupy all the streets in adjoining directions until you reach the rivers on either side. About two miles away from the lower part of the City, the dwelling-houses become the chief attractions.

All this part of the city is newly planned, having wide avenues running north and south, and streets extending from river to river, east and west. Many of these dwelling-houses are elegant specimens of architecture: all are of stone or marble. The Fifth avenue, Fourteenth street, and many of the streets extending almost from the Hudson River, west of Broadway, and near Broadway on the east side, are filled with private residences; and, now that the Central Park is being finished and is becoming a place of attraction, fine residences are being built all around it.

Trunways and omnibuses make easy, rapid, and cheap communication to all parts of the city. Thus, with busy people everywhere, richly-dressed ladies, as well as the toiling poor crowding the chief thoroughfares, elegant carriages, gaily-painted omnibuses, drays, and all kinds of vehicles passing to and fro, military companies, in their gay uniforms, on parade, with their noisy bands of music,—with the brilliant show of goods in the shop windows,

and a bright, joyous sky overhead,—we find a city much more like Paris than London, and one which, considering all its circumstances, the New Yorkers may well be proud of.

#### OPENING MEETING OF THE ARCHITECTURAL ASSOCIATION.

The opening *conversations*, for the session 1860-61, was held on Friday evening, the 25th ult., at the house in Conduit-street.

There was a very numerous attendance of members and visitors, including many ladies. The rooms were tastefully arranged, some fine specimens of Italian tapestry of the sixteenth century, from designs by Julio Romano, being exhibited, in addition to architectural drawings and photographs.

The chair was taken by the president, Mr. Roger Smith; and among the gentlemen present were—Professor Donaldson, Mr. G. G. Scott, Mr. Hayter Lewis, Dr. Barlow, Mr. Morgan, &c.

Mr. Arthur Smith (honorary secretary) read letters from Professor Cockerell, Mr. Tite, M.P., Mr. Godwin, Mr. Kerr, and others, expressing their regret at not being able to attend.

Mr. Penfold read the report of the sub-committee (consisting of Messrs. Roger Smith, Mr. Thomas Allom, and Mr. Penfold) appointed to consider the drawings submitted in the class of design, and the essays on street architecture. I stated that seventy sketches had been sent in by eleven gentlemen. Many of these were of great merit, and the committee recommended that the prize should be awarded to Mr. W. T. Sams. The designs submitted by Messrs. Rogers, Lewis, and Teeves, also deserved especial commendation. The committee regretted that but one essay on street architecture had been sent in, and they recommended that the subject should be again submitted for competition next year.

Mr. Sams having received from the hands of the president his prize for the best design, accompanied by a few words of congratulation and encouragement,

Mr. Arthur Smith announced that the following gentlemen had been admitted members of the Association:—Messrs. W. A. Moy, Edmondson, jun., H. Claydon, R. G. Mather, Henry Rack, Alfred Sansome, Charles Humphreys, Payne, Thomas Brown, James Dudley, W. G. Habersham, T. D. Wakeford, Clutterbuck, Clarkson, J. W. Browne, and Ridge.

The President then delivered the following address:—

LADIES AND GENTLEMEN, AND OLD FRIENDS,—In conformity with a long-established rule, which imposes upon the president for the year of the Architectural Association the duty of opening the proceedings of its session by delivering an address, it now devolves upon me to bid you welcome, and to invite your attention to a few observations suggested by the occasion which has called us together.

I have much pleasure in being the mouthpiece of the committee to thank you for your presence here this evening; and I congratulate you heartily on the return of those opportunities for friendly intercourse and mutual help, heralded by the recurrence of this our opening meeting, and of those that are to follow.

On occasions when our friends, after any lengthened absence, the talk commonly turns first upon all that has befallen themselves and their acquaintances since they were last together, and then gradually glides into topics of more immediate and personal interest.

It seems, therefore, only natural that our reflections to-night should take a similar course, and that I should ask you first to follow me in making a few remarks on those occurrences and features of the past twelve months that are of general interest to our profession; and then to turn the current of your observations towards ourselves, on our actual position, and our prospects for the coming session. It is on the whole cheering to advert to the state of things and prospects a year back, and to compare them with the condition in which architecture seems to stand at this present day. At the opening of our last session, we were in the depressing influence of that forced stagnation under which all buildings had languished, and by which most had been arrested; and a repetition of the same evils was looked for by many of those best qualified to judge; while the threatening aspect of the political horizon seemed to bode ill for the fate of peace. Our profession, too, seemed to be in some danger of being split into two factions, so strongly were differences of opinion urged and maintained by the opposed advocates of the Medieval and the Classicist styles, provoked by events connected with the proposed creation of a Foreign Office.

To-day we are able to congratulate one another that the year is nearly out, and we have had neither a strike nor a war. There has been a great deal of quiet activity in spite of the very unseasonable weather we have had to encounter, and there has been no deadly feud in our body. On two occasions, on the hand of death has been among us, and united action has been desirable, the most harmonious unanimity has been exhibited, and there has been, I think, undoubted evidence of a good spirit pervading all ranks of the profession.

It is, no doubt, a consequence of the depressing influences I have alluded to, that there seems to be much less in the architectural productions of the past year to warrant special notice than some other individual years that might be referred to have accomplished.

We have not had any strikingly attractive competition nor many buildings that have risen very conspicuously

scribing; and they miss altogether the practice, the enjoyment, of *vis-à-vis* speaking and actual hearing, the opportunities for criticism, and, above all, the agreeable intimacies and pleasant life-long friendships that have been formed in this society, and are perhaps its true secret of power.

Of the arrangements that your committee have made for the session this day commenced, the printed syllabus already circulated will have given a good idea, but there are several particulars to which I desire for a moment to invite attention.

You will remember that the committee whom you elected at the close of the last session was composed of a large extent of new members, and that to them you entrusted the task of revising several portions of the rules. This committee has held numerous sittings during the recess, and has applied itself to the preparations for the session with a diligence and a spirit that I hope will meet, as they unquestionably merit, your approval. This reference to the committee induces me to call your attention to their exertions in procuring the good list of papers on our syllabus, and their efforts and success in bringing together, and fixing for inspection, the many drawings, books, and other objects of art that are scattered about the room; and particularly in fixing the three noble tapestries lent us for exhibition by the kindness of Mr. Cowan. These tapestries are worthy of your best attention: the centre one (the subject of which is *Æneas and Dido*) is by Pierino del Vaga, the most celebrated, except only Giulio Romano, of all the pupils of Raffaele; and the other two (representing *St. George* and *St. Andrew*) are of uncertain authorship, but undoubtedly of the school of Raffaele. They are all fine, but the Pierino del Vaga strikes me as equalling the very best works of that great artist, even the frescoes which he painted in his finest pictures. But this is a digression. To return to what the committee have been doing. Various modifications in the rules, which have been all considered in repeated committee meetings, and which I have had the special business meeting; and I trust that so many members as can be present at that meeting will attend to discuss them; while, with such a discussion impending, you will not expect me to say any more of what I have proposed. I ought, however, to tell you of one intention, which, as the carrying out of it will depend a good deal more on myself than on any one else, it is appropriate that I should bring before you, and that you should have resolved that it is expedient that for the future the chair shall be taken at our public meetings with exact punctuality at eight; and I have, therefore, to inform you that you are invited upon the subject, and that, if it is intended, except under special circumstances, not to prolong our meetings after ten o'clock.

The offer of prizes for the best set of sketches in the class of design having had a satisfactory result, as you have this evening an opportunity of witnessing, it is proposed to offer a similar prize this session; and, as the committee of the class of design have made some regulations of their own respecting drawings, and especially one relating to the size of drawings, a step which, according to our constitution, they are empowered to take; I have to request all intending competitors, to put themselves in communication with the secretary of the class.

Since these words were written, I have had the very great satisfaction of receiving, and being requested by Mr. Tite to communicate to you, a most generous offer of an annual prize, conveyed in a letter from him, which I will read to you. In the first letter from Mr. Tite, already read, he volunteered a donation to our library, and the moment it was suggested that, though we are not in possession of a library, a donation to be applied to the purpose of a prize or prizes would be most acceptable; he, with the utmost promptitude, sent by return of post the reply, received this afternoon, which I have now the pleasure of reading to you.

"I am much obliged to you for your note and its suggestions; and I beg you to announce to your committee that I shall be happy to place at their disposal 5*l.* per annum, to be distributed in prizes in books, or in any way best calculated to promote the very praiseworthy objects of your Association.

If you will kindly call upon me, I will endeavour to make arrangements for the regular payment, annually, of this sum, at the period of the year most convenient for your purposes;—and also to say a word on the objects to which the prize or prizes may be devoted."

It will be observed that it is not till we have seen Mr. Tite, that we shall be able to publish the mode in which he will approve of his generosity being applied; probably it may be devoted to one or two prizes already announced, the Association furnishing the other. The moment the question is settled, it shall, however, be publicly known; and, in the meantime, we owe the warmest acknowledgments for the offer, acknowledgments which you will be asked presently to pay in the form of a definite resolution.

Having had occasion to refer to the class of design, it may, perhaps, be desirable to explain, to those that do not belong to us, the nature of this highly-important part of our constitution. The class of design might, perhaps, be designated by a more expressive name, because it is neither a class of design, nor a class of book-keeping names, and an expected or enforced attendance; nor yet is it formed for the purpose of getting instruction from any one person. It is simply a meeting, on the Friday evenings intermediate between our regular meetings of our members as like to attend and bring with them a sketch illustrative of the subject previously decided upon, a list of which subjects for the week is contained on the syllabus in your hands. The sketches are handed round, and afford subject for comment from the members present and the president; and, after this is over, the rest of the time is spent as the members think most profitable.

For a long time it was (except when a paper of some description was prepared and read by a member) customary to decide on a subject for a design to be made there and then, in a short fixed time, and hence termed the *half-hour's sketch*. It is now, I believe, proposed to practise drawing architectural ornament from casts; but any other advantageous way of spending an hour may be selected by the gentlemen who attend, subject to the approval of the committee.

Now, this class of design is, I have no hesitation in saying, an institution of great value. It has produced many first-rate designers: it is spoken of in the highest terms by those who have at different times belonged to it; and it is entirely free to any members. You will be therefore glad to learn that this is continued unaltered.

We also continue to keep up the registry for draughtsmen out of employ, and for architects desiring assistants, and are always glad for our friends to avail

themselves of it, as well as of any of the other little privileges of membership, such as, for instance, the possibility of being admitted to see the models in the British Museum, and to some other public institutions; and we are determined to take the best means in our power to promote the personal acquaintance of members with one another, and with the members of the committee, convinced that in so doing we are carrying out the best aim of the Association; in fact, the original aim, for the whole of our history had its start in an observation made by the founder, Mr. Wilson, "What a pity it is that architectural draughtsmen do not know one another more!"

The offer made last year of a prize for an essay is this year renewed; and as the subject of the last year's competition (which was, however, no competition) is one of the best that could be devised, it is again proposed, in the hope that several of the members may be induced to write an essay on "Street Architecture."

To meet a wish that had been expressed by some of the members to have some papers read on subjects of elementary but fundamental importance, it has been arranged to devote four of our regular evenings to the discussion of the four simple but important subjects of "Foundations," "Masonry," "Brickwork," and "Carpentry," and on these occasions it is intended that the paper succinctly introducing the subject shall be supplemented by short statements of portions of the subject by other members, who will be requested beforehand to prepare for this engagement: it is hoped that peculiarly valuable results may be thus obtained; and although on these four evenings the price of the subject by other members, information will be sought to be secured with the greatest care, it is by no means intended to limit this preparation to those evenings. On the contrary, the committee earnestly desire, if possible, that the subject by other members should be prepared to discuss the subjects of the papers proposed to be read; and it is their intention to take some trouble to seek out and bring forward those members of their own profession who are best qualified to do so, who may be supposed to be peculiarly conversant with the subject of any paper about to be read; and I sincerely hope that members will find a pleasure and an advantage in such a course.

One other new feature, which it is right I should bring before your notice, is indicated on our syllabus: it is the arrangement by which a few of us have agreed to meet in the evening, on the subject of the subject by other members, on the evenings of ordinary meetings, to study the subject of botany as it bears upon architectural and decorative design, under the guidance of Mr. Binslin, one of our members.

Those of my hearers who are in the habit of designing ornament will not need to be informed of the advantage derivable from a familiarity with the forms and modes of growth of the vegetable world; and, in fact, all our members that many of you will feel disposed to embrace this opportunity of obtaining that familiarity, under competent guidance, and with the advantage of specimens, dried and fresh, and diagrams. Should it be found desirable to close this series of evenings before the end of the session, there is a dim idea of taking up either the subject of chemistry or that of geology, in the same way; and there is also some idea of the subject of mineralogy, or of facilities for instruction in architectural modelling, as suggested last year; but, as these ideas have not yet assumed the form of definite proposals, and may not for some time, I do not dwell upon them.

And now, after this enumeration of the intended engagements of the year, it remains only for me to invite you all to contribute,—our lady visitors, by kindly "excusing" on association evenings, and generally, who are a society of such of our members as are their friends; our members by attending regularly and taking part warmly in the proceedings; and our other visitors by either themselves joining us, or that by their presence they give us the largest portion of our time, and his best energies of mind and body, has a claim upon him that, at least, whatever else is neglected, should be done nobly and well. There may be some excuse for those toiling in a dull unlightened routine of monotonous labour to throw their freshest and best energies into the recreations or employments of their leisure hours; and yet, even in this case, it is an inversion of the laws of life. If one sees a man keeping accounts all day with no interest in his work, and little or no pride in doing it well, so that he do but escape the rebukes of his superiors, and then returning to his home to tell with heavy good-will and unselfish enjoyment, of his day's work, one cannot help feeling affected earnestness in his garden; one cannot help feeling how much more good he would have done to the general human family, and how much happier a life he would have led, had he turned a gardener instead of clerk at his outset in life, and left the counting-house to his leisure to those who really take a pride in the beauty of their writing and the accuracy of their calculations.

But, however this may be in some cases, there can be no excuse for half-heartedness in the pursuit of a profession like that of architecture; one which more than any other calls into equable use all the faculties of the mind, and does not neglect the body. At once sedentary and active, speculative and practical, and of a business-like, the architect must combine the most opposite qualities, can make use of the most varied tastes, and can turn to profit the most comprehensive information; nor should he deem anything whatever in the whole domains of science, art, or history, foreign to his studies.

With a scope before him far greater than the most exalted facilities, the most stirring energy, and the most prolonged life could fully give, the architect, as yet, the satisfaction to know that, by limiting his efforts to one or two things at a time, it is within his reach to attain a very high degree of perfection in some, and at least an acquaintance with most, of the studies or forms of skill germane to his profession. This consideration furnishes an incentive and an encouragement to study and to labour with diligence, for, although complete and universal success, even within the narrow limits of one profession, is unattainable to human power, it is quite impossible to say how near an approach to that perfection may be practicable.

In this struggle, and with these objects before us, we

feel we can help one another; and on that ground it is that this association was formed; and it is from a conviction that our friendly co-operation here has been of value to us, and will be of more value still, the more energetically we prosecute it, that we adhere to this association, and desire its advancement. Let us, then, continue, in mutual assistance, and maintain and redouble our individual and collective exertions.

Lastly, let us all bear in mind that to the keeping of each one of us committed a portion of the *honour* of the profession. Circumstances may put a *brilliant* career beyond the reach of some, of many, of all of us; but stillness one is possible to all of us, and nothing short of that is allowable to any of us.

In integrity and honour, then, let us be perfect,—in friendship undivided,—and in study and practice let us resolve each to know no limit short of his utmost and his best, taking as a maxim of practical life those inspired words, "Whatever thy hand findeth to do, do it with thy might."

At the conclusion, the President having invited discussion,

Mr. G. Gilbert Scott observed, that, in attending that evening, he had not come to speak but to listen; and that all he could do was to express his extreme gratification at the able address which he had just heard.

Professor Donaldson stated that he also had been afforded much pleasure by what he had witnessed that evening. The various topics to which the President had referred in his address were of deep interest and importance to the profession to which they all belonged. With regard to the Continental style referred to by the President, he (Professor Donaldson) ventured to hope that they would not be indebted altogether to foreigners for their designs, and that native talent would not be found wanting either in fancy, imagery, or conception. With regard to the question of competition, he was of opinion that nothing could be more ill-advised than to attempt to interfere with or disturb the integrity of the decisions arrived at by tribunals of selection. Any attempt of that kind would infallibly introduce a flood of favouritism, and true merit might be sacrificed to personal influence. In his opinion, the only safe course was to uphold the decisions of those to whom competing designs were submitted, unless it could be shown that bad faith were practised in which case, of course, any decision that might be arrived at would be illegal.

On the motion of Mr. Allom, seconded by Mr. Penfold, a vote of thanks was accorded to Mr. Tite, M.P., for his offer to place at the disposal of the committee the sum of 5*l.* annually, to form a prize for the best sketch or essay in the class of design.

The proceedings then terminated.

The class of design have met, when designs for a verandah were submitted.

The next meeting of the Association will be held on the evening of the 9th inst.

#### FROZEN MUSIC.

MADAME DE STAËL, in one of her brilliant conversations, speaking of the soul-feeling displayed in architecture, called that art "Frozen Music." Hence the derivation of the title of my theme. Our subject will be about poetry and the beautiful in connection with architecture; and we shall, I think, find that the subject is as grand as it is exhaustless; and we shall, I trust, by the time we have finished, have gathered together the idea that a "Frozen melody" is after all a very beautiful thing.

Dr. Cheever, in speaking of the cathedral of Milan, says:—"If you can conceive of a river of liquid white marble shot into the air to the height of some 500 feet, and then suddenly petrified while falling, you will come to some approximate imagination of the beauty and rareness of this magnificent vision. It seems like a petrified Oriental dream." And Wordsworth sung the same theme,—

"But fancy, with the spell of fire,  
Hath fled to Milan's loftiest spire,  
And there alights, 'mid that aerial host  
Of figures human and divine,  
While as the snows of Aegæine  
Indurate by frost.

Awe-stricken she beholds the array  
That guards the Temple night and day:  
Angels she sees that might from Heaven have flown;  
And virgin suits, who not in vain  
Have striven by purity to gain  
The beatific crown.

Far-stretching files, concentric rings,  
Each narrowing above each,—the wings,  
The uplifted pinnacles, the silent marble lips,  
The stary zone of over-voiced height,  
All steep'd in this portentous light,  
All suffering dim eclipses."

Now, it is some such emotions as these I wish to awaken, and if I fail, believe me the fault will not be in the subject, but in the writer.

People, for the most part, seem to think (or rather dream, for thought is almost out of the

question) of architecture as if it referred only to "bricks and mortar," "measuring and valuing," or abstruse mathematics:—

"Surely the time shall come,  
When this fine overplus of night,  
No longer sullen, slow and dumb,  
Shall leap to music and to light."

Our archaeological societies are, indeed, teaching us to look behind the broken column, and the ivy ruin, and there see the genius whose subtle divine conceptions emanated, and which could impress itself into a material form.

In the grand poem of architectural history reposes much that is beautiful and true and noble, in which the lofty mind of man, aspiring toward heaven, has left its noble impress,—in which we may obtain glimpses of hygone nations, whose histories are written with an indelible hand on the stones. What should we know of Nineveh, without the magnificent Assyrian marbles? What of the gigantic types of thought and being of Egypt, without the sublime temples of Carnac and Apollonopolis; or the dim colossal ruins of Thebes? What of Greece, without the exquisite conceptions of Pericles, Ictinus, and others? or of Rome, without the Colosseum, temples, and arches reared by its pride? How necessary is it, then, that we should be able to read our poem. How much greater the enjoyment of the mind is by such a knowledge, more especially in these railway-excursion-times. An ignorant or a forgetful traveler cannot possibly see aright but the superficial scene before him; he cannot look into it, and hear its great heart throbbing, nor catch the exquisite dulcet tones of its historic life and being; in fine, to quote the poet's satirical figure:—

"A primrose by the river's brim,  
Or at the cottage door,  
A yellow primrose is to him,  
And it is nothing more."

Goethe somewhere says, that "man is so inclined to give himself up to common pursuits, the mind becomes so easily dulled to impressions of the beautiful and perfect, that one should take all possible means to awaken one's perspective faculty to such objects; for no one can entirely dispense with these pleasures; and it is only the being unaccustomed to the enjoyment of anything good that causes men to find pleasure in tasteless and trivial objects which have no recommendation but that of novelty. One ought every day to hear a little music, to read a little poetry, to see a good picture, and, if it were possible, to say a few reasonable words."

The person who can read our frozen poetry peoples it with great forms, sees in it grand moral lights and shades, surrounded by the many coloured lights of the past as well as the light of to-day's sun. Let us then take courage, "with a heart for any fate," let us arise and be doing, remembering always the immortal destinies of man, and the hopes that are ever surging in his heart, and ever rising upward. Let us

"Build on in hope, with pillar, dome, and tower,  
Not for the present, but for a distant hour.  
Brief is the span of life: the builder eyes  
His deep-thought plan, and sees the walls arise;  
Anticipates the whole, and then expires  
Greatly accomplished. Yet his genius fires  
The lasting pile. Not men, but nations too  
By such day oblivion."

Thus it is evident the beauty of our poem concerns us all; for its knowledge enables us to see in our travels something more than beautiful scenery and odd-looking ruins; and which in this England of ours is especially valuable from the many relics of antiquity still left us, and in *summa excellentia* to see living poetry in "those wrecks of another world whose ashes still are warm,"—those fallen arches, and arch-crushed columns, and choked up vaults; or in those beautiful heaven-aspiring pinnacles and spires, that flash meteor-like in the sunlight, and which seem to give us glimpses of the glory never to be forgotten, telling us, like gleams on a sunset sea, what once hath been.

"The architect:  
Built his great heart into these sculptured stones,  
And with him tould his children; and their lives  
Were builded with his own into the sculptured walls.  
As offerings unto God."

An enlightened mind beholds all things in their true and natural light, and in return (for there is a reward attached) receives from them such lessons of the true and beautiful as they are intended to convey. Such a mind does not shut itself up in a narrow gloomy prison, till it thinks the walls of its own self the limits of the universe, and the reach of its own chain the very verge of all intelligence; but it walks abroad, eyes open, ears open, and soul open; and so the sunshine and balmy air pour in their flood of effulgence, ex-

panding and enlightening the darkest recesses. And so the mind, becoming thus the glad recipient of light and wisdom, develops new powers, and assumes a nearer similitude to the Eternal Mind in whose likeness it was made.

The great principles and ideas of our poem have their answering types in science, literature, religion, manners, government—everything. In it we may find the hidden harmonies of being; and, by learning to read it and understand it, we contribute to the solution of the great problem of the universe. Our poem consists of two parts, an inner and an outer; the universal and the local; the perennial and the fleeting. Its inner or spiritual essence comes from the truest soul of the author, and findeth ceaseless response in the human soul: coming from the heart, it must for ever go to the heart. The nature of our poem is indestructible, and destined to appear and reappear in every age. It is our part to woo the immortal spirits of the past as well as of the future; and breathe the celestial fire that is in us into the material necessities of the day.

What we can see of the remote past, through the deepening shades of time, is as of some great unknown sea, on which some solitary ship is afloat, whose course we can but dimly trace through the clouds which every way gather around her. There is somewhat of this shadowy dimness woven into the warp and woof of the first canto of our poem, but which nevertheless is highly interesting, for therein we read of the early struggles of our race. That we must have raiment to cover us, houses to shelter us, food to eat, is all very true; but one of old declared that the race cannot live by bread alone; and how true this is for all time I need not specify. It is certain that those necessities are not the end, the aim, the purpose of our race. Created intellectually in the image of the Eternal, there are of necessity affections, desires, aspirations, in the human breast, which nothing can satisfy but the true, the spiritual enjoyment of those things peculiar to our moral and intellectual nature; and these enjoyments are obtained by the free exercise of the faculties which the Eternal has implanted in us for the contemplation and discovery of all truth—the indulgence of the exalted emotions arising from the view of the physical and intellectual harmony of the universe. The privilege of revelling in the bright dreams of poetry and science, and basking in the rays of genius; communion with the noble living and the noble dead: such are some of the true, the spiritual, the undying things. Being gifted, then, with such powers as these, we are enabled to penetrate the deep mysteries of nature, and read the handwriting of the Infinite.

The immortal Schiller somewhere remarks that "it is not enough that all intellectual improvement deserves our regard only so far as it flows back upon the character: it must in a manner flow from the character, since the way to the head must be opened through the heart." If we desire to be noble, to be manly, to enjoy our high intellectual nature, we must, as Goethe says, "Live in the Whole, the Good, the True;" for certain it is that purity and nobleness of life is an inspiration to the intellect. We have a voice that questions all the past and anticipates all the future;—a faculty to reconstruct what it sees according to its own ideal, and thus creates new worlds all its own.

The circumstances by which humanity is surrounded, and by which it lives, moves, and has its being, socially and intellectually, are seemingly, perhaps, but not really, a set of dull mechanical contrivances: the destiny of the race is for a higher purpose than sensual existence: the soul-life is a thousandfold more important, and the laws that apply to our moral nature are immeasurably more important, more solemn, than can be any other considerations. Those laws surround our spirits like an invisible but adamant circle, not to fetter but to guard, to develop and guide. There are silver chords that connect the inner life with the outward: these for the noble, the good, are connecting links between earth and heaven—a sort of Jacob's ladder,—on which bold, pure thoughts, like angels, wander up and down. Those laws, too, are designed to assist an upward growth of the soul, and to minister to that glorious development of the beautiful, the true, and God-like, which must be the never-ceasing aim of our being in its everlasting progression.

That philosophy which began with Socrates and Plato has now spread itself abroad in the world, and is becoming transferred into our literature and art. Art, whose direct mission is the representation of the true, the beautiful, by forms that speak rather to the soul than to the senses, and that awaken deep and earnest thought by the

noblest and most glorious images, can never be separated from that philosophy. Mons. Cousin, in his lectures on the "Beautiful," says:—"Tell me what sentiment does not come within the province of the painter. He has entire nature at his disposal, the physical world and the moral world; a temple, a churchyard, a landscape, a sunset, the ocean, the great scenes of civil and religious life, all the beings of creation; above all, the figure of man and its expression—that living mirror of what passes into the soul."

Things inanimate are possessed of life: the old ruin and grey relic of antiquity, pleading haughtily for glories gone, speak in voices which most people hear not, heed not: they are like eternal lamps in the bright city of God. But

"Vauhis'd is the ancient splendour,  
And before my dreamy eye  
Were those mingling shapes and figures  
Like a faded tapestry."

We feel that Ruskin was right when, in his "Seven Lamps," he says, "How cold is all history, how lifeless all imagery, when compared to that which the living nation writes, and the uncorrupted marble bears! How many pages of doubtful record might we not often spare for a few stones left one upon another! The ambition of the old Babel builders was but directed for this world. There are but two strong conquerors of the forgetfulness of men—poetry and architecture; and the latter in some sort includes the former, and is mightier in reality. It is well to have not only what men have felt and thought, but what their hands have handled, and their strength wrought, and their eyes beheld." This is indeed the grand æsthetic principle of our frozen poetry, the concatenation of the world history written in imperishable characters on the uncorrupted marble, and revealing to us the idiosyncrasies of every nation. These all may behold, and seeing, learn if they will "the primal art of man."

Thus in all time, from the monolithic column to the trillions of Surim, from the Propylæa of Pericles to the gorgeous fantastic Alhambra, we may trace the same spirit of beauty, the same eternal æsthetic principles.

Let us in imagination go back for a moment to the origin of these principles, and we shall find they may be traced even to the expulsion of our progenitor from Paradise. Return to yourselves, if possible, the feelings of the founders of our race on seeing the fiery swords of Eden's guardian angels forbidding their return, and all about them the "wide, wide world," full of strange unvisited scenes. How different from what they had recently left. They had erewhile been accustomed to hear the voice of the Lord God walking in the cool of the day; but now they must hear it only occasionally, and that under the dim, shadowy starlight. Oh! with what a whirlwind would the thought of what a home they had lost rush into their minds? Everything had heretofore exquisitely syllabled beauty, and intellectual happy home; the nightingale's ravishing melody to the departing sun, and the lark's thrilling song to its rise; the company and high intellectual talk of angels; the beaming light, the refreshing night, the dulcet notes of its fourfold waters, the sighing of the winds amid the leafy bowers, conveying, as it were, Arabian music to their souls;—all, all told of the dignity of their race, and the beauty of their home. And now they were exposed to the vicissitudes of wind and rain, of sunshine and cold, the piercing blast as well as the refreshing breeze. Then did the knowledge they had newly and recently acquired—of good and evil,—arise with irresistible force in their souls,—they thought of what they had lost and what they had gained; and the distress of their souls made itself known by an outward sign—the manifestation of protective art; and now in this latter time, under the twilight and starlight of past ages, we hear the voice of man walking amid the works of his genius. As vapours from the ocean floating landward dissolve into rain, and are carried back to their original source by the agency of rivers, so thoughts and the semblances of things that fall upon the soul of man in showers, flow out again in the living streams of art and beauty, and lose themselves in their original source—the eternal.

Thus, then, our frozen poem may be called a revelation of nature—of God speaking through man. It pre-existed in nature and nature is reproduced in it. Our poem is created—fashioned by the natural movements of the soul of our race. Statues, paintings, churches, poems, are the shadows of the race,—shadows in marble, colours, stone, words. We feel and recognize their beauty, and in return they act and re-act on us, giving birth, oftentimes, to vague images and shapes of

beauty, which float through the soul, as yet indefinite, but made perfect when put forth in art.\*  
F. D.

#### INFORMATION FROM ABROAD.

THE new constructions of the Palais des Beaux Arts advance rapidly. They consist principally of two vast saloons, which are to be appropriated, one, on the ground-floor, to the exhibition of Roman productions of art; the other, on the first-floor, being for an examination-hall. A large arched doorway, opening on the Quai Malouais, at present being terminated, gives access to the institution. It is proposed, at some future period, to unite these new buildings with those of the ancient school by means of a spacious gallery, somewhat similar to that of the Sainte-Genevieve Library, to be reserved for the collection of casts now in the Louvre; while two lateral galleries of less dimensions are to be devoted to paintings.

In the Rue de Bac, starting from the quay, a spacious sewer is to be constructed, and the ground is opened for the purpose. It is to communicate with that recently constructed under the Quai d'Orsay, and which is continued along the Quai Voltaire. This last, parallel to the Seine, will eventually be placed in communication with the grand collector of Asnières by means of a siphon, under the river below the Pont de la Concord.

The *Revue des Alpes* states that a Druidical altar has been discovered at La Motte-d'Aveillans, near the thermal establishment of La Motte-Saint-Martin. This stone consists of a cylindrical block, ten metres in circumference and five metres high. The first cylinder is surmounted by another, only fifty centimetres in height, but of a diameter of three metres, and disposed in such a manner as to leave a free space in front, upon this species of table, and a somewhat deep hollow cut out of the stone, in which it may be the victims were sacrificed. At the base, on each side, there are protuberances resembling wheels, evidently carved for facility of transport of the block.

In Savoy, the following works have been decreed by the Emperor to be of public utility, and are to be carried into effect:—the establishment of a port at Thonon, on the Lake of Geneva; the improvement of the port of Evian, as also that of the navigation of the Dranse and its affluents.

#### THE DEMOLITION OF THE ANCIENT PERCY'S DINING-HALL AT ALNWICK CASTLE.

AN apologetic account of the destruction of this interesting piece of antiquity, "the ancient Percy's dining-hall," appears in the *Newcastle Journal* of the 27th ult. The facts are so unfairly glossed over, that in the interests of history and archeology we think it desirable to lay before our readers a contrasting statement to that of the writer of the account in question.

It will be fresh in the remembrance of our readers that, in our recent paper upon the works at Alnwick Castle, we recounted the acts of Vandalism committed there, in the entire destruction of the Percy dining-hall, and the Falconer's and Armorer's Tower, with the Norman curtain wall between them, for the sake of the Italian internal arrangements and decorations. The interest that the narration created caused extracts to be copied into almost every journal in the kingdom. We then merely glanced at the broad facts: we now give them in detail. The writer of the account in the *Newcastle Journal* states:—"It appears that though the ancient dining-hall of the first Lord Percy of Alnwick was retained by the first duke, it had been greatly altered. The original entrance, which was from the outside, was walled up, and a new one broken open. The ancient fireplace had been abandoned, and another formed. The same was the case with the windows. A room had originally existed over the hall, the fireplace of which remained in the wall. This floor was taken away. The alteration had been badly done. The old openings were blocked up with loose rubble, covered by a thin skin of masonry. The wooden lintels had decayed. The wall had been greatly weakened by the new openings. The new roof had been made of common plantation timber: it, too, had decayed, and, settling down, was pushing out the walls." In vivid contrast to this mild narration we have, fortunately, in the laborious volumes edited by the Rev. W. H. Hartshorne, entitled, "The Feudal and Military History of Northumberland," a glowing account of the ancient features of the Percy dining-hall, just previous to

their demolition. After describing the hall previously to the removal of the Georgian plaster decorations in the following terms:—"An improved degree of taste would reasonably have found fault with the thinness of the mouldings, or with the ill-understood profuseness of its decorations. But when criticism had exhausted itself on the minor ornaments of the room, its proportions still remained massalable. They were those laid down by the architect of the first Percy."—he goes on to describe the interesting features discovered on the removal of the plasterwork:—"This revealed a most curious specimen of domestic architecture during the Middle Ages, showing not only the exact dimensions of the former baronial hall of the first Percy, but the various arrangements that were adopted for luxury, for entertainments, and for convenience. At the south end of this grand banquetting-room were the marks of the dais or high table that stretched across it. Over the dais was the buffet for the display of crystal cups, silver flagons, and plate, with a lion's paw as the termination of a hood mould; and on one side a small water drain. A door and staircase communicated with the cellar below, and the hooks for suspending the tapestry on the walls remained in the old plaster."

The writer in the *Newcastle Journal* completes his apology thus:—"To have endangered human life in the attempt to save a semblance of antiquity would have been worse than folly." We happen to know that, whenever it was determined to preserve a semblance of antiquity, daring feats of masonry were performed and human life endangered. His Grace the Duke of Northumberland on one occasion desired that a certain portion of the curtain wall adjoining the new kitchens should be preserved, and an enormous mass of wretchedly-constructed Norman walling was underpinned 20 feet deep, to a considerable length, at great cost and imminent risk. This feat was accomplished and a "semblance" of antiquity preserved; and again, even in the Percy dining-hall in question, when it was resolved that the external wall of the large round tower of this hall did not interfere, as the remainder of the building did, with the new Italian form for the interior; at great risk and imminent danger the inner and most interesting part of the tower only was destroyed, and the outer "semblance of antiquity" preserved.\*

#### FINE ARTS IN AMERICA.

AMONG the many rapid strides which the city of New York has taken in the few past years, in the higher adornments of life, none are more noticeable than a growing taste for the fine arts, and the consequent development of artistic works in that flourishing capital. The character which the American people had, with some reason, acquired of being devoted exclusively to commercial and money-getting pursuits, is rapidly changing; and as Jonathan, when he undertakes a thing, generally does so in earnest, we anticipate the time when the United States will take a foremost rank in the encouragement of art.

A fresh impetus is about to be given to the encouragement of Transatlantic art by the erection of a new establishment, to be termed the "Institute of Fine Arts," in New York. The Dusseldorf collection, once the property of Mr. Boker, forms the nucleus of the enterprise. Mr. H. W. Derby, the proprietor of the Dusseldorf Gallery, as soon as it came into his possession, seeing that the present gallery was inadequate to his purpose, determined to devote his energies towards establishing the largest art-gallery hitherto attempted in that hemisphere; and for this purpose he selected an excellent site on Broadway, between Houston and Bleeker streets.

The new gallery, erected at a cost of about 12,000*l.*, is intended to be supplied with varying collections of productions of painting and sculpture, not only from native American artists but from those of England, France, Germany, &c. It is 34 feet in width by 200 feet in depth, extending through the entire length from Broadway to Mercer-street. It is divided into compartments, or separate exhibition-rooms, lighted with skylights. If not too late, we should suggest a revision of these; as, judging from a section before us, we should doubt a favourable result.

The facade is Italian in style, and involves the introduction of sculpture to some extent. The

\* *Caution to Tourists.*—It has been stated to us that the first commoner in England (the Speaker of the House of Commons) journeyed one day last week to Alnwick Castle, and sent in his card to the Duke of Northumberland. His Grace sent answer that he could not be seen. The Speaker politely returned a message that he had arrived on purpose to see the castle, and begged permission. His Grace sent back a direct refusal!

architect is Mr. J. R. Hamilton, to whom not long ago the first premium, 500 dollars, was awarded in the competition for the Rev. H. W. Beecher's church in Brooklyn.

It will of course be understood that the establishment of which we have spoken is a private undertaking with a mercantile end in view; but, as a sign of the times, it is interesting in a wider sense.

#### DESIRED ENLARGEMENT OF THE BRITISH MUSEUM.

AMONGST the plans submitted to the Parliamentary Committee on the British Museum, and illustrated in their recent Report, that by Mr. Oldfield, who is employed in the Archeological department of the Museum, appears to have been viewed with considerable favour. It is thus summarily described in the draft Report submitted by the chairman:—

"Mr. Oldfield's plan, also printed in the Appendix, *supra*, is:—The purchase of the seventeen houses in Charlotte-street, numbers 1-29, and the three contiguous houses numbered 1-3, in Bedford-square, with the respective gardens (being such a plot of ground as has been recommended for purchase by your committee, under the condition of this Report); 2d. The erection thereupon of new buildings exclusively for the department of Antiquities; 3d. The transfer of the galleries now occupied by that department on the upper floor to the departments of Natural History. The new buildings in this plan would contain about 51,000 square feet of floor space on the principal or ground-floor for the exhibition of sculptures, and nearly 21,000 square feet in the two upper stories, for smaller antiquities, and about 8,500 square feet of space required for other purposes than for scientific studies. His plan also proposes some alterations in some of the existing galleries, to increase or improve their accommodation, partly in the Archeological, and partly for the Scientific departments. The amount of space which, upon this scheme, might be transferred to Natural History, or obtained for it by modifications of the existing building, would amount to 25,000 square feet, and includes two additional private rooms for scientific studies, and four studies for officers or assistants. It is further suggested by Mr. Oldfield, though not as an essential part of his plan, that the mezzanine floor over the secretary's office might be transferred to the department immediately above, if occupied by the department of Natural History, an arrangement which would increase the total space obtained for that department to about 27,000 square feet, and would provide four additional rooms, instead of two, for the private use of scientific students.

The expense of the proposed buildings has been calculated by Mr. Oldfield mainly from the data furnished in connection with the plan of Mr. Smirke, and is approximately stated at 161,000*l.* for additional buildings, with a further sum for alteration of the present buildings, for which no exact data of calculation exist, but which is conjecturally placed at about 16,000*l.*"

The plan assumes that the Natural History collections will be retained in the Museum, but that the additional accommodation provided for them will be on the principle of *limited* exhibition recommended by the keepers of these collections and the bulk of the scientific witnesses, not on the principle of unlimited exhibition advocated by Professor Owen, and requiring, according to his calculations, five acres of new ground, at the least. It proposes, however, to separate entirely the galleries of Natural History from those of Antiquities, by giving up to natural history the whole upper floor of the existing building, and removing the antiquities which now occupy the west side of that floor to new buildings.

The plan next proposes to purchase ground on the west side of the Museum, chiefly in Charlotte-street, but partly in Bedford-square, at a cost of about 65,000*l.*, and to erect thereon galleries for antiquities, at an estimated cost of about 145,000*l.* The west side is preferred to the north, both from the greater probable cheapness of the ground, and its superior convenience for the Archeological department, which is located in the west wing of the Museum.

On the new ground Mr. Oldfield's plan proposes to erect four long suites of galleries, parallel with the present galleries of Antiquities, and communicating with them. The present galleries, by slight modification, would furnish four more suites. These eight parallel suites would be obtained, to be appropriated exclusively to ancient sculpture, arranged chronologically in four principal schools—the first two Egyptian, the second two Assyrian, the third two Greek, and the fourth two Græco-Roman and Roman.

The Assyrian, Greek, and Græco-Roman (with the Etruscan) galleries would be lighted wholly by skylights, and consist only of a principal or ground-floor, with a basement for workshops, storerooms, &c.

The Roman gallery, which adjoins Charlotte-street, would be lighted by windows on the west side. Above it would be two upper floors for small antiquities. The lower of these would contain the galleries of Etruscan small antiquities, painted Greek vases, terra cottas, bronzes, and glass. The upper would contain British and

\* To be continued.

Medieval antiquities, gems, medals, and coins (including a room for public exhibition of these last).

The only frontage of the new buildings would be to the west; but the architectural elevation is left by the suggester to more competent hands. His province is limited to arrangement. Having for some years been employed in this duty at the Museum, he has necessarily acquired a certain knowledge of the requirements of the archaeological collections, and has planned each gallery with reference to its intended contents, varying the dimensions, form, and lighting, according to the peculiar requirements of the several classes of sculpture or other objects, so as to exhibit each in a favourable manner.

PHYSICAL EDUCATION.

A CONVERSAZIONE was held on the 25th ult. at the house of Mr. de Laspeyres; Mr. Robert Dickson, M.D., in the chair. The object was to explain Mr. de Laspeyres's system as applied to physical education, embracing the development of the constitution of man, consisting of both mind and body, and not one of these alone. This was sought to be brought to bear on what is at present a subject of great national importance—the training of the recruits for the regular army and the public-spirited members of the rifle corps. Mr. de Laspeyres explained that his system had been adopted in Nassau, in Prussia, and in France, and he was anxious to render a similar service to the defensive forces of Great Britain.

In the course of the evening some practical illustrations were given by four young gentlemen, pupils of Mr. de Laspeyres, whose performances, though some had had only nine lessons, greatly surprised and pleased the company.

A vote of thanks to Mr. de Laspeyres for his exposition was proposed by Mr. Cruikshanks, and seconded by Major-General Boileau.

In putting this vote of thanks, Dr. Dickson observed, that civilization in its progress too often exalts the mind at the expense of the body; so that we see many of our rising young men "sicklied o'er with the pale cast of thought," instead of glowing with the health, and being buoyant with the vigour, of early manhood. Fortunately, a reaction is taking place; and, instead of close confinement to the study, the desk, or the counting-house, our youth are lured out into the open air, to absorb the life-giving beams of the sun, and drink in the health-inspiring breath of heaven. To this more wholesome devotion of a portion of their time various causes have contributed to allure them. At the head of this may be put the volunteer movement; and whether the members of the rifle corps shall ever be called out to active service or not, it cannot be doubted that great good will result to the individuals themselves. Nor can we doubt but that the patriotic spirit which has called them forth will so nerve their arm that they will never permit a foreign invader to possess one foot of the sacred soil of our native land; or, at least, no more than may be needed, in Christian charity, to yield him a grave. To give a sound and permanently beneficial direction to these exercises, our friend Mr. De Laspeyres has generously come forward, furnishing the skill which nearly forty years' experience has given him, to contribute to restore our young men to the standard of health and powers of endurance, and that state of pristine strength and vigour possessed by man—

"When wild in woods the noble savage ran."

LONDON AND MIDDLESEX ARCHÆOLOGICAL SOCIETY.

A MEETING of the members of this Society was held on Thursday, 24th October, in the Library of Westminster Abbey. The chair was taken by the Very Rev. the Dean, one of the vice-presidents. Amongst other matters,

Mr. W. H. Hart read a paper descriptive of the library, and of some of the principal books contained in the collection. He stated that the present building was adapted to its purpose by the Lord Keeper Williams in the year 1622. Many of the works were gifts by Camden, and were signed by him. Not the least interesting in the collection was a series of narratives of local and historical value, being accounts of the coronation ceremonies of the sovereigns of England. In connection with this subject the visitor could not fail to be struck with the gradual filling off in the decorative art as applied to those records; the account of the coronation of Queen Victoria, for instance, being merely stitched together without care, and almost without decency. Mr. Hart re-

ferred to the organ in the cathedral. The original organ was, with many others, destroyed by the Parliamentary army. After the Restoration, organ-builders were in great request, and Bernard Smith was employed to build the organ for St. Paul's Cathedral, and also that now in use in the Temple Church. Bernard Smith was succeeded by his apprentice Schmieder (who subsequently became his son-in-law), and he it was who built the instrument in the Abbey Church of St. Peter, Westminster.

Mr. Joseph Burt made some observations on certain early documents found in the ancient treasury beneath the library. These records were brought to light some few years ago by Mr. Scott, the architect to the cathedral, who found a quantity of muniments beneath the rubble in a narrow passage, which had formerly been a portion of the treasury. The manuscripts included a letter of Thomas of Woodstock, date 1360, and a great number of documents connected with the Courts of Record at Westminster Hall.

At the conclusion of Mr. Burt's observations, the members proceeded to the interior of the abbey; and there, in the western nave, standing immediately above the grave of Robert Stephenson, Mr. Scott explained the principal architectural points of interest in the abbey, and exhibited diagrams, showing the original formation of the church, and also the portions which were gradually succeeded to the influence of time.

Mr. Henry Mogford subsequently commented on the monuments of a museum of sculpture.

Mr. John Hunter also read a paper in Henry the Seventh's Chapel on the institution of the Order of the Bath.

In the afternoon several of the members attended divine service; and, at the conclusion, the meeting was resumed in the Chapter-house, which was explained by Mr. Scott and Mr. Burt. From thence the members proceeded to the Jerusalem Chamber, where a paper was read by the Rev. Thomas Hugo descriptive of the building and its contents.

SCHOOLS OF ART.

The *Devonport School* is in a flourishing state under the mastership of Mr. Wardle. A successful meeting has just been held, at which the prizes were distributed, and many works of art exhibited. The attendance was very numerous, and a musical hand of the Royal Marines enlivened the exhibition. The mayor took the chair at the distribution of prizes and addressed the meeting, as did various other gentlemen. In the course of his address the mayor narrated a family anecdote of some interest. "Some forty-three or fifty years ago," he said, "a youth, poor, friendless, and unknown, accepted with gratitude a domicile in the house of an aunt of mine, in Curzon-street, May Fair, London: she, perceiving his youthful talents as a sculptor, invited him to reside in her house, appropriated to him a room for his hours, and introduced him to those who, she believed, would value his works and appreciate their merit. During his residence in that house he became attached to the daughter of the butler, whom he afterwards married. Time wore on: the innate talent of the man soon made it evident that he was possessed of no mean powers: orders quickly followed, and remuneration proportionately increased, till some years after, when my father had occasion to consult the then eminent sculptor regarding a monument which he wished to be erected to the memory of a deceased relative: no work would he undertake of which the cost was to be less than one thousand guineas;—and this was the late Sir Francis Chantrey, whose works many of you may know and all must admire." An address on art education, by Mr. R. Townsend, the president of the Devonport Mechanics' Institution, in the large hall of which the exhibition took place, was read by Mr. Norman, in which some of the advantages of art education, and its disadvantages of the want of it, were pointed out. Not very long ago, remarked Mr. Wilson, a brother civil engineer, of considerable ability, applied to me to recommend a good trustworthy mechanic to fill a situation of foreman of carpenters, wages 2/ 10s. per week, and the promise of future support if he acquitted himself in a satisfactory manner. I at once selected a carpenter from Keyham, who had for many years worked under my immediate eye. His character and practical knowledge of his trade were all that could be desired, but, on the question being put, "Can you draw a little, no matter how plain?" Alas! no: "he had never practised it." Consequently he is still earning his guinea a-week, instead of double that sum, which a slight acquaintance

with drawing would have undoubtedly secured to him probably for life. In August last a similar application was referred to me for advice, but for a higher position abroad, and on a work of much responsibility. The conditions were— to have a thorough knowledge of carpentry, be able to lay down a working drawing, and have a fair amount of arithmetic and mechanics. Salary according to ability, that is, from 5*l.* to 6*l.* per week; four years' employment guaranteed; expenses of man and family paid out and home. Well, up to this moment I have not been successful in finding a carpenter to fill the post. Were it not occupying your time, I could recount twenty such unsatisfactory cases. Now, as a contrast, permit me to draw your attention to a fairer view of life's struggles. Look at this outline—an engraved section of Westminster Hall, measured on the spot, and drawn by a George Allan, originally a working mason at Sheerness, foreman at Woolwich, and principal foreman for Messrs. Gissel, contractors for Westminster Palace. Now this man has risen to a high position in his trade; and, notwithstanding the many difficulties that obstructed his career at the outset of life, never failed to cultivate drawing, geometry, and such other branches of art as limited time would allow. The result is, that he is now independent for the remainder of his life.

Mr. J. Wilson, Mr. W. Eastlake, of Plymouth, and others, also addressed the meeting.

The *Wolverhampton School* is to be closed! Sufficient funds to carry it on cannot be procured. No effort on the part of its friends has been wanting, but no exertion that they have been able to make has enabled them to overcome the apathy and indifference with which the continuance or the discontinuance of the Institution has been regarded. At a meeting of the council of the school, to decide the question of continuance or discontinuance, it has been resolved, "That, considering the present position of the School of Art, which, after reducing its expenditure to the minimum point, is still labouring under an annual deficiency of 50*l.*, and that the manufacturers and commercial classes generally having failed to render it any adequate support, it has become incumbent upon the council to close it with the present quarter, ending on the 15th November next, having previously tried every means to maintain it in a state of efficiency." The effort of the students to raise funds was all but abortive, only 35*l.* of donations, and 6*l.* annual subscriptions having been promised towards the future support of the school.

Miscellaneous.—The result of the drawing examinations held at Southampton, Romsey, and Ringwood, is as follows:—

	Second Grade.	Excellent.	Good.	First Grade.	Passed.	Fail.
Southampton . . .	106	21	24	118	31	30
Romsey . . . . .	18	2	5	20	6	6
Ringwood . . . . .	31	7	10	45	7	4
	155	30	39	163	44	40

The whole result is held to be very satisfactory, when it is recollected that "excellent" is a very high mark, and that, hitherto, "good" has received a prize. Arrangements are being made for an early distribution of the medals and prizes.

INDURATION OF STONE BY THE ANCIENTS.

SIR HENRY RAWLINSON, writing with reference to silicating stone, says,—

"The art of indurating stone by the application of a solution of silica to the surface was certainly known to the ancients, and the substance actually employed by them is still to be obtained in sufficient quantities to admit of minute chemical analysis. In a notice of the great cuneiform inscription of Darius Hystaspes on the rock of Behistun, which I published thirteen years ago ('Journal of the Royal Asiatic Society,' vol. X., part iii., page 193), I gave a remarkable instance of the successful use of liquid 'silica' by the ancient Persians. The passage is as follows:—

"It would be very hazardous to speculate on the means employed to engrave the work in an age when steel is supposed to have been unknown, but I cannot avoid noticing a very extraordinary device, which has been employed apparently to give a finish and durability to the work. It was evident to myself, and to those who in company with myself scrutinized the execution of the work, that after the engraving of the rock had been accomplished, a coating of silicious varnish had been laid on to give a clearness of outline to each individual letter, and to protect the surface against the action of the elements. This varnish is of infinitely greater hardness than the true stone rock beneath it. It has been washed down in

CENTRAL PARK, NEW YORK.—*Bridge for Carriage-drive over arm of Lake, near the Raabla.*  
MR. C. VAUX, ARCHITECT; MR. E. C. MILLER, ASSISTANT.

several places by the trickling of waters for three-and-twenty centuries, and it lies in flakes upon the footledge like thin layers of lava. It adheres in other portions of the tablet to the broken surface, and still shows with sufficient distinctness the forms of the characters, although the rock beneath is entirely honeycombed and destroyed. It is only, indeed, in the great fissures, caused by the outbursting of natural springs, and in the lower part of the tablet, where I suspect artificial mutilation, that the varnish has entirely disappeared.

I would only correct this description in so far as to suggest that the flakes of silicate which lie on the footledge are the original droppings of the varnish when it was first laid on in a liquid state, rather than the effect of the subsequent trickling of water over the surface of the rock. These flakes might be easily detached from the rock with a chisel and hammer, and their analysis would show if any other ingredient were employed in the composition than flint and caustic alkali. The substance looks like opaque glass, but has no perceptible effect on the colouring of the rock. It is certain, moreover, that it was absorbed into the stone, and prevented decomposition, so far as it penetrated. The sculpture, indeed, which extends over several hundreds of square feet, and which was executed about 500 B.C., is, although exposed to the full force of the prevailing storms from the south-east, for the most part in as good a state of preservation as if it had been engraved but yesterday."

If a commission be appointed to report on the silicate zopissa question, it would be worth their while to obtain specimens of the flint varnish of the ancients from Persia, and perhaps also from Egypt.

#### THE TENDER FOR THE WORKS FOR THE OUTFALL SEWER.

METROPOLITAN BOARD OF WORKS.

At the usual meeting of the Metropolitan Board of Works held on Friday, 26th Oct., Mr. J. Thwaites in the chair, the following report was presented from the Main Drainage Committee on the subject of Mr. Furness's tender for the Northern Outfall Main Sewer Works:—

"Your committee have to report that, pursuant to the resolution of the board of the 19th inst., they have made the necessary inquiries as to the competency of Mr. Furness to carry out the works for the Northern Outfall Sewer, and the responsibility of his sureties. The result

of such inquiries has satisfied your committee as to Mr. Furness's competence. With regard to the sureties, your committee have received letters from Sir Joseph Paxton, and Messrs. Smith & Knight, the contractors for a portion of the Metropolitan Railway, offering themselves as Mr. Furness's sureties for the due performance of the works: your committee entertain no doubt, and they recommend that the tender of Mr. Furness for the execution of the works for the Northern Outfall Sewer, with Sir Joseph Paxton and Messrs. Smith & Knight as his sureties for the due performance of the works, be accepted."

Mr. Doulton moved, and Mr. Moreland seconded a motion, that the recommendation of the committee be adopted, which was put and unanimously agreed to.

*Amendment of the Metropolis Local Management Act.*—Mr. Tito, M.P., gave notice that, this Friday, he would move that the Board do take steps for the purpose, in the next session of parliament, of obtaining an amendment of the Metropolis Local Management Act.

#### THE WEDGWOOD INSTITUTE, BURSLEM.

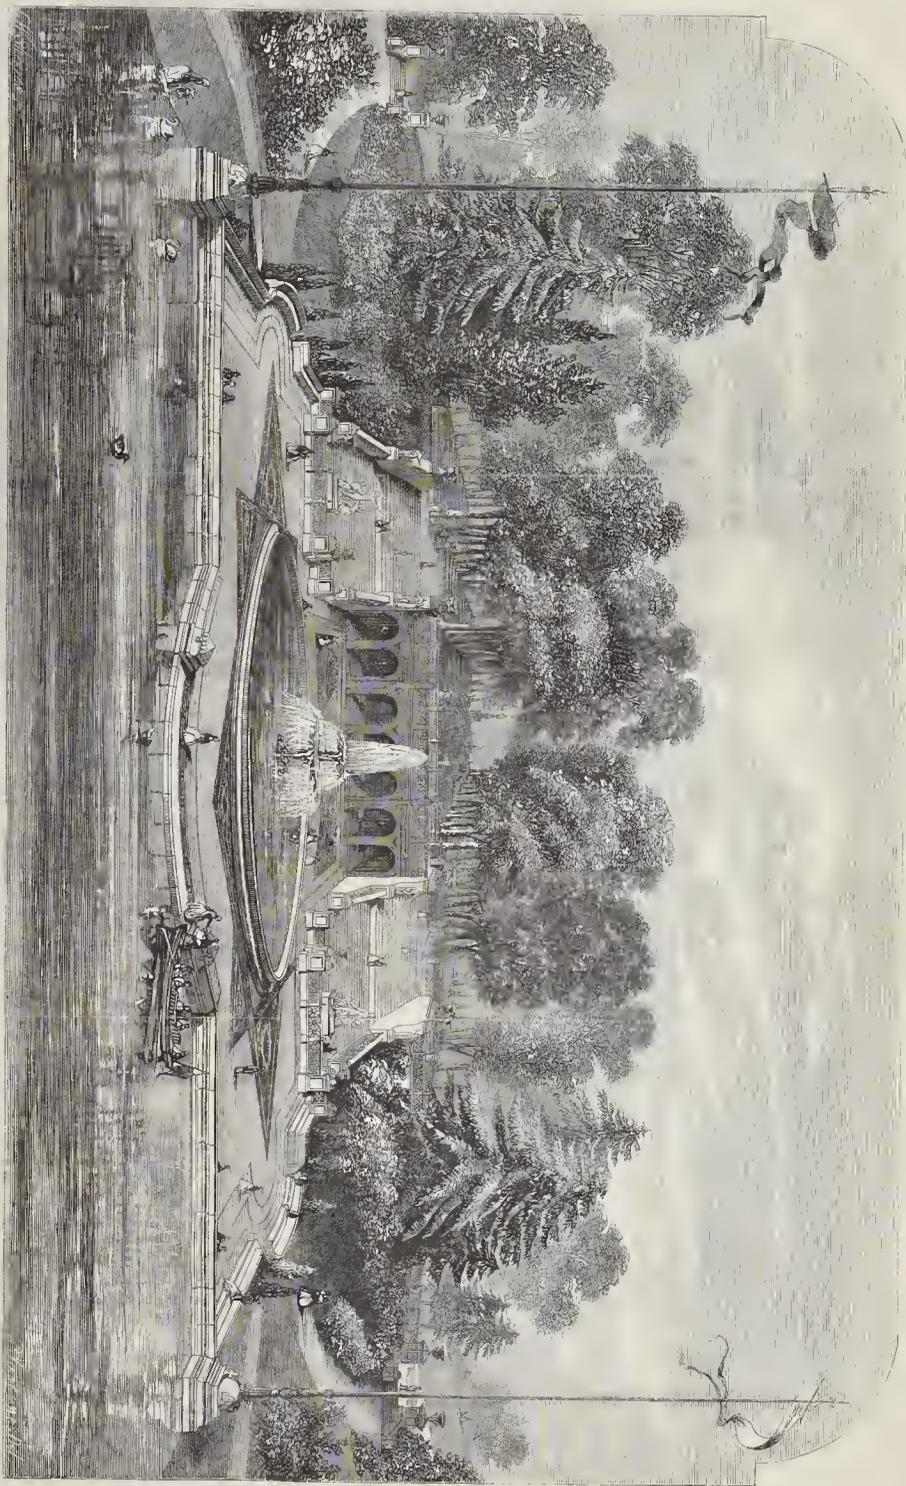

The committee for promoting the erection of this building met on Wednesday evening, to receive the report of the sub-committee; and after adopting that report, which acknowledged the very great merit in each of the plans, and expressed a strong preference for the one prepared by Mr. G. B. Nicholls, of West Bromwich, the committee unanimously resolved to select Mr. Nicholls's plan, as combining a greater number of points of appropriate adaptation than the others submitted, and he was therefore appointed as the architect to carry out his design.

#### MONUMENTAL.

A PUBLIC meeting has been held at the London Tavern, to originate a movement for the erection of a national monument commemorative of the services of the celebrated navigator, Captain Cook, Dr. Corner occupied the chair, and the meeting unanimously passed a resolution to the effect, that they heartily concurred in the efforts which were being made for the erection of a monument worthy of the virtues of the man, and that the subscriptions for that purpose be formed into a fund, to be called "Captain Cook's National Testimonial Fund." A com-

mittee was then formed to carry out the objects of the meeting.—Three sculptors were invited to send in designs or models for a memorial of the late Mr. Joseph Sturge, at Birmingham, the design to embrace a statue and fountain to cost 9000. Two of the three gentlemen accepted the invitation,—Mr. Hollins and Mr. John Thomas,—and their models have been received, and will be submitted to the committee forthwith. Mr. Hollins's design consists of a statue standing on a pedestal. On either side, but considerably less elevated, are pedestals supporting fountain statues—female figures emblematical of Peace and Temperance. The whole design rises from two granite steps. Mr. Hollins proposes to execute the design in best Portland stone, or the statue alone, without the subordinate figures, in Sicilian marble for the proposed sum. As an alternative, he suggests that the statue and the figures should be executed in marble, the cost to be 2,000. The height is said to be 16 feet. The design of Mr. Thomas is more elaborate. On the base project tazza-shaped basins, from which jets of water will arise. On each side are seated figures typical of the leading characteristics of Mr. Sturge, and between are the pedestal and statue. Underneath these figures are simple drinking-fountains, the water issuing from lilies and falling into a marble shell. In this design it is proposed that the subordinate figures should be executed in Portland stone, and the statue in Sicilian marble, for the stipulated sum of 9000. The height of this group is 24 feet, the size of the statue being the same as that of Attwood.—At a meeting in Hereford as to a monument to the late Mr. Wallace Hall, after various suggestions, it was eventually resolved, "that an obelisk be erected near the railway station, to commemorate the deceased and his extensive public services, and that a sum of 800. be expended for that purpose." Mr. Luckes undertook to advertise for plans and estimates in the *Builder*, the *Hereford Times*, the *Gloves' or Journal*, and *The Man of Ross newspapers*.

**SOOTH KENSINGTON MUSEUM.**—During the week ending 27th October, 12,216 persons have visited the Museum.

CENTRAL PARK, NEW YORK, U.S.—View of Terrace looking South from the Ramble.\*

**THE INSCRIPTIONS ON THE MONUMENT OF THE GREAT FIRE, FISH STREET HILL.**

As a matter of taste, it is more than doubtful if a column, in form and design originally intended for the support of the superstructure of buildings, should be raised into the air without apparent purpose, or to serve simply as the pedestal of a statue. To us those pillars, beautiful as they may be in proportion, and much as they may aid to the distant general effect of a city, seem, like the statue of the Duke of Wellington on the arch at Hyde Park-corner, sadly out of place. There are more fitting ways of forming lofty structures in honour of individuals or as records of important events. As regards the oldest of the pillar monuments, not only of the metropolis, but of the kingdom, there are certain commendable points worthy of note. Before alluding to them, it may be interesting to some to know that the column on Fish-street-hill is 202 feet high; the pedestal 40 feet high, and plinth 28 feet square; the shaft of the column is 120 feet high, and 15 feet in diameter. In the hollow is a staircase of black marble, consisting of 315 steps, which leads to a balcony within 32 feet of the top. The cubic measurement of the column is as follows:—

The solidity of the whole fabric from the bottom of the lowest plinth to the black marble under the eury, the cylinder of the staircase only deducted, and the stone for carving not allowed for .....	37,396
The black marble that covers the capital .....	287
Ditto .....	64
From this solidity deduct,—	37,747
For eight great niches .....	284
For three doors and passages .....	239
For three sides .....	486
For rough block .....	1,499
For rubble work .....	7,185
	9,740
	28,007
Deduct on account of carvings in the front, the four dragons and festoons .....	510
	27,497

On the west side the *basso relievo*, by Caius Gabriel Cibber, is well worthy of notice. It is picturesquely designed, and ably executed. The whole is allegorical of the rebuilding of the city. In one compartment the city appears in flames, the inhabitants, with outstretched arms, calling for succour; while a female, wearing a civic crown, and holding a sword, shows that the civic authority is still maintained. King Charles II. occupies a conspicuous situation, and is represented in a Roman habit: he is trampling under his feet Envy, which seeks to renew the calamity by blowing flames out of its mouth. Near the sovereign are three females, representing Liberty, Imagination, and Architecture. Time is offering consolation to the distressed, and Providence giving assurance of peace and plenty. There are also several other figures, representing Mars, Fortitude, &c.

The inscriptions written by Dr. Thomas Gah, afterwards Dean of York, are as such compositions should be graphic and explanatory, and would be read with interest by many a passenger. Unfortunately, however, they are in Latin, and illegible to the multitude. The translation of that on the north side is as follows:—

"In the year of Christ, 1666, the 2nd day of September, eastward from hence, at the distance of 282 feet, the height of this column, a terrible fire broke out about midnight, which, driven on by a strong wind, not only wasted the adjacent parts, but also very remote places with incredible noise and fury. It consumed eighty-nine churches, the City gates, Guildhall, many public structures, hospitals, schools, libraries, a vast number of stately edifices, 12,200 dwelling houses, and 420 streets. Of the twenty-six wards it utterly destroyed fifteen, and left eight others shattered and half burnt. The ruins of the City were 430 acres from the Tower by the Thames side to the Temple Church, and from the north-east along the City-wall to Holborn-bridge. To the estates and fortunes of the citizens it was merciless, but to their lives very favourable, that it might in all things resemble the conflagration of the world. The destruction was sudden, for in a small space of time the City was seen most flourishing, and reduced to nothing. Three days after, when this fire had built all human councils and endeavours, in the opinion of all, it stopped, as it were, by a command from Heaven, and was on every side extinguished. But papistical malice, which perpetrated such mischiefs, is not yet restrained."

On the south side is—  
 "Charles the Second, son of Charles the Martyr, King of Great Britain, France, and Ireland, Defender of the Faith, a most gracious prince, commiserating the deplorable state of things, whilst the ruins were yet smoking, provided for the comfort of his citizens, and the ornament of his city, remitted their taxes, and referred the petitions of the magistrats and inhabitants to the Parliament, who immediately passed an Act that public works should

be restored to greater beauty, with public money, to be raised by an imposition on coals; that churches and the cathedral of St. Paul should be rebuilt from their foundation, with all magnificence; that the bridges, gates, and prisons should be made new, the sewers cleansed, the streets made straight and regular, such as were steep levelled, and those too narrow made wider; and markets and shambles removed to separate places.

They also enacted that every house should be built with party-walls, and all in front raised to an equal height, and those walls all of square stone or brick, and that no man should delay building beyond the space of seven years."

On the east side is—  
 "This pillar was begun, Sir Richard Ford, Kt., being Lord Mayor of London, in the year 1671. Carried on to the majorities of Sir George Waterman, Kt. Sir George Hanson, Kt. Sir W. Hooker, Kt. Sir Robert Viner, Kt. Sir Joseph Sheldon, Kt. And finished in that of Sir Thomas Davies, in the year 1677."

Respecting another part of the inscription, which has little foundation, and has given much offence, we will say nothing.

**SCHOOL-BUILDING NEWS.**

*West Cores (Isle of Wight).*—The first stone of West Cores National Schools was laid on the 24th ult. Mr. Charles Turner, of Southampton, is the architect. The building now in course of erection is intended for an infant school, 60 feet by 20 feet, and about 23 feet high, affording accommodation for 150 children. By the general plan it is intended to erect three schools of the same dimensions, affording accommodation for 450 children; also residences for the master and mistress. Mr. George Wheeler is the contractor, and the clerk of works is Mr. W. T. Roberts.

*Bath.*—The structure erected in the Saw Close for the Bath Blue-Coat Schools has been opened with some ceremony. It contains two school-rooms,—one for boys, and one for girls,—with committee-rooms and offices, and a residence for the master and mistress. The architects were Messrs. Manners & Gill, and the contractor Mr. Mann. During the removal of the old building a portion of a Roman tessellated pavement was found near the foundations. This was removed under the direction of Mr. Mann, junior, and has been relaid, under his superintendence, in the entrance-hall of the master's private residence.

**PUBLIC BUILDINGS IN THE PROVINCES.**

*Regate.*—There is a movement here for the erection of a new public hall, at an estimated cost of 3,000*l.*, of which two-thirds have already been promised.

*Berkhamstead.*—The corn-market here, which for some years has been discontinued in consequence of the destruction of the old market-house by fire, has been re-opened in the new building which has been erected, containing a market-house for the sale of corn on the ground-floor, and two rooms over, one of which is to be used as a library, and the other for the accommodation of the members of the Mechanics' Institute. At the back there is a hall 52 feet by 32 feet, for holding meetings, balls, &c. The architect was Mr. E. B. Lamb, of London; and the builders were Messrs. Nash and Matthews.

*Bradford.*—Designs of buildings proposed to be erected (at a cost of 1,000*l.*) for the Bradford Volunteers have been on view in St. George's Hall, in this town. The buildings will include a large drill-room, 97 feet long by 60 feet broad, in the centre; a gymnasium, 44 feet long by 20 feet broad; and sergeants' orderly room, 20 feet by 15 feet, on the other side. A residence for the drill-sergeant will stand at one corner, in the rear of the building. The elevation, in the Italian style of architecture, presents a broad entrance, with folding-doors in the centre, and has a verandah, with seating beneath, running along its entire length. The designs are contributed by Messrs. Andrews & Delaunay.

*Blairstown.*—The foundation-stone of a new public hall, now in course of erection in the village of Blairstown, has been laid by the Duke of Atholl, as grand master of Freemasons in Scotland. The expense of the building, including cost of site, but excluding interior decorations, will be about 800*l.* The new hall is to be built at the west end of the present Townhall; is enclosed on every side by buildings; and presents no front to the street. The principal entrance is proposed to be through the present Townhall, and a passage is also made opening the new building about the centre, and crossing the street on the south. Its length and breadth will be 70 feet by 40 feet within walls; its height, 34 feet; and it will accommodate

800 individuals. The interior is to be finished in a very plain manner, the roof being an open timber one, and lighted along each side. Attached to the hall are two committee-rooms and two dressing-rooms. The architect is Mr. John Carver, of Meikle.

**STAINED GLASS.**

*Llangattoe (Crickhowell).*—Four painted-glass windows have recently been erected by Lady Bailey in memory of her late husband, Sir Joseph Bailey, bart., and of her daughter, Mrs. Spearman; two in the chancel of the parish church of Llangattoe, and two in the new church lately erected in Glan Usk-park. The two windows fixed in the chancel of Llangattoe Church were by Messrs. Clayton & Bell, London. The subjects are, the Crucifixion and the Resurrection. Underneath the Crucifixion, in a series of base panels, is a representation of the Lamb glorified by angels. In the tracery openings of the Crucifixion window are represented the four greater prophets; and in that of the Resurrection, the four Evangelists. The subjects of the two windows fixed in the church erected in Glan Usk-park are—first, our Lord blessing the little children, with an angel in the uppermost opening; second window, the three holy women at the Sepulchre receiving the angels' announcement of the Resurrection. A medallion of our Lord in glory is represented in the top opening. The style of the chancel windows in Llangattoe Church is the Perpendicular, and that of the Park Church windows is Middle Pointed.

**CHURCH-BUILDING NEWS.**

*Twinstead (Essex).*—The new church of St. John the Evangelist has been consecrated by the Bishop of Rochester. The church is in the style of the fourteenth century. The internal walls are all worked with black, white, and red bricks, into arcades, arches, and geometrical designs. The nave is bancelled with open seats, and is separated from the chancel by three arches with ornamental brass work, in the centre of which is fixed a large gilt cross. The pavement is of encaustic tiles, which in the chancel are of a blue tint. There is an altar screen of stone with carved angels with wings extended at the corners, divided into compartments painted and gilt in the Medieval style, with scenes in the life of the patron saint of the church. Above is a painted window with the Crucifixion in the centre light, and there are other windows of stained glass in the chancel. The roofs are stained. There is a small vestry, and organ chamber, a gable and bell, and ornamental crosses at the apex of the roof.

*Cople (Beds).*—The church of Cople has been re-opened, after a renovation of the interior. The whole area both of nave and chancel has been cleared out, and new floors laid. The blocks of sittings are arranged on a more convenient plan. The best of the old oak seats have been re-erected, but by far the greater portion are new, of pitch-pine or red-oak. Those in the nave, with the pulpit, are varnished, with a few mouldings pricked out with colours. The pavements are of Portland cement, with red tile borders and coloured mosaic patterns in the centre. The designs and specifications were furnished by the Rev. H. E. Haverall, vicar. The woodwork of the nave has been executed by Mr. G. Bryant, of Bedford; that of the chancel, including its new roof, by the workmen of the Duke of Bedford.

*Leafield (Oxfordshire).*—St. Michael's Church, Leafield, the first stone of which was laid by Lady Churchill on All Saints' Day, 1858, was consecrated on the 19th ult., by the Bishop of Oxford. The style of the new edifice is Early English, from the design of Mr. Scott. It consists of a nave, with north and south aisles; a chancel, also with aisles; and a vestry at the north-east corner, with a vault under for hot-air apparatus, supplied by Messrs. Hayden, of Trowbridge. There is a central octagonal tower, and spire, surmounted by a weather-vane, rising 145 feet 6 inches from the ground line. The tower is ornamented by four double lancet windows, with Milton stone shafts, moulded hases, and carved capitals; and the spire by four gabled single lancets, similarly decorated. The nave is divided from the aisles by an arcade of four bays on either side, supported by circular piers, with moulded bases and square capitals, from which the arches spring square, with labels over them, above which are inscriptions painted on zinc: the clerestory windows are square-headed triplets, with detached mullions, standing fair with the inside of the wall. The tower is supported by four piers, with carved capitals and moulded arches, which rise nearly to

\* The concluding part of the inscription savours too much of the prejudices of the times.

the bell floor. The whole of the roofs are of stained deal, open framing, plastered between the rafters, and covered with felt under the Stonesfield slate. The sittings are open, of pitch-pine, stained and varnished, and will accommodate about 500 persons, 250 free. The church is entered from the west by a recessed doorway, with a carved medallion in the tympanum, and on the south by a porch. It is built of local stone, the external face of the walls being hammer-dressed, and the internal finely chipped and pointed. The whole of the dressings are of Milton stone. The length of the nave is 66 feet by 21 feet 6 inches wide, and the chancel, including the choir and sanctuary, 41 feet by 16 wide; the height, from the floor to the ridge of the roof, 43 feet 6 inches: the total length of the church internally is 107 feet. The carving was executed by Mr. Irving, of Leicester. The builder is Mr. Thomas, of Abingdon; clerk of works, Mr. H. Roome.

**Christ Church (Hants).**—The restoration of the old priory church of Christchurch is making progress under the superintendence of Mr. Ferrey. The north porch has been completed, and its groining restored: a lozenge tiling, red and black, has been laid down, but the open ironwork gates remain to be added. The interior of the north transept, also the Norman arcade, and series of Decorated windows in the south aisle of the nave, and the window in the apsidal chapel of the south transept have been restored. The large east window of the north choir-aisle has been filled with stained glass by Messrs. Lavers & Barrand, the gift of Admiral Walcott, M.P. for the borough. It is now proposed to make use of the large triforium of the nave for congregational accommodation; to remove the flat ceiling of the lantern and expose the old timber roof, and, at the same time, open the roof of the south transept, and throw down the block of masonry which divides the latter from its chapels. 2,000*l.* have already been spent upon the works, but external help is desired for their completion, as the population is neither large nor affluent.

**Croscombe.**—The little parish church of Croscombe, near Wells, which has been for some time past closed for repairs and restoration, has been re-opened. The alterations consist principally in the removal of a gallery which formerly stood at the western end of the church. The organ has been removed to the north side of the chancel, and, in preparing a place for it, it was found necessary to make some alterations, which brought out an arch that had been previously filled up, the vestry being behind it. The removal of the gallery has exposed to view the western arch of the church, and a window has been placed above the entrance. This window is plain, but is to be replaced as soon as possible by stained glass. The belfry, which was on a level with the floor of the church, has been removed to the next floor above. The removal of the belfry and gallery has made the western entrance available for use. The high-backed pews and the carved wood screen and pulpit have been cleaned and varnished, as also has the carved wooden roof. The roof and the windows have been repaired. The designs for the alterations were furnished by Mr. C. Wainwright, of the firm of Wainwright & Heard, architects, of Shepton Mallet. The execution of the work was entrusted to Mr. Walter Rawlings, contractor, Darshill, near Shepton Mallet. The cost is about 100*l.*, besides 100*l.* for improvement of the organ.

**Bishop's Castle (Bridgnorth).**—St. John's Church having become deeply buried by the soil of the surrounding graveyard, the walls untrustworthy, and the accommodation for worship insufficient, it was considered desirable that something should be done to improve it. The parishioners accordingly borrowed 1,000*l.* from the Public Works Loan Commissioners, on security of the parish rate; and 1,000*l.* was raised in the parish from voluntary contributions: the Earl of Powis, patron and proprietor, contributed 1,000*l.*, and Beriah Botfield, esq., M.P., 500*l.* The Diocesan Church Building Society voted 350*l.*; the Incorporated Church Building Society, 250*l.*; and a remainder was given by friends. The new chancel contains sittings for 750 persons on the ground floor. It has been reopened for divine service.

**Wolstanton.**—The parish church of Wolstanton, one of the oldest, it is believed, in North Staffordshire, has been rebuilt and re-opened. The stone was brought from Alton, and corresponds with the former red sandstone of the church and the existing stone of the steeple. The church has been restored on its original foundations. The roofs have also been restored. The steeple has been added to the church internally by the throwing open of the tower arch. The exterior has

been repaired and pointed, the window tracery restored, the former parapet replaced by one in keeping with the rest of the church, having pinnacles at the corners, and the staircase carried up as a spirelet. The spire itself, which had been struck by lightning and was defective and unfinished at the top, has been taken down some distance, and then carried up higher, and surmounted, as well as the spirelet and pinnacles, with iron crosses and vanes. The moulded pillars and arches inside have been reproduced from the old ones, of which the stone was found to be too friable to re-work. The church is fitted up throughout with long pews, having standard and carved poppy-heads and low doors. It is paved with Minton's tiles, and the whole of the pillars, arches, windows, and doors internally are executed in clean stonework. The chancel arch has been widened several feet, still preserving the original mouldings, &c. The entire building is warmed by a hot-water apparatus furnished by Mr. Whitehead, of Preston, and gives the heat both through gratings in the floor and by pipes above it round the walls. The whole of the windows are filled with stained glass. The church, together with the fittings of the chancel, have been done from the designs and under the superintendence of Messrs. Ward & Son, architects, Hanley, in the style of the existing steeple and the original church, namely, Decorated Gothic, of the middle of the fourteenth century. The contractors were Messrs. Robinson & Son, of Hyde. Mr. W. M. Thomas was clerk of the works, and Mr. G. Gladwin executed the carving. The chancel was erected from the designs of Mr. Salvin, under the superintendence of Mr. Lewis, of Keele, Mr. Bryan, of Stoke, being the contractor. The work of rebuilding the church commenced in the month of January, 1859, and is just completed. The chancel is enriched with three painted windows, the gift of Mr. Edward Wood, as indeed are all the other windows in the church, with one exception. The large window at the east end is figurative of the Ascension of Christ, the two others in the chancel being designed as memorials. That to the memory of Mrs. Wood has two principal figures—one of John the Baptist, illustrative of the passage of Scripture, "After me cometh a man which is preferred before me," and the other of "St. Margaret," to whom the church is dedicated; the lower compartment being filled with representations of the Baptism of Christ and the Crucifixion. The other, to the memory of Mr. Wood's daughter, has two principal figures, expressive of the passages, "He shall gather the lambs in his arms," and "Behold I stand at the door and knock;" the lower portion representing the adoration of the shepherds, and the Saviour's command to Peter, "Feed my lambs." A window in the body of the church, the gift of Mrs. Stanier, illustrates the texts of Scripture, "I was an hungered and ye gave me meat," "I was naked and ye clothed me," "I was sick, and ye visited me;" "I was a stranger, and ye took me in." The total cost including the chancel will, it is supposed, be about 4,500*l.*, towards which, coupled with the painted windows, the stalls in the chancel, and many of the fittings and ornamentations of the interior, Mr. Wood has contributed more than one-half. The expenditure of Mr. R. Sneyd, who, in addition to rebuilding the chancel, has assisted the general building fund, must have exceeded 750*l.*

**Leicester.**—The restoration of St. Mary's Church, Leicester, is now completed. Within the last twelve months alterations, additions, and improvements have been made, at, if we are rightly informed, the sole cost of Mr. Nevinson. The works have been carried out, under the direction of Mr. Scott, by Mr. B. Broadbent. The north arcade of the nave is rebuilt, and moulded arches are substituted for the old dilapidated plain ones. There is also a new clerestory upon the model of the ancient one, taken from a portion of the old arcade found remaining at the west end, with lancet lights of the Early English period, and a carved new corbelled parapet. Carved oak doors, copies of the original Perpendicular doors, have been hung to the Norman doorway on the north side, and the west-end doorway, formerly blocked up, has been thrown open, and a new oak door inserted. Carved oak doors, similar to those at the northern entrance, are to be hung to the south doorway, and the porch doors are to be ornamented with foliated ironwork. The carvings have been executed by Mr. Hamilton, in the employ of Mr. Broadbent. The whole church has been lighted with ornamented gas pendants in brass, manufactured by Messrs. Skidmore, of Coventry. A reading-desk and pulpit, in carved oak, have been presented by Mr. Broadbent. The parishioners, it is

said, purpose filling in with stained glass one of the east windows in the chancel. The organ has now been erected by Messrs. Forster & Andrews, of Hull. The case is of carved oak, in keeping with the style of the church, and the cost, which will be defrayed by voluntary subscription, is between 500*l.* and 600*l.* It has three rows of keys, thirty-three registers, thirty notes of German pedals, and four composition pedals.

**Bamford (Derbyshire).**—The new church at Bamford, dedicated to St. John the Baptist, has been consecrated by the Bishop of Lichfield. The architect was Mr. Butterfield. The style of architecture is the Early English Decorated, and the edifice contains a chancel, nave, and north aisle. The floor is laid with encaustic tiles; the part within the chancel with tiles and Derbyshire marble, the steps being marble; and the wall at the back of the communion-table is also inlaid with marble. The windows are filled with stained glass. The seats are all free. The tower and spire are each 54 feet—together 108 feet high—and there are six bells of steel, cast by Naylor, Vickers, & Co., of Sheffield.

**Birmingham.**—St. Barnabas's Church, which has just been completed, and is situated in Rylandstreet North, has now been consecrated. The front of the building is surmounted by a Decorated spire. The church is fitted with low lead pews, and paved with Broseley quarries of red and black. A gallery runs round three sides of the building. The roof of the nave is high-pitched, boarded, and supported on laminated pinnacles. The building, including the gallery, will accommodate nearly 900 persons, the dimensions being, length, 80 feet; width, 44 feet 4 inches; height, 50 feet; and side walls, 20 feet. The cost of erection exceeds 3,000*l.* The architect was Mr. Bourne, of Dudley; and the builder, Mr. Melson, Birmingham.

**Sheffield.**—The chief stone of a new Unitarian chapel at Upperthorpe has been laid by Miss Urith Lydia Shore, of Meersbrook. The edifice is being built on a plot of ground adjoining the Crookes-road and will accommodate about 550 people. It will be a plain stone building, with gallery at one end for the use of the school children; and the cost will be about 1,400*l.* The architect is Mr. John Pirth; and the builder, Mr. Pearson.

**Scarborough.**—The threatened rupture amongst the projectors of the proposed new church on the South Cliff, rumours of which got abroad, has been settled by the selection of Mr. Bodley, of London, as architect. Mr. Bodley's plans were at first rejected by the committee, on the ground that they could not be carried out for the specified sum. In other respects they were preferred by the committee to those of other architects. It appears that Miss Mary Craven, who is the donor of 2,000*l.* to the church, desired the selection of Mr. Bodley; but the committee chose to act on their independent judgment. However, in order to secure the services of Mr. Bodley, the further sum of 1,000*l.* has been subscribed by Miss Ann Craven, which will enable the committee to carry out the architect's plans. Nevertheless, upwards of 2,000*l.* are yet required to liquidate fully the cost of the erection.

**Sunderland.**—The foundation-stone of "Salem Free Chapel," Pemberton-street, London, has been laid. The building will be 68 feet by 42 feet, and will be capable of accommodating 600 persons. It will be so constructed as to allow of the erection of a gallery at some future time. The material will be bricks with stone dressings. The interior will be fitted with a fan light, by which it will also be ventilated. The whole of the seats will be open benches and free. Behind the chapel will be a building 40 feet by 20 feet, of two stories, to be used as Sunday school-rooms, capable of accommodating about 400 scholars. The schools will be so adapted that they can be thrown into the chapel. The total cost will be near 1,000*l.* The architect is Mr. John Tillman, jun. The contractors for woodwork are Messrs. Rankin; mason work, Messrs. T. & A. Cook; painting, Mr. George Kirkup.

**Newcastle-upon-Tyne.**—The foundation-stone of a free Methodist Chapel has been laid in Copland-place, Shieldfield. The designs were prepared with the view of having a school-room underneath. The size of the building will be 61 feet by 34 feet, although the chapel itself will not exactly approach to these dimensions, the difference in size between it and the school-room being caused by vestries and class-rooms. The chapel will afford seats for 350 persons, and the school will accommodate 450 children. The architect is Mr. Hunter, and the builder Mr. Simpson, the estimated cost being 800*l.*

**Whitfield (Northumberland).**—The new parish

church of Whitfield has been consecrated. This church, which is substituted for the old parish church, which was inconveniently situated for the greater part of the parishioners, has been built at the sole cost of the Rev. J. A. and Mrs. Blackett Ord, the owners of the surrounding property, in memory of the late Wm. Ord, esq., M.P., of Whitfield. The style of the church is Early English: it is cruciform in plan, with central tower and spire, the latter rising to a height of 150 feet. It is simple in its arrangement and general outline, but is moulded and carved; and is finished inside with chiselled stone, no plaster being used in any part. In plan, the structure comprises south porch, nave, north and south transepts, and chancel and vestry. The nave is one bay longer than the north aisle, from which it is separated by three arches springing from clustered piers. The nave and aisle are each lighted by coupled lancets, and have slender shafts standing detached on the inner piece of wall, opposite each outside centre mullion: they support coupled arches above, which spring at each side from foliated corbels. At the west end of the nave are two long lancets, between which is a memorial niche with inscription. In the gable is a rose window of six lights. The chancel occupies a considerable portion of the area of the whole church. It is divided into three bays by the principals of the roof, and is lighted at the east end by triple lancets, on the north side by one, and on the south side by three lancets. These windows are ornamented with banded shafts; and are variously adorned with rows of nail-head and dog-tooth flowers, and the hood mouldings terminate in heads of saints, prophets, and martyrs, and with bosses of foliage. Below the east window is an arcade of seven trefoil arches, supported on detached shafts, with the spandrels and capitals carved with roses, passion, and other flowers. In this part of the church the floor is raised a considerable height above that of the nave. The roofs are of open construction. Under the tower the system of ornamentation has been designed to culminate. Externally the church is less ornamented than the interior. The roofs are of high pitch, and are covered with Westmoreland slates: they converge to the centre of the tower at the same level, and their gables are finished with floriated crosses. Two kinds of stone have been used in the construction of the building; that for the dressings being light in colour, and the walling something darker. The design for the church was furnished by Mr. A. B. Higham, of Newcastle, and the building has been erected under his superintendence.

**Blyth.**—The foundation stone of a new Roman Catholic church at Blyth was laid on the 10th ult. The building stands upon an open site close to the railway station, and consists of a nave measuring inside 115 feet long and 36 feet wide, terminated by an octagonal apse, the centre of which rises in a high-pitched gable, filled with a traceried window. There are north and south transepts, with large wheel windows in each; a porch, and a bell-turret. The roofs are open and high, after the manner of the French churches, and the style is Early Decorated. Mr. Archibald M. Dunn is the architect; Mr. James Howe, of Cowpen, the contractor.

#### BUILDERS' BENEVOLENT INSTITUTION.

On Thursday evening, the 25th ult., the thirtieth anniversary dinner of the above excellent Institution was celebrated at the London Tavern, Bishopsgate-street; Mr. George Plucknett, president, in the chair.

The chairman was supported by Alderman W. Cubitt (Lord Mayor elect), Alderman W. Lawrence, Mr. G. Smith, Mr. G. Spencer Smith, Mr. T. Piper, Mr. Dunning, Mr. T. Lucas, Mr. Rogers, Mr. O. Bell, Mr. W. G. Gardner, Mr. T. Cozens, Mr. G. Bird, Mr. Joseph Bird, Mr. Nesham, Mr. Barnett, Mr. H. A. Hunt, Mr. Kent, and about 200 other gentlemen.

The band of the Twentieth Middlesex Volunteer Rifles occupied the gallery, the chairman being captain in the regiment, and performed several pieces of music with good effect.

"Her Majesty the Queen" was drunk loyally.

"His Royal Highness Prince Albert and the other branches of the Royal Family" was the next toast proposed, accompanied by a speech setting forth the admirable qualities of the Prince Consort, in his desire for the advancement of science and art, as also his generous assistance in all matters likely to promote the moral and social welfare of her Majesty's subjects.

"The Army and Navy and Volunteers of England" was next given with marked compli-

ments to the Volunteer Rifle Corps, and brought up Mr. Lucas, who replied with much spirit.

The Chairman then proposed the toast of the evening, "Prosperity to the Builders' Benevolent Institution." He said that the Institution had taken its position as one of the philanthropic bodies of the country, and as such, from the good that it had performed, deserved the utmost support. He heartily hoped that, year by year, their field of action would become extended, and that their funds would be materially increased; for at the last election, he was grieved to say, eighteen poor applicants were turned away for want of means. There was another thing,—almshouses were much needed, the occupation of which would be a blessing to their poorer brethren. Funds were accumulating for that purpose; but they should not be content until such houses were completed. Since the establishment of the Institution great good had been done; but still there was much more to do; and, therefore, though in a very few words, he would appeal to them the more earnestly. He did not confine himself to the gentlemen connected with the building trades: he wished for a more extended sphere. There were very many benevolent persons who gave their assistance to such charities as the Builders' Benevolent Institution, and he was sure that there was not another institution of a similar character that was conducted with greater ability and economy.

The toast having been enthusiastically received, Mr. Thomas Piper proposed "The Health of the Chairman and President," and in doing so briefly referred to the strife with which they had been beset, but from which they were then happily free, merely for the purpose of showing the mischievous tendency produced by separating class from class, and contrasting what they were then engaged on, the cause of charity—the best for the community at large. It was a course that was the means of bringing together all classes. Their chairman was connected with the volunteers as Capt. Plucknett; and he craved in that no desire to be separated from those with whom he was associated day by day. It was an admirable movement. In the temples of Rome, if there had been some foundation of public liberty, they would not have been in the ruins to which they had fallen. With respect to the Builders' Benevolent Institution, he thought that material assistance might be rendered by the subscribers. There were 365 days in the year, and if each subscriber felt that he was pledged to produce one subscriber, he might during that period be successful. They could not be engaged in a higher, holier object, than in the relief of those suffering from adversity or depressed by sad affliction. Trouble fell upon us as the sparks flew upwards. It was necessary that we should remember and recognise the great principle of holy religion—love to all. Mr. Piper concluded with expressing a hope that the health of the chairman would be drunk with cordiality, with entire affection, and respect.

The toast having been duly honoured,

The Chairman returned thanks for the kindly feeling of the assembly; and next gave, "The Patrons of the Institution," coupling with that toast the name of Alderman William Cubitt, the Lord Mayor elect.

Alderman Cubitt, who was most warmly received, said—As one of the patrons of the Institution, which in number amounted to twenty-one (the title "Patron" was theirs, not his), he was very happy to see one-third of them now present, that being a proof that the interests of the Institution were thought of by them. They had heard from the chairman, his esteemed friend, and it was quite true, that the building business was exposed to great vicissitudes; various changes were continually taking place, and while in a state of prosperity they were liable to something occurring which would lead to adversity. He considered that if persons who had become thus unfortunate applied to their society, they should at once be assisted and not be allowed the disgrace of going for parish relief. This was the thirtieth anniversary of the existence of the Institution, and he thought that if it were better known, it would be far more liberally supported, and thus they would be able to meet the great claims upon them. During the following year, it occurred to him that if the society called upon the then Lord Mayor, he would preside at their festival, a general effort might be made, and no doubt something extra might be done. He would not further engross their attention, but returning thanks on the part of the twenty-one patrons, would hope well for the future.

Alderman William Lawrence said he was per-

mitted to propose the next toast, and, in doing so, had great pleasure in testifying to the benevolent purposes of aid to the distressed and afflicted with which that Institution had been established. He thought the Builders' Benevolent Institution was now looking up. The gentlemen assembled had come determined to support that to which they had given countenance. They recognized the necessity of their assistance. The building trade was one amongst others most liable to misfortune, which no foresight could prevent. They might be in a state of prosperity, and, from causes which might arise, they might fall into adversity. Such difficulties, in fact, might present themselves that it would be impossible to surmount them. This Institution, then, formed one of the means to aid in that cause, as well as to afford comfort in the decline of years, and he felt confident it was founded on a true principle. Whatever contingencies might arise, the building trade must go on. It was different from a fashionable trade, because fashion might be overthrown; with building, the mode, manner, and materials might be changed, but building must go on, and therefore he believed that that Institution must be a continuing one. He concluded by proposing the health of the Vice-Presidents and Trustees, which was duly responded to.

"The Health of Mr. Thos. Cozens," the founder of the Institution, was next proposed, and a high encomium passed upon him for his great perseverance and exertion in the establishment of the Institution.

The toast having been well responded to,

Mr. Cozens said he could hardly find words to thank them for the kind feeling of the meeting towards him. He alluded to the requirements of the institution, and referred to the eighteen poor applicants whom they had been compelled to send away at their last election, and exhorted all present to exert themselves in the welfare of the institution, in order that the necessities of their poorer brethren might be relieved. He knew of many cases that if not speedily relieved, according to their rules, the applicants would be shut out from the benefits of the Institution.

Mr. A. G. Harris, the secretary, next read over the list of donations, which included Mr. George Plucknett, 21l.; Alderman W. Cubitt, 10l. 10s.; Mr. Wm. Webb, 21l.; Mr. E. H. Toak, 10l. 10s.; Mr. W. J. Freeman, 10l. 10s.; Messrs. Lucas, Brothers, 10l. 10s.; Mr. Gardner, 5l. 5s.; Mr. Geo. Smith, 10l. 10s.; Mr. Spencer Smith, 5l. 5s.; Mr. W. C. Andrews, 5l. 8s.; Mr. C. Brown, 5l. 5s.; per Mr. Josh. Bird, 50l. 8s.; per Mr. W. Downs, 7l. 7s.; per Mr. C. Head, 9l. 18s.; per Mr. Geo. Head, 15l. 15s.; per Mr. W. Lavers, 11l. 11s.; per Mr. D. Nicholson, 25l. 7s.; per Mr. J. Outwaite, 15l. 15s.; per Mr. A. A. Robinson, 10l. 10s.; per Mr. T. Sterling, 18l. 6s. 6d.; Mr. Venables, 5l. 5s.; Mr. W. Morris, 5l. 5s.; Mr. F. P. Cockerell, 2l. 2s.; Mr. R. R. Arutz, 2l. 2s.; and per W. Harrap & Son, no less than 152l. 15s. 6d., including Messrs. Whitbread, 10l. 10s., and Mr. Styles, 10l. 10s. The total was about 530l.

On "The Health of the Treasurer, Mr. George Bird," being given—

Mr. George Bird thanked them very warmly, and said he felt their kindness greatly. He referred to the wants of the Institution, and said that, having been through the country, almost everywhere he saw buildings springing up, which was a sign to him that the building trade was flourishing, and as such was the case, he hoped that their Institution would become a recipient of some part of the fortunes they were making.

The Chairman then gave, "The Architects and Surveyors," speaking strongly of the builders' obligations to them, and coupling with the toast the name of Mr. Godwin.

Mr. Godwin, in his reply, urged, much as the Institution had done, that, considering the magnitude of the interests involved,—that our builders and contractors went forth to the east and to the west, executing works to bridge the world,—dealt in millions, and commanded armies of men,—it had not yet taken the position it might, and probably would take. He argued for it a fresh start next year under the presidency of Lord Mayor Cubitt.

"The Brighton Branch," "The Directors and Stewards," and some other toasts followed, and then the meeting broke up, determined to make the next year an epoch in the history of the Institution.

**GAS.**—The Louth Gas Company have declared a dividend of 10 per cent. The 6 per cent. guaranteed on the additional capital raised a few years since has also been paid. The same dividend was paid last year.

PROPOSED INSCRIPTION ON THE MONUMENT OF GEORGE STEPHENSON, AT NEWCASTLE-UPON-TYNE.

STR.—In the interest of truth I ask you to insert the following suggested inscription for the monument of George Stephenson.

This monument is erected to prove to the world that fortune and honour, and all earthly respects, are the fitting and inevitable recompense of him who, directing the energies of a comprehensive genius to the appropriation of other men's ideas and discoveries, dazzles the unthinking portion of mankind by an accumulation of reflected light, and ultimately succeeds in rearing a superstructure of fame upon a foundation of credulity.

As strictly demonstrative of the truth of this position, the following facts in connection with the development of the railway system are hereto appended in the order of their dates.

1. Horse tramways for the conveyance of coal and mineral produce have been practically known to the world for more than 100 years, and one of these ways was in use at Prior Park, near Bath, in the middle of the last century, for the daily carriage of stone from a neighbouring quarry.

2. In 1802 Trevithick and Vivian obtained a patent for their high-pressure locomotive engine, and in 1804 succeeded in drawing with one of these engines a load of ten tons of bar iron upon a tramway at Merthyr Tydvil, at the rate of nine miles in two hours. The steam-hoist was first introduced in the chimney of this locomotive.

3. In 1812, William Hedley, of the Wylam Colliery, demonstrated, upon a working scale, that the mere friction of the wheels of a heavy carriage upon the smooth rails of a tramway was sufficient to enable it to draw a train of loaded waggons; and, by the early part of 1813, he had constructed a steam locomotive upon this principle, which was then and there put into working use for drawing the coals from the pit's mouth to the river. The steam-hoist was also used in this engine, but with increased effect, by reason of the chimney and effluent orifice of the steam-pipe having been much contracted in size.

4. In 1814, George Stephenson, after repeatedly inspecting William Hedley's engine at Wylam, constructed an engine himself, at Killingworth Colliery, for Lord Ravensworth, which was employed in drawing coal-waggons as in the last-named instance.

5. In 1820, 1821, and 1822, William James, with the assistance of his eldest son, William Henry James, projected and completely surveyed the original Liverpool and Manchester Railway, for goods and passenger traffic, in which great public work he lost the whole of his large private fortune, with no other result to himself than to meet with the common fate of inventors and public benefactors; for, soon afterwards, and with scarcely the mention of his name, all the honour, prestige, and profits of the undertaking were carried off by George Stephenson, through the medium of powerful party intrigue and interested machinations.

6. On the 1st of September, 1821, William Henry James communicated to William Losh and George Stephenson his invention of the *introduction of tubes into locomotive boilers*, and for certain considerations gave them permission to use the same, as specified in an agreement of that date, signed by the several parties.

7. In 1829, the Messrs. Stephenson for the first time introduced *tubes* in the boiler of the Rocket engine, by which introduction they were enabled, not only to distance all competitors, and carry off the 500*l.* prize, in the celebrated contest of locomotives, which took place on a portion of the Liverpool and Manchester Railway in the same year, but to demonstrate to the world, once and for ever, the comparative annihilation of time and space in railway travelling, and the thorough practicability of passenger traffic by steam, at any required velocity.

8. In 1833, the Liverpool and Manchester Railway was completed, and formally opened to the public, and with a success which immediately led to the extension of the railway system over the whole civilized world, to the immense employment of labour and capital, the economy of transit, the multiplication of the conveniences of life, and the general equalization of the products of nature and the works of human industry.

9. In 1859, Samuel Smiles published his *Life of George Stephenson*, and, with the above-named facts before him, very properly declared that individual to be the inventor of the locomotive engine, and the originator of the railway system.

With due regard, therefore, to the history of

this great and magnificent invention, as here briefly detailed; and seeing how one man has therein dextrously covered himself with the whole fame and glory rightfully belonging to other labourers, as witnessed in the introduction of tramways, whose origin is almost lost in the lapse of 100 years; in the invention of the steam locomotive and blast, by Trevithick and Vivian; the principle of adhesive traction, by Hedley; the steam-generating tubes of the younger James, and the conception and original survey by his father of the first engine passenger railway ever opened to the world—the Liverpool and Manchester;—seeing these things, and as an encouragement to others to follow in the same laudable and successful career, the committee entrusted with the erection of this monument almost regret that it has been constructed of perishable stone, in place of more appropriate and enduring brass.

JUSTITIA.

DAMP ON WALLS.

FROM the particulars given by your correspondent last week, it is, I think, evident that the damp he complains of does not come from the outside of the wall. The cause is doubtless that usually occurring where gas is used without good ventilation—viz., the escaping hydrogen combining with the oxygen of the atmosphere and forming water. The hand of wet being on a level with the burners, shows the connection of cause and effect.

An opening in or near the ceiling for ventilation might do much to remedy the evil.

Works of art should not be left uncovered where gas is burnt, as the disposition to form moisture on smooth surfaces, combining with the dust of the apartment, forms a cake of dirt.

P. E. M.

THE SITE OF WOOLWICH HOSPITAL.

STR.—You say, in your comments on hospital construction last week, that Dr. Couche had pointed out in the *Builder* other sites for the Woolwich Hospital. I am able to state positively (I send you my name) that these were all noted at the time, but on an examination only one of them was available either for size or position, and that one could not be had for money.

AMICUS.

VENTILATION.

WITH reference to the suggestion of "Salus," as to forming an opening in the ceiling connected with an air-brick in the external wall, the contingency of direct down-draught may be prevented by fixing or suspending below the opening in the ceiling either a ledged woodslap or a zinc plate, leaving a clear space of 1 inch between the plaster and the zinc. The air will thus be spread along the upper portion of the room: a centre flower may be secured to the wood or the zinc, if in a decorated apartment. The spreader should be one-fourth larger than the opening above it, and the floor in the apartment over it should be made air-tight.

"Salus" might look at the remarks upon page 77 of your present volume.

THOMAS GOODCHILD, F.S.A.

I wish to suggest to your correspondent who seeks to ventilate a room a method which I have tried myself and found very successful.

If the chimney is square, a metal pipe can be easily fixed inside in a corner. The lower end should be open into the room near the ceiling; for the upper end an opening should be made in the side of the chimney as high as the leads on the top of the house, with a grating to keep out rubbish and birds. The opening into the room should be trumpet-shaped. The pipe should be made of copper, and of course thin enough to imbibe heat from the chimney. When there is a fire in the room and the chimney is warm, a pipe, 3 inches in diameter, will be found very efficacious; but I think that, even if the pipe be not warmed, it is of some use. Of course all the rooms through which the chimney passes may be ventilated by the same pipe, and the kitchen chimney would be useful, as it is always warm. If the chimney be round, perhaps there would be some difficulty in fixing the pipe and sweeping the chimney so as not to injure it; but I think, if the pipe were rather flattened, it would succeed.

M. G.

In your impression of last week there appeared a letter signed "Salus," asking for information about the ventilation of houses.

The writer, who he acknowledges the merit of Dr. Arnott's chimney-valves, says that the objec-

tion to them is, the "frequent admission of smoke and dirt from the chimney."

I beg that you will allow me to give my grateful testimony to the usefulness of these valves. I have had them for ten years, and have never, in any instance, been troubled with smoke or dirt from the chimney, the ceiling of my rooms being as free from smoke above the valves as at any other place.

In fitting up these valves, however, care must be taken to have them of a right construction, and to have the fire-grate below properly fitted in, so as to ensure a good draught up the chimney. The valves should also be taken out occasionally and have their bearings cleaned, while the soot that has lodged in the chimney opening may at the same time be swept away. This last operation has, in a room where in winter there is constantly a good fire, been only performed once during the last eighteen months.

The other means of ventilation suggested by your correspondent will, in most instances, result in the admission of air from without, and their action will not be certain or regular, the air sometimes coming in and sometimes going out by the openings being influenced by the direction of the wind, the opening and shutting of doors, &c. The air so admitted would also be mixed with the hot and impure air which constantly floats near the ceiling.

In the absence of any provision for the admission of air into houses, the window of an unoccupied apartment answers very well. I have one partly open night and day; and, as every one of my apartments is fitted with an "Arnott" chimney opening, the air so admitted flows constantly and almost imperceptibly through them all.

I conclude by wishing that the importance of ventilation were as generally understood as "Salus" assumes it to be.

W.

THE PUGIN TRAVELLING FUND.

As the Institute will now shortly be reopened and we shall once again assemble for the purpose of promoting the interests of our art, it is I think a fitting opportunity of reminding the profession generally, and the members of the Institute in particular, of the efforts which are being made, to provide for the rising men amongst us those opportunities of travel which, during the recess, so many of our professional brethren avail themselves of. I refer to the "Pugin Travelling Fund," by which it is intended to honour Pugin's memory and to advance the principles he so ably advocated and applied. As the Institute will be solicited to become trustees of the fund collected, all its members may naturally be expected to show an interest in its progress, not, perhaps, greater but of a closer nature, than our other professional brethren;—but surely a fund for endowing a travelling studentship, such as that proposed, should not only be most liberally supported by those in the practice of architecture, but by those in the study of it also. By the side of the many very handsome contributions which have been received from all quarters we hope to see subscriptions (we care not how small they be) come in from every architect's office in the kingdom.

A movement is already afoot amongst the art-workmen, whose shillings and half-crowns will have a peculiar value. The workmen are well aware of the benefits conferred on them by the stimulus which Pugin's enthusiasm gave to every branch of art handicraft; but equal benefits have, certainly, been shared by architectural students, for whose special advantage the "Travelling Fund" is intended. I hope, therefore, you will kindly call the attention of the profession throughout the kingdom to the claims which we consider we have upon their students and assistants. Without them a memorial to Pugin,—especially when it is a "Travelling Studentship,"—cannot be complete.

JOSEPH CLARKE, Hon. Sec.

THE WEST CENTRAL DAY INDUSTRIAL SCHOOL.

A MISSING RENOVATION.

STR.—Since you were good enough to insert my last note in your journal a most curious circumstance has occurred to us. Some charitable person (perhaps in consequence of your recommendation of our school) sent a letter (addressed to me) by a messenger to the Refugees in Great Queen-street. The messenger gave the letter to the master of that excellent institution, saying that it contained twenty-five guineas; but he, seeing that it was directed in my name, sent the messenger to Tichborne-court with it. I have made every possible inquiry, and have even advertised in the

Times for it, but without avail; and to this day I have heard no further tidings of the donor, messenger, or money. Whether the man was unable to find Tiebhorne-court or not I cannot tell; but he never came there. In fact, we have virtually lost 26l. 6s., which you may imagine is a very serious matter in the case of a young institution. I do trust, however, that, if you will give publicity to this note, possibly the account of the circumstance may meet the eye of the donor, who, perhaps, is wondering why he has received no acknowledgment of his munificent donation.

Allow me, in conclusion, to say that we are still very anxious to obtain more work for our boys. We have been engaged in fancy-box making, paper-hat making for grocers and the London and Westminster Bank, Bloomsbury branch, and also in the getting up of mouldings and rollers for maps and almanacs, &c. If any of your readers can assist us in obtaining an increased supply of work in any of these branches, we shall be extremely thankful, and they would have the pleasure of helping forward the very arduous work of preventing juvenile crime. At present we are obliged to keep our numbers very low, because of our limited means of giving them employment. If we can only increase these, we shall be able to take as many as the premises will conveniently hold. A visit to the school (Tiebhorne-court, near Great Turnstile, Holborn) will give a better idea of the plan of our working than any correspondence can do; and therefore I earnestly request that any of your readers who are willing to assist those who cannot assist themselves will be kind enough even to pay us a casual visit.

B. A. HEYWOOD.

ILLUSTRATED GIFT-BOOKS.

MESSRS. LONGMAN'S "LALLA ROOKH,"\*

As the immigration of swallows is viewed as the prelude to summer, though it is to be hoped there were none mendacious enough to take quite their ordinary flight this year, so we have unfailling and conspicuous harbingers,—albeit professed story-tellers,—to remind us that Christmas may be shortly expected in the gorgeously-arrayed emissaries that certain excellent publishers consider it a duty to send forth as ambassadors extraordinary from the lands of literature and art to the festive court of the snow-crowned monarch who is supposed to reign for a dozen days a year. How they struggle for supremacy of splendour! How they contend one with the other the most magnificently to represent their respective sovereign,—or one-pound-one! Some in crimson and gold, others in azure and gold, and a few in mauve or Magenta. Truly the livery of Paternoster-row is a gay one. But it is not only outward show, good reader, that is to recommend them to your notice. Mark you their titles; listen to their introductions; and, going further still, you will find them possessed with such learning, such wit, and such a power of pleasantly imparting counsel and pleasure, as to induce a wish to know them better.

The Messrs. Longman have been fortunate in their selection, both with regard to poet and artist. Of the poet nothing remains to be said, the book has taken its place; but to Mr. Tennyll, one of our most accomplished illustrators, more than usual acknowledgment is due, for the assiduity with which he has laboured to turn to the best account knowledge, the acquirement of which must have cost him considerable research,—to what purpose is sufficiently manifest in the additional value and interest that correctness of costume and architectural detail gives to his very admirable designs.

We will preface the little wo notice as exceptional, by pointing out that the more striking instances of success combine some of the highest attributes of art. Indeed, it rarely occurs to find so much academic knowledge with such power of expressing it invested in book illustrations, even in these days.

Moore's "Lalla Rookh" is pre-eminently adapted to receive any amount of pictorial embellishment. So minutely descriptive, so full of life and colour as it is, it affords a rare opportunity, of which, if the artist has not availed himself to the fullest possible extent, it may be, perhaps, from a notion that he was treading on dangerous ground. Strictly avoiding the anaeracronic element, which, to an allowable degree, tinctures portions of the poem, he has gone to the opposite extreme, and absolutely ignored its existence:

\* "Lalla Rookh," By Thomas Moore. With illustrations by John Tenniel; engraved by the Brothers Dalziel; and five ornamental pages by T. Sulman, jun., engraved by H. N. Woods. Longman, Green, Longman, & Roberts,

consequently, some of his pictures are out of tune with the verse they are intended to illustrate. For example, the illustration of the dance, so glowingly described by the author (p. 59), might almost appertain to a religious procession. The types of feminine attractiveness throughout the work, indeed, are seldom to be precisely identified with the description, graceful and charming as they often are. This failing only applies to the chief impersonations. Where more license is admissible, great advantage is taken of it; as witness (p. 50) the composition heading the second part of "The Veiled Prophet," in which national individuality is so happily conveyed.

"That wild Zelica, whose every glance Was thrilling fire, whose every thought a trance!" has not been handsomely treated; with two exquisite exceptions (p. 102 and p. 117)—her death scene,—which, for its delicacy, expressiveness, and beautiful drawing, excepting, perhaps, the horse, may be pronounced to be as nearly perfect as a book-illustration can be.

Altogether, there is very little to qualify the highest praise of the illustrations. Considered as a series, they are far beyond what we are in the habit of seeing; in the majority of which dexterity and prettiness alone are creditors for their charm; and there can be no doubt that this edition of "Lalla Rookh" will meet with the thorough appreciation it deserves from all who can distinguish real excellence from the merely pretentious claim to it.

With reference to such gift-books, *en masse*, welcome as they are, they are apt to raise the question as to how far a general elaboration of engraving benefits the draughtsman's production, as in many cases it may be readily perceived that the principal points of the drawing have lost their intended influence from the fact of their not being susceptible of a proportionate share of the labour lavished throughout. We merely propound this, however, for consideration, with a confession that we should like to see a more distinctive character imparted to the several volumes, and a hope that they may nevertheless form a lasting institution, however modified.

Books Received.

*A Complete Practical Guide to Her Majesty's Civil Service.* By a Certificated Candidate. London: James Blackwood, Paternoster-row. This volume contains, it is said, "in full the examination papers for every department used since the appointment of the commissioners; full details of the limits of age and qualification of candidates; hints to candidates for every office; and copious tables of the emoluments and superannuation allowances of every civil servant in Great Britain, Ireland, India, and the Colonies." The work, under present arrangements, cannot but be of great use to all seeking public employment in the civil service, either for themselves or others. The hints to candidates how to obtain a nomination, however, which, it is stated, is almost always procured through the mediation of Members of Parliament, will not be regarded by these gentlemen with much favour.

*The Statute Book for England: Collection of Public Statutes passed in 1859.* Edited by JAMES BIGG. London: Simpkin, Marshall, & Co. 1859. Specimen volume.

*Proposals for Reformation of Statute Book: ordered by House of Commons to be printed.* 1860.

The author of the specimen volume under notice made a proposal to the Government, that they should so far sanction and support his intention to issue a series of volumes containing the statutes of the realm in a consolidated and intelligible form, by guaranteeing the purchase of 2,500 copies, at a reduction of 40 per cent. from the publication price, which would amount to 2,340l. per annum; and he estimated that the whole work would be completed in eight years. He also asked that his edition might be made admissible in evidence. The Government authorities, however, have neither accepted nor declined Mr. Bigg's proposals; but meantime they appear to have themselves employed two other gentlemen to edit a new edition of the statutes.

The consolidation of the statutes into available compass is certainly most desirable; but, whether Mr. Bigg be the proper person to do the work or not, we are unable to say. Mr. Bigg appears to be a person whose turn of mind specially recommends him for such a work, while the volume he has already produced bids fair to supply a great public want.

Mr. Bigg has again requested a decision as to his proposals, which have been modified; and he now only asks the Government to aid him to compete with their edition by purchasing 1,000 copies annually.

*A Primer of the Art of Illumination, for the Use of Beginners.* By F. DELAMOTTE. London: K. & P. N. Spon. 1860.

*Outlines for Illuminating and Missal Painting.* Designed by CHARLES HENRY DRIVER, Architect. Drawn on stone by M. & N. HANHART. Winsor & Newton, Rathbone-place.

DEMAND leads to supply, and then the supply aids, up to a certain time, in increasing the demand. Mr. Delamotte, in his "Primer," has given some practical directions for the exercise of the art of illumination, and a list of specimens which are to be found in the British Museum. The illustrations which he gives include, with a number printed in their gold and colour, outlines only, of the same specimens, so that they may be traced and filled in with colour with the least possible exercise of mind or skill.

The set of *Outlines for Illuminating*, cleverly designed or compiled by Mr. Driver, are twelve in number, and include the Lord's Prayer, Collects, &c. The text is exceedingly well formed, and is literally black-letter, to the great credit of Messrs. Hanhart.

Miscellaneous.

THE PRINCESS'S THEATRE.—Mr. A. Harris has re-opened his theatre with a great success. Mr. Fechter, an English-born French actor, the original representative, in their original tongue, of the principal character in the Corsican Brothers, Pauline, and other dramas known to London playgoers, has, by a curious turn of the wheel, been brought to play them at the Princess's in their English dress. He wisely, however, opened in a piece not known here, a free adaptation, by Mr. Edmund Falconer, of Victor Hugo's, "Ruy Blas," and has established unmistakably the right to be considered an admirable actor of high melodrama, so to speak. The piece itself is very well put together, and most tastefully mounted; and Mr. Fechter is ably supported by Mr. Walter Lacy (who has not done anything so good for some time), and by Miss Heath, and the lessee. We must give praise, too, to Mr. James Hates, for his scenery, which is admirably painted, and preserves the traditions of the house in this respect. The scenes consist chiefly of apartments in the Palace of the Escorial, and are alike appropriate and beautiful.

ST. ALBAN'S ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—A meeting of this society was held last week. Professor Donaldson presided. Mr. W. Pollard, of the *Herts Guardian*, read a paper "On certain Monastic and other Ruins in Lincolnshire." Mr. W. L. Donaldson, nephew of Professor Donaldson, read a paper "On the Life and Times of Offa, King of the Mercians."

NEW MARKET AND CORN-EXCHANGE FOR SHERBURY.—A more than usually large share of public attention, says the *Shrewsbury Chronicle*, is now being devoted to the subject of market accommodation in this town. Schemes for a market have been propounded by Mr. R. S. France and Mr. Ashdown. By the plan proposed by Mr. Ashdown, an available space of 4,365 yards is secured, being 428 yards more than that given by the Mardol site, as at first proposed. The estimated cost Mr. Ashdown places in round numbers at 23,000l., a sum lower by at least 10,000l. than the Mardol site was computed to cost. A third—or rather the first scheme—is that of Pride-hill. The cost of erecting a market there, containing some 2,800 yards, is calculated at from 15,000l. to 16,000l. It is proposed to take down the present butter-market, and the Drapers' Almshouses in St. Mary's-street, and the front to that street will be 140 feet. The Pride-hill front will be 95 feet. The rateable property to be taken down will not, it is estimated, reach 200l. The whole of the plans will shortly come before the local Improvement Commissioners for discussion. As to the proposal for erecting a corn-exchange, the present site is considered to be better than any other. By a moderate expenditure it is thought the present market-hall could be made available. Mr. Ashdown's proposition for having a corn-exchange near to the site of his suggested general market would cost some 7,000l. or 8,000l. The town-council, the *Chronicle* thinks, will not consent to destroy the features of the present market-hall, so as to meet the wishes of those who desire to turn it into a corn-exchange.

**THE NINE HOURS' MOVEMENT.**—The daily papers have published an "Address to the Community at large, and particularly to the Gentlemen of the Press and the Employers of Labour," by the building operatives, signed "George Potter," in which the writer says,—“The price of anything is 'just so much as it will bring.' We are the sellers of labour, and if we unite to claim, it is not pretended that the buyers do not seldom unite to refuse. We are not at variance with right political economy till we shall ask a price which shall limit the demand for it: it is open market, with the sellers agreed for an advance to the extent of 10 per cent., which we propose to take out 'in time.' Which of the many public writers and speakers who have been aghast, during the late lock-out, with the dreadful ignorance of political economy by the workmen, would have held the same language on hearing that the holders of any other commodity were standing out for an advance to a similar extent? Gentlemen, the question of supply and demand in any contest, can be solved only by the issue. Spare even your compassion till you find us in the wrong. We do not doubt we shall learn of you both new and good reasons why we deserve to be successful, when we shall in reality have become so. We are then certain of your praise.”

**ELECTRO-TELEGRAPHIC PROGRESS.**—M. Vêrard de Sainte-Anne, a short time ago, sent a paper to the Académie Française on a project for establishing a belt of electric telegraphs all round the world. From a table given by the author, it appears, according to *Galvani*, that the trade of England with the East amounts to 2,723,000,000f. per annum; that of France with the same, to 401,300,000f.; of Holland, to 295,222,000f.; of Russia, to 150,000,000f.; of North America, East and West, 3,061,680,000f. (?); of South America and the West Indies, 1,730,723,000f.; and so on. In the United States the network of telegraphic lines comprises a length of 70,000 kilometres, or 47,250 English miles; and when the New York and San Francisco line is completed—the line over Europe and Asia being supposed to exist—there would only be 3,500 leagues of cable to be sunk in order to enable Paris and London to receive intelligence from Canton in one hour and 50 minutes, from New York in two hours and 20 minutes, and from Valparaiso in three hours and a quarter. A considerable number of partial lines, which, according to the author, may easily be collected into one great whole, are already in existence, or about to be established. Thus, in Japan, the lines have been granted to a company, and one of them is in course of construction; New Zealand is already connected by a cable with Australia, Melbourne with Sydney, and Batavia with Singapore; and the whole continent of India, thanks to English enterprise, is now being intersected with telegraphic lines, connecting Calcutta with Madras, Benares, Lucknow, Agra, Delhi, Hyderabad, &c. Again, from Bombay, a line goes to Goa, and westwards to Kurraehce, whence it will soon reach Hyderabad.

**ACCIDENTS.**—While the navies engaged in making the line to Dover were at work at a bridge at Temple Ewell, the whole structure suddenly gave way with a crash. Three men were at work under it at the time, and they were all buried under the ruins and killed. At the inquest, Thomas Russell, one of the navies, said he heard the bridge fall just as he had got out of the cutting. He had seen the bricks as they now lie. Most of them seemed as clean of mortar as ever they were. Some have a little mortar, but many, he should think, could never have had a particle of mortar on them. The coroner asked Mr. Macdonald (Mr. Cranpton's agent), who was responsible for the building of the bridge? Mr. Macdonald said Messrs. Hawley, of Dover: they had the sub-contract for its erection, and they did not sub-let it to any one. The coroner said it would be necessary to have a professional opinion as to the erection of the bridge, and whether the proper materials had been used, and in the proper way; and, after a little discussion, the inquest was adjourned.

An accident has just occurred at Sheffield, in the Hanover Chapel, which shows how little will produce a panic, and endanger the lives of hundreds. The giving way of a little plaster beneath the gallery was the cause of the excitement in this case. A great rush was made to the doors, and the utmost confusion ensued. After a time many became reassured, and took their seats again, but a little more plaster fell, and the confusion became worse than ever, and several people were severely crushed in their attempt to escape from the expected fall of the chapel. The plaster, it is thought, had been too hastily dried by the gas which burnt near it.

**SMOKE FLUES.**—The "curious smoke-flues" mentioned in the *Builder* of September 23, are by no means uncommon. There are several at both Rochester and Heddingham Castles, and at Winwall, in an old house. Sometimes these holes have on the outside a sort of pseudo chimney, as at the Lavatory, Lincoln-gate: to these succeeded roof chimneys.—P. E. M.

**NEW WATER-ELEVATOR.**—Mr. Robert Nelson, an American, has invented a new water-elevator, in which the vacuum is produced by the combustion of volatile matters, among others, naphtha. The elevator consists of a large cylindrical reservoir, at the base of which the suction-pipe is placed. In the upper portion are several valves, communicating with a reservoir of naphtha and a little furnace placed between this latter and the cylinder. Upon closing this latter, it is sufficient to light the little fire, and allow the naphtha to fall upon it drop by drop: the vivid combustion that ensues, creating a vacuum, causes the water to rise rapidly in the cylinder, as much as 100 gallons at a time.

**THE TELEGRAPH IN THE OPERA.**—In the new French Opera-house about to be erected, says the *Constitutionnel*, the electric telegraph will, it is stated, play a very prominent part. An instantaneous line of communication is to be established between the cabinet of the Minister of State and that of the director of the theatre: a wire will also run from the box-office to the principal hotels, so that strangers will be able to engage places immediately on their arrival in Paris, and by the aid of the same electric power, the prompter will be enabled to give notice to the actors and actresses in their rooms when the curtain is about to rise.

**THE THAMES EMBANKMENT.**—The President of the Metropolitan Board of Works has received a communication from the Right Hon. William Cowper, the First Commissioner of Works, stating the views of the Government on the subject of the Thames embankment. A special meeting of a committee of the whole board was at once convened to consider the communication, and the course resolved to be pursued in reference thereto will, it is asserted, lead to the realization of this greatly desiderated work, in conjunction with the construction of the low level main sewer along the bank of the Thames, instead of bringing this great sewer along the Strand, Fleet-street, &c., as originally proposed.

**THE MILAN EXHIBITION OF PAINTINGS AND SCULPTURE.**—A long and interesting account of this exhibition appears in the *Morning Post* of 25th October, written by a correspondent at Milan. From this account it appears that landscape paintings are numerous, portraits few, and architectural drawings remarkably scarce. Sculpture forms a chief feature as respects number of works, Milan excepted being well known to possess a greater number of sculptures than any other Italian city, Rome included. About half of the best men of the Milan School of Sculpture, however, are missing from the present exhibition. The Cavonius School is on the decline, the new and pictorial school of Vela, the professor of sculpture at the Turin Academy, in the ascendant. The uniform contour of the whole exhibition, it is said, produces a kind of monotony which wearies the public, and the want of commissions gives it the character of an open market.

**STROKE INSTITUTE OF ARCHEOLOGY.**—The quarterly general meeting of the members and friends of this society was held at Woodbridge, and presided over by the Rev. Lord Arthur Herve, the president of the association. The members assembled at the lecture-hall, where the exhibition of antiquities, &c., was arranged. After an address from the president, a paper was read by Mr. Colchester, on the Archeology of the Glacial Drift, in which it was held (not for the first time) that the flint implements, found together with bones of extinct animals in divers localities, had been subject to re-arrangement by floods from the chalk lagoons, burying them 20 feet deep in the drift gravel. After the reading of this paper the company proceeded to Woodbridge Church, where Mr. Tymms, of Lowestoft, the secretary to the Institute, read a paper on the church. The abbey was next visited; then Seckford Hall; Mr. Tymms reading a paper on the hall; then Great Bealings Church and rectory, and Playford Hall; at which last a paper was read by the president on the families to whom Playford had belonged. Here the company, sixty in number, partook of a cold collation with Mr. Clarkson, and they afterwards visited Playford Church and the village of Grundisburgh and its church, as also Mr. Acton's collection of Roman and other antiquities, now for sale. The party then dispersed.

**LONGSTAFF AND PULLAN'S PATENT TRACTION ENGINE.**—The new patent traction engine of Messrs. Longstaff and Pullan made a trial trip recently, from the works of Messrs. Crosswell, Blackfriars-road, the engineers by whom it has been constructed, to Clapham-common and back, affording evidence of its value as a means of draught for heavy goods on common roads. In this engine, an attempt has been made to remove what has been regarded as a defect in other machines of the kind, which makes the boiler itself the support of the moving part of the machinery. It is represented as capable of ascending the sharpest gradients met with on common roads, upon which, it may be remarked, it scarcely leaves a trace of its passage. Messrs. Crosswell are constructing six of these engines for Spain, and the cost of each is about 900l.

**WHERE TO BUY A WATCH.**—“The practical utility of a good watch—the habits of regularity it generates, and the advantages of the punctuality it assists in securing—are facts proved beyond a doubt. The establishment, then, where at a reasonable charge these advantages can be obtained, must be worthy of attention. At Mr. Benson's, 33 and 34, Ludgate-hill, may be purchased the chronometer for sixty guineas, the mechanic's watch for two guineas, and the various other kinds of watches (duplex, lever, horizontal, or vertical) at various prices—all displaying the utmost finish and superiority of manufacture.”—*Daily Telegraph*. Benson's Illustrated Pamphlet, post free for two stamps, is descriptive of every construction of watch now made. Watches safe by post to all parts of the globe.—Advertisement.

**TENDERS**

For the erection of the new Dracny Premises, for Messrs. Weistred & Co., Broad-street, Reading; Mr. Wm. Brown, of Reading, architect. Quantities supplied by the architect:—

Newman & Mann	£2,575	0	0
Nacey & Co.	2,450	0	0
Brass & Co.	2,378	0	0
Asby & Horner	2,345	0	0
Biggs	2,344	0	0
Orton & Child	2,331	0	0
Wells	2,210	0	0
Hutton	2,203	0	0
Nichols	2,189	0	0
Atamson & Son	2,183	0	0
Matthews	2,173	0	0
Shepherd	2,118	0	0
Woods (accepted)	2,109	0	0

For taking down and rebuilding the "Sailors' Return," at Grays, Essex; Mr. W. C. Homer-ham, architect. Quantities supplied by Mr. J. A. Banker:—

Ward	£1,870	0
Powder	1,850	0

For new Church, Barton-on-Trent; Messrs. J. W. and J. Hay, architects:—

	For Church.	For Lecture-Room and Vestry.	Total.
Yeomans	£1,069	£130	£1,218
Deardis	950	124	1,074
Hunter & Bennett	953	130	1,083
Wilcman & Wigley, & Maddocks	819	133	952

\* Accepted.

For the erection of Four Six-roomed Dwelling-Houses, with cellars, &c., at Malvern Link, for Mr. W. Blizard, Mr. Edward C. Albutt, architect, Malvern Link:—

Smat	£599	0	0
Nott	608	5	0
Davis	605	0	0
Holt	617	10	0
Allen	645	0	0
Moore (accepted)	520	0	0

Accepted for Oil Mills and Machinery, for Messrs. Meek & Co., at Limehouse; Mr. James Edmonston, architect:—

*The Refinery.*

Case, Builder's Work	£711	0	0
Rolls, Iron Work	155	11	0
Rolls, Warming Apparatus	103	10	0

*Enlarging Seed Warehouse.*

Case, Builder's Work	£1,385	0	0
Rolls, Iron Work	300	6	0

Machinery to crush 100 tons of Seed per Week. Balfour, of Fife, with Waygood, machinery, without engine, boilers, and shafting, £1,993 0 0

Steam-engine, boilers, and shafting, will cost about 1,000l.

For alterations, additions, and repairs, to Frank's Hall, near Farningham, Kent, for Mr. Robert Bradford; Mr. R. L. Rommey, architect. Quantities supplied by Messrs. Welch & Atkinson:—

	House.	Stables.	Lodge.	Total.
l'Anson	£,772	1,798	426	8,996
Brown & Robinson	8,999	1,576	394	8,969
Myers	6,222	1,978	412	8,612
Keyes & Head	5,937	1,825	359	7,821
Mansfield	5,413	1,497	316	7,226

# The Builder.

VOL. XVIII.—No. 927.

The Nation's Progress in an Architectural Point of View.

AIRLY inaugurated now is the Architectural Session. The Royal Institute opened its doors, as will be seen elsewhere, last Monday evening; the Architectural Association had previously done so; the Architectural Museum is beginning to stir and will demand our early attention; while in Glasgow, Liverpool, Birmingham, and elsewhere, the Bodies have met and are preparing for action. There has been more than usual stir in architecture of late, and it will be well if in one quarter or another a retrospective glance be

taken at what has been achieved in that field during the last ten years. In the course of a long up-hill journey, it is sometimes desirable to pause and survey the difficulties that have been surmounted. The sight of the long track behind, already accomplished, gives fresh energy to pursue the route. We have got thus far, we reason, and the same vigour that has brought us to this stage will enable us to pursue our journey to the end. It has been a decade of great activity. The spirit of restoration has swept from Land's End to Berwick-upon-Tweed, resting there but to plume her wings for a further flight across the border. The sister arts and industry have followed in her wake; and ancient buildings have been renovated, and modern edifices erected on all sides. A combination of circumstances,—the public baths and wash-houses movement, the Extra-mural Burial Act, the great improvement in the national appreciation of the beautiful,—materially aided, we may be permitted to say, by the publication of illustrated periodicals of an art-teaching purpose; the agitation of the educational question;—a combination, we say, of these and other causes has given an impetus to the erection of public buildings that has no precedent. So much has been done, albeit so much remains to be accomplished, that we could scarcely realize the fact that the immense amount of work achieved is but the result of ten short years' labour, if we did not keep before our eyes the multitude of workers. Not only new churches, whose number at a moderate computation must considerably exceed a thousand, but new castles, new colleges, new schools, new town-halls, new vestry-halls, new literary institutions have arisen around us in incredible numbers. Countless new cemeteries dot the green landscape, as do numerous industrial schools, and asylums for lunatics, paupers, and invalids. All this speaks of vitality and of well-doing; as well as of "faith, hope, and charity." Britannia, in her time-honoured chariot, presses up the hill of progress through a country, which, if not flowing with milk and honey, is enriched with the wealth accruing to industrious effort and thought-directed labour. May her shadow never be less!

The battle of the styles has been fought in the progress-path. It is remarkable that the spectators of the great fight have not awaited the result. They have gone to their homes, and, in their private capacity of peaceable citizens, have facilitated the building of town-halls, mechanics' institutes, free libraries, and whatever else the spirit of the times required of them, unblinded by any opinions but their

own. Those inclined to the Classic styles will point to St. George's Hall, Liverpool; the sets of "Chambers" of the same city, the Townhall in Leeds, the warehouses of Manchester and Nottingham, railway stations in many parts of the kingdom, club-houses, residences such as Bridge-water House, and business-house premises in London; while, throughout the country, whether in the recesses of Northumberland, in the wolds of Yorkshire, in the labyrinths of streets in our cities, the public feeling, as evidenced by recent erections, such as All Souls', Halifax; All Saints', Margaret-street; and a host of other instances, is seen to be in favour of Gothic architecture, as a fit rendering of ecclesiastical expression. The Dissenters would appear to have the same feeling. Within the last ten years the Wesleyans have built Gothic chapels at Ilkerton, Lincoln, Liverpool, and many other places; the Independents at Liverpool, Weston-super-Mare, and, as reference to our Church-building news will show, in various other localities. Nor is Gothic without its important exemplars in other departments, giving notably a museum at Oxford.

The popular views respecting national education have called for the erection of numerous scholastic edifices: Wellington College, Kneller Hall, St. Aidan's College, Birkenhead; and Bishop Stortford, are among the most considerable of these; while St. Olave's, Southwark; Huddersfield, Swansea, Liverpool, and Tamworth, are in the long list of national and grammar schools. When we remind our readers that it would be difficult to take up any number of this journal in which there is not a notice of new schools being built, it will be seen that it would be a very serious undertaking to enumerate them all.

It has been urged that in this Victorian age we have no need of new castles, as some few may mistakenly think that our Volunteers are equally out of date. Nevertheless, we are favoured with both. This decade, of which we write, has seen new castles arise at Ruthin, at Cloughanodfoy, at Hornby, not to mention the restoration of several ancient strongholds, of which Alnwick is an example. Of "gentlemen's residences," Clifden, Tortworth Court, Somerleyton Hall, Blylaugh Hall, Mr. Hope's in Piccadilly, Mr. Holford's, in Park-lane, are the first that occur to us of a long list. Much, too, has been done in the way of improving labourers' cottages. In this respect the last ten years outdo all others. The Prince Consort's model cottages, as shown at the Great Exhibition, and illustrated in these pages, incited many to turn their attention to a matter but too little thought of, whether in Edwardian, Tudor, or Georgian times. An estate without a row of pretty cottages, with roses and creeping plants trained round the mullioned windows, will soon be rare, it may be hoped, though at present there are plenty of exceptions. Some ladies of rank and wealth hestow as much attention on their model villages as it was the fashion, in the *Spectator's* time, to lavish on China monsters and black pages. We need not say with how much more advantage.

We would confine these retrospective glances within architectural bounds; but we must mention—perhaps their gateways may be a sufficient link to our subject—the two new parks in the metropolis. Nearly two centuries intervened between the grants that gave us St. James's and the Regent's; and here, in ten short years, we have two for the metropolis, Aston for Birmingham, and others at Manchester, Halifax, and elsewhere. The drinking-fountains, with which most of our towns are now supplied, are entirely the fruits of the period we are reviewing. They ought to be better, but there they are. For the one "Man of Ross" of the last century we have a score in the present day, though they do not forget to mark the marble with their name. The transportation of the Marble Arch was an incident which, like that of the erection and removal of the Great Exhibition building, appears to be part of some Eastern fable rather than one of the prosaic proceedings of John Bull in the nineteenth century,—something posterity will regard as we view St. George's combat with the dragon, and deem half mythic,

half historie. Perhaps the removal of the Marble Arch will be considered a myth, expressing the shifting of some fiscal burden off one shoulder on to another; and any representation of the Great Exhibition building that may be handed down, a hieroglyph typifying the Volunteer review. The sites they once occupied are so utterly devoid of any token of their presence, that we can pardon the prospective unbeliever in their existence that we have imputed to posterity. Some statuary has been scattered about, in London and the provinces, and architects have been enabled to make more use of sculptors in their designs than heretofore, and it is to be hoped will do so still more.

Perhaps in no respect is our progress made more evident than in a comparison of our recent street architecture with the dreary profiles presented in almost interminable succession in Harley, Baker, and Wimpole streets. Our shop-fronts present occasional instances of the application of architectural skill of a high order. A style, to all intents and purposes new, growing out of the application of new materials and processes (such as we have often urged) to the existing mode of house-building, is making itself evident.

Amongst modern streets on an older type, Cannon-street will be specially noticed; and other parts of our merchant princes are scarcely less palatial. Then we have a new Covent-garden Theatre, with its Floral Hall; St. James's Hall; a noble reading-room at the British Museum; three new bridges over the Thames; a new market at Billingsgate; the Oxford-street bazaar; and innumerable banks, clubhouses, life, fire, and other offices of architectural consideration, all belonging to the last decade. The metropolis, of course, presents us with a larger cluster of new buildings than is to be found elsewhere; but the same vital principle is apparent all over the country, as well as in the sister kingdoms. To enumerate the new town-halls, such as those at Bideford and Cardiff, and some to which we have already referred, or the new baths, such as those erected by the Duke of Devonshire at Buxton, or those with washhouses in London, Newcastle, Birmingham, Maidstone, or Bilston; or to mention by name only the new asylums for the blind, for idiots, for lunatics; the reformatories, and the almshouses, would fill a column. Monster hotels form a fresh feature, and will be still further developed. The great accessions to our wealth in our museums we have already treated upon at large. It is sufficient for our present purpose to have sketched this panoramic outline of these things.

The advance of stained glass in the public estimation, though scarcely to that extent in excellence which could be desired, is another peculiarity of the time. Ten years ago a memorial window was looked upon as remarkable; but now the use of glass for that purpose is general. Hence our churches are becoming enriched with colours, though as yet not always harmoniously, instead of being defaced with cold, tasteless mural tablets.

Here we must withdraw the lingering glance we have thrown hae upon part of the road we have travelled, and again face, with fresh courage, the steep path before us. If so much has been accomplished in the last ten years, what may we not achieve in the next! We must not stand still:—"There is nothing so revolutionary, because there is nothing so unnatural and convulsive, as the strain to keep things fixed, when all the world is, by the very law of its creation, in eternal progress."

## OPENING MEETING OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The first ordinary general meeting of the session 1860-61 was held on Monday evening last, at the House in Conduit-street. The chair was taken by the president, Professor Cockerell, and there was a numerous attendance of members.

The minutes of the last meeting having been read and confirmed,

Mr. T. Hayter Lewis (honorary secretary) read a letter, addressed to himself, by Mr. Titc, M.P., of which the following is a copy:—

"The illness of one member of my family has sent me hither (Brighton): the same cause will prevent my being

present on Monday, which I very greatly regret. I pray you to present those regrets and my compliments to your kind and learned lecturer, Mr. Sydney Smirke, to lament my inability to hear him, which I fully intended.

May I also ask you to say to the council, that I should be very grateful to them if they would undertake to arrange for the distribution of an annual prize of ten guineas, to be given in books or money as they may determine, for the best set of sketches or suggestions in the Italian style of architecture, adapted to modern wants, such as churches, townhalls, railway termini and stations, public offices, &c.?

I think the suggestions should not be less than two or more than three, and should be confined to the associates and students of the Institute.

Of course by Italian I mean the architecture of Palladio, Sansovino, Vignola, Fulgo Jones, Sir Christopher Wren, Perrault, &c. This is my hasty notice of what I wish, which may be somewhat modified and doubtlessly improved.

If the council think well of it, and as they are a chartered body, I should be disposed to make this prize permanent one, even after I am gone.

It may be modified, of course; but my object is to promote and encourage the study of this class of architecture. With compliments to the council,

W. TREV.

Mr. Penrose, having announced the receipt during the recess of a large number of donations of books and architectural publications to the library,

Professor Donaldson moved that a vote of thanks be given to the several donors, for the important and interesting additions which they had made to the library. Many of those donations were rare, valuable, and interesting; but another contribution had been made to the members of the Institute during the recess, which was not undeserving of mention: he referred to the printed volume of their Transactions, which was not only extremely interesting and important in itself, but reflected the highest honour upon the officers and members of the Institute who had devoted their time to its preparation. Few of those to whom the volume had been delivered could be aware of the labour, judgment, and discretion which had been brought to bear in its production. The illustrations were numerous and well executed, while the information conveyed in the letter-press was most useful to them all as architects, and would go far to make a return for the subscription paid to the Institute. Before dismissing the subject, however, he felt bound to say that, while he, in common with other members, was gratified at finding in the volume an eloquent and judicious memoir of Sir Charles Barry, he regretted that there was not also some notice of his funeral in Westminster Abbey. Such an important and interesting circumstance in the history of their profession ought, in his opinion, to have been recorded in these "Transactions." He also thought that the Institute was indebted to the authors of the papers contained in the volume; and without at all wishing to make an invidious distinction (for great care and application were required in the preparation of all), he felt that their thanks were especially due to one to whom they all looked up for his genius, taste, and the high position which he held in their body. He meant Mr. Scott, whose "Gleanings from Westminster Abbey" was one of the most delightful and instructive papers that had ever been submitted to their body. He might also be allowed to refer to the paper read by Mr. Edward Barry, "On the Construction of Covent-garden Theatre," which was conceived in such good taste, and which indicated the possession of not only a fine and original mind, but of a vigour and grasp of intellect, combined with eminent professional talent, that reflected honour upon the whole body of architects. Their thanks were also deservedly due to Mr. Digby Wyatt, for his well-written memoir of Sir Charles Barry, and for the admirable paper which he had contributed "On Illuminated Manuscripts, with reference to Architectural Design." When the Institute was able to publish such a volume as that which had just been completed, it furnished a proof that its objects were not without an aim, and that it performed its mission by raising the standard of professional knowledge and scientific acquirements.

Mr. G. G. Scott, in seconding the vote of thanks to the donors to the library, referred to the necessity of taking some means to increase their collection, so that they might not be dependent entirely upon the gifts of their friends. He feared it had become too much the habit to trust to donations alone, and that if they were to go through their library they would ascertain that it was still very defective. If, for instance, a member wished to refer to the higher class of architectural works, which were not usually to be found in private libraries, he suspected he would be doomed to disappointment. He was indeed to offer these remarks with the view of suggesting whether a standing committee, consist-

ing of two or three members of the council, might not be appointed to prepare a list of the works which were wanting, and to take some means to procure them. He feared that their money surplus just at present was small, and inadequate to the purpose; but still he thought they ought to make an effort to borrow the necessary funds, and repay it by instalments, so that their collection might be made something like an architect's library.

The President said he hoped the meeting would take this valuable suggestion into consideration, and that Mr. Scott would himself form one of the proposed committee, as no one could be more competent to advise upon the additions which ought to be made to their library.

Mr. Nelson said that such a committee had been appointed, but that in consequence of the state of the funds there had been no need of their services. The members must remember that the last year had, owing to the removal of the Institute from Grosvenor-street, been one of unusual expenditure, and that, although the funded property had not been touched upon, there were no surplus funds to devote to the library. He believed, however, that, in the course of the next year, there would be ample funds at the disposal of the Council for the improvement of the library.

Mr. Scott suggested whether, in order to avoid delay, a voluntary subscription might be set on foot.

Mr. T. H. Lewis observed that the contents of the library had been carefully gone over, that all the books had been numbered and indexed, and that he hoped a grant would be made in the course of the ensuing year for reprinting the catalogue. The last year had been necessarily one of heavy expenditure, but the Council had been fortunate enough to be able to meet it without trespassing on the funded property of the Institute. In the ensuing year, however, as nothing beyond the ordinary expenditure would have to be met, he hoped there would be a considerable sum in hand applicable to the extension of the library.

Mr. Charles Barry said that as they had been enabled to pull through a year of great expense without interfering with their funded capital, there was every prospect of their being in a position in the course of the new year to carry out the valuable suggestion of Mr. Scott, and that the same exertion, which had enabled them to meet the extraordinary expenditure of last year, would, he was persuaded, not be wanting to enable them to carry out so essential an undertaking as the improving and enriching of their library.

Professor Donaldson expressed his hope that the catalogue referred to by Mr. Lewis would not be published until they had procured the works suggested by Mr. Scott. He had always been in favour of the appointment of a library committee; and in his opinion the library ought to be an essential feature, and a main principle, of the Institute, he did not think there would be any harm in taking a few hundred pounds from the funded property to provide the necessary works. There could be no doubt that there were omissions in the library; but, for all that, he ventured to say, that there was not a better architectural library in Europe: it was worth some thousands of pounds. At the same time it was not becoming that it should be deficient in those very high class works to which gentlemen in the position of Mr. Scott and others might have occasion to refer. He was, therefore, in favour of carrying out the suggestion for its improvement as soon as possible.

The vote of thanks to the donors was then put, and carried *non. con.*

On the motion of Mr. Kerr, a special vote of thanks was also passed to Mr. Tate, for the liberal offer contained in his letter.

Mr. Godwin said that, appended to the circular convening the present meeting, there was a paragraph to the effect that, "in conformity with a resolution passed at the special general meeting, held on Monday, July 2nd, 1860, the consideration of the proposal of the council on the subject of architectural examinations will be resumed on the second Monday in November next, the 12th inst." He believed that replies had already been received from several provincial societies; but, as the Architectural Association had appointed the 9th and the 23rd of the present month to consider the subject, and as the Scottish Society had not yet considered it, and as the Institute desired to have the opinion of all their professional brethren, he took the liberty of moving that the consideration of the subject be deferred until Monday, the 10th of December.

The President.—You have heard the motion of

Mr. Godwin on the important, and, I may add, vital subject of architectural examinations, and is it your pleasure that the consideration of it be postponed until the 10th of next month?

The motion having been carried in the affirmative, the consideration of the subject was accordingly postponed.

Mr. Sydney Smirke, R.A., Fellow, then read a paper, entitled "Recollections of Sicily," which we give separately.

At the conclusion,

The President said,—I am sure you have all been delighted, especially you who may be old Sicilians, like myself, at the description which our friend, Mr. Smirke, has given of the wonderful island of Sicily. Mr. Smirke says he was there thirty years ago: why, that is nothing; for I was there myself forty-eight years ago. He has told us a great deal which has interested us; and I am sure, if he had entered into the more recouite matter connected with the personal incidents of his journey, he would have equally gratified us. The Sicilians, as you know, are not destitute of humour. You remember, no doubt, the case of a gentleman, of great wealth, named Gelon, of Agrigento, who on one occasion extended his hospitality to fifty knights, caught in a storm, who were half-famished and drenched to the skin. Having relieved their necessities, he furnished them all with dry cloaks, fed them well, and sent them on their journey. This gentleman subsequently became ambassador to a city called Leontina, and his fame having gone before him, the people crowded to the theatre to see him. When he made his appearance, every one rose to stare at him; and, as he was not so highly favoured by Nature as by Fortune, their disappointment was considerable. Gelon, perceiving their astonishment, and finding, to his annoyance, that they looked upon him with less respect on account of his undignified presence, exclaimed—"Gentlemen, don't be astonished at my appearance, for the city from which I am accredited reserves its fine-looking and handsome fellows for great and important cities, and to small, insignificant places, they send such fellows as myself." Mr. Smirke has referred to the application of pumice-stone in the construction of arches in Sicilian buildings; and as a practical member I think his suggestion for coke as a substitute is a valuable one, and I hope that experiments may be made to test its utility. I beg to move that a vote of thanks be accorded to Mr. Smirke for his interesting paper.

Professor Donaldson said he entirely approved of the suggestion with regard to coke, and hoped that the subject would be referred to the committee of construction, with a view to trying experiments. He had himself a lively recollection of his sojourn in Sicily. He had passed a fortnight under the walls of Syracuse in quarantine; and after his release he spent a month exploring its ruins, which he found to contain a mine of antiquarian wealth. Many of the tombs were still unopened, which no doubt contained vases and other ornaments of great value. The island of Sicily was alike wonderful for its natural productions and artificial wealth. The coins and remains of sculpture found in various parts of the island were alike beautiful, the architectural wealth of the land was enormous and almost inexhaustible, and it was impossible to go to the right or the left without discovering new beauties. There were also fine illustrations of Greek art; and the place was altogether such a treasure-house of ancient art, that he recommended some of their students to make it their residence for some months.

Mr. Mylne also bore witness to the great attractions of the island of Sicily in an antiquarian and architectural point of view; and, referring to the engravings to which Mr. Smirke had called attention in his paper, said that his grandfather had made the original drawings, with many others, 110 years ago, and that many of them were of very great merit, not only in an architectural but artistic sense.

The vote of thanks to Mr. Smirke having been carried by acclamation, a ballot was taken, and the following gentlemen were elected Fellows of the Institute: William Milford Tenon, Associate, of 42, Guildford-street, Russell-square; Edward Habershon, Associate, of 37, Bedford-place, Russell-square; Alfred Porter, Associate, of Fort-place, Bermondsey; and George Thomas Robinson, of Leamington.

The next meeting of the Institute will be held on the evening of Monday, the 19th inst., when a paper will be read on Architectural Drawing by Mr. W. Burges, Fellow.

## RECOLLECTIONS OF SICILY.\*

THERE is probably no part of Europe which, within such narrow limits, offers to the traveller so many objects of archaeological and artistic interest as Sicily, and yet it may be truly said that hardly any part of Europe is so little visited by the architectural or antiquarian tourist. The causes of their neglect may, perhaps, be found in the fact that the island lies out of the ordinary track of tourists: it offers but few of the facilities for internal travelling found in most other countries of Europe, and therefore cannot be traversed without a good deal of personal inconvenience. The inns are, for the most part, wretchedly bad, and very often altogether wanting. Bridges are few in number, and roads are often mere mule-tracks. Sometimes, indeed, the only road, if road it may be called, is the dry bed of a mountain stream.

Whatever may have been the causes, certain it is that Sicily has been very imperfectly explored by artists and archaeologists, although it is a land abundantly rich in the remains of every age of historical interest—Phœnician, Greek, Roman, Arabian, Norman, and Medieval.

I will not dwell on the strong claims this island has on the attention of the naturalist. It is here only, in Europe, that we find growing wild the papyrus and the palm, productions which seem to link it with the East, and aid the remains of Saracenic art in recalling to our memories the age of the Caliphs, whilst there are not wanting traces of architecture which forcibly remind us of the times of our first Henrys and Richards.

So multifarious, indeed, is the interest with which this sequestered island is invested, that I cannot but be surprised at the slender amount of knowledge usually possessed by some even of the best informed artists and antiquaries on the subject of Sicily.

I feel persuaded, therefore, that I shall be excused if I venture to occupy your attention for a short time, whilst I bring before your notice a condensed record of my recollections of a professional tour made in that country by me upwards of thirty years ago.

In most countries of Europe observations made from notes of so old a date would be obsolete or of little value, or, perhaps, wholly inapplicable to the present day; but I think I need entertain no such apprehension in this case. Until the memorable events of the last few months, Sicily has long been, as it were, a land of the dead for the purposes of the traveller or the student; neither its moral, political, nor physical improvement has been developed or attempted under its later dynasties, but both the place and its population have remained stagnant, neglected, overlooked, and asleep. Let me refer, for example, to that silent and dormant wilderness of antiquities which extends for miles over the site of the ancient Selinus, where some thirty or forty years ago two young English artists, Mr. Harris and Mr. Angell, turned up a few stones, and found on them fine specimens of archaic Greek sculpture. The attention was awakened of the sleeping antiquaries, who seemed never to have dreamt that such treasures existed beneath the dense mantle of cactus and myrtle trees that lay over the prostrate temples. Yet when I visited those ruins a few years afterwards, this discovery appeared to have led to but trifling further researches; the upturned metopes were deposited, it is true, in the nearest museum, but were still being gazed at with barren astonishment. They were talked about abundantly by that loquacious and inactive people, but the interesting discovery excited few efforts to explore the mine which the stranger had opened to their hands, and the listless antiquaries were again folding their arms, and composing themselves for another cycle of sleep.

There were, no doubt, a few individuals more enlightened than their fellows, who wrote their "Suggie," and "Trattati;" but, like earth-worms, they laboured sedulously only on the spot where they chanced to be born, with little consciousness of what was going on around them in the outer world.

Some idea may be formed of the contracted vision and tepid zeal of these local savans from the fact communicated to me on the spot, that a very eminent antiquary of Catania, who had written and published a treatise on archaeological subjects, had never in his life been at Syracuse; and that Pisani, a local savant, who wrote a work on the sculptures discovered by Harris and Angell,

had never himself visited the spot where they had been discovered. I would by no means include in this category such authors as Hittori, and Serradifallo, and our own writer, Gally Knight, whose finely-illustrated works are noble contributions to our art, and are ample expositions of the known remains; but even they have done little towards increasing the stores of antiquarian knowledge. The great cities of antiquity in Sicily owe their ruin not so much to gradual decay as to external violence—such as sieges, earthquakes, and volcanic eruptions. Sudden and general *bouleversements* of this nature overwhelming a whole city may be reasonably expected to have caused the interment of much that is valuable to the artist and the antiquary, without positively destroying it. Such proved actually to have been the case at Selinus, as I have just stated, and it cannot be doubted that much remains throughout Sicily to reward the labours of a diligent explorer. I will now request you to accompany me whilst I cursorily review some of the objects of professional interest that presented themselves to me on my tour.

My course commenced at the beautiful port and city of Messina, many of whose handsome buildings I found still bearing marks of the ravages of repeated earthquakes. There is, however, not much here to attract the attention or invite the study of the architectural student. The cathedral is not without considerable interest, presenting as it does specimens of almost every successive style, from Byzantine to Cinque-cento; whilst the pillars of the nave consist of shafts derived from the ruins of some far more ancient temple, affording an example of the practice once so prevalent throughout Italy of the adaptation of classical relics to Christian purposes. This practice, founded on expediency, and prevalent among the builders of the early churches, is analogous to that also prevalent in the early ages of Christianity, of attempting to reconcile Pagan doctrines and rites to the principles of Christian theology, for the purpose, it would seem, of making the work of conversion more easy for the missionary and more acceptable to the convert. Whether this was a justifiable instrument is open to doubt; but certainly it was carrying the doctrine of expediency very far when it was thought proper to dedicate churches to St. Mercurio and St. Venere.

In various parts of the city may be observed examples of late Gothic, somewhat purer, or at least somewhat more nearly allied to our own Northern Gothic, than is usually met with on the adjacent continent of Italy. I am but little acquainted with Spanish Gothic, but I am inclined to suspect that the later Gothic of Sicily will be found to resemble it in many respects. There is here an octagon tower, much shattered by earthquakes, and but little of it left to identify its age, which is traditionally reported to have been erected by our first Richard, and which bears his name.

A small Early Norman church, which I observed at the southern extremity of the city, called La Nunziataella, is remarkable for having on its door-jamb, inlaid in coloured marble or porphyry, part of an Arabic inscription, purporting to be in honour of Messala, a Saracen chief. These jamb had no doubt formed part of some previously-existing building, which the Moslem masons employed by their Norman conquerors were glad of the opportunity of reinstating. It struck me at once as much resembling the ornament designated by Dr. King, in "Monuments Antiquæ," the "scribed ornament," which may possibly be an Eastern tradition, testifying to the Oriental origin of some of the features of the Medieval architecture of Europe.

I purpose in these notes to confine myself almost exclusively to professional subjects, but I may say, in passing, that near Messina I observed a treadmill very similar to the machine which with us has obtained so unenviable a notoriety, but which here was worked in the open air by six no doubt perfectly honest women, for the purpose of pressing calico.

The next place I visited was Taormina, after passing the Gothic port of St. Alessis, which had been repaired by English engineers during the late war; passing also La Forsa, a small town, which although built high up on the side of a mountain, was described as grievously liable to be afflicted with malaria, and affording an instance of the apparently capricious but subtle and inscrutable character of that insidious scourge.

Taormina is placed on a most commanding eminence, and is said to have been the last city in Sicily to yield to the Arabian invaders. Here are very interesting remains of an hypothetical theatre, a naumachia, and a reservoir for water, resembling

the "Piscina Mirabilis" on the Neapolitan coast. Its groined vaulting rests on piers of brickwork, coated over with cement, 2½ inches thick; there are also many tombs of classical character. Among the ruins of the theatre I observed examples of the practice of the Roman masons of lining the surface of stone with extremely thin slabs—I might almost call them *films* of coloured marble. It is a nicey open to much question whether this practice comes under the denunciation of *shams* in architecture. The block of common limestone so lined presents the appearance of a marble, which it is not, and is therefore so far deceptively; yet in fact a charge of fraud seems scarcely tenable, seeing that the material used is really what it seems to be, although the quantity of the precious substance falls far short of its apparent bulk. I cannot leave Taormina without remarking how these vast and silent ruins testify to the vicissitudes to which the island has been subjected. Numerous and prosperous must have been the population of this city when one of its places of amusement alone was capable of receiving 30,000 spectators. A few straggling, dreary streets, exist to mark the site of this great centre of ancient civilization.

My next resting-place was Catania, a city which owes its modern and regular appearance to the frightful eruption and earthquake of 1693, which destroyed the old city, and devastated the surrounding country, causing extensive districts to be covered with volcanic scoria, which remain to this day piled up in amorphous masses, dark and arid, relieved by few indications of vegetation, except where the cactus has found a hold for its roots in the hollows and indentations of this wide waste of cinders. Beneath the surface on which the city is built lies another bed of volcanic ashes; and within this bed lie the remains of various fine Roman buildings, including a noble amphitheatre, itself built of blocks of lava, and vaulted with pumice-stone, the products of still remoter eruptions; so persistent has been the activity of these Etnæan fires.

The application of volcanic scoria or pumice to the construction of the vaulting of the corridors of this amphitheatre is worthy of observation, and bears witness to the constructive ability of the Roman builders; the springings and various main ribs are executed in very sound brickwork, while the interstices, spandrels, and other parts of the vaulting are wholly executed with this light, yet hard, material, in its rough state, but run in solidly with Pozzolana cement. That this mode of construction is substantial is evident from the permanence of the work in these ancient corridors. The dome of the Pantheon at Rome is executed in the same manner, and has stood the sieges, earthquakes, and all other causes of damage and decay for nearly 2,000 years.

Perhaps I may here be permitted to say that I think it worthy of inquiry whether a safe, permanent, perhaps even economical vaulting might not be similarly executed with *coke*, a material which has many of the properties of a volcanic scoria; is extremely light and yet so hard as to be able, like the diamond, to scratch glass.

Notwithstanding the labour of Prince Biscari much remains unexplored in this amphitheatre and still more of the adjoining Odeon, which was also entombed, like Heracleum, beneath the fiery shower. Far below the present surface and beneath the modern Duomo lie the remains of a magnificent building used during the occupation of the Romans as public baths. Glimpses of its ornamented halls are obtainable by descending to a considerable depth, with ladders and torches, into the excavated portions of the building.

There are also various other Roman antiquities of less importance, but now half-deserted spots; evidence, too, of the deplorable want of energy and enterprise in the Government and in the people, who can permit objects of so much interest and historical value to be unexplored under their very feet.

A spacious and handsome Benedictine monastery is one of the most conspicuous modern buildings of Catania. It existed before the great convulsion of 1693, and its exemption from the common calamity is attributed to the wonderful forbearance of the flood of lava which, after having destroyed in its course all around it, miraculously stopped abruptly short as it approached the sacred edifice.

The museum of Prince Biscari here is well known to most European antiquaries; it is rich in fictile works and bronzes, and contains some good sculpture, including a Torso of the highest character of Greek art. There is in the town also a small collection of natural history; and another similar collection is at the University; and a third,

\* By Mr. Sydney Smirke, R.A., as already mentioned.

consisting of objects of natural history and of works of mechanical art, contained in four or five good-sized rooms at the monastery to which I have just alluded.

The road from Catania westward lies over a tract of country once so fertile as to have become the fabled cradle of agriculture; but now, through neglected drainage, it is little better than an unproductive waste. A few miles inland is the Beviere, or Lago di Lentini, the drainage of which was one of the labours of Hercules, and one in which he certainly showed but little engineering skill, for the lake is to this day a frightful source of malaria.

The next place of interest, in my progress along the coast, was Syracuse, a city of highest historic interest, but presenting an extraordinary scene of decay and desolation. An inconsiderable seaport now, it was, 2,000 years ago, a great centre of luxury and civilization, the extent of which may be judged by the vast tract of country strewn with the fragments of buildings. The ride from one extremity of these heaps of ruins to the other, occupies some hours, and almost every step passes over some remnant of fallen grandeur. I shall not stop to enumerate the various objects of interest here. The theatres, tombs, temples, latomie, have all been described by travellers, although by no means illustrated, or, indeed, examined as carefully and thoroughly as they deserve; and there can be no doubt that an earnest, intelligent, and systematic exploration of that which lies beneath this wild scene of decay, overthrow, and dilapidation, would be abundantly productive.

The labour of riding and scrambling over these relics of antiquity was in my case agreeably relieved by a boat excursion up the Cynae, a small stream having its source in a lake of inconsiderable size, which produces the papyrus in great abundance. I was informed that this is the only habitat of that aquatic plant in Europe; at all events, its occurrence is of extreme rarity there. It is, indeed, a graceful, and even noble, reed-like plant, of which the value and importance have yielded, in modern estimation, to the superior claims of old rags.

In the ancient and entirely ruined part of the city, called Neapolis, are two ruined towers named the Epipole, parts of the ancient fortifications which are traceable over a great extent.

Shortly previous to my visit, several subterranean galleries had been discovered within these fortifications. The theory of the local antiquaries is, that they had been formed as sally-ports in case of a siege. The gallery I measured was 9 feet wide, and is covered by a flat segmental arch; a fact of some interest if the workmanship could be satisfactorily proved to belong to the Greek period, which appears, as well as the history of Syracuse, seem to favour.

In the more modern part of the city, called Ortigia, are some interesting remnants of Mediaeval date, for the most part widely differing from the type of northern Europe. The Duomo itself is an epitome of the vicissitudes to which the city has been subjected. The side walls consist of a range of Greek Doric columns portion, evidently, of some temple. The intercolumniations are walled up with more modern masonry. The principal front is a somewhat overloaded modern composition, whilst the ceiling within is undoubtedly Mediaeval.

I visited the museum here, which was small, consisting exclusively of miscellaneous antiquities found in the town and its neighbourhood. It contained a statue of Venus, life-size, found in the quarter of the ancient city called Aerudina, near the entrance into the Catacombs. I should here mention, that as the Port of Syracuse is more frequented by visitors, naval officers, and others, than probably any other ruined site in the island, a somewhat large and active traffic is carried on here in antiquities of very doubtful genuineness. Considerable bagfuls of Syracusean coins were freely offered to me by dealers of questionable character; and there are local potters who have acquired a dangerous dexterity in the manufacture of terra cottas.

I must not dwell on the latomie, the ancient stone quarries here, though presenting scenes highly picturesque and interesting; nor on the so-called Ear of Dionysius, about which so many fantastic, though by no means plausible, theories are propounded. Nor does my time admit of my entering upon any description of the numerous tombs of undoubted Classic age; nor on the famous fountain of Arethusa, whose poetical character is sadly at variance with its present degraded aspect: much of the dirty linen of the modern Syracusans seems to be cleaned in it.

I must, however, allow myself to note, that somewhat removed from the city is a small church, dedicated to St. Marcan, which is reputed to be one of the earliest Christian buildings in Europe. The crypt of this church, containing the sarcophagus of the saint, wears certainly an aspect of extreme antiquity. A seat in it, which is regarded with great reverence, as the first episcopal throne in existence, consists of an ancient Roman Ionic capital inverted, so as to make the volutes form, as it were, the elbows of the seat.

From Syracuse I was induced to deviate inland from the main road skirting the coast, by the accounts that had reached me from time to time of certain remarkable excavations then in progress by the Baron Jutica, on his own estates near Palazzuolo, about twenty-four miles from Syracuse.

After riding that distance, I had to pass the night at a Capuchin convent, for here a traveller who quits the main road soon finds himself without even the slender accommodation of a locanda.

Less than a mile from Palazzuolo were the excavations that I sought for. The hill of Acramonte, where they are situated, is the site of the ancient city of Aera. The baron considered, from the evidence afforded by the remains he had himself discovered, that on this spot originally stood a Phœnician city; that it had been successively inhabited by Greeks, Romans, Christians, and Saracens. There are here remains, only in part excavated, of a theatre and an odeon; the former similar to that at Syracuse, but smaller; there are also a naumachia, an amphitheatre, a forum, various temples, and numerous tombs.

These multifarious ruins lie like geological strata successively superimposed on each other. The lowest excavation, about 50 feet below the general surface, present remains of what the baron pronounced to be a kind of barracks with a prison attached. There are fifteen rooms leading into each other, and in one of these rooms is a shaft leading down into some deeper, and still unexplored, recesses.

Several pits, also, have been discovered into which various horizontal subterranean passages lead from the outer surface of the hill.

The purpose of these singular excavations is not obvious: the baron's opinion seemed to be that they were intended as vents for dangerous vapours pent up within the bowels of the earth in this volcanic district. There is, indeed, an extinct volcano at no great distance from this spot.

Some remarkable bas-reliefs are cut on the face of the rock at or near the foot of this hill of Acramonte. These Santoni, as they are locally called, are of very Archaic and almost Persepolitan character; but my view was too hasty and superficial to admit of my forming any opinion as to their precise age.

Baron Jutica's museum was rich in bronzes and terra cottas; some bearing Phœnician characters, others of decidedly Greek workmanship; others, again, Roman. These articles are as various in their nature as may be supposed, seeing that they are derived from the reliquæ of a great city. Many glass vessels were found of undisputed Phœnician workmanship; some of opaque glass, others coloured through their whole substance. Among many other curious objects was an armlet of iron plated with silver.

I proceeded afterwards to explore a remarkable necropolis at Ipsica, about five miles from Acramonte. It lies in a rocky valley, and consists of a multitude of caverns cut in the face of the rock, which being stratified in regular horizontal beds, offer great facilities for such excavations. Many of these caverns are catacombs lined with tombs, on some of which early Christian inscriptions, in Greek characters, are still traceable. There are, however, many caverns without any indication of interments having been made, and I found that the prevalent not improbable belief on the spot is, that this valley presents the remains of a troglodytic city, occupied by the earliest, perhaps Celtic, inhabitants of the island, and that it had been in after-times applied to the purposes of sepulture. It is worthy of remark, as perhaps confirmatory of this local opinion, that at Modica, a town scarcely a day's journey off, there are many separate habitations, and even streets, formed exactly as these caves at Ipsica are formed, by excavating the face of a cliff, or rather the escarpment of a stratified rock.

I should, however, state, as regards this valley of Ipsica, that the decided opinion of the baron was that the caves had been originally excavated by the early Christian population expressly for burial; that it was, in fact, a great Christian necropolis. It seems to me not improbable that these rocks may have been excavated and dwelt in by the

earliest occupants of the island, and that long afterwards the deserted caves may have been regarded as a fitting resting-place for the bones of the earliest Christians. Nothing, indeed, can be well imagined more secluded and desolate than this rocky valley, well illustrating the difference of feeling on the subject of sepulture between the Christians and the Pagans, who were wont to parade their tombs along the highways and by the roadsides.

From Comosso to Terranova the road lies over a richly-cultivated, but somewhat sandy and perfectly level plain, apparently redeemed from the sea; gradually upheaved, perhaps, by subterranean forces, such as have undoubtedly operated, and possibly may be still operating, in this volcanic region. From thence by Palma I reached Girgenti, adjacent to the ruins of Agriguntum.

I will not dwell in any detail on these highly-interesting ruins, for they have had a fair share of the attention of the architectural and antiquarian world. Wilkins has illustrated some of them; Hittorf and Serrodisfaleo have published careful illustrations of them; and I need not remind you that our own accomplished president gave much attention to them.\*

#### FROZEN MUSIC.†

BEAUTY and sublimity form a very large ingredient in our poem. What is beauty, and what is sublimity? Much has been said and written in answer to these questions. Coleridge defined the principle of beauty as "Multitude in unity." Schiller somewhere says, that "All the disputes which ever reigned in the philosophical world, upon the conception of beauty, have only this origin, that the inquiries commenced either not with a vigorous discrimination, or resulted in a combination not sufficiently perfect." Into these disputes we will not enter, but simply take Coleridge's definition of beauty and sublimity, as that which answers best to the ideal of æsthetic mind. "The Greek art," says he, "is beautiful. When I enter a Greek church my eye is charmed, and my mind elated. I feel proud and exalted that I am a man. But the Gothic art is sublime. On entering a cathedral, I am filled with devotion and with awe; I am lost to the actualities that surround me, and my whole being expands into the infinite: earth and air, nature and art, all swell up into eternity, and the only sensible impression left is,—that I am nothing." There can be no doubt that, notwithstanding the general resemblance, there is a distinction between the sublime and the beautiful; and nothing can, I think, be more happy than Coleridge's illustrations of it. Not only in the works of men's hands, but in all nature, there is less of the sublime than of the beautiful. It must be evident to all, that the cultivation of a taste for the beautiful and sublime must produce a most refining influence on the mind; kindling into a holy fire all our better feelings, exciting the delicate as well as the loftiest emotions of which the mind is capable, softening the heart, and purifying our aims and aspirations.—

— "Ingenuas didicisse fideliter artes  
Emollit mores, nec sinit esse feros."

The beauty of nature around us but stimulates our aspirations for a loftier, more ethereal beauty; and in our endeavours to fulfil this grand destiny, we strive after perfection itself; and yet the hand of man unconsciously inscribes upon all his works the sentence of imperfection, which the finger of the invisible hand wrote upon the walls of Belshazzar; but, notwithstanding this, the "primal art of man," next to nature, is capable of producing the loftiest emotions of the beautiful and the sublime.

There are, as we all know, periods in the history of nations, when the seeds of civilization have sprung up and blossomed, which are characterized by a visible progress in science, art, religion. There are two periods when the blossom expands into the full delicious fruit, which are characterized by the meridian splendour of civilization. There are likewise periods of decay, when all progress is stayed—when civilization declines—when science becomes a retrogression—when art is lost—when religion is well nigh forgotten; and there elapses a long decade of ignorance and barbarism before the dawning of the next cycle of civilization and progress. Such is the history which our frozen poem teaches us. Let us endeavour, then, to catch a few of its leading ideas. Very briefly have I drawn attention to the first canto,—the Expulsion from Eden and its consequences. Between this and the second canto a very long space

\* To be continued.

† See page 709, ante.

intervenes, about which we know next to nothing, and which ended in a dread catastrophe. After this our second Canto opens with the giant Babel builders, whose conceptions were so unspiritual, that they thought it possible to scale the very heavens. These artists were suddenly confounded, and a mighty hero lays the foundations of in the first empire, which anon becomes swallowed up in the mighty Assyrian vortex. Retrogression, decay, destruction, quickly and early followed each other, and darkness for ages covers all the scene:—

"The tents are all silent, the banners alone,  
The lances uplifted, the trumpet unblown;  
And the widows of Asshur are loud in their wail,  
And the hoofs are broke in the Temple of Baal,  
And the night of the Gentile, unsmote by the sword,  
Hath melted like snow in the glance of the Lord."

The sublime denunciations of Isaiah have been fulfilled, and desolation of desolation has taken the place of palaces, hanging gardens, and temples. It forcibly recalls to memory Ossian's sublime picture of desolation,—“I have seen the walls of Balclutha, but they were desolate: the flames had resounded in the halls, and the voice of the people is heard no more. The stream of Clutha was removed from its place by the fall of the walls. The whistle shook their lone heath: the moss whistled to the wind: the fox looked out from the windows; and the rank grass of the wall waved round his head. Desolate is the dwelling of Moria: silence is in the home of her fathers.” But now, in this latter day,—

"The ancient worlds their mysteries yield:  
The Chaldean sages' secrets are unsealed:  
The history of old time, that seem'd unchange,  
Proves in the last of days but yet begun;  
And prophecy awaits the child of Time,  
To give fresh beauty to its truths sublime."

And so ends our second canto. The third canto opens with luxuriant scenes on the banks of Nilus. Arts, science, literature, religion—each finds here a resting-place and a fostering nurse, and expands into sublimity. Carnae, Thebes, and Dendera, with undying astral sculptures and symbolic representative delineations of the creation, immortality, the deluge, the judgment, their own history, works, and religion, inscribed on the living stone, and

"Their's gnomons rising o'er the banks of Nile,  
Unchanging while he lies, serene and grand,  
Amid surrounding ruins,—mid the works  
Of man unparalled."

Egypt may with propriety be called the secular teacher of the old world. All the nations of antiquity seem to have drunk deep draughts from her strange fountains of symbolic myth. The Greeks and Romans received from this source the ideas which animated their highly-poetic mythology, and which expanded into the dramas of Æschylus, and the fancies of Homer and Virgil: the one sensual and grovelling; the other lofty, poetic, heavenly.

"Strange race of men! more anxious to prepare  
Their last abodes, and make them grand and fair,  
Than grace their living homes. Oe gloomy thought  
Their souls possess'd, one honour still they sought,—  
To be a splendor, and to bear in death  
Life's form and seeming—all things but its breath."

Their sculptured monuments tell us indeed of a people refined, poetic, and highly symbolic in their lofty ideal, yet practically sensual, corrupt, and debased, their highest aim, in dust embalmed, to dream in shrouded pomp eternal years away. Retrogression, decay, destruction, quickly and suddenly followed each other; and there, in the waste of sands and dust of ages, lies all that was grand of a noble though sensual people. The lotus, the palm, the papyrus, the date, and the reed, carved on the living stone, still startle the modern by their truthfulness and freshness. Babylon, Thebes, and Carnae must ever excite the wonder of mankind. The wonderful spirit, the truth and vigour, which animate the sculptures of these great nations, and the gorgeous colours which illumine them, are indeed indicative of a very advanced proficiency. And thus our third canto ends.

The whole of the fourth canto is dark and mysterious, and full of strange import. As in the last two cantos, so in this, symbolism is the great instructor and conveyancer of hidden truths. It treats of the ruined cities of Central America: Who were the people that built them? Where did they come from? Where are their descendants? And the answer is but the echo of our own questions. Architecture, painting, sculpture, poetry, and all the arts which embellish life, found here a safe resting-place, and flourished exceedingly: orators, statesmen, and warriors; beauty, ambition, and glory, here reigned gloriously, and have passed away, and no remnant of the race remains to tell whence they came, to whom they belonged, or what caused their destruction: not a tradition remains to tell of their

generation,—nothing but sculptures, vases, ruins. All is mystery—dark impenetrable mystery. In Egypt the colossal skeletons of gigantic temples stand in the unwatered sands, in all the nakedness of desolation. Here, an immense forest shrouds the ruins, hiding them from sight, heightening the impression and moral effect, and giving an intensity and almost wildness to the interest.

"The dense royal wood that hid the magic seat,—  
The lofty palms that creaked the winding street,—  
Man's hand hath felt; and now, in day's fair light,  
Xenon's broad ruins burst upon the sight;—  
City whose date and builders are unknown,  
Gracing the wild, mysterious and alone."

These cities of the West seem to have been nothing less in extent than those already spoken of in the East. Their pyramids inscribed with hieroglyphics, their vases, their terra-cotta relics, their sculptures, and their paintings, exhibit no similarity to Egyptian ruins.

"World! wrongly called the New: this elime was old  
When first the Spaniard came in search of gold.  
Are after age its shadowy wings had spread,  
And man was born and gather'd to the dead.  
Cities arose, ruled, dwindled to decay,  
Empires were form'd, then darkly went away:  
Race follow'd race, like cloud-shades o'er the field,  
The stranger still to strangers doom'd to yield;  
Till to invading Europe bow'd their pride,  
And pomp, art, power, with Montezuma died."

And thus ends our fourth canto.

I am sure the classic land of art, of song, of liberty, of philosophy, and of eloquence, must ever awaken our heat affections, familiarized as we are, from our school-days, with the literature, history, and social habits of the Greeks, who must ever rank foremost amongst the civilized races of the great human family. From them we have inherited the exact sciences, the laws of reasoning, philosophy, and æsthetics. We acknowledge their poetry and their sculpture, their architecture and their philosophy, as rarely equalled, never excelled. Abundant remains of astonishing beauty and magnitude still exist to illumine and illustrate their written history, and to furnish models and laws to modern Europe. We therein see, perhaps, for the first time, the varieties of taste and inventive design, subjected to definite rules of arrangement and relative proportions, and made to combine according to fixed laws. The subjection of the mind to the restraints of castes, formulas, and despotism, exercised a baneful influence on the arts and literature of Egypt; while Greece owed its elements of progress to the enfranchisement of the mind from all such restraints. In a word, Egypt devised the materials out of which Greece afterwards educed the laws and principles of beauty. Its Acropolis may still be said to crown the world of art and beauty, embellished as it is by the enchanting buildings of Mnesicles, Callicrates, and Ictinus, and adorned by those matchless creatures of genius—the ravishing sculptures of Phidias.

The Parthenon! There is right magic in the sound: its surpassing beauty, towering to the sublime, puts to silence all criticism by its incomparable impressions. That temple of temples, built by Ictinus, ordered by Pericles, adorned by Phidias, is a unique model of the beautiful, in the arts of architecture and sculpture; a sort of divine revelation of ideal beauty, petrified in marble—a frozen epic; perhaps the most perfect classic poem on the face of the earth. What loftiness was that which could conceive! what a race of artists who could decorate! what splendour and intelligence in a nation that could not only willingly part, but admire also! Such epochs can not often occur: the visits of such men are few and far between. The epic of Job, the song of songs, the music of Mozart, the poems of Milton and Homer, are not given twice to the earth, and so likewise this Parthenon. They prove to man what man can do.

The magnificent harmony of the forms of the Parthenon and the majestic elegance of its columns,—the admirable bas-reliefs, on its interior frieze, of the combats of the Centaurs with the Lapithe, and the opening in the centre through which the blue and resplendent sky diffused its serene and mystic light on the cornices and salient figures of the bas-reliefs, which seem as if they would move, come before us. And you feel that this is no illusion, but a painful truth, that the artist infused a portion of his own life—his own individuality into the forms of the beings he was creating. Can any deny that these men were poets, and their works immortal epics? The poet is he who creates ideas in bronze, wood, or stone, prose or rhyme: all such are poets. The poet stirs up what is imperishable in nature, and in the human heart: ages pass away, languages are worn out, but he lives for ever all entire. His destiny is less human, more divine. Alas! how different is

now the state of Greece, both intellectually, morally, artistically:—

"The solemn scene  
Blates the soul, while now the rising sun  
Flames on the ruins in the pure air."  
And thus ends our fifth canto.  
Our sixth canto treats of the Eternal City.  
"The Noble of nations! there she stands,  
Childless and crownless, in her voiceless woe;  
An empty urn within her wither'd hands,  
Whose holy dust was scatter'd long ago.  
The Scipio's tomb contains no ashes now:  
The very sepulchres lie tenantless  
Of their heroic dwellers: dost thou flow,  
Old Tiber, through a marble wilderness?  
Rise with thy yellow waves, and mantle her distress."

Originally can scarcely be said to have taken her abode here: as their religion so their fine arts, all were conquered from the peoples who originated them, and made subservient for the most part for state purposes, and not so much from innate love. This empire, having extended its existence near to our own times, is still a great and splendid vision. Engulfing as it did all pre-existing powers, all the known world, into its own vortex, and leaving everywhere the stamp of its superior organization and civilization, illustrated by colossalness, temples, baths, theatres, villas, laws, and roads, it naturally excites our liveliest interest, especially when, as in our own "brightest gem of the sea," we are surrounded on every hand with remembrances of their dominion. The fiercest spirits of the world were, by her, tamed into abject subjection: kings and princes, whose nod had been law; queens, whose charms captivated even their stern conquerors; noble matrons and drooping maidens, beautiful even in the intensity of their grief; artists, whose genius but fired the ambition of the proud conquerors; all were made subservient to the one idea,—the grandeur and the embellishment of the "Eternal City," the "City of the Sun," the "Queen of Cities." How well this was accomplished, the elegance, the magnificence, the colossal magnitude of her remains eloquently attest. Of all the fine arts that of architecture best suited the aspiring genius and greatness of this people, and this art was carried to its greatest pitch of sumptuousness, often, indeed, reaching the highest degree of sublimity. Even the jealous and fastidious Greek, familiar with higher art and with purer temples, owned the matchless splendour, and paid his involuntary tribute to the superior grandeur of this epitome of the universe and a home worthy of the gods. Strabo describes the magnificence of Rome as "of transcendent glory that surpassed all expectation, and rose far above all human competition."

Surrounded with temples, approached through triumphal arches and avenues of statues, overlooked by the proud magnificence of the imperial palace which crowned the Palatine Hill, and by the Capitol whereon Jupiter ruled all the minor gods,—intersected with squares, forums, lofty columns, theatres and splendid places, tombs, baths, fiery-like gardens, and a colosseum capable of seating a hundred thousand people,—the gigantic trace of a superhuman race, rivalling by its immense bulk the works of nature,—the Tiber will cease to flow between its banks of mud, and the Colosseum will stand and tower above its dried-up channel,—all these gave her a fair title to be called the "Epitome of the Universe," the "Eternal City." Once more and again retrogression and decay mark the close of our canto, and

"All that was  
Of them destruction is; and now, alas!  
Rome—Rome imperial, bows her to the storm,  
In the same dust and blackness, and we pass  
The skeleton of her titanic form,  
Wracks of another world, whose ashes still are warm."

But, unlike the other cantos, this one extends its song even to our own times. Rome did not pass into oblivion, but gave place to that new and unparalleled empire, half spiritual, half imperial, which at the present time rears its rickety head above the Seven Hills, and whose son is enthroned the spiritual ruler of Christendom, mighty to wield the keys of heaven and hell. But present Rome lacks indeed the stern manliness of other days, and the associations which awaken the generous sympathies of a people. Yet it is vital still a great and wonderful centre, around which the history of Europe revolves. Its present greatness dazzles the eye but does not win the heart.

"The double night of ages, and of her,  
Night's daughter, ignorance, hath wrapt and wraps  
All round us: we but feel our way to err:  
The ocean hath its chart, the stars their map,  
And knowledge spreads them on her ample lap;  
But Rome is as the desert, where we steer  
Stumbling o'er recollections: now we clap  
Our hands, and cry 'Eureka!' It is clear,  
When but some false mirage of ruins rises near."  
FRANCIS DRAKE.

\* To be continued.

## PHOTOGRAPHS.

*Victoria Cross Gallery.*—The photographs which Mr. Louis W. Desanges has published of his very remarkable set of pictures, illustrating noble actions that have won the Victoria Cross, though they scarcely do justice to the pictures themselves, form a very interesting collection. Mr. Desanges says in his preface,—"I have been my endeavour to render as literally as possible each scene and event as described by my gallant sitters, many details having been supplied to me by their friends and companions in arms. Thus assisted, I placed myself as a workman in their hands, so that whatever may be the demerit of the pictures as pictures, they have the positive value attached to national records of events that must live for ever in the history of our country's glories." The life and movement, and general air of reality, exhibited by the pictures fully confirm this statement. Amongst the photographs which are more particularly admirable and effective, we should place No. 33, Corporal Robert Shields seeking his wounded adjutant, Lieut. Dynely, under a heavy fire; No. 6, Lieut. Prendergast, Madras Engineers, charging at the action of "the Betwah;" No. 7, Col. Sir Chas. Russell dislodging the Russians from the Saub-hag Battery; and 24, Lieut. William Hope aiding Lieut. Hobson in the trenches, under a heavy fire from the Russian batteries. Some who are connected with the heroes commemorated may thank us for saying that these photographs may be obtained at 16, Stratford-place. They deserve to be in every house where noble deeds are honoured. Mr. Desanges has done a service to his country, which will be more highly appreciated one of these days than it is now.

*Mr. John Adams, Sculptor.*—Mr. John Adams, who, it will be remembered, obtained some time ago the medal of the Royal Academy, is working efficiently in Rome. We have before us photographs of two statues by him, "The Sacrifice of Abel," and "The Lady of the Lake," which give promise of more than usual excellence, and are indeed themselves achievements. Abel (from a Greek type, to which we leave etymologists to take objection) stands with upturned eyes by the side of his rude altar, his face displaying faith and fervent adoration. The second is a noble female figure, fully draped in the lower part, and with a thin, tight-fitting vest, her right hand resting on the upraised head of a dog by her side. We should prefer to call the group "Fidelity," but can fairly praise it, and that warmly, too, under the name given to it. We shall be disappointed if Mr. John Adams do not aid materially in maintaining the reputation of British sculptors.

## METROPOLITAN STATUES.

*Richard Cœur de Lion.*—The statue named Richard Cœur de Lion, exhibited by Baron Marochetti at the Great Exhibition of 1851, has been cast in bronze and set up in Old Palace-yard, Westminster, midway between the Peers' entrance to the Houses of Parliament and the end of Westminster Hall, and in a line with the centre of the great window in the Hall. It is placed on a pedestal of granite about 8 feet 6 inches high; in which two panels are left apparently to receive bronze relief. Fully appreciating the picturesque beauty of the group, we are amongst those who think it has been over-praised. The ugliness, if not error, apparent in the hind quarters of the horse, and the fatiguing attitude of the man, would of themselves prevent us from joining heartily in the songs of praise which the accomplished Baron appears able always to command, and usually with invidious and unjust reference to British sculptors.

*The Guards' Memorial, Pall-mall.*—The crowning figure, Honour distributing Wreaths, has been raised to its place, and we may now expect to see the monument speedily completed. The lower figures being at present covered up, and the ornamentation of the pedestal incomplete and tentative, a conclusion can scarcely be arrived at. We have a strong impression, nevertheless, that the pedestal is too large and clumsy for the surmounting figure. Honour should have been at least double the size, and even then the pedestal would need refinement.

*INDICATION OF STONE BY THE ANCIENTS.*—On reading Sir Henry Rawlinson's observations with reference to silicating stone, I would suggest whether the ancients might not have applied the first varnish in a fused or heated state, which would at once render it impervious to the weather, and might in some measure account for the deposit, so desirable to obtain.—A. B. C.

## RENOVATIONS AND SPOLIATIONS IN HEXHAM ABBEY CHURCH.

OUR statement of the erroneous course pursued at Hexham, coming as it did amidst the plans and complimentary accounts in the local papers, has excited very considerable interest far and wide, and, of course, is not to be allowed to pass unquestioned. We have received a letter, signed "J. Oswald Head, Hexham," and would print it if it showed that any part of our statement was untrue. As it does not do so, the writer must be content with a digest of it. Mr. Head pretends to assume that, because we assert that what has been recently done has more disturbed the important features of the choir than the earlier Vandalism, we consider whitewash essential to the beauty of cathedral walls; desire the "bases of pillars to be concealed below the level of the floor; and think that the spaces between the pillars cannot be more appropriately filled than by an incongruous series of hideous galleries." He knows better than this, or he is incompetent to write on the subject. As to the Ogle screen, he proceeds—

"I may state, that the beautiful Perpendicular screen consisted, in other words, of an oblong box, open on one side, lined with green baize, and not possessing one single architectural characteristic of any description whatever; with the exception of the specimen of fifteenth century painting to which you refer, and which was concealed in the roof.

The frial-stool remains in the church as much an object of antiquarian interest as ever. True, it has been removed; but, if any of your readers will be kind enough to inform me of its original position, I have little doubt but what it can be again placed there.

The most original and inexcusable criticism which you have passed upon the committee, however, remains to be noticed. This is neither more nor less than that they have done wrong in attempting to rescue the choir from its deformity; and by placing seats in it, &c., have unfitted it for cathedral services!

To offer any remark upon this would be to admit its infallibility, a concession which I must confess myself utterly unable to make.

In one respect the antiquarian superintendent recommended by you, I will allow, might have been of service. The contractors were perfectly unjustified in using any lead-stones for any purpose whatever. That "fragments of Norman coffin-lids" were used as you state I do not believe, but that grave-stones of more modern date were employed in covering an air-drain I had ocular demonstration, and remonstrated at the time against it.

In reference to the Ogle shrine, we deem it probable that our correspondents is still unaware of the open transeptal screen with which it was surrounded. This may have been, (like the fifteenth century altar painting, claimed by the joiner as old materials, whose existence he admits), concealed by what he terms "an oblong box." In October large portions were lying, placed among the rubbish in the passage leading from the cloisters at the south end of the south transept, and the remainder—portions of a cornice with the crescent, for the Ogle crest, carved upon it—we ascertained to be dispersed, and in the possession of various individuals in the town. In support of our observations we may mention that the more debased, and consequently less valuable, stone oratory of Prior Richard was chosen for re-erection; while this earlier and consequently more valuable monument has been completely scattered.

The right position of the frial-stool (seat of peace) was the chancel, or chancel aisle, whence it was taken. As the most sacred refuge of those who sought the privilege of sanctuary, it was near the altar. The one other known example, in Beverley Minster, stands in the same position as did that at Hexham.\*

With reference to the use of the ancient grave-stones, it was scarcely likely that the contractors would have chosen the identical model that Mr. Head was present to use up fragments of Norman sculptured stone, to cover the air-drain; but, as he had ocular demonstration that part of our statement was correct, it is difficult to guess by what mental suppressing process he is able utterly to disbelieve the rest of it. As we stood by the edge of the cutting made through layers upon layers of coffins and skeletons, and looked down upon the men at work within it, we saw "fragments of Norman coffin-lids, with zigzag ornaments" so used, as surely as our correspondent admits having seen grave-stones of more modern date employed for the purpose.

The great question respecting the restorations remains the same. Here was an abbey church, consisting of choir and transepts, of dimensions equal to the requirements of episcopal ceremonies, existing in a town which has a probability of becoming a cathedral see. The choir possessed ancient stalls, appropriately situated, and was

additionally enriched with two ancient shrines, and a still rarer relic—a Saxon frial-stool; the transepts were unappropriated. Side by side with these valuable remains of ancient art were galleries and other modern disfigurements. What has been done? One indiscriminate sweep has cleared away gold and cross—the carved stalls, and "the hideous galleries," the shrines and "the three-decked pulpit," the Medieval painting, and the transparency "with a goose," the whitewash and the seat of refuge! The choir, thus denuded, has been packed with new benches: the immense space in the transepts is still unappropriated.

## THE ARCHITECTURAL EXAMINATION QUESTION.

## LIVERPOOL ARCHITECTURAL SOCIETY.

At a meeting of this society, held on Wednesday evening, October 31, Mr. James M. Hay, the president, in the chair, it was announced that two drawings had been sent in on the terms of the proposition made at the close of the last session. One was that of West Derby Church: the other was a book of drawings of buildings taken during the recess. The council awarded the prize to the drawing of the West Derby Church, provided the competitor was prepared to say that it was taken by measurement on the spot, and not from the architect's or builder's plans.

Mr. Brown, of Norwich, described his patent for making doors and windows air-tight and water-tight, noticed by us some time ago.

The chairman then invited a discussion on the nine propositions submitted by the council of the Royal Institute of British Architects, which were as follow:—

Proposition 1. That it is desirable to afford an opportunity for a voluntary professional examination to the present associates, and to the future fellows and associates of the Royal Institute of British Architects. That a climatic examination be therefore established for the students and associates of this Institute under the age of twenty-five years; and a higher examination in the theory and practice of the profession for associates above that age, and for future fellows. 2. That the rates as to students and their prizes be reconsidered by the council so as to lead educationally towards the last-named more important examinations. 3. That the elementary examination embrace pure and applied mathematics, land-surveying, mensuration, geology, ordinary construction and materials, drawing, the styles of architecture, the history of architecture, and chemistry. The examiners to define the subjects absolutely necessary; the marks to be apportioned to each; and the aggregate number essential to entitle such candidate to a certificate. 4. That the chief subjects for the higher examination be such as occur in professional practice, with the general theories on which the detail of such practice is based,—e.g. languages, architectural jurisprudence, the Building Act, sanitary arrangements, the history of architecture, the theory of the beautiful, the analysis of the styles of art, architectural composition, the literature of architecture, the theory of the higher subjects of construction,—e.g. arches, bridges, and domes, the application of iron, &c. That the subjects for the higher examination may also be a development of those enumerated for the elementary examination, to an extent commensurate with the information on other subjects expected from the persons examined. 5. That a curriculum be prepared and circulated, giving a general outline of subjects for examination. 6. That the examiners be authorised to take into consideration any diplomas or certificates of competency that may have been obtained elsewhere,—e.g. from the Universities of Oxford and Cambridge, the professors of architecture at University College, and King's College, London. 7. That the examination be carried on by means of writing as well as orally, and that they take place in the months of July and October. 8. That the examiners be chosen by the president, the vice-presidents, the past vice-presidents, and the council for the time being, from among the members of the Royal Institute of British Architects, so far as may be possible; and that they receive fees for their attendance. 9. That the following rates be paid by the candidates on entering their names for examination, viz. 1.—For the elementary examination, two guineas; higher, three guineas.

Mr. II. P. Horner communicated his views to the meeting in a letter to the chairman, dated from Windermere on the previous day. The following are extracts from it:—

"Believing that in certain respects the profession, and through it the public, would be benefited by a general system of examination, publicly recognised as preparatory to the practice of architecture as a profession, I still think it quite consistent with this belief to balance very deliberately on the other hand the difficulties which the arguments of those who most strongly advocate a system of architectural examination and diploma. As regards the peculiar character of our profession, it must always be remembered that it is essentially a *fine art*, while dependent on the *science* of its construction on a material means; but the conceptions themselves, which constitute the art, are primarily independent of these means, though so far concerned with them as tritally dependent on the physical structure made to express upon sound and satisfactory architectural design. This admitted, and a competent theoretical knowledge of the principles of construction on the part of a designer be requisite, it is without this, however, that he can scarcely design at all; it seems to me that the practice of architecture takes its place with that of the other modern arts, sculpture and painting, and can no more be made the proper subject of a license or diploma than

\* According to Spelman, as quoted in the Oxford "Glossary," the seat at Beverley had this inscription:—"Hec sedes lapideis frontalibus ductor, or, parvis cathedra, ad quum reus fugiendo perueniens omnimodum habet securitatem."

could these. No one would more than myself deplore the neglect of practical construction as a subject of study by the architectural student; but in proportion as this, which seems to me the branch of architectural knowledge alone capable of the test of examination in its strict sense, takes precedence of design the imaginative part of architecture, and that proportion will architecture decline as a fine art; and this, I fear, be one tendency of the establishment of a system of architectural examinations, which might prove the possession of mathematical knowledge sufficient for a Cambridge examiner, and of classical lore enough for accomplished pedantry, but still leave the possession of real architectural skill utterly untested. The kind of examination sketched out in the paper of the Royal Institute of Architects would include the elements of a liberal education with a leaning towards architectural history and the ground-work of engineering knowledge; but I do not see that architecture as a fine art would be, as I hold, indeed it scarcely could be, a part of such curriculum. With respect to the position of the profession among us at the present day, I do not believe that, with English independence of feeling and opinion, any material change could be wrought by the existence of a diploma system in education: I would disparage in no degree the worthy aim and careful deliberation of those by whom the course proposed has been framed; but I cannot see the offering scope for the test of professional skill; regarding that, I must repeat, as an essentially artistic power. I do not question the advantage to the profession and to the community of any means which shall tend to ensure the practice of a calling bearing so intimately on many important interests being confined in any considerable measure to the hands of men of liberal education and good general attainments; and if the prestige attaching to it, and the respectability of the examination shall occasion a preference in the public mind for the employment of those who have passed it, each good would, doubtless, be accomplished; but still I cannot see that the art of architecture will be necessarily advanced. With regard to the higher examination, I hold that executed works, really the production of their fessed authors, afford the best diploma for a practising architect. If the Institute should continue to hold their doors open, as heretofore, to those who, seeking admission as fellows, prove themselves worthy of it by their executed works, and who associate those who are distinguished for professional skill in primary and direct reference to the imaginative element of the art; granting, if need be, their certificate of the attainments of these latter, I cannot see that, for the present, any new exists among us, its interests will be, in all probability, better served than by an attempt to systematise to form what the very state of things must in a great measure render inoperative, and which would occasion separation and invidious distinctions where unity now happily subsists."

The Chairman said.—The first question to consider in this discussion is the object to be gained by a diploma, and whether a diploma will effect that object. The object aimed at is to raise the status of the profession, by excluding all from its ranks until each has undergone an examination upon subjects more or less essential to the practice of architecture. What those subjects are will be discussed under the third and fourth propositions. This examination will compel the student to undergo a long and tedious preparation; for, although architects generally may be more or less acquainted with these subjects, it is a very different thing to be called upon to answer every question at a moment's notice; and the best men may not always be the most successful in their answers. Still the result will be to improve the education of the architect. There is just a difficulty in the introduction of a system which, without being too lenient to him mere mockery and a sham, would yet not be so severe as to exclude any one who would be at the pains to prepare himself for it. When the system is fairly established the examination should gradually increase in severity till a proper standard is reached; for I conceive it would be unfair to many who are just about commencing practice, though possessing undoubted architectural ability, that they should be subjected to an examination which they never contemplated or anticipated when they first entered on their articles of apprenticeship. There must be a unanimity on this question throughout the kingdom, otherwise the profession will be divided into two great factions which will be injurious to its interests. The greatest care and caution must be adopted in introducing the system—liberal treatment and fair play—so that the minority excluded may neither be formidable in numbers nor ability. Anything like stringent measures or severity at the outset will defeat the object aimed at.

Mr. Boulton said he should submit some resolutions which would seem to embody the answer which the society should return to the Royal Institute of British Architects. He thought there was an inconsistency in Mr. Fowler finding fault with the curriculum because it did not embrace any test of fine art in architecture, and then saying that such a test was impracticable. The question was, how could the quality of an architect be tested before he commenced practice. And here he took exception to what appeared to be the view of Mr. Horner, that old men as well as new beginners should go through some examination. The result of these examinations would be to induce young men to go through a regular course of study, and he should therefore move—

"That this meeting, having carefully considered the propositions of the council of the Royal Institute of British Architects, for securing a professional examination, are of opinion that it is highly desirable a course of study should be defined for all who may desire to become members of the profession of architects; and that an examination should be established to test the manner in which the studies defined have been pursued; those who may pass the examination with credit or distinction being furnished with honourable certificates of merit.

That this meeting are further of opinion that it is desirable the certificates granted to gentlemen who may pass the examinations should ultimately have the value of diplomas, which shall secure to the architect upon whom they may be conferred full exemption from the special provisions of any Metropolitan and other Local Building Act; and from the bye-laws for regulating building construction which may have been adopted by any local board, under the provisions of the Local Government Act, 1858.

That similar exemption should be conferred upon all architects who have practised as principals on their own account for a prescribed minimum period.

That this meeting hopes that the Royal Institute of British Architects will continue to give that cautious and enlightened consideration of the subject of professional examination which its importance demands, as they believe a judicious solution of the problem will tend to elevate the status of the profession, and will entitle the Institute to the gratitude of the whole body of architects.

Mr. John Hay would second the resolutions, with the exception of that part referring to the Building Acts, which, he thought, impracticable.

Mr. Weightman was in favour of a voluntary examination. The question at present was one of principle, not of detail, and he should move that a voluntary examination was desirable.

Mr. Frank Howard begged to move a direct negative to Mr. Boulton's proposition. He would, if he felt competent, practise as an architect, in spite of any diploma, and protested against any examination which should be conducted by a self-constituted body of men who had not been themselves subject to the test, and who were not at all superior to Liverpool architects. He never heard anything so absurd in his life as that these self-elected judges should be paid for damning their opponents, who were cleverer than themselves.

Mr. Audsley would let the Royal Institute of British Architects do as they liked with their own members, but would not tolerate any interference with others.

Mr. Callihan, student member, objected to an examination by men in London, and read the following resolution, which was passed at a meeting of the student members of the society on Tuesday night:—

"That, in the opinion of the students present, the granting of a diploma, before being allowed to practise, was very desirable; but they did not think it proper for the Institute of British Architects to take upon themselves the power of examining all candidates. In their opinion the Society formed in the town where such candidates are studying can have the power to grant a certificate, such certificate to hold as good as that granted by the secretary of the Board of Architects, and being the same."

The resolution submitted by Mr. Boulton was then put to the meeting. Professional members only were entitled to vote, and the resolution was carried by three to one.

It was then proposed by Mr. William Weightman, seconded by Mr. John Hay, and carried *neg. co.*—

"That the local examinations, especially the elementary ones, be conducted under the auspices of the respective local Architectural Societies."

#### FROM VIENNA.

THE new exchange, by Herr Ferstel, of one front of which the *Builder* gave an engraving some time ago, is much admired. The interior decoration, ceiling painting, walls in mosaic of imitation marble, and metal-work, are in a motif Gothic, with ideas from the Romanesque and Cinque Cento. This building has very many things in interior decoration that would interest an English architect, and would be new to him.

Herr Ferstel has just finished a country-house in the Pointed style, with constructional polychrome, at Gmunden; and is about to commence a large private house in Vienna, on the quay near the Ferlland-bridge, a simple massive Gothic building, in brick and stone. His work has this character,—it is massive and solid, thoroughly constructional, and its decorative feature is German Gothic, not of the wiry nature, but more French. His votive church in Vienna is progressing. He is well acquainted with the works of Street, Burgos, Scott, Woodward, and others, through your paper.

Professor Smith has commenced his new large Gothic church for the Lazzarists here. It is an interesting design, solid, and not wiry in cha-

factor. It is necessary, in criticising works from here, as to their depth and light and shade in the windows, to remember that the windows must be double, to suit the climate; hence it is difficult to get that depth you can get in an English modern Gothic work, where the glass is single; and it is necessary here at least to have 6 inches between the two windows.

There is a competition open in Vienna for a new Opera-house. The programme could be had by applying through our embassy, or to the Austrian consuls in London. T.

#### INFANT SCHOOL FOR THE DEAF AND DUMB, NEAR MANCHESTER.

CONSIDERABLE efforts are being made at this moment, in the metropolis and elsewhere, in favour of the deaf and dumb; a movement in the success of which we feel much interested. A few weeks ago an institution for the reception and education of deaf and dumb infants was opened at Old Trafford. It is said to be the only one of the kind in the world.

The Rev. Canon Clifton, in opening the proceedings, said a school for the infant deaf and dumb was an entirely new idea: similar institutions did not admit children under eight years old, while here they were received between the ages of three and seven. Children are most susceptible of cultivation when very young; and this was particularly true of deaf mutes, who were not generally deficient in mental ability, but their minds became early dented by isolation and neglect. This institution, therefore, supplied a very great want. There would be accommodation ultimately for fifty children. Already more applicants had appeared than could be accommodated, so anxious were the parents of these unfortunate little ones to use the institution. There had been raised for the Institution the large sum of 11,500*l.* Of this amount 4,500*l.* was obtained in donations, and the unexpended sum of 7,000*l.* had, thanks to the ladies, been raised by a bazaar.

Allusion was made at the meeting to the intelligence often displayed by the deaf and dumb; and it was shown that one of them had thus ably answered the following questions:—

"What is hope? Hope is the blossom of happiness.—What is the difference between hope and desire? Desire is a tree in leaf; hope a tree in blossom; enjoyment is a tree in fruit.—What is gratitude? Gratitude is the memory of the heart.—What is time? A line that has two ends; a path that begins with the cradle and ends in the tomb.—What is eternity? A day without yesterday or to-morrow; a line that has no end.—What is God? The necessary Being, the sun of eternity, the mechanism of nature, the eye of justice, the watchmaker of the universe, the soul of the universe.—Does God reason? Man reasons because he doubts; he deliberates, he decides. God is omniscient; he never doubts, and therefore never reasons."

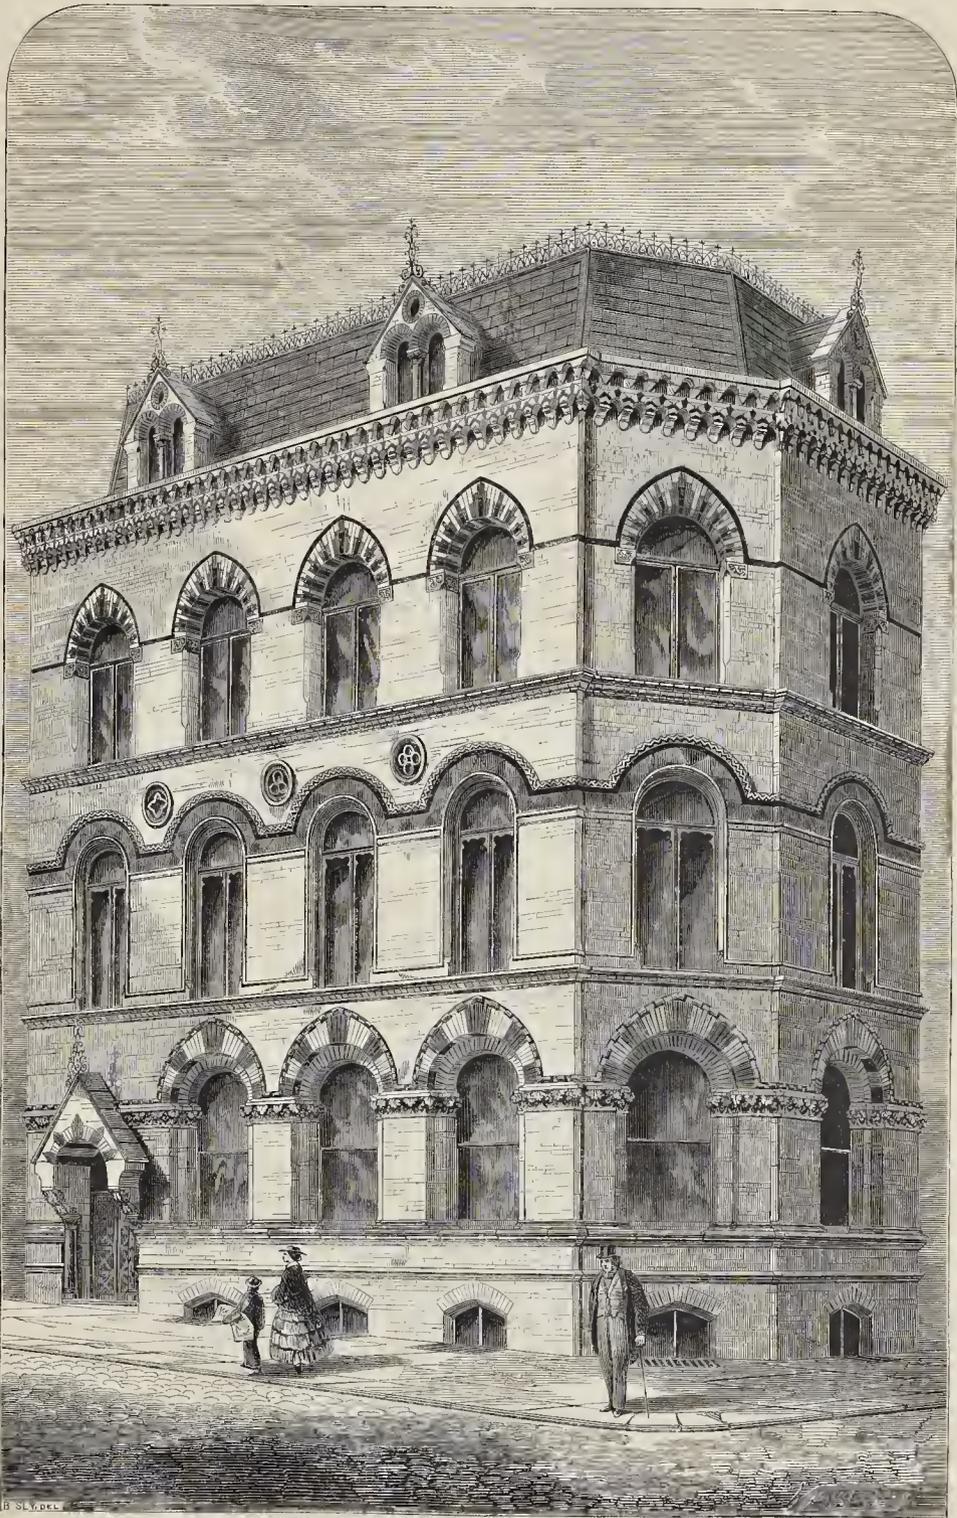

The structure, of which we give views, was built by Messrs. Bowden, Edwards, & Forster from the designs of Mr. J. Redford, at a cost of 4,700*l.*, and is situate at Old Trafford, adjoining the Botanic Gardens. The site selected is in the rear of the present institution, but abuts beyond the left wing, so that the front of the edifice is visible from the road; forming a detached addition connected by a covered way. The foundation stone (as noticed by us at the time) was laid on the 8th August, 1859, by Mr. Thomas Turner, F.R.C.S., the originator of the school. The structure is assimilated in exterior to the Tudor style of the time of Henry VIII., which was adopted for the main building. The façade is of "summit" stone. It covers an area of 577 yards, although from the circumscribed form of the land a frontage of only twenty yards could be obtained. It comprises sheltered playgrounds in the lower story, over which is a schoolroom 40 feet by 25 feet, dining-hall 29 feet by 20 feet, boys' dormitory 40 feet by 25 feet, girls' dormitory 45 feet 6 inches by 20 feet, sick ward, lavatories, committee-room, nurses' rooms (divided from the infants' by a glass partition), apartments for the housekeeper, domestic servants, &c.

The principal rooms are upon piers: the staircases are fire-proof; the dormitories, with an open timbered roof, give 800 cubic feet of space to each bed. The dining-hall and schoolroom have low-pressure hot-water circulation in addition to fire-places, and dwarf wallscaling; to the latter room the panels are formed of slate, upon which the children are taught their lessons. The walls are of second bricks, painted in the dining-hall and schoolroom, and lime-washed in the dormitories. The woodwork (including exposed carpentry, beams, joists, bridging, spars, boarding, and principals) is stained pine varnished.

## INFANT SCHOOL FOR DEAF AND DUMB, OLD TRAFFORD, MANCHESTER.

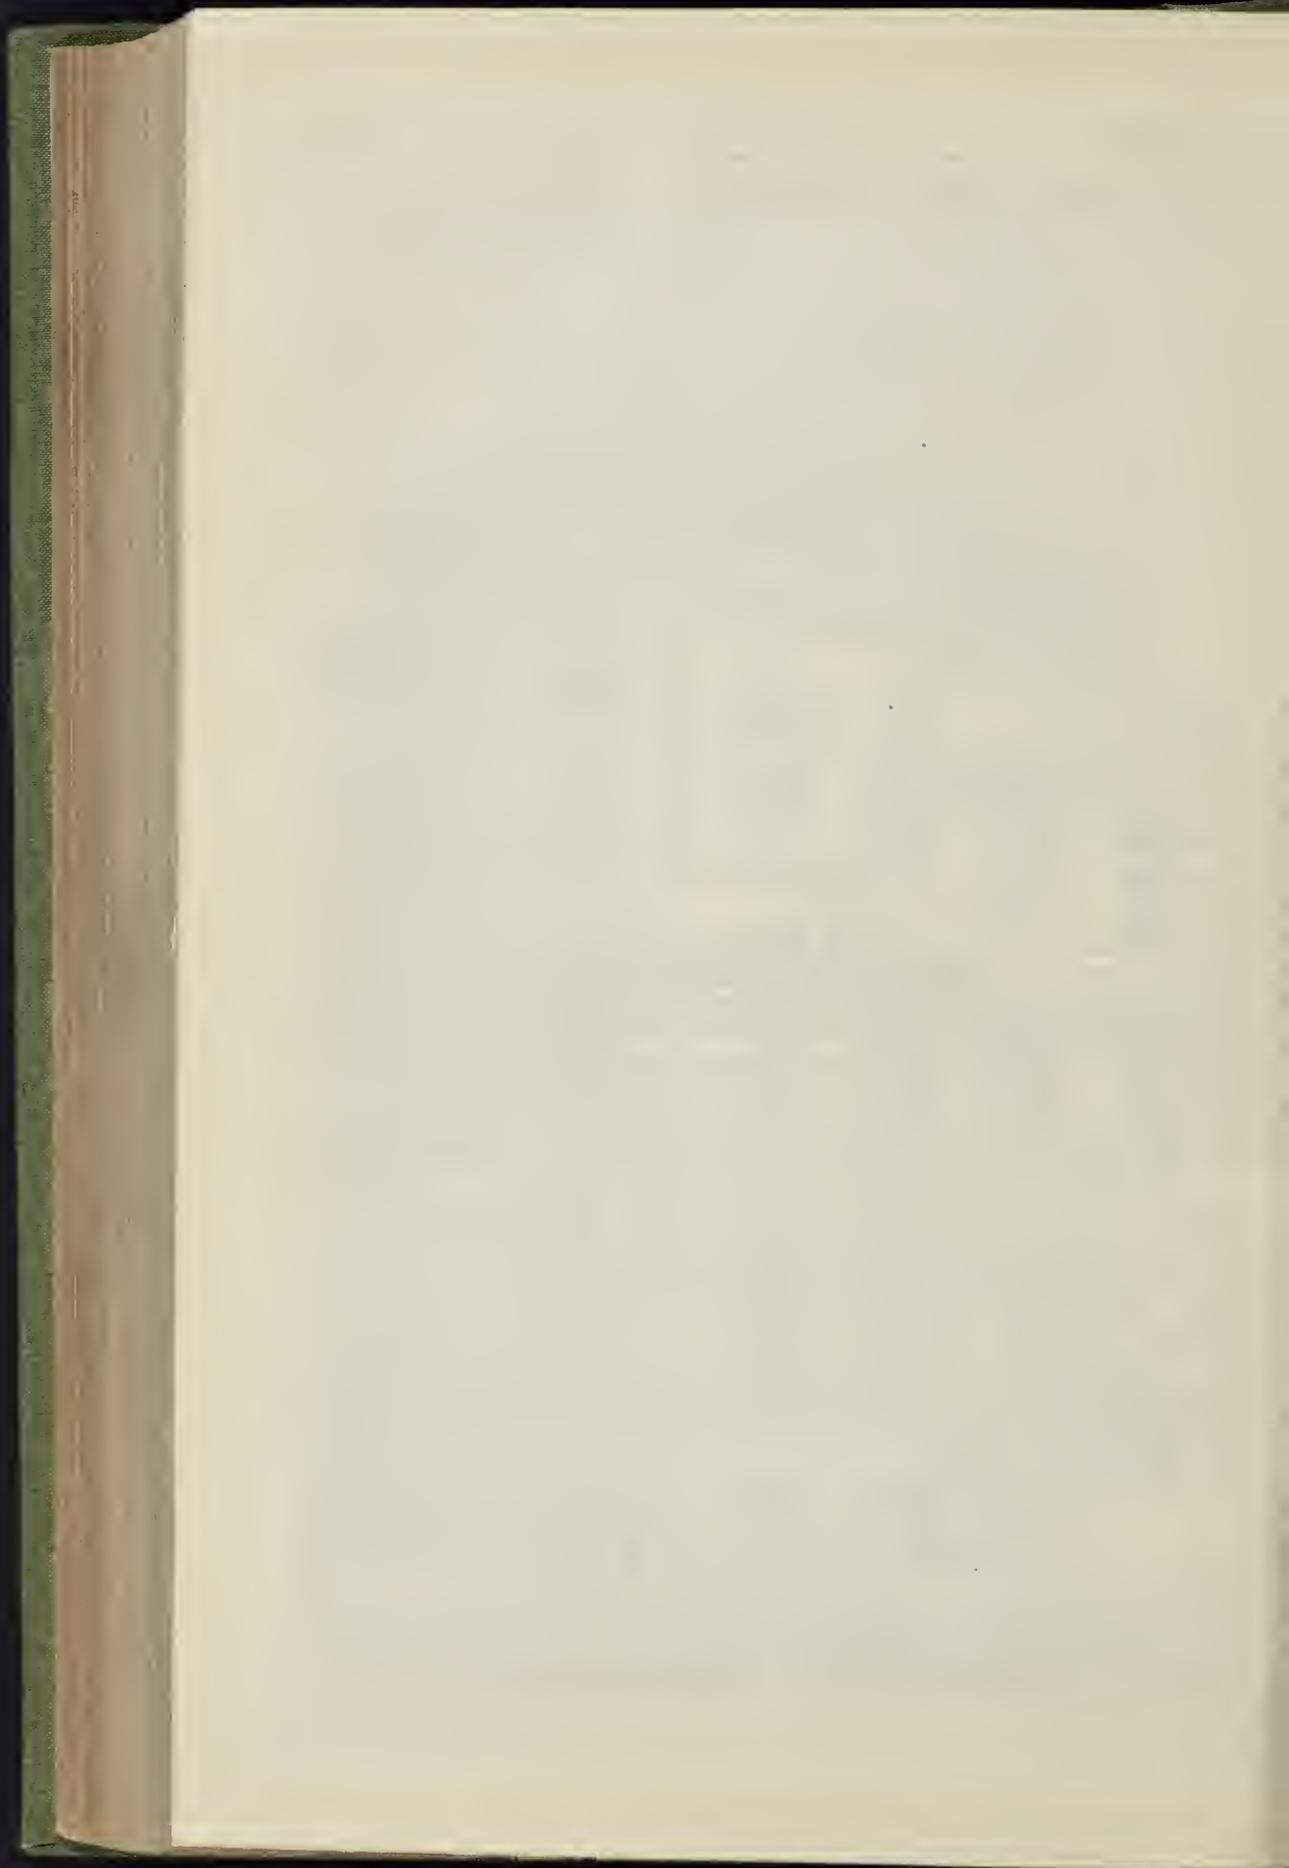

MR. JAMES REDFORD, ARCHITECT.

*Entrance Front.**Dormitory.*

H. ST. Y. DEL.

RECTORY HOUSE FOR THE PARISH OF ST. THOMAS APOSTLE AND ST. MARY ALDERMARY, LONDON.  
MESSRS. TRESS & CHAMBERS, ARCHITECTS.

**THE RECTORY HOUSE OF THE PARISH OF ST. THOMAS APOSTLE AND ST. MARY, ALDERMARY, LONDON.**

The rectory of the parish of St. Thomas Apostle is built upon a piece of ground at the corner of Cloak-lane and Queen-street, Cheap-side, formerly a part of the site of the church or churchyard of St. Thomas Apostle. The church was destroyed in the Fire of London, but the churchyard remained until 1848, when a large portion of it being required to widen Queen-street and to form new Cannon-street, it was, with the consent of the parish and the Bishop of London, purchased by the City,—the consideration being a sum of £1,000, paid over to the parish for the erection of a dwelling-house for the rector on the remainder of the site. This amount was afterwards increased by a subscription from the united parish, St. Mary Aldermary.

The building is faced with white Suffolk bricks, with string courses and arches of red and red and black brickwork. Ambury stone is used for the architraves, string courses, and dressings generally. The course of inlay over the first-floor windows and in the circular panels is intended to be of coloured marble and granite. The works have been carried out by Mr. Macey, builder, of Milford Wharf, Strand, under the superintendence and from the designs of Mosses, Tress & Chambers, architects. The present rector is the Rev. L. B. White, M.A.

**TRAVELLING STUDENTSHIP IN MEMORY OF THE LATE A. WELBY PUGIN.**

The subscriptions towards the endowment of a permanent fund, to be entitled the "Pugin Travelling Fund," the interest arising therefrom to be awarded to an architectural student in such manner and at such periods as may hereafter be decided, now amount to about 750*l*. To the studentship, as our readers know, it is proposed to add a medal.

This memorial, whilst providing a lasting recognition of the services rendered to art by the late Mr. Pugin, will be the means of promoting in a thoroughly practical manner the study of architecture. It is most desirable that the support of this proposed foundation should not be looked on as a party badge. Men on both sides of the style-question have already subscribed to it, and the Institute of Architects will, it is understood, accept the office of dispensing the funds. While we have Mr. Beresford Hope and Mr. Scott acting as joint treasurers, we find Mr. Tite, who seems just now bent on doing liberal and wise things (all praise be to him for it), subscribing his twenty guineas to the fund. The committee will need at least 1,500*l*, or 2,000*l*., and we shall hope to see provincial architectural societies, architectural students, and art-workmen, lending their aid to bring up the amount to the latter sum.

**HEALTH AND CRIME.**

The Registrar-General's quarterly report, just published, offers some points worthy of notice. The season has been remarkably healthy: the death rates have decreased; the births are about the average; and the increase of the marriages shows the general prosperity of the country. *Sanitary improvements have gone on: the temperature has been remarkably low; and the rains have purified the sewers, and retarded putrefaction.*

The epidemics of diarrhoea and cholera have been frequently attributed to the extensive supply of fruit. In the present season, whatever may be the scarcity of grain and vegetables, the supply of fruit has been remarkably abundant throughout the whole country; and, in the poorer neighbourhoods of the metropolis, apples, pears, plums, and other fruits have been sold in greater quantities and at smaller prices than we ever remember. Apples, of not bad quality, have been offered in some of these districts for 3*d*. a pound weight. Notwithstanding, diarrhoea has declined in the metropolis.

86,423 deaths were registered in the three months ending in September. In the corresponding quarter of the last year the deaths were

Deaths last quarter .....	164,330
.....	86,423
Difference of deaths.....	17,916

and it is to be noted that the largest amount of saving has been in the large towns.

Notwithstanding that the price of nearly all kinds of provisions has been high, the number of marriages has increased, particularly in the

great manufacturing districts of Lancashire and Cheshire. Pauperism is declining on the average. The number of paupers in receipt of relief was

At present the number is .....	783,449
.....	789,360
Decrease .....	14,069

All the above figures, with the exception of the high price of food, are of a favourable nature. We learn, however, that in consequence of the general prosperity, the extent of employment, and the price of labour, the public health has not, so far, been generally affected by disease from scarcity of the necessities of life. As probably always will be the case, there are classes suffering at present, and a vast multitude, amid all our prosperity, are in distressed circumstances. We may hope, however, that,—with the great development of our national resources and industry, by the improvement of the condition of the children of the poor and others, by the institutions which are in progress for rendering useful the younger portion of these populations, who are at present a waste to the community, and by adopting a sensible and efficient system of emigration, and opening out sources of employment for the suffering thousands,—the amount of distress, even in the most favourable circumstances of health, which causes so much anxiety, may be abated, and by this means a considerable amount of life saved and much ill health prevented.

We may just now note that the average number of deaths in the town districts in the summers of 1850-9, was, yearly,

The deaths in last summer were....	52,651
.....	45,495
Below the average .....	7,356

In the country districts, where, generally, sanitary improvements have been less attended to, the deaths for 1850-9, averaged, yearly

In last summer .....	43,607
.....	49,028
Below the average .....	2,769

For the purpose of battling with crime in England and Wales, we have an army of 20,507 men: 152 of this police force are detectives;—and the cost of the whole force was last year 1,485,029*l*. 10*s*. 10*d*. This, however, as we have before shown, is but a small part of the cost of crime in Great Britain. The number of persons employed in the jails and other prisons, the judges, councillors, and others, to whom the large extent of vice gives employment in England, would make a body almost sufficiently numerous to repel a foreign invasion.

Although unpleasant, it is useful to look steadily at these figures, and to know that the cost of crime, taking it in all its pounds, shillings, and pence considerations, is probably over five millions a year. Nor is the extent of prostitution less shocking to contemplate. The whole matter, however, shows that all should work most strenuously in their various ways to endeavour to abate the monster evil which is such a disgrace to our civilization. In order to do the greatest amount of good, it is necessary to discover the chief causes of these evils; and it is worth while to consider calmly, and with care, the opinions of persons who have had by observation and experience opportunities of obtaining useful knowledge on these points. Amongst the opinions which have recently been given, the chaplain of Horsemonger-lane Jail has, in his annual report to the Surrey Justices, which has been printed, thus said:—

"From my experience of predatory crime, founded upon a careful study of a great variety of prisoners, I conclude that habitual dishonesty is to be reformed neither by ignorance, nor to drunkenness, nor to poverty, nor to overcrowding in towns, nor to temptation from surrounding wealth, nor, indeed, to any one of the indirect causes to which it is sometimes referred, but mainly to a disposition to acquire property with a less degree of labour than ordinary industry."

The above statement, made by a gentleman who holds an important position in our metropolitan prisons, is very different from those of the chief authorities who have written, after much thought and investigation, on this most important subject: if such a statement should be to any extent agreed with, it might lead to the fresh introduction of the whip and treadmill as means of curing laziness. Whether the chaplain of the above-named prison be right in his statement as to the true cause of our crime, or whether that true cause do not at least involve the neglect of those measures of a more humanizing character which have been shown to be the means of preventing a large amount of national disgrace and exposure, remains to be seen; but, certainly,

the experience which we have gathered from long observation, the opinions of hundreds of distinguished authorities, the police reports and statistics of crime, and the working of reformatories, are all against this gentleman's theory.

**THE LUTHERIAN MUSEUM.**

THE LUTHERIAN MUSEUM, a collection of various objects gathered together by an inhabitant of Hallerstädt, has been, according to the *Illustrirte Zeitung*, transferred from the latter place to Wittenburg, where it is to remain for exhibition, in Luther's own house. It is well known that the purchase was ordered by the Prince Regent. The heirs have sold it for the moderate sum of 3,000 thalers,\* fully aware of the wishes of its late proprietor that the collection should find a permanent resting-place at Wittenburg. The contents are, among other objects, thirty-four paintings, principally portraits of Luther, Catharine de Bora, his wife, Madeleine Luther, the Elector of Saxony, Melancthon, Erasmus, Pontanus, and Ulrich de Hutten. Many are by L. Cranach; for example, those of Luther and his wife, in the year of their marriage, and which remained in the family of the Reformist up to 1720.

The second section of this museum contains, in thirty-four portfolios, nearly 7,000 portraits of Luther and his contemporaries, including those of his family. Then follow the autographs of Luther and his contemporaries, in number about 2,000, contained in 213 cases of different sizes; and 294 medals, struck in honour of Luther and his friends.

**CROYDON.**

WHITGUFF'S Hospital has just undergone a renovation both internally and externally. The alterations and improvements are rather extensive. Some time since, the trustees caused the quadrangle to be sunk or dug out about the depth of 2 feet, so that the earth outside the floors of the dwellings of the old inmates might be on a level with the inside, thus preventing the previous dampness of the room in the first floor, and rendering it more easy for the aged people to gain admittance to their different apartments; as, before this alteration took place, they had to descend into their rooms by a flight of steps. After this alteration had been effected, and the quadrangle space laid out with grass plots and flag pavements, the trustees determined to put the old building into a better condition by repairs, alterations, and decorations. The work was accordingly contracted for by Mr. C. Hyde, builder, Croydon, while the designs for the work were furnished by Mr. Willoay Mullins, of London.

Drainage tenders have been sent in to the Local Board, for the construction of a new brick sewer, proposed by the surveyor (Mr. Fenton), which will be laid from Pitlake, through Church-road, and continued on to the Brighton-road, terminating near the Swan and Sugar-loaf Inn. The tenders were as follows:—

Mr. Adam Bull .....	£1,955	0	0
Messrs. King, Burton, & Hipwell .....	1,685	0	0
Mr. Thomas Morris .....	1,380	0	0
Mr. E. Thirst, London .....	1,338	0	0
Mr. John Laid .....	1,304	1	8
Messrs. Hartland & Bloomfield, London .....	1,300	0	0
Mr. John Walker .....	1,240	0	0
Mr. James Hayward .....	1,225	0	0

The lowest tender (Mr. Hayward's) was accepted. The Croydon drainage already in operation appears to be now contributing not a little to the healthfulness and prosperity of the town. From the usual quarterly reports of the mortality of the parish it appears that the mortality of the whole parish, at the commencement of the current year, was at the rate of only 15½ per 1,000 of the population, which itself contrasts remarkably with the twenties and thirties of many other places; but in the central and western districts of the parish the percentage was only a little over 14 per 1,000, apart from the Union House, which happens to be situated in this part of the parish. The remarkable circumstance also now occurs, that the hitherto least healthy district ranks as the most healthy; and to what can this be attributed but to the sanitary improvements, which would of course be directed most especially to the unhealthy parts? The number of infant deaths in the past quarter was only 42, as compared with 104 for the same period in the previous year. Under all these encouraging circumstances it is not to be wondered at that a great increase in

\* About 44*s*.

building operations has of late been going on. The number of houses in the parish, which in 1851 was 3,234, is now 4,794; and the population has increased from 26,734, in 1855, to 29,144 in 1860. The large number of 102 notices for new houses, moreover, have been approved for building in the quarter last past.

A prospectus has been issued in this now thriving town of a "Croydon Sewage Irrigation Company," with a capital of 30,000*l.* in 10*l.* shares. The board is composed of eminent agriculturists and landowners, and a hope may, therefore, be entertained that the experiment will be so conducted as to aid greatly in leading, through its successful example, to a general utilization of the sewage of the large towns of the kingdom. In the present instance a concession has been obtained from the town of Croydon for 100 years, and the quantity of sewage to be obtained is estimated to be sufficient for 9,000 acres of land per annum. This will be pumped to a reservoir on an elevation about two miles distant, whence it will flow to each farm and field by gravitation. The works could be completed by March or April next.

The benefits derivable from irrigation with town sewage have been recently urged in a statement made to the new company just notified by Mr. George Shepherd, C.E., of London, in which he points out,—1st, the beneficial results obtained from the sewage during the late winter of 1859 and the late cold spring of the present year; 2nd, the great advantage obtained by the use of this invaluable manure during the late wet, cold, and extraordinary harvest season. While non-sewage farms were suffering all the horrors of a famine, it appears from this statement that sewage-manured farms were revelling in abundance of food for their stock.

"In May last," continues Mr. Shepherd, "the sewage of Croydon was used to irrigate several fields; the land is undrained, and the soil was very poor. The land was sown with clover and rye grass; one field of grass and one of oats. The fields were irrigated in a most crude manner, but the result has been most astounding. The hitherto poor soil, since May, has produced two heavy crops of clover, also two heavy crops of rye grass, while the third crop is now ready for cutting for the farmyard in a green state. One heavy crop of hay was obtained from the grass field; the second crop has been grazed off, and at the present moment yields most abundant pasture of rich green grass. "Had this season been favourable so that the produce could have been cut when ready, three, if not four, crops would have been obtained from each field. Comparing the present state of the pastures in these fields with those adjoining, in the former there is sufficient food to fatten several hundred head of sheep, while the other non-sewaged fields are comparatively bare. Nor has the crop of oats irrigated with the sewage been less satisfactory. It was the finest field of oats I ever saw, notwithstanding the abundance of cold rain, and the absence of the heat of the sun to ripen it. The oats were fit for cutting full three weeks earlier than the grain in the adjoining fields, had the weather permitted the operation. When cut it was found, from being over-ripe, a great deal of the oats had shed. (I have noticed many farms this year, and this is the only instance I have seen the crop ripe enough to shed, as it is termed, while standing. In many parts the crops have been cut in a very green state. I have heard this expression from the farmers in too many instances:—'The land is too poor to ripen the grain.' " \* \* \* As soon as the oats were carted, the well my friend Mr. Morrison, late of the Links farm, Malvern, says:—'My opinion, after six years' experience is, that irrigating with sewage is the finest manure possible for grass lands; the quantity of stock it enables you to keep is surprising, the bite on the fields is much earlier and continues much later than on the non-sewaged lands.'"

#### GLASGOW ARCHEOLOGICAL SOCIETY.

At the annual meeting and *conversazione* of the Glasgow Archæological Society, Mr. James Smith, of Jordanhill, was voted into the chair, and the proceedings commenced by the reading of the annual report, by Mr. Honeyman, jun., the honorary secretary.

The following were elected the office-bearers for the year 1860-61.—President.—Mr. James Smith, of Jordanhill, F.R.S., &c.; Vice-presidents.—Mr. Laurence Hill, and Sheriff Strathern; Councillors.—Messrs. J. T. Rothead, J. B. Thomson, Wm. Burns, John Buchanan, Gabriel Neill, R. Hart, J. Baird, Alex. Galloway, James Fleming, Sir A. Orr, Dr. Straug, and W. Euing, hon. sec.; Mr. John Honeyman, jun., architect, hon. treasurer; Mr. Wm. Church, jun., accountant.

The President then gave a few short sketches of the "Pre-historic Antiquities of the West of Scotland." He said the stone hatchet belonged to the rudest and earliest state of society, and it had been the same here as elsewhere. John Buchanan had left him nothing to do with regard to the caucos of antiquity part of the question. Where these caucos had been found it must have been under water, for they were found imbedded in the sand, and sometimes nearly in a vertical position, as if the vessel had been run down. Then the question presented itself—Was that water fresh or salt

water? Both were possible, for they knew that in elevated land, which had either been the sea-bottom or that of an ancient lake, marine shells were found, but then they were edible ones, and might have been brought up from the sea coast; but he thought it belonged to a period before the last upheaving. The study of silts of elevated lands, then stone hatchets and stone arrow-heads, which had recently attracted much attention, was the same with the canoe question of this part of the country. They knew that such changes of level did take place in the human period, although in great periods of time. He then remarked that there were a few stone monuments of a single stone in this country, which were doubtless erected "in memory of" some of the great and important persons of the day, who were now quite unknown to fame. One of these was at Inverary, and another at Strachlar. There were what were called Druidical circles of stones also, although no one knew what they were for; and in Bulderock parish there were three cromlechs, or, as they were called, the "Three Old Wives' Lifts."

After some discussion,—  
Mr. Smith read a paper on the Old Church at Ruffrew.

#### THE RESERVOIR IN HYDE PARK.

VARIOUS schemes have been proposed, including the design for an elaborate Gothic fountain, with a large amount of sculpture, for the transformation of the circular reservoir in Hyde-park, close to Park-lane, into "a thing of beauty." We now understand that the large Waterloo vase which stood in the vestibule of the National Gallery is to be conveyed there, and made to form a prominent object, with what necessities and arrangements we have yet to learn.

The works at the National Gallery are being vigorously proceeded with by Messrs. Cubitt & Co., under Mr. Pennethorne's direction, but we can scarcely believe that they will be completed within the few weeks originally spoken of as the length of time during which the Gallery would be closed.

#### PROVINCIAL NEWS.

*Stow.*—On Thursday, October 24, the principal stone of the new mausoleum in course of erection by Mr. Charles Higgins, on his recently-purchased estate at Stow, was laid. Boycott Manor Farm formed a valuable part of the Stow property, and was bought, together with some adjoining land, by Mr. Higgins, when the Stow sales took place a year or two since. Mr. Baillie is the architect of the new building; Mr. Johnson, of Maid's-Norton, the master carpenter; Mr. Madock, the head bricklayer; whilst Mr. Harrison and Mr. Mansfield are commissioned to execute the necessary stonework.

*Bramford (Suffolk).*—The new Church of England schools at Bramford have been opened. These schools have just been erected at a cost of 725*l.* The building is erected on a piece of land, the gift of Sir G. Broke Middleton, on the north side of the churchyard, and abutting on the public road. The school-room is 48 feet long by 18 feet wide. At the upper end is a glass door opening into the class-room, which latter is 21 feet long by 15 feet wide. Accommodation is provided for about 150 children. The warming is effected by two open fire-places in the school, and one in the class-room; and ventilation by means of a lantern in the roof. At the end next the road is a house for the teacher, consisting of parlour, kitchen, scullery, and three bedrooms. The walls are built of rubble stone, faced with cracked flint, and red brick quoins to the exterior angles and round the door and window openings. The character of the building is plain, effect being obtained by the grouping of the gables and other features requisite for the arrangement of the plan. The principal front consists of the school as a centre, with two porches giving separate entrances for boys and girls, and three gabled windows between them, the wings being formed by the house at the north side and the class-room on the south, in the gable of which is placed the "memorial stone." The works have been executed by Mr. Girling, of Ipswich, for the sum of 630*l.*, from the design and under the superintendance of Mr. F. Barnes, of the same place, architect.

*Peebles.*—The opening of the new corn exchange in Peebles was celebrated by a dinner in the exchange. The building, which is situated to the west of the Chambers Institution, and immediately behind the stance on which the market has been hitherto held, is a plain structure, lighted from the roof. It is 60 feet long, 16 feet wide, and 25 feet high. There are two stalls or offices

at the south end of the building. Mr. John Lessels, of Edinburgh, was the architect; the contractor for the woodwork, Mr. Dickson, of Peebles; and Messrs. J. & R. Veitch, Peebles, for the mason-work. The cost, which will be about 4,000*l.*, has been defrayed from the funds of the town.

#### CHURCH-BUILDING NEWS.

*Folkingham (Lincolnshire).*—The church here has been restored and reopened. The nave has been rebuilt. The clerestory walls are cased with ashlar, and covered with an open timber roof of the Perpendicular style, the brackets of which rest upon carved corbels, representing various leaves and flowers. The side roofs are of the Decorated style. The greater part of the north aisle wall has been rebuilt and also cased with ashlar. The pulpit is of carved oak. In the east end of the chancel a stained four-light window has been placed, representing the birth, crucifixion, resurrection, and ascension of our Saviour. The donor is Mr. John Ward, of Folkingham. It is from the firm of Ward & Hughes.

*Leckhampstead.*—A chapel of ease to the parish church of Chieveley, has been in course of erection at Leckhampstead since March in last year. It is dedicated to St. James the Great, and has just been consecrated. The church consists of nave and chancel, with aisle on south side, and small vestry: it will accommodate about 250 persons. The internal dimensions are—the nave, including chancel, 70 feet long by 22 feet wide, and the aisle 8 feet wide. The style of the church is Geometrical Decorated. The walls are built externally with brick quins at the angles, filled in between with flints crossed with brick hands, and internally faced with bricks of different colours, formed into patterns. The windows and floor-dressings are of Bath stone. The windows in the chancel are filled with stained glass. The roof is plain open timbered, and is covered with tiles laid in patterns. At the junction of the nave and chancel rises a timber-framed bell-turret. The body of the church is filled with open seats, with bench ends. There is an open timber porch on the south side. The vestry, which is about 9 feet by 13 feet, is on the north side of the chancel. A stained glass window over the altar has been placed there through the efforts of the Misses Witts (daughters of the churchwarden, Mr. E. Witts) and a few friends. The whole of the timber is stained. The entire cost of the church has been about 1,200*l.* The architect was Mr. Teulon.

*Southampton.*—The sanctifying of St. Lawrence Church spire has been removed, according to the *Hampshire Advertiser*. In building the spire it was considered advisable not to adhere to the original intention to build it with brick, the committee having decided in favour of stone; but both spire and tower have been curtailed of the dimensions intended by the design. The spire is relieved by the introduction of finialled gables and trefoil openings. The builder was Mr. S. Stevens. The decayed stonework will be renewed; but the committee want funds to have the brick-work cleaned and pointed, which is much required. The architects are Messrs. Hinx & Bealborough, of Southampton. The amount expended in completing the tower and building the spire has been about 500*l.*: the estimate to renew the decayed stonework is between 80*l.* and 90*l.*

*Winterbourne.*—The church of All Saints, Winterbourne, has been consecrated, after having been in use for two years. The church consists of nave, chancel, and north aisle, from designs by Mr. Street. It is erected on the elevation of Winterbourne Common, through the liberality of the family of the Rev. F. W. Greenstreet, the clergyman who officiates in it. It will accommodate 250, all free. After the consecration of the church and burial-ground by the bishop of the diocese, there was a dinner in a marquee, at which 600 parishioners were present, when the bishop stated that had he known in time that there was a piscina (with drain) in the church he would not have consecrated it; and that as it was he could not sanction the conversion of the edifice into a district church till the piscina was removed, which he had ordered to be done. His lordship added, according to the *Gloucester Chronicle*, that it was the fault of the architect, who had done the same thing before.

*Clevedon.*—All Saints' Church, East Clevedon, has been consecrated. The edifice is situated about a mile from the Clevedon railway station, and from Clevedon Court, the country seat of Sir Arthur Elton, Bart., through whose family the church has been built, and it is known by the residents as Lady Elton's Chapel. The style is Early

English. Mr. Giles, of London, was the architect. The contractors for the masons' work were Messrs. Palmer & Green, of Clevedon; Mr. Bennett, of Portishead, having taken the contract for the carpenters' work. Sifting accommodation is provided for 400, mostly free. The total cost of the building will be short of 2,500l. The organ (a Scudamore) is from the manufactory of Mr. H. Willis, of London.

#### STAINED GLASS.

*St. Giles's, Camberwell.*—In a former number we gave a short account of two stained glass windows, then just placed in the chancel of this church. We may now state that the remaining four windows have since that time been erected, and the work, therefore, is complete. The subjects of these windows are incidents in the lives, or connected with the writings, of the Apostles, one in each light, so that the six windows comprise the twelve Apostles. The east window, dedicated to St. Simon and St. Jude, was completed by Sunday, the 28th of October, the festival of these saints. We understand they are from designs and have been executed by Messrs. Lavers & Barrard, and that the whole cost has been about 570l. The money is raised by subscription from the congregation.

*Great St. Mary's Church, Oxford.*—There is a project afoot for erecting a memorial of the late Archdeacon Hardwick, who was killed in the Pyrenees last year. It will take the form of a window in Great St. Mary's Church, and a partial restoration of the church of Slingsby, Yorkshire, the archdeacon's native village.

*Bradfield College, Reading.*—Mr. Jones, according to the *Athenæum*, has executed for the window of the dining-hall of Bradfield College, Reading, three subjects from the Old Testament:—1. Adam and Eve, after the expulsion from Paradise, undergoing the effects of the curse: he is uprooting thorns; she spinning and nursing: behind him the Eden guardian angel, red-flaming sword in hand, with outspread wings of various dyes. 2. The Confusion of Tongues: the Angels of Judgment are seen casting down the Tower, with levers, &c.; the people are wrangling amongst themselves down lower: lower still, Nimrod is seen led out between the swords and wide wings of two angels: at the foot is a furnace burning, the architect looking at his plans, and the people labouring about him, who are not as yet affected. 3. The Procession of Solomon and the Queen of Sheba: he is leading her down to look at the works of the new Temple; trumpeters go before and attendants following behind. Messrs. Powell & Son have executed the work.

*Bromsgrove Church.*—A few ladies in this town have formed themselves into committee to collect funds for the purpose of filling the east window of the church with stained glass. The cost will be about 300l.

*Hanley Castle Church.*—A stained window, by Messrs. Lavers & Barrard, of London, has been placed in the north aisle of the church, to the memory of the late Mr. William Moore, breeder of storthorns and Shropshire Downs, and a liberal friend to the industrious labourer. The design for the window and the cartoons were prepared by Mr. G. R. Clarke, architect; the subject for the first light being "The Good Samaritan," and for the second, "The Good Shepherd." The canopies over the figures are composed of vines, lilies, and passion flowers.

*St. Peter's Church, Derby.*—A stained-glass window has been placed at the west end of the south aisle, over the place occupied by the font. It consists of six incidents from the life of John the Baptist; the central subjects representing him preaching in the wilderness; and the baptism of Christ. Messrs. Clayton & Bell, of London, were the artists. This window is the gift of Mr. J. L. Davenport, and is an obituary memorial of one of his sons.

*The Sharpe Window, Doncaster.*—The committee have determined on requesting designs from Messrs. Hardman, Messrs. O'Connor, and M. Gérôme, Paris. The cost of the window is not to exceed 1,000 guineas.

A "Student in Art," writing us on this subject, says:—

"That all parties wishing a good design for a stained glass window should make it a public competition for the best idea of filling the window. Let such idea be properly drawn out and coloured to a certain scale; but let there ever be a careful guard against looseness of drawing, or richness of colouring usurping the place of a noble scene. If three penmen were held forth for this, the best might be given to the best, the second for the next colouring, and the third for the best drawing. But

that would form a matter for reconsideration. If the best points out of three such designs were chosen, or if the three artists combined harmoniously to draw out the whole window, what a glorious one it might be. One distinct rule, then, should be, that it did not follow the designer was to carry out his own design in execution. If it is to be a memorial window, some account of the person or persons to be memorialised should be taken to the competitors; and last, but not least, those who combine with others to decide upon the best production, let them do it impartially, and with an honest wish really to have the best. Their position is a responsible one, for in them lies the power either to encourage the noble mind up the bright path of glory, or to thrust it back sometimes into the dark tunnel of despair—greatly to promote, or sadly to hinder, their country's advancement in Art."

The chances are that those best qualified would not risk the loss of their time in such a competition.

#### SCHOOLS OF ART.

*The Taunton School.*—At the annual meeting of those interested in this school, Mr. A. Mills, M.P., took the chair. In his address the chairman congratulated the meeting on the progress of the school. Out of the eighty Schools of Art in England, he remarked, he had selected a number, in towns, some of which had a population five or six times—all more than twice—the size of Taunton; these towns included Nottingham, Cheltenham, Wolverhampton, Bath, Yarmouth, Carlisle, Halifax, Lancaster, Leeds, and he found that the fees paid by the Taunton School of Art exceeded any one of them. It was a very encouraging circumstance that the school, now in the fourth year of its existence, should have attained so very favourable a position; but it should be stated that by far the largest proportion of those fees came from the morning class—a class attended only by the wealthy portion of the community. He regretted that the school had not succeeded so well with regard to the artisan and tradesman class. Now, considering that there was one department of art manufacture in which Taunton had attained considerable celebrity—that was the art of carving—he thought it especially desirable that prizes should be awarded for the encouragement of this art. He had therefore resolved to offer a prize in drawing with a view to encourage the department of wood-carving, in the hope of inducing more mechanics to join the classes; for he believed that the main object for which schools of art were established would not be attained unless they attracted that class of which he had been speaking.

Mr. G. C. Bentinck, M.P., also addressed the meeting, and offered a prize for competition.

The report stated that the number of pupils returned in attendance during the year ending June, 1860, was as follows:—Pupils at the Central School, 158, including 49 from private schools; children from public schools, Wellington and Taunton, 216; making altogether 574 pupils receiving instruction in drawing from the Master and Art Pupil Teachers of this institution.

*The Coventry School.*—The annual meeting of the friends and subscribers to this school has been held in St. Mary's Hall, the mayor presiding. The hall was crowded, chiefly with ladies. The report, which was read at the outset, stated that "the number of students entered on the books during the past year was 365, against 363 in 1858-9, and 346 in 1857-8. In addition to these the pupils of the British School receive regular instruction in drawing from Mr. Frost, the pupil-teacher of the School of Art." It also stated that "the accounts of the school for the year show a balance against the school of nearly 30l. This most unsatisfactory state of accounts has arisen from some decrease in the annual subscriptions, and from the balance brought forward last year. As some of the items of expenditure may now be fairly reduced, there is nothing in the real position of the school to create alarm, especially as a slight revival in trade would enable the subscription list to be materially increased."

Alderman Browett, in speaking to a resolution, said,—"If ever there was a time for special exertion to improve the production of articles of taste, it was the present. When the manufacturers of this country enjoyed a sort of protection over their manufactures, it might be price that would tempt the purchaser; but now that there was a "fair field and no favour," it would be their own faults if they were not in the race of competition. There were no reasons why this city should not rank as high as any in the world in the production of ribbons. The production of articles of taste had hitherto been placed too much in the hands of the French. Now, to recover, or rather to obtain the rank that the manufacturers of Coventry ought to occupy as manufacturers of ribbons and watches, it was one of the first essentials that they should have a school of art of the highest possible

standard; that we should stimulate our youth to those exertions that were necessary to enable them successfully to compete with foreign rivals; and he was quite sure that in this we should further, not only the interests of Coventry, but should advance the interests of the nation at large. The very circumstances of the time should stimulate them to special exertions. He did not take at all a discouraging view of last year's exertions. He thought, as compared with former years, they had not gone back; but if a suitable building had been erected, where ladies as well as gentlemen, boys as well as girls, could assemble, with proper accommodation and proper appliances at their disposal, to enable them to study efficiently, in the course of twelve months they would attain a much higher position. He hoped, therefore, next year, to see a building erected suitable for the reception of the works supplied by the Government, and worthy of the City of Coventry.

Mr. Dresser, in also speaking to one of the resolutions, showed, from statistical details, that the state of depression in which the trade now stood was not confined to Coventry, and was not the result of any peculiar competition to which the trade of this country was at this moment exposed, but was shared alike by all the silk-producing countries and districts throughout the world; and he was satisfied that, when a change of fashion came—when the manufacturers here had adapted themselves by improvement, by additional application and additional energy to the carrying on of their business,—they would not be left behind in the race of competition in which they had now to contend.

*The Carlisle School* held its annual meeting in the local Academy of Arts, Finkle-street. Mr. Davidson, banker, took the chair in the absence of the Mayor.

The Chairman said he was delighted to see the number of prizes for distribution. It was very creditable to the Institution. He thought they might congratulate themselves that the school was in a more prosperous state than it had been at any previous period of its existence.

The prizes were then distributed, but no report of progress appears to have been read.

*The Brighton Art Society's Conversazione.*—About 500 ladies and gentlemen attended this conversazione in the Pavilion, where, besides an exhibition of paintings, drawings, photographs, and antiquities, the amusements of the evening also included national and other music, and dancing. The company included most of the chief patrons and friends of art in Brighton.

#### ARTICLED PUPILS AND THEIR MASTERS.

Sir,—That such a feeling as you described in a recent number of your journal between masters and their pupils *should* exist is self-evident, but that it always *does* exist is, perhaps, not quite so evident. Masters are not in every case respected as they ought to be, and pupils are not always treated as they should be. There are men calling themselves members of the architectural profession whose chief care seems to be not to do honour to that profession, but to put it to an open shame. You, sir, are, doubtless, aware of their existence, and I unfortunately am only too well acquainted with it. These are the men who are continually advertising that "A vacancy has occurred," &c., or "An architect, &c., has a vacancy." A vacancy! yes, they have always a vacancy ready; if not in their office for a youth, in their pockets for a premium. No matter to them whether they have any business to employ the lad upon, no matter whether or no the lad has the slightest artistic taste (100l. will cover a multitude of sins); they take him into their office, give him a pretty elevation to copy, with green trees, blue windows, and red curtains. The poor boy "thinks he shall like it," and there he is, bound for three years, along with three or four more pupils, in different stages of their articles, left to their own devices for nearly half their time. And what is the natural impulse of youth when thus left alone? Will they work? Will they study? Have all the diligence and the genius of a Pugin, a Turner, or a Barry? And what are the consequences? At the termination of their articles, they awake to the mortifying discovery that they have wasted the three best years in their life, and in all probability they in their turn will become those pests to architecture, the so-called "Architects, Builders, and House Agents." Let me ask you this question, is it not the duty of the master, in consideration of the premium he has received, of the services of the pupil, and, last but not least, the honour due to the profession, *not* to instruct his pupil *only* to

those branches of the profession by which he can make him immediately useful, such as to trace and to copy—not to convert him into something between an assistant and an errand-boy (thus depriving the two latter of their lawful employment), but thoroughly and systematically to teach him, and to endeavour, by all means in his power, to train him up in that love of true art which shall render him an ornament instead of a disgrace to his profession? Again, the public are able to discern between a quack and a professional medical man,—between a dissenting minister and a clergyman,—but how can they distinguish a false architect from a true one? A PUFF.

#### INTERIOR DECORATION. ST. JOHN'S CHURCH, DORSET.

THE embellishment, just completed, of this church affords another proof that art is becoming more and more a necessity to all grades of society. Since the year 1823, when the church was built, until now, the congregation have been content to worship in a dreary barn-like room, fitted with rows of drab-coloured pews, and having a whitewashed expense of ceiling and walls. Now the woodwork throughout is grained oak and varnished; the walls are carefully jointed and coloured; the ceiling has been tinted cream colour, the lines and bands being picked out with a judicious tone of blue. All this is nothing more than doing up, perhaps, but the altar may claim to be something more. It is in a deep recess, flanked by wall pilasters: in the centre of the recess is a circular-headed window within a larger arch, the space between the architraves having radiating panels. The architraves spring from a cornice with pilasters to each, having panels between: these pilasters stand on the entablature of the rosettes, which has columns under the pilasters, the whole forming one composition, supported by a dado slightly higher than the communion-table. The window is filled in by a painting of St. John baptizing our Saviour, from a design of the late Mr. Ward, R.A., and the architectural work has been well painted in imitation of various Italian and Belgian marbles by Mr. Rule, of Stratford, the cornice, mouldings, &c. being heightened by gilding. The general effect is enhanced by a stained glass mosaic window on each side, executed by Mr. Clutterbuck. Certainly the transformation from the shabby, irreverent badness of whitewash is very decided, and suggests the advisability of sparing a carved capital or two outside for the benefit of the inside; indeed the Italian masters and our own great master, Wren (witness St. Stephen's, Walbrook, and St. James's, Piccadilly), if driven to select, always attended to the interior first.

AN ARCHITECT.

\* \* \* Our correspondent is more easily pleased than we are. We must see something more done than "graining and marbling" before we can offer any congratulations.

#### STATE OF FURNACE ABBEY.

SIR,—I would say a few words with regard to the present state of Furnace Abbey. I was amidst the ruins of that venerable pile on the 2nd instant; and, to my great sorrow, while looking at the refectory from the vestibule, which is at the southern extremity of the abbey, I perceived that the eastern wall of the refectory was leaning in a most painful and fearful oblique. My anxiety about its immediate dissolution may cause me to exaggerate, but it certainly did seem to me as if the next turbulent equinoctial gale would prostrate the tottering wall to another earth. Some steps to prevent this should be taken forthwith. I hope that, by the influence your paper has on the minds of those mostly concerned and deeply interested in archaeological remains, this notice may tend to the conserving of that time-worn and time-admired relic of former grandeur.

W. B. D'A.

#### VENTILATION OF HOUSES.

If "Salus" your correspondent of the 27th October, refer to the *Builder* of the 29th September, he will, under the heading "Condensation of Moisture on Glass" have the result of practice as a confirmation of what he states in the second paragraph of his letter on "Ventilation of Houses."

With regard to the query contained in the third paragraph, "What is the best remedy in houses already built and not provided with ventilating flues?" an opening in the centre of the ceiling concealed by a simple *rosace* allowing the heated atmosphere to escape to the external air is certainly a good plan I think; but I am persuaded, unless

there be a counteracting *ingress* to the *egress* channel, that a down-draught will ensue when horizontal ventilation is desired. Where arrangements of joisting prevent the following, something else must be tried.

On the one pair and other floors, when the joists run from front to rear, between the two centre joists in the front and back walls build a common cast-iron metal ventilator—a current will thereby be established in the direction of the wind between the two ventilators, and so draw off the vitiated air through the *rosaces*. This plan I am at present carrying out in some 24-foot houses to do away with the expense of air-flues; and, as to its efficiency as well as to its defects, if any, I will be happy, by-and-by, to communicate for the benefit of "Salus" and others, unless some one else in the mean time, who may have hit on the same plan, may be good enough to favour us with the benefit of his experience.

R. A.

#### CARVED STONEMARK TO SHOPS.

MR. EDITOR,—Architects seem just now to be very fond of introducing many of my class with our friends the stone piers and bases when they are engaged in erecting new shop houses; and I must say, without vanity, that we are very justly admired when first completed; but in a few months our faces begin to look dark and dim, and in twelve months we become black as soot. Our owners, the shopkeepers, then think we do not look so handsome as when they first paid for us, so they set to work to have us scraped, or they apply the paint-brush, in either case taking off the sharpness from our features, which I, as an individual eap, particularly object to. Can you, now, Mr. Editor, suggest some way or wash to keep our faces clean, and to prevent the horrid paint being plastered on our cheeks or having them scraped, whereby we become "small by degrees and beautifully less?"—I am, Mr. Editor, with sorrow, still beautiful, but

A DIRTY STONE CAR.

#### ST. PATRICK'S, DUBLIN.

SIR,—My attention has been drawn to a letter in your paper signed "Medievalist," in which, referring to St. Patrick's Cathedral, Dublin, he alludes to the "debased restoration" from the design and under the superintendence of the late Mr. Carpenter.

The facts are simply these: Mr. Carpenter certainly did prepare designs for the restoration of the whole cathedral, but only furnished details for, and superintended, the stonework of the lady chapel; and as, for these portions, the ancient work was most strictly adhered to, I am at a loss to understand the precise bearing of the word "debased" as applied to Mr. Carpenter's works.

WILLIAM SEATER.

#### SUBJECTS FOR PREMIUMS.

INSTITUTION OF CIVIL ENGINEERS.

THE council have issued their list of subjects for premiums, including, with those before published, the following new ones:—

On the Effect of Shunting, in removing and preventing Deposits at the Entrances of Docks on the Coast and in Tidal Rivers.

On the Measure of Resistance to Steam Vessels at high Velocities.

On the Forms and Materials for Floating Batteries and Iron-plated Ships ("Frégates blindées"), and the Points requiring Attention in their Construction.

On the Initial Velocity, Range, and Penetration of Rifled Projectiles, and the Influence of Atmospheric Resistance.

Description of Street Railways and Carriages, as used in the United States of America, in Paris, and at Birkenhead, with the Results.

On the Application of the Electric Telegraph to Railway Train Signalling.

#### WATER GAS.

THE *American Gaslight Journal*, of the 15th ult., contains a detailed account from *Le Journal de l'Eclairage au Gaz*, of the renewed and apparently successful attempt to introduce water gas into Narbonne, in France. The gas, according to *Le Génie Industriel*, quoted by its French contemporary, is made without retorts. The decomposition of water-steam into gas is effected by passing the steam over a mass of burning coke in a close furnace, and the more rapidly this is done the more effective and economical is the process. The oxygen and hydrogen of the steam are of course separated, and the oxygen forms with the carbon of the coke carbonic acid gas, leaving the hydrogen unattached even to carbon, so that the water gas is pure or mere hydrogen. The carbonic acid is withdrawn by means of damp quicklime, which, however, rapidly accumulates in quantity, and it is proposed to use

carbonate of soda instead, as the carbonate of soda will unite with the carbonic acid and form bi-carbonate, from which moderate heat will again expel all the gas absorbed, so that the carbonate of soda, if calculated, may be used over and over again indefinitely. Could not the carbonic acid also be made use of, as in the production of aerated drinks? Bi-carbonate of soda itself, too, is of some value. One chief peculiarity in the water gas is in the mode of burning it. Hydrogen yields a very weak light of itself, but each burner is supplied with the well-known contrivance of a small wirework of platinum, which, by adequate pressure on the main, becomes white hot, and produces an intense light with the hydrogen, without wasting the rather expensive platinum. The price of the gas, however, is still high, from the limited number of consumers, it is said. The experiment is one of direct interest in London, where the water gas is now being tried.

#### LIGHT AND AIR CASES.

*Terms of an Award.—Ford v. Gye.*—In the Court of Queen's Bench, on the 3rd instant, Mr. Raymond moved for a rule to show cause why an award should not be set aside, or why part thereof should not be struck out. This was an action for obstructing light in Hart-street by the erection of the Opera-house. The arbitrator was to say what the plaintiff was entitled to for any past or future damage he had sustained or might sustain, and also if Lord Gardiner, the reverser, close to come in, what sum he should be entitled to. The whole matter was to be determined by the reference. The arbitrator made his award, and certain sums to be paid to the plaintiff by annual payments for ten years, and other sums to be paid to Lord Gardiner; and he added this clause:—"So far as I lawfully may order that the actual payments of the sums shall be a condition of the permanent continuance of the walls and buildings of the Opera-house." The defendant now contended that there was no finality in the award, as, if there was default in payment, the walls might be taken down. It was a reference of all matters in difference, and it was awarded what sums should be paid for damages by reason of the permanent erection of the walls and buildings.

The Chief Justice.—How long is the payment to go on for?

Mr. Raymond.—For ten years.

Mr. Raymond now wanted that clause struck out. The arbitrator said he found for the plaintiff, and ordered the amount of damages to be increased to 800*l.* for the damage he had sustained and would sustain in respect of his interest in the premises, by reason of the permanent erection of the walls.—300*l.* on the 5th November next, and 50*l.* on each 5th November for ten years.

The Lord Chief Justice.—In default of payment what becomes of the walls?

Mr. Raymond.—It is a question whether the party may remove the walls, suspending the payments are not made according to the award.

The Lord Chief Justice.—Take a rule.

#### DECISIONS UNDER METROPOLITAN BUILDING ACT.

*An Equestrian Circus.*—At Greenwich police court, Mr. Frederic Ginnett, the equestrian circus proprietor, appeared to a summons, at the instance of Mr. Browne, the district surveyor under the Metropolitan Building Act, charging him with erecting a building, used as an equestrian circus, without giving the notice required by the Act.

The complainant stated that the building in question was erected within 12 feet of the footpath in the thoroughfare of Greenwich, being boarded in at the front with canvas covering, and was capable of holding at least 1,500 persons. His (the surveyor's) attention had been directed to the building by the notice of a similar character, but the present building was so large, and there being also danger from its taking fire, that he had considered it his duty to take the present proceedings.

Mr. Ginnett said he was not aware that any notice to the district surveyor was necessary. He held that the place was not a building within the meaning of the Act, having canvas surrounding it merely as a screen from the weather, and a canvas roof.

Mr. Trail said from the drawing he held in his hand the defendant appeared to have the place boarded in at the entrance, which brought it within the meaning of the building.

Mr. Ginnett observed that the boarding had only been put up to prevent persons improperly obtaining entrance to the performance, but that, if necessary, the woodwork might be removed and replaced with canvas. It was also merely intended for a temporary purpose.

Mr. Trail said the Act made no difference in the application of its provisions whether the building was for temporary or permanent purposes, and therefore notice ought to have been given.

Mr. Browne said that being his worship's opinion, it would then become necessary for the permission of the Metropolitan Board of Works to be obtained for the building to remain.

Mr. Trail said that in order for this application to be made and an answer obtained, he would adjourn the case until the 26th instant.

*STREET RAILWAYS FOR CORK.*—At a meeting of the "standing committee" of the town council, held to hear a proposal from Mr. Hugh H. Roche, agent to Mr. Train, a resolution was carried to the effect that tramways be permitted to be laid down by Mr. Train from the Passage Railway Terminus on Albert-quay through the South Mall, the Grand Parade, Patrick-street, and the Lower Gaudin-road to the Great Southern and Western, and Cork and Youghal termini.

## Books Received.

*A Description of the Human Body: its Structure and Functions.* Illustrated by Physiological Diagrams. By JOHN MARSHALL, F.R.S., F.R.C.S., Surgeon to the University College Hospital, London. London: published by Day & Son, Lithographers to the Queen, 6, Gate-street, Lincoln's Inn-fields.

On reading the voluminous text which accompanies and purposes to explain these beautifully-executed physiological diagrams, the question immediately suggests itself, to what class of the community is it adapted? We are told in the prospectus and preface that the book is intended to convey "precise information of anatomy to the nobility, gentry, and clergy!" to tutors and teachers in non-medical schools, and to young men "destined for the medical profession." We must confess, however, with a strong feeling in favour of the intention of the work, that it seems to us to go too far for one class, and not far enough for the other. To teach anatomy, even to a limited extent, the grand essential is the possession of a perfect knowledge of the groundwork of the science,—the anatomy of the bones; and until this is thoroughly known it is impossible for any one to learn it properly, much less teach it. In the present work the bones might almost as well have been neglected altogether: they are too loosely described for any practical purpose. Again, with regard to the muscles, the only way, or, at any rate, the best way, to learn and remember them, is by mastering their origin and insertions; but these it has not been thought desirable to mention (*vide p. 23*); and without this knowledge it is almost impossible to retain them in the memory. There is a large amount of information in the work very interesting and instructive to the curious in these matters; but it is very discursive, and calculated, we fear, greatly to puzzle any eager aspirant for anatomical knowledge.

It appears to us that if fewer subjects had been taken up, and more thoroughly treated of, it would have been much better calculated to attain the wished-for object.

To the artist the first part of the book is likely to be useful; but the latter and greater part he would scarcely meddle with. By the amateur it may be read for a time, but it is doubtful if he do not get thoroughly tired and perplexed before he has accomplished a third of it; and should any "young man destined for the medical profession" have it presented to him, he will be wise if he refrain from opening it until he has acquired his anatomy from other sources.

The plates, which are in a portfolio, are admirably executed by Messrs. Day.

*Observations on the Niagara Railway Suspension-bridge.* By P. W. BARLOW, C.E., F.R.S., &c. London: Weale, High Holborn, 1860.

ONE of the most remarkable results from Mr. Barlow's personal and careful examination of the Niagara Railway Suspension-bridge is that the favourable conclusions to which that examination has led induced him to suggest the formation of two cross lines of suspension railway over the central districts of London, one commencing at the Elephant and Castle, and terminating near the Shoreditch station of the Eastern Counties Railway; and the other commencing at the junction of Oxford-street and Tottenham-court-road, and terminating at Whitechapel. Street railways, he suggests, might converge from the outskirts to these lines. The cost of a wire suspension-girder viaduct, with a span of 1,000 feet, would not, he estimates, exceed, for a double line of street omnibus traffic, 150,000*l.* per mile. The only land required would be for the wrought-iron towers, as a wire-bridge might be erected without the least interference with intermediate property. Allowing 100,000*l.* per acre (the average cost of the terminus of the South-Eastern Railway) for the land required, or 50,000*l.* per mile, the whole scheme might, he calculates, be carried out for a little above 1,000,000*l.* He further suggests the adoption of wire suspension-bridges where bridges have been long projected and abandoned from their cost and interference with property as hitherto proposed; and as an example he suggests the connection of Holborn and Newgate-street by a suspension-bridge, thus avoiding Holborn-hill. A wire suspension-bridge, with towers of wrought iron, constructed like a vertical lattice beam, he urges, would offer little obstruction to the light, and would not exceed in cost the sum of 75,000*l.* Mr. Barlow also proposes to connect Liverpool with Birkenhead by a wire suspension-bridge, 150 feet

above the level of the river, at an estimated cost of 1,000,000*l.* sterling, passengers to be raised to the level of the bridge at one end and lowered at the other by steam power. The span of this bridge would be no less than 3,000 feet. He also proposes to suspend a similar bridge from New York to Brooklyn, with a span of 2,000 feet.

The Niagara bridge, notwithstanding certain defects, Mr. Barlow is convinced, "is the safest and most durable railway bridge of large span which has been constructed;—firstly, because it is less liable to deterioration; and, secondly, because the greatest strain to which it can be submitted is a less proportion of the ultimate strength of the supporting material."

## VARIORUM.

"The Sewage of Towns, its Value and Distribution" (Lynn & Gough, Camberwell-gate), by Mr. F. C. Maguire, repeats some of the more striking evidences as to the value of town sewage, and advocates its distribution to the land by pipes, but does not, as it seems to us, solve any of the difficulties of the question.—A pamphlet by Mr. A. Scratchley, M.A., barrister-at-law, titled "Remarks on the Post-office Savings Bank 'Plan, extracted from part 5th of the forthcoming practical Treatise on Savings Banks" has been published by Layton, 150, Fleet-street. The scheme referred to, or one very like it, was proposed by Mr. Whitbread, M.P., so long ago as 1807; and the establishment of the penny-postage system since that time must go far to encourage the hope of its realization now; although the additional work implied in making the Post-Office a medium of transmission to and fro between savings banks and their customers seems to constitute a very grave element for consideration in reference to the practicality of such a scheme, more especially as it is proposed to make all such transmissions post free. That saving habits would thus be vastly facilitated and promoted there cannot be a doubt; but the formal titles of "Poor's Fund," and "Poor's Assurance," incidental to the plans proposed, do not seem to be calculated to favour the ends in view; inasmuch as those of the working classes who are likely to be benefited by the opening up of a frugal access, as it were, to the savings bank and the assurance office, are just those who are most likely to revolt at the idea of "Poor's Funds" and "Poor's Assurance," the word "poor" having become so inseparably associated with "poor-houses" and pauperism. And truly the man with 1,000*l.* a year who has difficulty in meeting his yearly liabilities is virtually as poor a man at least, as he who can save even a shilling a week out of his twenty or thirty. The plan referred to, however, seems to be essentially an excellent and desirable one, and would do great good were it carried out into full practice.—On "The Progressive Screw as a Propeller in Navigation," by Julian John Révy, C.E. (Weale, High Holborn), is a scientific pamphlet, the object of which is to consider the phenomena connected with the screw as a propeller in navigation, from the general physical point of view, as well as to show by mathematical formulæ the laws which govern these phenomena. The second section is devoted to the author's special subject—the "Progressive Screw," or the means of obviating the loss occasioned by the "slip" of the screw and by the shock of its concussion with the water.

## Miscellaneous.

THE BISHOP OF LONDON AND THE RAILWAY WORKMEN.—At the close of service at All Saints' Church, Derby, on Thursday last week, a deputation of workmen from the Midland Railway Station requested an interview with the Bishop of London, who received them with courtesy and cordiality. They expressed on behalf of themselves and their fellow-workmen a wish to hear the Bishop preach to them in their workshop, to which his lordship gladly assented, and appointed Friday, at dinner-time. The workshops on Friday furnished a congregation 2,000 strong, to listen to the bishop's address. The workshops on Friday were the place appointed for the service, and the platform of an engine, on the hand-rail of which was fixed a book-ward, served for a pulpit. The large shop was filled; and, after the service, his lordship expressed his delight with the attention that was paid during the service. After inspecting the locomotive-carriage department, the library, reading-room, lecture-room, and board-room, he expressed himself as having been highly gratified with his visit to the station.

THE GLASS TRADE.—Last week, the glass-polishers at the Ravenhead Glass Works, St. Helen's, numbering upwards of 100, turned out in consequence of a reduction in their wages from 2*s.* 6*d.* to 2*s.* per 1,000 feet of glass. They expressed their willingness to submit to a reduction of 2*d.* per 1,000 feet, but the employers would not agree to it.

ARTESIAN WELL, PASSY.—The interesting operation of boring at Passy is drawing to a close. It is well known that, after the rupture of the tubes or casings for the boring-rods for a distance of 46 metres from the surface, it was deemed necessary to excavate, in that damaged portion, a shaft, lined by cast-iron cylinders, 3 metres diameter, firmly bolted together. By this means the fragments of the tubes which were compressed by the weight of the surrounding sand were arrived at, and the boring continued again in full operation. It had already reached a depth nearly approaching that of the aquiferous green sand, supposed to be 550 metres below the plain of Passy. Before going any deeper at present, in order to avoid any sudden up-bursting of the water, a wooden shaft is being constructed of oak timbers, lining the whole shaft lately excavated. The chisel is of wrought iron, with seven teeth, and weighs over two tons.

EXPLOSION OF A LOCOMOTIVE AT KING'S-CROSS.—The frightful explosion of the bottom of the fire-box of an engine used at the tunnel of the underground railway by the contractors, whereby two persons were instantly killed, and another nearly so, while several others were more or less injured, has led to a coroner's inquiry, which was resumed on Monday last, and then adjourned. On Monday two or three scientific men were examined as to the cause of the accident. Mr. Amos gave it as his opinion that there was some defect in the original construction of a part of the engine; but Mr. England, another engineer, attributed the accident to an insufficient supply of water in the boiler,—an opinion which was shared in by an engineer in the employ of Mr. Jay, the owner of the engine. As the Government inspector did not arrive, and the friends of the deceased persons were desirous of further inquiry, the proceedings were adjourned for a fortnight.

AMALGAMATED SOCIETY OF ENGINEERS.—A dinner has been given in Radley's Hotel, Blackfriars, at the presentation, by the executive council of this society, to Mr. William Newton, of a testimonial for services rendered to their society and trade. Mr. Thomas Hughes occupied the chair, and was supported by some gentlemen who took an interest in the cause of the engineers during the strike of 1851. After the Chairman had spoken on the subject, an address, recounting the services of Mr. Newton, was presented to him, together with a silver goblet containing 300*l.* Mr. Newton, in acknowledging these gifts, incidentally observed that after the strike, "when they were bent, but not broken," the society commenced with only 7,000 members, to a certain extent disorganized and demoralized, but they had now more than 20,000. According to a statement made by Mr. Heaps, the president, the society has, since the amalgamation, about nine years ago, distributed among unemployed, sick, and disabled members, &c., 209,837*l.* exclusive of the expenses of management.

METROPOLITAN BOARD OF WORKS.—At the usual meeting of the Board last week a report was presented from the committee on drainage, and adopted, in reference to the stoppage of the works for the Northern Middle-level sewer. The report, after stating that Mr. Rowe, the contractor, had declined to proceed with the works, recommended that a notice be immediately served on Mr. Rowe, requiring him to proceed with them with due diligence, or threatening in three days to let them to other parties, holding him and his sureties responsible for all loss and damage. Mr. Tite, then moved, "That the Board take the necessary steps for a renewed application to Parliament in the ensuing session for the amendment of the Metropolitan Local Management Act." Mr. Tite stated that there was a general desire on the part of the different vestries of the metropolis that there should be a renewed application to Parliament for this amendment. Mr. Bristol, M.P., seconded the motion, which was carried. Mr. Tite then said that he would follow up this motion by moving "That the bill withdrawn by Mr. Tite in the last session of Parliament be referred to a committee of the whole Board, with a view to the consideration if any, and if so what, alteration should be made in it previous to its introduction to the House of Commons, and that the requisite notices be given." This motion was also carried.

Gas.—The Eastbourne Gas Company have determined to reduce the price of their gas to 5s. 10d. per 1,000 feet, being a reduction of 10d.

THE QUEEN'S STABLES, BUCKINGHAM PALACE.—The old riding-school and the stable adjoining Buckingham Palace have been improved and beautified very considerably. Mr. Theed has just now completed a group, "Hercules Taming the Mares of Diomedes," which is placed in the tympanum. It will probably be uncovered in a few days. The size is beyond that of life. The Americans will put it down as an idealism of Rarey.

WATERING THE STREETS.—Can you explain why our parish "authorities" do not make annual contracts, as they tell me that the reason the streets are now unwatered is, that the contracts expired last quarter-day, the 20th. Is there no dust apprehended in October, November, and December? Our streets require constant sprinkling, not flooding, with water: the same quantity of water properly applied would water twice the area. The common sense of the matter is, they should be systematically watered—done by the parishes themselves, and not left undone by a contractor.—A HOUSEHOLDER.

THE LATE ACCIDENT ON THE RAILWAY WORKS NEAR DOVER.—The adjourned inquest on the bodies of the three men who lost their lives by the falling of the bridge at Ewell, near Dover, was resumed, Mr. Vincent, of Canterbury, had, by the directions of the coroner, made a professional survey of the bridge. Mr. Warden, from the office of Messrs. Freshfield, the company's solicitors, attended to watch the proceedings. Further evidence bearing upon the case having been heard, the jury retired for about an hour, and then announced that they had agreed upon the following verdict:—Accidental death, and the jury suggest that the company should be more careful in building such bridges in wet weather. The verdict was not a unanimous one.

THE FIRE AT CHAPPELL'S PIANO FACTORY: DISASTROUS EXPLOSION.—While the firemen and others were engaged in extinguishing the serious fire at the extensive factory of Messrs. Chappell & Co., a fearful explosion of steam-piping suddenly took place, more or less injuring, it is said, no fewer than twenty persons, one of whom, a woman, who was looking on, died in the course of a few minutes on the ground. A piece of the piping which flew through a window and a partition fell upon and injured a man in head, and set fire to the sheets. The explosion, it is believed, was caused in this manner:—The fires in the furnaces having been extinguished, the steam in the boiler and the pipes had turned to water; and, when the heat of the fire became intense, the water suddenly generated steam so fast and in such quantities, that the pipes, being red with heat, gave way by the pressure of steam, and hence the melancholy catastrophe that ensued. Independent of the large loss of veneers and other goods, upwards of 100 valuable instruments have been consumed.

ART-NEWS FROM ABROAD.—We find the following in the Athenæum.—The church of Santa Croce, at Florence, displays, in the front now building, various figures of saints, prophets, &c., in inlaid marble, which are good examples of modern architectonic art in their way.—In the very extensive modern Campo Santo at Bologna, there is a regulation, probably a year or two old, that nothing new is to be put up save in marble. Meanwhile provisional monuments are erected, painted in imitation of sculpture.—The Townhall at Piacenza, a famous Mediaeval edifice, now a mere lumber-room, of no particular use inside, is to be cleaned out and employed for public purposes.—In the Brera, Milan, there has recently been held an Exhibition of the works of modern Italian artists: these being hung over the old pictures to a great extent, prevent the visitor from inspecting them. The former are generally poor in character, imitations in French styles.—At Luca it is reported that the barbarous atrocity is to be perpetrated of entirely removing the wonderful Lombardo-Gothic front of the church of San Michele, on the ground of dilapidation, and putting up a modern facade-simile of the sculptures and decorations.

HANDSWORTH SCHOOLS COMPETITION.—Sir,—In reply to your correspondent, the Handsworth Bridge Charity trustees, with the assistance of an architect, have selected my plans for their proposed schools. Some little delay was occasioned by the trustees desiring a detail bill of quantities, together with a contractor's tender, both of which I submitted at a meeting held on the 15th ult., when the resolution in my favour was adopted. GEORGE BIDLAKE.

THE WELLINGTON MONUMENT IN ST. PAUL'S. An "Inquirer" asks "What has become of the monument of the Duke of Wellington? It is now eight years since his death, and we seem to have no chance of ever seeing the 20,000l. voted for his monument made visible." We believe Mr. Stephens is making progress with the full-sized model. Mr. Calder Marshall and Mr. Woodington are commissioned to execute bas-reliefs to be fixed round the chapel at the west end of nave (south side), in which the monument is to stand, and they are at work upon them.

THE DOCK-WORKS AT LIVERPOOL AND BIRKENHEAD.—The total expenditure at Birkenhead, for works, exclusive of land, from its commencement, according to returns read last week in the Liverpool Council, has been:—The Great Low-water basin, 103,191l.; Great Float, 256,710l.; restoration of walls of Great Float, 60,720l.; Morpho Dock, 14,895l.; Northern entrances, 45,878l.; graving docks, 24,217l.; river wall, 46,724l.; Wood-side enclosure, 23,754l.; Seacombe sewer, North-road, and other new works, 36,915l.; repairs of old works, 10,844l.; engines, machinery, &c., 8,508l.; total, 709,093l.; total stock in hand, 40,000l. Grand total of expenditure on Birkenhead, 749,093l.—Expended on Egremont and Seacombe river wall, 14,043l.; paid Corporation of Liverpool on account of works constructed by them, 79,911l. Total expenditure at Birkenhead from 1st January to 31st October last, 275,557l., of which 48,000l. was expended on Great Low-water basin. The expenditure at Liverpool for works, exclusive of land, from the commencement, was,—upon Inland Carriers' Dock, 228,770l.; and from 1st January to 31st October, 19,312l.; Canada Half-tide Basin, 59,000l., of which 47,000l. incurred this year; Branch Dock, 27,905l., of which 22,504l. expended since 1st January. Total expenditure this year, so far, at Birkenhead, 275,557l.; at Liverpool, 89,782l.

INAUGURATION OF A TESTIMONIAL DRINKING-FOUNTAIN AT NORTHAMPTON.—A meeting was recently held in the Town-hall, Northampton, at which Mr. W. Collins presided, in reference to a testimonial to the Rev. Mr. Hutton, M.A., late chaplain of the Northampton County Gaol, and now rector of Stilton, Hants. An address was presented to the rev. gentleman by the mayor, Mr. E. F. Law, stating that the subscribers desired to record their appreciation of his services during a residence of eleven years, by permanently associating his name with a substantial monument erected as a drinking-fountain, under the conviction that such a testimonial would be most in accordance with his own feelings, and contribute most to the welfare of those on whose behalf he had invariably manifested so warm an interest. The reverend gentleman cordially thanked the subscribers. The inauguration of the fountain then took place. It is a standard or pedestal one, and built of stone in the Gothic style, and was designed by Mr. E. F. Law, of Northampton, architect. It is situated at the intersection of four roads, and affords a supply to animals as well as man, the water flowing out of an octagonal basin down the shaft into four dog-troughs at the base.

LECTURE ON PRINTING.—Mr. Ellis A. Davidson, head master of the local Government School of Art at Great Neston, in Cheshire, recently delivered a lecture in the new school-room there on "Printing; its History, and its Application to the Arts and Commerce." The chair was taken by the Rev. R. W. Gleadowe, who opened the proceedings with a short address. Mr. Davidson illustrated his lecture by various mechanical appliances and processes to show how types were cast, wood and copper-plates engraved, and lithographs printed, &c.; and exhibited fac-similes of illustrations from the "Book of Chess," the first book printed in the English language. The lecturer then quoted from Mr. Knight's work an interesting account of a meeting of the printers after Caxton's death,—their doubts, hopes, and fears; they wished to print the Bible; for, they said, "no doubt the time may come when each parish will require a Bible, but they said they despaired of ever getting them circulated, as the king would never mend the roads, and men would be frightened of having their throats cut, and of starvation." One of them was more hopeful than the rest, and wonderfully indeed, said Mr. Davidson, have his most sanguine hopes been accomplished. The average number of Bibles, Testaments, and religious works published annually by the British and Foreign Bible Society, and the Society for Promoting Christian Knowledge, is 38,000,000, printed in about 150 languages, and again sub-divided into dialects; and this is besides the large number published by private firms.

TENDERS

For taking down and rebuilding a Foreman's House and Office Buildings, at Grays, Essex, by Mr. W. A. Homerdam, architect. Quantities supplied by Mr. J. A. Barker:—  
Ward ..... £665 0 0  
Fowler ..... 647 0 0

For a house for Mr. Thomas Cole, Clapham-road, Wandsworth-common. Mr. G. H. Page, architect:—  
Eastman, Battersea ..... £1,177 0 0  
Notley, Clapham ..... 1,149 0 0  
J. & C. Todd, Brompton ..... 1,049 0 0

For the erection of a house and premises in Houndsditch. Messrs. Richard Tress & Chambers, architects:—  
Corder ..... £3,404 0 0  
Hawtry & Son ..... 3,393 0 0  
Deards ..... 3,350 0 0  
Macey ..... 3,298 0 0  
Brass ..... 3,247 0 0  
Lawrence & Sons ..... 3,240 0 0  
Brown & Robinson ..... 3,157 0 0  
Willson ..... 3,111 0 0  
Coleman & Son ..... 3,059 0 0

For alterations at 59, Upper Stanhope-street, Lambeth. Mr. F. F. Holsworthy, architect. Quantities supplied by Messrs. Lansdown:—  
Battenbury ..... £785 0 0  
Keys & Head ..... 754 0 0  
Wicks ..... 732 0 0  
Tyler ..... 720 0 0  
Patrick ..... 715 0 0  
Jeffs, Brothers ..... 409 0 0  
Keut ..... 672 0 0  
Shenan ..... 615 0 0

For alterations at Brunswick House, Old Kent-road. Mr. F. F. Holsworthy, architect. Quantities supplied by Messrs. Lansdown:—  
Wicks ..... £459 0 0  
Keut ..... 448 0 0  
Patrick ..... 422 0 0  
Jeffs, Brothers ..... 409 0 0  
Tyler ..... 398 0 0  
Shenan ..... 267 0 0

For the erection of three villas at Woodford, for Mr. Bartholomew. Mr. W. Williams, architect. Quantities supplied by Mr. Robert Carls:—  
Page ..... £2,250 0 0  
Stevenson ..... 1,594 0 0  
Hedges ..... 1,350 0 0  
Hill ..... 1,245 0 0  
Rivett ..... 1,513 0 0  
Raby ..... 1,467 0 0

For building "Palace rooms," Kensington, for Mr. F. Hellewell. Mr. Withers, architect:—  
Evans ..... £1,620  
Sutton ..... 1,590  
Rowland ..... 1,557

Elm Schools and House.—A tender has been accepted from Mr. Brown, of Lynn, by the committee for the above buildings, under the direction of Mr. S. S. Teulon.

TRADE CATALOGUES.—"One cannot but be struck with astonishment at the innumerable ways in which an enterprising tradesman appeals to the public with a view to increase his trade. Printing in all its branches, assisted by the skill of the wood engraver, seems in the present day to be one of the media most generally employed in spreading the knowledge of various manufactures. These arts have ably been brought into use by Mr. Benson, the eminent watchmaker of Ludgate-hill, who has sought, by means of an "Illustrated Pamphlet" (consisting of nearly 60 pp., and containing upwards of 250 beautiful designs for watches, clocks, &c., with an elaborate description of every construction of watch now made), to enable persons living in any part of the world to select the watch best adapted for their use, and have it forwarded free by post."—Sun, 23rd August.—ADVT.

ADVERTISEMENTS.

MR. WILLIAM ELLISON, CONSULTING SURVEYOR, late of STAINBURY ROAD, 13, FENCHURCH-BUILDINGS, FENCHURCH STREET, E.C. Where he continues to advise BUILDERS. ON TENDERS OF CONTRACT, DISTURBED ACCOUNTS, &c.

ARCHITECTURAL ASSISTANCE.—Every description of Architectural Drawings, Plans, Elevations, and Sections prepared, and Perspectives Painted, Etched, or Coloured, by Mr. T. T. BARNUM, Junr., also, Designs, and the Contracting of Engineering Drawings, Survey, &c.—Address, Mr. BARNUM, 6, Great James street, Bedford-row, W.C. Office hours, Ten to Four.

TO ARCHITECTS AND OTHERS.—Competition, Working, and Detail Drawings, Suggestions, and Estimates, for Building Colonnades, and other works, from notes or sketches, SURVEYS, LEVELLING, LAYING OUT ESTATES, and all descriptions of Professional Assistance, RENDERED.—Apply to E. BASSSETT KEELING, 3, Upper terrace, Edlington, N.—City Office, 32, Fleet-street, E.C.

# The Builder.

VOL. XVIII.—No. 928.

Some of the Work we have to do.

LENTY of work remains to be done,—work architectural and work sanitary, work artistic, and work social,—notwithstanding the progress which has been made,—as we showed in our brief retrospective sketch last week,—since the commencement of the present half century. It may not be useless now to point out some few of the tasks that require to be performed—some of the obstacles lying in the road that will need removal, when we turn our faces towards the work we have before us. These are no new difficulties: we have known all through that they are in the path, just as Christian knew he would

have to pass giants, lions, dragons, and tempters, on his road to the Celestial City. But there is the same armour for us that there was for him: we have only to suffer Energy, Knowledge, Charity, and Discretion, to huckle it on, and the difficulties that beset us will disappear: we shall find, like Bunyan's hero, the lions chained and the dragons harmless.

There is a big giant lying in the sludge who must be slain early. A mighty river runs through the heart of the richest city in the world. This stream, instead of bringing health and healing on its bright waters to the three millions of inhabitants living around its banks, is suffered to become so foul, by the discharge of common sewers into it, that at certain seasons it is as a rotting sea, where "a thousand thousand slimy things" disport themselves, and whence is wafted into the crowded streets an odour that even the long-suffering statesmen, legislating in the palace on its shore, have pronounced unbearable. If we were to hear of this circumstance in connection with some foreign city—St. Petersburg, Constantinople, or Damascus,—we should exclaim,—“Benighted people! they should bargain with English enterprise and English energy, and their river would be purified in a month!” But the current rendered so offensive—thus converted into a *Cloaca Maxima*—is no other than the Thames: it flows past regal Windsor and through commercial London. And what has our proverbial indomitable pluck been doing? With the exception of calling meetings, and appealing to the public through the columns of the press, this giant has been left unfettered, to work as much ill as summer-heat permits him. Thanks to an overlooking Providence, he was this year weakened with rain: his nasty strength was washed out of him. The higher and middle levels of London sewerage are being attended to, but the attack upon the lower level and its attendant Thames embankment has yet to be made. When the health and pleasure giving river, transformed into a pestilent sewer, has been brought back to its original condition, and that which befouled it and plagued the nostrils of the town has been made to fertilize the earth and minister to man's support, we shall indeed have done a work of mark.

We find, not only in the metropolis and its suburbs, but in country towns, and more fre-

quently still in villages, houses built upon undrained land, without the slightest provision for sewerage. Here then, again, head and hands are needed. We know that the effluvia arising from the deposits that must necessarily be made around such places, must so affect the air in the immediate and surrounding neighbourhood, as to render it fruitful with fever and other epidemics: and we calmly suffer this state of things to continue. This absence of compulsory drainage is the next enemy we must vanquish. There is already a force in the field against it. Local boards of health should obtain powers, and stringently insist upon proper means of drainage being afforded to every inhabited building; whether new or old; whether in remote or public places; whether occupied by a pauper or a peer. They should get powers, too, to look into all buildings let in tenements, even if they stopped there. Having disposed of these monster evils, we should have leisure to consider how many lives might be saved annually, by the more general use of fireproof floors and staircases. The expense of the former might be too considerable for the lower rate of houses; but no consideration of this kind should prevent the universal use of fireproof staircases in habitations of many stories. A glance at Mr. Braidwood's statistics shows us that there have been upwards of 800 conflagrations annually, of late years, in the metropolis; and, what is more to our purpose, that the number of fires is on the increase. Who, that has seen the pale figure of a human being at the windows of a house on fire, wildly imploring rescue,—who that read the harrowing details of the burning last week of the Kildare-street Club-house in Dublin, when James Wilson Hughes, the hookkeeper, showed us what heroes live amongst us unknown, can have a doubt about the propriety of building all tall houses with fireproof staircases, and with proper arrangements for escape? In the construction of our houses generally, other great changes are desirable: they are full of evils which wait to be conquered.

Then, in the matter of homes or harbours for our noble fleet and the still more noble seamen therein employed, we have a large margin for improvement. The recent instance at Alderney, where the frigate *Emerald* was jammed hard and fast upon a hidden rock, in the very centre of the harbour, shows that we do not always take the trouble to learn whether we are enclosing a man-of-war, or a reef, or any other danger, in the bosom of our refuges from sea storms. We have diving-hells, we have dredging-machines, and we spend, ungrudgingly, many thousands of pounds weekly on our harbours and docks. When we are about to build a harbour, we must ascertain whether we shall have any enemies to contend against in its deep bed. And we should also take careful soundings of our existing harbours, to prevent the recurrence of danger similar to that which the ship we have named, with the two batteries of the 15th brigade on board, so narrowly escaped. Then, too, we must form many additional harbours of refuge, and more lighthouses, to render our seas, under Providence, as safe as our high roads.

Many of our provincial towns, wealthy and thriving, are in a discreditable state, and need thorough revision and improvement. A correspondent entitled to speak writes to us thus appositely:—

“I was at Leeds,” he says, “about ten days since for three or four hours, and I was surprised and disgusted to think that such a wealthy place should be so mean and filthy. It forms a sad contrast to the towns abroad of a like description, where, by means of ample local funds, the municipalities can afford to do noble works and found grand establishments.

Their Brigade at Leeds is a wide thoroughfare, but with low-class shops on each side, and reminded me of the High-street in the Borough (Southwark): the end is blocked up by a building running quite across. There are no cross streets of any ample width, and you have to go from one side to the other of the town through streets about the width and character of Drury-lane.

Look also at Portsmouth. Imagine the millions that must have been spent there commercially. Yet no percentage, however insignificant,

has been set aside to render it tolerable, convenient, or healthy.”

He continues:—

“We want an autocrat, as at Paris and Lyons, to compel noble lines of access and thoroughfare to be formed, and introduce salubrity, comfort, and nobility into most of our towns. This should not be left to the enterprise of an individual, as at Newcastle, or to the spinniness of low interests and selfish money-makers. Here is a fine topic for the *Builder*. Analyse our provincial towns in detail—lay bare their biddensness, and suggest their improvement. Shame them, and good must be done. Our recent legislation for such matters has been only *permissive*; it should be *imperative*. The *Builder*, I know well, has done much in this way already: let it do more.”

The want of enlarged views in our cities and towns is undeniable. We may presently take some additional steps to make evident the necessity for change in this respect.

We have so often and so recently called attention to the great need of still further and more general improvement in the dwellings of the poor in the metropolis and elsewhere, that we should forbear to touch upon it here if the subject did not stand out from the work we have to achieve as a task of gigantic magnitude. The poor, we have been assured, we shall have always with us. It well becomes us to do our utmost to lighten their lot. Sunshine was given alike to all, save the blind; and as its vivifying influence is now so well understood, how resolute we should be in securing its admission into all dwellings, more especially those of the poor and those intended for the sick! The repeal of the window-duty has left the matter entirely in the hands of the public. There is no reason why large and numerous windows should not permit the glorious sunrise, daylight, and sunset to flood into the meanest home. We are taught, in a proverb, to regard cleanliness as standing next among the virtues to godliness; and we all fully recognize the advantage of cleanliness in a class that it is the fashion to call “the great unwashed.” But who, unless endowed with more than average energy and health, could he clean with no water, but little light, and less air? So it behoves us to urge, and re-urge, as we have done before and hope to do again, the imperative necessity of seeing that all the children of Adam and Eve under the rule of our most gracious Queen are properly housed, allowed to breathe fresh air, and supplied with pure water. Not only those whose daily course is run in the dingy, melancholy back streets of the metropolis, or who are engaged in the various trades of our manufacturing cities, but field and farm workers and labourers of every description require protection, or instruction which would enable them to protect themselves.

In the northern counties, for example, the homes of shepherds, or, as they are there primitively termed, herds or hinds, consist but too frequently of four bare walls spanned by a roof. Even the fireplace and the window are considered fixtures, and must be furnished by the poor tenant. When he takes possession of this attractive tenement he puts up two wooden beds, resembling euphoards, across the chamber, by which contrivance a division of the premises is effected,—the one side of the box-heds to be the living and sleeping-room of his family, the other the manger of the cow, if he be a hind and possess one. Where there is no cow the same division is effected in favour of the coals. The window and grate, brought from the last home, have to be fitted to the present openings, or *vice versa*. The widow is of the smallest dimensions, because, when it was made, glass was costly: the grate is absurdly large, because coals are cheap. The dresser is next set up, and the wife arranges her delf; then the man pulls out his pipe, and is “at home.” If he is not particularly fond of it, he is looked upon as a social monster. But this is seldom the case! The love of home—even of such poor homes as these—seems part of our common nature; and, in case of foreign invasion, the hinds and herds we speak of will be as ready to protect the land, sacred to this beautiful sentiment, as the lords who own it. Consider, then, the height to

which their patriotism would attain if their homes were decent, with no vague smell of cows pervading their bedding, their food, their clothes; if the wife had a wholesome larder to keep her bacon, milk, and home-made bread in; and if the barns had plenty of water to wash with!

Model lodging-houses are essentially an institution of these latter days. If we made them a little less like factories and barracks, it would go far to give an air of home to them—a quality those experimentally erected can hardly be said to possess. As a suggestion for further consideration, we might inquire how far infant schools and playgrounds in connection with the lodging-houses for married people would be conducive to the general weal. But we must here leave our prospective sketch, though it be but washed in, and does not embrace half the subject. Our workhouses, hospitals, manufactories, and barracks, all offer evils to be conquered, and we have not said one word of the victories that wait to be achieved in the higher realms of architectural art. The Usefulness of the Beautiful must be everywhere enforced. We must not merely get rid of the ugly, but we must set up what is handsome.

#### THE PROPOSED EDUCATIONAL QUALIFICATION FOR ARCHITECTS.

WHEN the president of the Institute calls this proposal a *vital* question, he assigns to it no exaggerated importance. It is by far the most weighty question that the Institute has ever raised. It is a question to which the past policy of the Institute may not be found to apply. It is the question whether the Institute itself shall assume a character, perhaps ultimately a form, essentially new. It is the question whether the time has arrived when our profession may safely abandon those principles of recognition which have hitherto been accepted, and initiate a system more advanced and more honourable, but more difficult and severe. If such a question should be settled at haphazard, without adequate investigation,—if the programme of a few should be accepted on personal considerations, without thorough discussion among the many,—or if the project should be abandoned, as is not unlikely, for the sake of avoiding a little confusion and controversy,—then in either case the danger is considerable that the effect upon professional progress for the next twenty years may be very prejudicial indeed.

Whether the promoters of the scheme now before us have adopted the best possible means of bringing it forward, or what may have been the influence of a policy which for many years has caused much serious complaint, are points which are not unimportant practically, but which there is no pressing need to discuss: but certain it is that for a *vital* question the amount of public interest excited by the *pronunciamento* of the council has been small. A short note of warning on the part of our most respectable old school has once or twice appeared in your columns; and we have seen certain formal reports of the opinions of provincial societies, as called forth by the invitation of the Institute; but of that public comparison of opinions, through the medium of the press, which in such a case must necessarily precede official action, if this is to be of good effect, there has been none.

The judicious postponement of the Institute discussion gives us now several weeks (and several numbers of your journal) to remedy this condition of the question; and it is to be hoped that those who really feel an interest in it will come forward, even at this eleventh hour, and let us know their views.

The point for investigation, as it seems to me, is this: here is a craft of grand antiquity, numbering on its long list of brotherhood many of the most illustrious names of mankind; a craft which, in its highest efforts, deals, not merely with large amounts of property, but with the most enduring and the most impressive of all human works; a craft high in merit and public esteem, the pride of an extended class of refined minds in every country of the civilized world; a craft, lastly, in whose fascinating art and responsible science we have reason to assert that, at the present day, England, to its infinite credit, takes decidedly the lead. Other crafts, of dignity no greater but often less,—of value not superior, but often inferior in public estimation,—demanding, in respect of that quick and subtle judgment which is the test of professional usefulness, no more and often not so

much,—present themselves to the fastidious criticism of the day, with all the advantages of that complete elementary training for which nothing else, whether under the name of experience, or talent, or genius, will be fit for criticism for a moment accepted. Query, then, has the time come, or has it not, when this craft of ours shall be able to admit into its organization the element of special education?

Special education! exclaims the outside public. Is it possible that in 1860 a vocation such as yours has not even attained to special education? Is it true, indeed, that one half of the "architects and surveyors" of the Directory, have never been even "brought up to the business," pitiful as in the hands of some of them that business is? That of the other half, who have at least had a few years of office-routine in their youth, not one can boast of having pursued a recognizable curriculum of study? "Why," says the public, "that is a state of what is called *quackery*!"

Accordingly, when the Institute comes forward at length, and asks leave to amend itself, and through itself the profession at large, in some educational direction, the project must inevitably receive the support of the entire voice of the intelligent classes of the community.

Now, if the educational principle be really the question which is before us, we become prompted to make such inquiries as these:—1st. Whether it has been properly so understood out of doors; 2ndly. What the scheme is in detail; 3rdly. What is the *modus operandi* suggested; and so on.

I propose just now to go no further than the first inquiry,—whether there is reason to think the body of architects at large have understood the scheme of the council aright as an educational measure.

I venture to think we have not so understood it. Whatever discussion has as yet taken place, seems to turn altogether upon another idea—the idea, namely, of a *diploma of license*, as the be-all and end-all; not that of a *curriculum of training*, to which a diploma may be a useful appendage, and no more. Some have even gone so far as to call for a legislative enactment,—positively to suggest that the House of Commons should pass a Bill,—to confine architectural practice to the possessors of the diploma! And this diploma to be conferred upon what principle? The mere principle of *regular-dustmanhood*! The sole object in this view of the case actually seems to be the establishment of a fictitious certificate, with academical pretensions, to distinguish the *soi-disant* regular from the irregular practitioner!

No one, I am proud to think, can charge it against the programme of the Institute council that any word of it is meant to encourage so wild and so unworthy a notion. It is beneath the level of the scheme; and it only seems surprising that any class of architects should have so misunderstood a question so plain. The fact, however, of such a misconception having been entertained to any considerable extent goes far to show that the time has *not* arrived for the movement to be carried into effect; but I hope it will at least appear, for the credit of the profession, that the error has been but a passing inadvertency, which a word of explanation suffices to correct.

The duty which is suggested to us is the origination, not of any trades' union for the present, but of an academy for the future. We are called upon, in view of the deficiency of our own education, to establish for our pupils a hetero-system. I can well understand that there is something here which on the surface may appear to certain minds distasteful; and hence one other source of hesitancy. Why should he who is too advanced in age to cram for examination, or too much occupied in business to find leisure for the remedy of his own shortcomings,—why should he confer upon his juniors an honour and substantial mark of merit which he himself cannot obtain? Why should he proclaim his pupil to be more worthy of the public confidence than himself? Let me ask another question. Who says that an Englishman is made of no better material than querulous, jealous, envious stuff like this? The men of our noble craft, when they come to think over it, are proud of the boys that are about them: they are not rivals, but sons; and I will never believe of any one of us that he would prefer the delusive appearance of a trilling personal advantage to himself, to that magnanimous motive which is inherent in every man's spirit—the desire to leave the world better than he found it.

Moreover, it could be very easily proved that in respect of public standing there is nothing to be dreaded by the established practitioner from the possession by the beginner of an educational

certificate. It would be long before the value of a diploma came to be recognised. Indeed, that it must fight its way by merit, and that this would be a slow process, everybody knows. If an educational system were established to-day and the first diploma signed to-morrow, there are many of the strongest of us who would never live to see the practical value of either the one or the other. We are looking twenty years ahead at least: we ourselves may feel perfectly safe. And if another argument is wanting, let it be this. When we are asked, even if it be only ten years hence, how it happens that young So-and-so has his diploma and we have none, our answer is—*we gave it him!*

After all this, however, it does not follow that the time has come for the organization of a system. This question must be decided on proper evidence. I hope such evidence will be in favour of the affirmative; but I cannot say as yet how it will be. But one thing I can say: this question is the preliminary of further inquiry; and if evidence goes to the negative it is vain to discuss the project in detail. To force an educational system, even of the best, upon the profession prematurely would be a more serious error than to delay it too long. When it is done it must be well done, but it must also be done wisely. R. K.

#### RECOLLECTIONS OF SICILY.\*

THE temples which are specially referred to in my own notes are those of Juno Lucina; of Hercules; of Concord; of Jupiter Olympius; of Esculapius; of Proserpina; and of Castor and Pollux. At least such are the deities to whom these ruins have been assigned by the local antiquaries. Most of the buildings present but a confused mass of mutilated blocks and fragments piled together. This is especially the case at the temple of Hercules and that of Castor and Pollux. So confused a heap have they become, that it is impossible to define their plan on a mere superficial inspection.

Some of the blocks of stone thus piled together are of colossal dimensions. Even at the small temple of Proserpina I measured a block 8 feet 6 inches by 3 feet 10 inches, by 2 feet 10 inches, weighing, therefore, five or six tons.

Indeed there are, when viewing these stupendous ruins, few things that excite more surprise in the mind of the architectural observer than the wonderful solidity of the mode of building practised by these Greeks. It is not flattering to contemplate the wide difference of practice in this respect between the builders of the sixth century *before*, and of the nineteenth century *after*, the Christian era. It was a saying of Plato, as reported by Elian, that "the people of Agrigentum built as if they were to live for ever, and feasted as if they were always about to die." Elian goes on to say that "Timaeus reports that they use oil-flasks and strigils of silver, and had entire couches of ivory." Such was the luxury in which they lived.

It should not, however, be overlooked that the contrast between the *domestic* architecture of the Greeks and that of our present generation would probably have gone far to redress the balance, if the Greeks had left behind them any adequate means of comparison.

The temples of Juno and Concord are the least mutilated, and in their ruin present most beautiful and picturesque objects. The temple of Jupiter is the most remarkable, both for its magnificent size, with the flutes of its columns 16 inches wide, and for the singular example it offers of the use of Caryatides in interior temple architecture. These Caryatides were built up in courses, like columns, and are about 25 feet high and 6 feet across the hips. One was lying on its back at the period of my visit, having been recently put together by Signor Politi. There had been then found portions of nine other similar statues.

An idea of the huge proportions of this temple may be gathered from the fact that the diameter of the columns of the peristyle is not much less than two-thirds the size of that of the monument on Fish-street Hill.

Little need be said of the modern town of Girgenti. It is built very irregularly, but is of some extent, and is not without some visible signs of a certain degree of prosperity. There is an extensive ecclesiastical seminary, and a cathedral. The latter is a modern structure, remarkable for a portico-voce, which it is usual to point out to the notice of strangers. Although the building is of great length, a low whisper at the west door is said to be distinctly audible behind the altar at the eastern end, and that notwithstanding the

\* By Mr. Sydney Smirke, R.A. See p. 715, ante.

interception of a transopt. I had, however, no opportunity of observing the phenomenon myself, on account of the sounds attending the performance of service at the period of both my visits to the building. I should add that the nave consists of a Doric colonnade, with a continuous, unbroken entablature,—a circumstance no doubt favourable to the conveyance of sound.

The baptismal font is remarkable, being an ancient sarcophagus, of classic workmanship, applied to this very different purpose. The sides are sculptured with figures about 3 feet high, the subjects being taken from Phœdra and Hyppolitus.

Many doors and windows, and other details are met with in the town of Girgenti, of Norman architecture, in which the Chevron ornament is profusely used,—a peculiarity the more notable from the general absence of that ornament in Italy; contriving, therefore, to strengthen the presumption that the Norman adventurers brought their arts as well as their arms to this island.

I cannot quit Girgenti without here bearing testimony to the kind courtesy of Signor Politi, a highly cultivated antiquary and scholar, whose refinement was the more striking when found amidst a semi-barbarous and ignorant people. Nor can I in these desultory notes refrain from jotting down the inscription which I observed painted on the exterior of his bookcase, bearing melancholy testimony to the irregular habits of some of his ungrateful visitors:—

"Perduto o multo libri col prestanti;  
Contentati. Letter, soldi intratti,  
Se dell' avviso a proffitar se' inabile,  
Un grande minchione sei immolchionabile."

A ride of forty miles over a level and richly-cultivated country brought me to Sciacca, a large rambling town, wearing an aspect of so much poverty as to excite one's regret that a country so richly endowed by nature should not be in the hands of a more active and industrious people.

The only architectural object here was a convent of nuns, outside the eastern gate, which was a large and striking building of perfectly Medieval character, and, as far as could be judged from the exterior, but little modernized. The impossibility of gaining admission of course greatly increased my desire to enter: a visit to the interior would doubtless have been, as it were, to step back into one into the Middle Ages: but my curiosity was not destined to be gratified. Twenty-four miles' ride brought me to Castel Vetrano, a town at no great distance from the ruins of Selinunte. This ancient city is now only a dreary waste of mutilated masonry. It is, in fact, even more entirely ruined than Agriguntum. It appears to have been built upon two low hills, close to the seaside. Little of all this vast tract of ruin is now traceable, except some of the external walls, and portions of some temples. While wandering over these relics of a wealthy and active population long since passed away, I met with a well of undoubted antiquity, and of peculiar construction, being lined with cylinders of terra cotta, still in excellent preservation. This Greek mode of forming a well appears to me to be on a sounder, more sensible, and more workmanlike principle of construction, than the modern mode of staining wells with bricks or small stones. The internal diameter of these cylinders is 2 feet 1 inch; the uppermost cylinder being a trifle larger; the thickness of the sides is about 1 inch, and their ends are thickened to 1½ inch, for the purpose of increasing their strength, and giving them a better bearing on each other. The durability of the mode of construction is proved satisfactorily enough by the present perfect condition of this example, and that it would exclude impure and superficial springs better than ordinary brick staining, must be obvious.

Adjacent to the ruins of the city are the remains of three fine Doric temples. That which is the farthest from the sea is of magnificent dimensions; very little smaller than the great Temple at Agriguntum. I will not dwell on these temples, for they have been already made familiar to most of us by various published illustrations. Their style is somewhat heavy and archaic. The metopes found here by our respected member, Mr. Angel, together with Mr. Harris, are well known to all of us, and being in our great national Museum. These bas-reliefs are carved in a limestone quarried at the Istoma of Campo Bello, seven or eight miles distant, which appears to have supplied materials for much of the architecture of the ancient city; although many fragments of white marble are to be found scattered about.

At this quarry, which I did not fail to visit, I observed the mode adopted of getting out the

cylindrical blocks, or drums, for the shafts of the columns. They appear to have been cut or scarified out *in situ* from the living rock, the cylindrical blocks being worked out to nearly their true size and form by forming a channel, or interval, all round, so as to render them insulated, although still undetached from the living rock. The length of each block was of course regulated by the depth of the cutting around it, or rather perhaps by the depth of the vertical face of the rock at its escarpment. In some cases I found these drums 10 feet high. By what process they were detached and lifted from the parent rock does not appear from any indication that I could discover. Many of these portions of great Doric columns remain in various stages of completion at the quarry, just where they have lain undisturbed ever since the overthrow of the Selinuntines, in 409 B.C.

What a picture of retrogression do these appearances present! When the world was not much more than half as old as it is now, there existed here a great, rich, and even civilized population. That the people were vigorous and energetic we see plainly by their works; that they were highly civilized we may infer from the character of their art; yet now the silence of desolation prevails amidst a scanty and degenerate people, who allow all these remnants of their ancient greatness to be unheeded.

As to Marsala, my next resting-place, I have a livelier recollection of its *wine* than of any more professional object of research. I have a few notes, however, on the cathedral here, which is in an ornate, but modern, style, with marble pillars, said (but I know not with what truth) to have been originally intended as a presbytery, or oratory, to the chapel of St. Thomas à Becket at Canterbury. It is unnecessary here for me to inquire how far these Roman Doric pillars would have consorted with the architecture of that venerable archiepiscopal pile.

From thence I proceeded to Trapani (where is a great fishery for the shells used by the carvers of Cameo ornaments), and then Catalini (or, more properly, Calatafimi), and three or four miles beyond the latter place brought me, over a rugged, mountainous country, to the remains of ancient Segesta.

Except the striking and beautiful remains of the one well-known temple, and part of the external walls of an amphitheatre, the whole city presents an undistinguishable mass of mutilated fragments of worked stone, covering a very extensive area, and baffling all attempts at defining any separate building. Never was there a picture of more complete destruction; but it cannot be doubted that an explorer, having abundant leisure and energy, might reap here a rich harvest, were he to proceed methodically to lay open the contents of the piles of worked stones that have been lying there undisturbed for so many centuries.

I will not enter from my note-book upon any description of the temple here. Justice has been done to it by Scarradifaleo and others. I would, however, remark that there are various unmistakable evidences of the building never having been completed: its progress, we may presume, was arrested by the utter and final discomfiture of Segesta by the Carthaginians. There are rough bosses projecting from the face of most of the stones of the plinth; left there, no doubt, to facilitate the hoisting and setting of the stones, and intended to be subsequently worked off. The shafts of the columns, also, are unfinished, the surface appearing to be left for the flutes to be worked afterwards. We may infer from these indications that the practice of the Greek masons was to finish their work in detail when up, and subsequently to the erection of the building.

Were this practised more frequently by ourselves, we should both save expense and gain effect; for it is impossible to prevent a mason from over-labouring his work when done on the banker. But our workmen are too apt to be opinionated and intractable, and influenced by routine and prescription.

After a ride of about thirty-six miles I reached Palermo, situated in a beautiful bay, and surrounded by the richest country, and by, perhaps, the loveliest wooded hills I have ever seen.

No traces remain here, as far as I know, of the more ancient inhabitants of this island; but that it was the favourite resort successively of the Saracen and Norman masters of the country is abundantly testified by a variety of existing remains.

The cathedral is remarkable for a diversity of styles; with a modern dome, a florid Gothic porch; the rest of the exterior for the most part Norman,—such, at least, is the term which conveys nearest to its correct designation, for it was built

during the Norman rule, although it is a Norman widely differing from that of the north of Europe. This deviation is, probably, due to the strong infusion of Saracenic workmanship, which it is easy to account for. The Norman ecclesiastics, no doubt, would bring their knowledge of architecture to bear upon whatever churches they may have caused to be built when the island fell under the dominion of their race, and the plans of their churches are strictly Norman; but the actual carrying out of the work must have necessarily been entrusted for the most part to the Saracenic natives, who were excellent masons, and belonged to a far more æsthetic faith than the rude crusaders from the north. It was natural, then, that much of the ornamentation, and many even of the leading forms, should savour of the Eastern art, both Byzantine and Arabian.

The Royal Chapel, the church of S. Martorana, and the cathedral at Morreale, a few miles distant from the city, are, as regards their earliest portions, interesting examples of this modification of Norman architecture, and are in their style generally similar. The walls and other flat surfaces are incrustured with inlaid marbles; their vaultings, spandrels, and soffits, as well as portions of their walls, covered with mosaics of Byzantine workmanship, as is apparent from the Greek costumes, prevalent throughout. These arches are pointed, without mouldings or splays; and for the most part they rest on ancient marble shafts, no doubt derived from Classical buildings, with capitals often imitating in a rude way the Roman work.

The subject of Saracenic art in Sicily is not yet in a very satisfactory position. Since a paper in the twenty-first volume of the "Archæologia," written by myself when but a tyro in the archæology of our art, and before the existing examples had been critically examined by travellers, various writers have treated on the subject, who have not in all cases had any personal knowledge of the buildings themselves.

There can be no doubt, with respect to the churches I have named, that they are of Christian, and therefore Norman, origin, dating from the early to the later part of the twelfth century. But there are two secular buildings, the Ziza and the Kooba, that belong to a very different category.

That they were the palaces of the Saracenic emirs before the invasions of the Normans, there are, I think, the strongest possible grounds to believe. The fountains and alcoves, the interior courtyards, the numerous Cupic inscriptions, all savour of Oriental taste and art, and are identical with the domestic architecture of the neighbouring Asiatic continent.

The very name of the Ziza may be identified with the name of a caliph of the tenth century; and as to the Kooba, that is a Saracenic equivalent to a cupola, a covering, a tent; and there are said to be Koobas all over the Moslem world.

Roger, the first Norman king, in an existing diploma, speaks with regret of the marvellous palaces ("Palatiorum suorum studio mirabili compositorum") of the Arabs, which had been piteously destroyed by their conquerors; and there can be little doubt that, during the two centuries of their undisturbed rule in Sicily, the luxurious Arabs erected many such *maisons de plaisance*. As such they are stated by Smyth to be specially referred to in an Arabic MS., preserved in the library at Morreale. As the residences of the emirs, these palaces are referred to by other early Sicilian historians, quoted by Farello, in the sixteenth century. Alberti, a little later, so treats them. More recently D'Agincourt so regards them; whilst Hitton and Gally Knight do not hesitate to point them out as examples of Saracenic art of the tenth century. It is true a certain Benjamin, who visited Palermo, in 1173, speaks of the Ziza as one of the marvels of that city, built by William; but, as Gerault de Prangcy, one of the latest authorities on the subject, truly says, it was a common practice in the Middle Ages to speak of one who had but repaired or even greatly embellished a church or monastery, as the *builder* of it.

M. de Prangcy is an eminent authority on such a subject, and he has evidently referred to these two Sicilian examples with great care and caution. He admits the absence of direct proof, but he clearly leans to a belief in the pre-Norman and Saracenic origin of, at all events, one of them, the Ziza.

On the whole, I may say that the force of evidence satisfies my mind that these buildings, which in their exterior are identically alike in style, were originally built during the rule of the Saracens; that they went to decay during

the strife with the Normans; and that they were ultimately renovated by, and adapted to the use of, the Norman conquerors, when those interior works were done which so closely resemble the Siculo-Norman portions of the churches to which I have adverted.

The beauty of their situation could with difficulty be paralleled, and such, indeed, appears to have been the opinion of the builder; for, inscribed in large Gothic characters along the parapet of the Kooon, are words which are stated by Smyth to have been translated thus:—

"Europe is the glory of the world; Italy of Europe; Sicily of Italy; and the adjacent grounds are the pride of Sicily."

Lying among the wooded hills to the east of the city, is the Benedictine Monastery of S. Martino, a magnificent modern structure of great beauty. The library especially is large and handsome, and the principal staircase, rich in polished marbles and alabaster, is one of the most striking features of this very noble building. Perhaps a less indulgent critic, in the interest of morals rather than of aesthetics, might suggest the incongruity of this ostentatious display of art and decorative luxuries in a building dedicated, not so much to the service of God, as to the domestic uses of a religious community professing a rule of self-denial, and an abnegation of all personal enjoyments.

It seems probable that to secular pride, and a spirit of rivalry with some neighbouring ecclesiastical establishment, we are indebted for many such great works in connection with the church, and its various orders and endowments.

A showy picture in the hall represents a colossal S. Martin, mounted on a prancing charger, and cutting off the skirts of his crimson cloak for the benefit of a prostrate beggar, not without a certain air of swaggering and vainglory.

About three miles north of Palermo is La Favaria, a royal residence of most fantastic character, both gardens and palace being strictly Chinese. I need not dwell on this elaborate foy; but I can not refrain from noting that so anxious did the royal occupant appear to be to disencumber himself from the restraint imposed upon him by the presence of servants that his dining-table was contrived so that the dishes and plates should rise and descend through apertures in the floor; thus, when a fresh course had to be served, a bell was rung, the dishes disappeared downwards, and after a short delay rose again from below, with their varied burden of fresh delicacies. Other whimsical arrangements I noted, with which I will not trouble you.

About eight miles south of Palermo is La Baglaria, a village where many of the Palermitan nobility have their pleasure-houses. That of Palagonia is a remarkable specimen of the grotesque. The quantity of marble sculptured into deformed figures, uncouth animals, and shapes that defy all natural classification, is almost beyond conception. The ceilings of the principal rooms are of looking-glass, and the same material completely lines also the walls, together with polished marbles, agates, and jaspers.

As a specimen of the affectation, not very uncommon in Italy, of attempting to make their furniture the vehicle of a sentiment, the following inscription appears on one of the walls of this palace:—

"Spechiati in quel cristall e nell' istessa  
Magnificenza stupolar," contempla  
Di fretta mortal l' imago espressa."

In the library I took note of an easy-chair which was readily convertible into a short flight of steps, for reaching the upper shelves, a contrivance which I have occasionally since seen attempted nearer home, but never, I think, so successfully as in this piece of Palermitan joinery. At the villa of Prince Butero the chief curiosity was a large building in the gardens, called La Certosa, being, in fact, a counterfeit convent, with its separate cells arranged exactly after the manner of such establishments; these cells containing monks of waxwork worthy of the atelier of Madame Tussaud, and each cell provided with bed, seat, table, cooking apparatus, books, &c. I never happen to have seen elsewhere a baby-house on so colossal a scale! I have some recollection, too, of waxen representations of *nuns*, as well as monks, occupying these cells in most uncanonical companionship; but so preposterous a *divertissement* for the amusement of the princely owners of a country house seems incredible, if I had not found it duly recorded in my note-book. Another curiosity, but of a very different character, is the burial-place of a Capuchin convent near Palermo. It consists of various galleries, of considerable extent. There are twenty-five small chambers

leading out of these galleries, into which bodies are placed on their first arrival, and where they remain six months shut up for desiccation by heat. When thus prepared, the bodies are brought out, like dried mummies, and clothed in their ordinary costume during life; priests in their canonicals, monks in the habit proper to their order, and so on. The shocking-looking objects so dressed up are then placed in a standing posture, each in its niche. Nothing possibly can exceed the hideous deformity of the spectacle presented by the avenue of niches so tenanted, on either side of you, as you pass along the galleries. Each body is held up in its place by a cord round the waist, attached to the back of the niche. But this cord by no means always suffices to support them in an upright position: the ligaments of the limbs gradually yield to the weight of the body, which consequently falls, or rather stoops forwards, and is prevented from falling down only by the cord. The ghastly head droops downwards or sideways, the dark brown countenance looking truly frightful: the arms, too, droop; and the legs give way under the weight which they are no longer fit to support. Under each niche are written on a tablet the name, age, and period of death of the individual it contains. The miserable remnants of mortality thus exhibited present a combination of the ghastly and the ludicrous which, I suppose, could hardly be equalled. Certainly the had taste of the exhibition may well be supposed to be without a parallel; unless, indeed, it be found in Rome, where, at the cemetery of a Capuchin convent, near the Barberini Palace, are vaults containing niches tenanted by the bodies of the dead brethren, preserved with the skins on, and clothed in their ordinary dress. The roofs of these vaults are ornamented with human bones formed into panels and patterns, and are lighted by lamps shaped out of the bones of arms and legs symmetrically arranged and adapted to this new, posthumous, use.

I have now cursorily touched upon some of the chief objects of interest or curiosity that attracted my attention. Although my stay in the island extended over two months, and my whole time was spent in constant activity, I felt regret at leaving its shores, for my visit had been one of the highest interest. My regrets were further enhanced by the conviction I felt that much remained unseen. The coast road from Palermo to Messina remained unvisited, including Cefalu, Tyndaris, and Termini, where, besides what has already been made known, I cannot doubt but that there is much of antiquarian interest, at least, to reward the researches of future explorers. But reports reached me of some thirty *fiumi* that had to be crossed, and of the almost total absence of bridges over them. These *fiumi*, be it remembered, although dry ravines in the summer, are very formidable torrents during the two or three wet months of the year.

As to the interior of the island, all accounts agreed in describing it as devoid of architectural interest, few buildings of the best periods having survived, it is said, the ravages of the frequent earthquakes with which this beautiful island has been for so many centuries afflicted. I was still further deterred by the reported absence of roads and inns—evils for which, not nature, but man alone, is answerable. Still I have always regretted that I did not make any exploration inwards, and I strongly recommend those whom the altered circumstances of the country may induce to visit Sicily to traverse its little-known central districts, where I feel convinced that there is a rich harvest still unreaped. Such a student will do well to provide himself with a sound and correct knowledge of the early history of this remarkable country, and of the races which have successively, and even simultaneously, occupied it. He will find traces more or less distinct of at least eight populations—namely, Celtic, Greek, Punie, Roman, Ostrogothic, Arab, Norman, and Italian. Perhaps no country of like extent in the world has derived its population from so great a variety of sources.

But if antiquarian and artistic wealth lies concealed in this shattered island, how infinitely richer are the hidden and unheeded sources of physical wealth! Although the cultivation of the soil is most primitive and imperfect, and although the nature of the tenure on which land is usually held there is most adverse to agricultural improvement, yet it is still a land abundant with corn, wine, and oil. Captain Smyth, who knew this country intimately, pronounces it to be "one of the most fertile spots on earth."

Untold wealth in flax, timber, sulphur, marble, and no doubt very many other natural products, only wait the capitalist and merchant.

Of the articles I have last named, only the white

veined marble finds its way into this country; yet various-coloured marbles and jaspers, of great beauty, are produced, and were, we know, duly appreciated by the architects of ancient Rome in its best days.

The following may be named as the localities of some of them, as furnished to me by an intelligent mason at Palermo:—

Marble, of	Trapani, of a grey colour.
"	di Castelnuovo, yellow "
"	di Segesta, yellow "
"	di Taormina, red "
"	di Parso, yellow "
"	di Ogliastra, red "
"	di Castelaccio, grey "

The two last-named marbles are readily obtainable in blocks, 12 or 13 feet long. Specimens of some, if not of all these, I found included in the fine collection of polished marbles made by the learned and amiable Avvocato Corsi, of Rome, which collection was subsequently brought to England, and exists now, I believe, at Liverpool. Each specimen it contained is no less than eight Italian inches long by four inches, and two inches thick, and is highly polished. It comprises ten varieties of agates—a mineral in which Sicily is so rich that one of its rivers, the Achetes, is supposed to have given to it its name.

There are also in that collection at least eighteen varieties of jasper, in which beautiful substance Sicily is stated by Corsi to be more abundant than anywhere known locally. A recent writer has stated that there are no less than fifty-four varieties of Sicilian jasper. That a trade has not been established in these precious productions can only be due to the want of enterprise and capital in the island—a want easily accounted for by the long-continued course of wretched and degrading misgovernment.

What may we not hope for from the country when it shall have firmly established its political freedom, and re-entered upon the path which freemen alone are destined to tread! The present apathy, indolence, and ignorance of the people will, it is to be feared, oppose many and heavy obstacles to the re-establishment of a durable and prosperous administration. But such was not always the character of Sicilians. When in early times Palermo was besieged, the patriot women are said to have given up the hair of their heads to serve as the bowstrings of their gallant defenders. May we not then reasonably hope that in the councils of Providence it may be permitted to this ancient people to vindicate for themselves some portion of that moral and material eminence which their forefathers of old so worthily achieved?

#### LORD MAYOR'S DAY.

The chief feature in the decoration of Guildhall on the 9th instant, when the Right Honourable William Cubitt, M.P., was inaugurated Lord Mayor of London City, with the hearty goodwill of even a larger circle than that of his fellow-citizens, was the sculpture which Mr. Bunning, on this as on many former occasions, had gathered together. We have before now expressed our appreciation of Mr. Bunning's endeavours in this direction, especially in respect of the statues commissioned for the Mansion House. Can he not persuade the Corporation to do something for Painting? The history of the City would afford noble subjects, and the Guildhall and Mansion House offer walls to be covered.

The works contributed were by W. Calder Marshall, H. Weekes, S. S. Westmacott, J. Hancock, Felix M. Miller, J. H. Foley, P. Maedowell, Signor Fontana, and others.

At the dinner there was, as might be expected, a stronger muster of men connected with architecture and building, and other art and science, than usual. Within our own ken, for example, were Messrs. Donaldson, Tite, M.P., Peurose, Lewis Cubitt, Bunning, E. Barry, P. C. Hardwick, Bidder, Mylne, Jennings, Fowler, John Shaw, Piper, Gassiot, Hart, R.A., Jous, R.A., and John Thwaites (chairman of the Metropolitan Board of Works); and there were, doubtless, many others. Politically viewed, the banquet was one of great importance, and all Europe has read with eagerness the utterances of the two P.s. England is just now "master of the situation;" and Palmerston and Persigny were wholly at accord.

The new Lord Mayor has well begun his year. The Chancellor of the Exchequer bore more than ordinary testimony to the opinion of him entertained in St. Stephen's; and all who heard it ratified the statement with hearty applause.

Another Lord Mayor of the ancient city has passed in a civic triumph from the Guildhall to Westminster; and although, of late years, much

has been said against these public spectacles, if we may judge from the good-humoured aspect of the vast multitude of all ages and grades who thronged to witness the sight, the Lord Mayor's Show has not lost all favour with the masses.

In looking at the procession of the other day, arranged as it was without any attempt by art or allegory to afford materials for more intellectual ideas, many portions of the sight contrasted strangely with all around. The picturesque and antique dresses of the Lord Mayor's hargemen, although their occupation is gone, came out bravely; and the dingy and faded coats of the watermen, who bore the banners of departed worthies connected with the City, showed the changes which are going forward on the Thames,—how steam-packets, steam-forges, bridges, and tunnels, are superseding the once familiar craft which plied in hundreds along the bustling banks of London,—causing little demand for the waterman's occupation, and thus accounting for the faded coats. The careful observer, in various parts of the procession, would note, in the costume of the headles of companies, the maces, and other details of the show, matters which reminded them of old times.

The knights in armour, followed by their esquires, also in suits of armour, passed on amid the roaring laughter of the crowd. Singular did these sham ghosts of the past look in the modern streets; and thoughts went back to the days when stalwart warriors, in steel casing, attended by low and buckler men in buff, would have done useful service. Miserable and uncomfortable looked these imitation knights of antiquity, and sad the shaking of the plumes, when comparing them with the active riflemen who kept unbroken ranks, their improved weapons, and the wonders which have been achieved by the locomotive steam-engine and other matters which have been brought into use since the days when real knights, in substantial armour, on their prancing war steeds, moved along the City streets.

The quaint-looking houses and shops, the embattled and strongly fortified houses of the nobility, the high walls and gates of the City, the darkness of the nights, the evil condition of the roads, the terrible outbreaks of pestilence with which those of the present day in England are not to be compared, and other evils contemporary with the ancient knights, have nearly passed away; and along the Strand and Fleet-street, where stood so many of the dwellings of those persons of rank who once overawed the industrious citizens, are steam-printing presses busily at work, producing newspapers and periodicals for the use and instruction of the multitude.

In times very far remote, it does not seem that the show on Lord Mayor's-day was remarkable for any very great display; the procession chiefly consisting of the minstrels, the headles, and livery-men of the companies. We have accounts of brave processions in the olden times, in honour of royalty; but it was only about the beginning of the sixteenth century that the Lord Mayor's Show came to be famous. In the accounts of London there are many particulars of royal processions: we will, however, just now only refer to one of comparatively recent date. On the 29th May, 1660, when the King approached London, the Mayor and Aldermen proceeded to St. George's-fields, Southwark, where tents had been erected, and great provision for feasting made. From this point the following procession was formed:—

First marched a gallant troop of gentlemen, in cloth of silver, brandishing their swords; then followed another troop of 200, in velvet coats, with footmen and liveries in purple; then another troop in buff coats, with cloth of silver sleeves, and very rich green scarfs; and after these a troop of about 200, with thirty footmen, in grey and silver liveries, and four trumpeters, richly habited; then another troop of 105, with grey liveries, and six trumpeters. Other troops followed. Then came the sheriff's men, in red cloaks, richly lined with silver, to the number of three-score; then followed 600 of the several companies of London, on horseback, in black velvet coats, with gold chains, each company having footmen in different liveries, with streamers, &c., kettle-drums and trumpets. His Majesty's Life Guards and the various City officers followed in succession. Then the two sheriffs, in scarlet gowns, and all their rich trappings, with footmen in liveries—red coats, lined with silver and cloth of gold. After came the Lord Mayor—bareheaded—on horseback, carrying the sword, with his excellency the General and the Duke of Buckingham—bare-headed also;—and then rode the King himself, between his royal brothers, the dukes of York and Gloucester:

several regiments of cavalry closed the gay and stately procession.

Turning from this royal bravery to the civic shows of Sir William Draper—Lord Mayor, 1566,—there was, we learn, much display on the river. In 1568, Sir Thomas Roe, of the Merchant Taylors' Company, was elected to fill the honourable office of Lord Mayor: at this time, his company voted him 40*l.* to help to defray the expenses of the progress to Westminster. The pageant selected on this occasion had reference to the patron saint of the company—St. John the Baptist,—consisting of an allegorical representation of the saint, and other similar personages. There were also four boys who spoke complimentary speeches, which in parts alluded to the name of the Mayor; for instance, St. John is made to say, "I am that voyce in the wilderness which once the Jewes did call." *1st Boy:* "Behold the Roe, the swiftest in the chase;" and such-like sorry wit. There were allegorical personages who, for some time, figured in the shows: these consisted of children and females, dressed in peculiar costumes, who represented London, the Thames, the Country, the Soldier, Sailor, Nymphs, &c. There were also representations of Magnanimity, Loyalty, and other virtues, all of which were of course ascribed to each new Lord Mayor.

In 1613 Sir Thomas Middleton was in office. This gentleman, who was a grocer, attempted an emblematical and scenic representation. On this occasion a water spectacle was prepared in imitation of a pageant mentioned to have been exhibited by Sir John Wells to Henry VI. This device consisted of five islands artfully garnished with all manner of Indian fruits, drugs, spices, and the like: on the middle island was a fair castle, especially beautiful, which probably was intended as referring to the forts about that time established in the East Indies. From the period above mentioned to 1708 the shows were similar: at this date pageants of a more elaborate and poetical description came into use. An attempt was made to add to the interest by giving to the shows something of a dramatic character. Poets were engaged to compose what were called projects, that is, the arrangement of scenes with action. These were dialogues, songs, &c. introduced, and speeches made descriptive of the Lord Mayor elect and his company. The painter, dress-maker, and mechanic were also brought into use, whose united efforts surprised the Londoners. Before this date the pageants shown on land were fixed in certain positions, but now the stages were made to move along the streets with the Lord Mayor's processions.

The machines used for the pageants were unwieldy affairs, and were also too costly to be destroyed on each year. Some of these were stowed away in the roofs of the companies' hulls. There was also a pageant-chamber in the City, in which the smaller matters connected with the shows were preserved. In the companies' accounts mention is often made of the cost of fitting up these, and for setting up beasts and other lustrate fittings. The repair or making up of these articles was managed in the Leadentail. A conspicuous feature of the pageants were the firemen, sometimes called monsters or terrible men—hair-clad savages with torches and fireworks. We read, also, of allegorical pageants of trade—the factory of commerce, the palace of pleasure, the house of riches, and the arbour of delight.

#### THE EAST INDIA HOUSE.

LONDON changes go on with amazing rapidity, and circumstances are frequently happening which a few years before could scarcely be looked for. Amongst these may be noted the altered circumstances of the great building of the East India Company in Leadentail-street; a structure which is in some respects handsome, and so substantial that it promised to remain for some centuries to come. Few who passed it a dozen years or so ago but thought it about as likely for the Lord Mayor and the Mansion-house to be removed to Piccadilly as that the offices of the East India Company should be removed to Westminster, together with the splendid library and valuable collection of manuscripts and articles of curiosity and instruction which so thickly occupied the museum.

When looking at the long front of this building, its lofty and well-proportioned portico and wide-spreading wings, one observes the execution and design of the sculpture of the pediment and other parts, by Bacon. George III. is a principal figure, representing for a time the power of England, and marking the date of erection of the edifice: he is leaning on his sword with one arm, and

with the other extending a shield of protection. Figures of Liberty; Mercury, attended by Navigation and followed by tritons and sea-horses, emblematical of commerce, are introducing Asia to Britannia, before whom she spreads her products. On the other side appears Order, accompanied by Religion and Justice. In the background appear the city large and other emblems and representations of Integrity and Industry. The western angle contains a view of the Thames, and the eastern that of the Ganges. On the apex of the pediment is a figure holding in her left hand a spear and a cap of liberty. On the east and west corners are Asia seated on a camel, and Europe seated on a horse.

In connection with the Company will be remembered an account of a building, curiously constructed of wooden framework and turned ornaments: on the top was a carving of a ship. This was engraved in a previous number of the *Builder*. This, the first house of the East India Company, stood near where the west wing of the present edifice now is.

In the commercial history of this nation there are few incidents of our progress more remarkable than the rise and progress of the East-India Company. In 1599, 101 persons subscribed for the purpose of carrying on an Eastern trade to the amount of 30,139*l.* 6*s.* 8*d.*, in various sums of from 13*l.* to 3,000*l.* For long after the establishment of the Company the attendance of one managing director at the old wooden house was sufficient. It seems that, owing to some treaties which were in negotiation with the Government of Spain, the Company did not obtain their charter of incorporation until 31st December, 1600, and then it was limited to fifteen years' duration. By the time the above-named privilege was granted the money subscribed amounted to 68,379*l.*, of which 39,771*l.* were expended in the purchase and equipment of ships; 28,742*l.* were appropriated to hullion, with which, and goods to the value of 6,860*l.*, was commenced by England a traffic with the mighty empire of Hindostan. The first expedition, which was destined to produce such marvellous results, started from Torbay on the 2nd of May, 1601. Great was the success; for, with a single exception, during eleven years, the profits ranged from 120*l.* to as much as 340*l.* per cent. In 1609 the charter was renewed, and still the merchants prospered. It is worth while to mention the following anecdote connected with the early days of the company. A merchant named Bragge made a claim against the East-India House for upwards of 6,000*l.*, for services said by him to have been rendered. This gentleman pressed his claim in language and in a manner which seem singular. He backs his views by goodly sayings and quotations, and balances much good with a considerable amount of selfishness. For instance, after making what seem to be some very large charges, he says,—“For thirteen negroes, or Indian people—Well, for the estimation of these poor souls, they are not to be valued at any price.”

Another item:—“For twenty dogs and a great many cats, which altogether, under God (as by your books written), of late ridd away and devoured all the rats in that island, which formerly ate up all the corn and many other blessed fruits which that land afforded,—Well, for this I will demand 5*l.* apiece for the dogs, and as to the cats, they may go.”

Some idea of the enormous profits of those connected with the East-India trade may be gathered from the following comparative prices of teas and other articles (this about 1612): a book of muslin cost in India 20*s.*: in England it sold for from 30*s.* to 40*s.*; Zurat satins, per piece, in India, 40*s.*, in London, 60*s.*: a Taffeta quilt cost then in London from 10*l.* to 20*l.*; and raw silk was 20*s.* a pound.

When the first expedition was sent away, Capt. Lancaster, the chief in command, took royal letters of introduction to various Eastern potentates; and in 1614, so important had become this traffic, that an ambassador was sent to the Great Mogul. The diplomacy of this gentleman was attended with great success, and amongst other advantages obtained permission for the English to establish factories on any part of these dominions. The ambassador saw from the first the troubles which would result from territorial acquisitions or military expenses, and cautioned the Company against such measures. In 1617-18, the increase of the trade made it necessary to raise a fresh fund of 1,600,000*l.*, and the Company now consisted of 954 proprietors, and had 36 ships, of a tonnage ranging from 100 to 1,000 tons burden each. In 1631, a third joint-stock capital of 4,200,000*l.* was raised.

In 1611-12, the first important settlement was

made on the shores of India by the erection of a fort at Madraspatam, which was afterwards called Fort George, and erected into a presidency. In 1698, an opposition East-India Company was formed, which, after a feeble management of four years, amalgamated with the original company, and the firm was named the United Company of Merchants trading to the East Indies. Soon three presidencies were formed, all under the control of the Company at home: one was at Madras, and the others were at Bombay and Calcutta.

The English population did not advance in proportion with the increase of the traffic, for we find that, in 1716,—105 years after the first settlement was made at Madras,—although the presidency extended for five miles along the shore and one mile in breadth, the number of Englishmen there did not exceed 300 persons, of whom 200 were soldiers in the garrison.

As time rolled on, the French attempted to oppose the Company in India, and rebellion—if it might be so called,—was raised. The victories of Lord Clive, Lord Cornwallis, and the Marquis of Hastings vastly extended the British dominions in this direction.

In 1813, the Eastern trade was partially broken open, and this largely increased the export, which in 1815 amounted to 570,177*l.*; but in 1819 it amounted to 3,052,710*l.*

It is tempting to follow the effect of British enterprise, and the comforts and advantages it has afforded to the western and other portions of the world: we must, however, be satisfied with giving the following note.—In 1677, the quantity of tea imported into England amounted to 100 lbs. weight: in 1814 the quantity was 25,000,000 lbs., which yielded to the Government a revenue of 4,000,000*l.* sterling.

In the interior of the Leadenhall-street building there are several matters worthy of notice, statues of famous men connected with India, paintings, and bas-relief decorations. The great hall and other chambers in which so many remarkable men have met, and in which important subjects affecting the welfare of millions have been discussed, have historical interest. The library has been collected with great skill, labour, and expense: it contains everything—either in manuscript or printed books, drawings, sketches, &c.—which illustrates the past and present condition of the Queen's wonderful empire in the East. The museum is to the student of these matters a valuable aid to the library. The former has also much interest to the public generally; and these collections are particularly useful in a combined state, not only as a class collection intended to throw light on a most important subject, but as containing a vast amount of historical facts and other evidence.

This museum and library, whatever changes may take place, should never be allowed to merge into the British Museum, or any other collection, where its individuality and chief interest and utility would be lost.

We have had three Royal Exchanges, each illustrating the progress of British trade, architecture, and taste; and not long will have passed, before the third East India House will be reared, in a style—in all its parts—which, it is to be hoped, will be a credit to the age. Great ideas are suggested by the fact of the Home Government of such an immense empire, and lofty thoughts should be inspired in the architect who designs, and the artists who may be called upon to decorate, a building appointed for the centre of such great power.

From the comparatively small beginnings at which we have above hinted, and since the days when in the wooden house one director managed the affair, the British power in India has grown to be an immense responsibility and the cause of national anxiety. Great is the benefit which may be bestowed on the masses of people in India by the intelligent, firm, and unselfish management which, it is hoped, will be connected with the India House at Westminster.

#### THE ARCHITECTURAL ASSOCIATION.

THE first ordinary meeting of the Architectural Association was held on Friday evening, the 9th, at their house in Conduit-street. The President, Mr. T. Roger Smith, occupied the chair.

Routine business, including votes of thanks, having been transacted,

Mr. Arthur Smith, hon. sec., read the report of the committee for the session 1859-60, which, after enumerating the papers read and discussed at the various meetings held during the past year, stated that, in addition to the class of design, it was proposed to have a class on botany, under the

direction of Mr. Blasbill, which would assemble half an hour before the hour appointed for the ordinary fortnightly meetings. The committee had met several times during the recess, and had recommended certain modifications of, and alterations in, the rules and regulations of the Association. These included, *inter alia*, the personal introduction of new members to the president at the next ordinary meeting after election; the fixing of the subscription of town and country members at half a guinea per annum, instead of 12*s.* 6*d.* for town and 5*s.* for country members, as heretofore; and certain other verbal amendments calculated to improve the efficiency of the Association for the objects for which it was promoted.

Mr. J. A. Bunker moved the adoption of the report and the recommendation of the committee with reference to the rules.

Some discussion ensued as to the expediency of considering the recommendations *in globo*, as proposed by Mr. Bunker, or in detail; and ultimately, at the suggestion of Mr. Hammond, it was resolved that they be taken into consideration *seriatim*.

The question of subscription was then raised, and the general feeling of the meeting was declared to be in favour of abolishing the distinction between town and country members.

The President and others urged the desirability of fixing the subscription at a sum which would enable members to bring in as many of their pupils as possible; and it was contended that no country members who really had the welfare of the profession or of the Association at heart would be deterred from joining the latter by the payment of so modest a subscription as half a guinea per annum.

Several other rules having been considered and amended, a regulation was agreed on to the effect that each class should report annually to the general meeting of members.

The report of the committee was then agreed to, without a dissentient voice.

The Vice-President (Mr. A. Blomfield) next brought under notice the proposal for a memorial to the memory of the late Mr. Pugin, for his services in the promotion of the true principles of Mediæval architecture. It was, he remarked,

proposed to solicit donations to be devoted to the endowment of a permanent fund, to be entitled the "Pugin Travelling Fund," the interest arising therefrom to be awarded to an architectural student, and to be expended by him, within one year of the time of its allotment, in travelling in the United Kingdom, and in examining and illustrating its Mediæval architecture, sculpture, and painting. To the studentship it was proposed to add a medal, and it was the intention to request the Royal Institute of British Architects to become trustees of the fund. This was a subject in which the Architectural Association, as a body, ought to feel great interest, and he would be happy to be the medium of transmitting to the treasurer any sums which members might not wish to send in their own names, and which would be acknowledged as a contribution from members of the Architectural Association.

On the motion of Mr. Bunker a resolution was passed requesting the curators of last year to lay upon the table at the next ordinary meeting a list of the property of the Association in their possession.

The President then called attention to the offer of Mr. Tite, M.P., to place at the disposal of the Association the sum of 5*l.* annually, to be devoted to a prize or prizes for the best design, essay, or other object which might be considered most desirable in the interests of architecture. Mr. Tite, when making the offer, had intimated that, if the President would call upon him, he would make arrangements for the payment of the amount, and also offer a suggestion or two as to its application. In accordance with that intimation, he (the President) had called upon the hon. gentleman, who handed him a cheque for the amount for the present year, and at the same time expressed a wish that the prize or prizes might be awarded in the course of the current year. In that case he held out the hope that he might be enabled to present them personally. Mr. Tite also suggested that perhaps the Association might consider it advisable to divide the amount into two, one of 3*l.* and one of 2*l.* He also made some inquiries about the class of design, and seemed to think it might be useful to give the prize to that class, although he expressed his desire that the matter should be left to the unfettered discretion of the Association, and intimated his readiness to concur in any course which might be considered the most desirable.

Mr. H. A. Reeves suggested that the 2*l.* prize might take the place of the Association's prize,

and that the 3*l.* might be awarded to the best sketch in the class of design, and presented at the next *conversazione* of the Association, which would be held in April, 1861; at which time it might, perhaps, suit the convenience of Mr. Tite to be present. Should the Association still continue to give its prize, there would then be three prizes. He hoped, however, that the highest prize would be given for a selected subject in the class of design. In conclusion, he moved a resolution to the effect that 2*l.* be the value of the prize to be given for the best series of designs by the class of design, and that 3*l.* be the prize for the best selected subject, to be competed for by members of the class of design only. He was of opinion that some such regulation was necessary to prevent the elder and more accomplished members of the Association from competing.

Mr. Wimbridge seconded the motion. After some desultory conversation Mr. Blasbill moved, and Mr. Bunker seconded, an amendment on Mr. Reeves's motion, to the effect that 3*l.* be given for the best series of sketches in the class of design, and that 2*l.* be given for the second best.

A division was ultimately taken, when there appeared for the amendment nine against ten; majority against, one.

The President then put the original motion, which he declared to be carried by twelve to nine.

It was then announced that the next subject for the class of design would be an entrance-lodge and gates for a mansion.

The President observed, in reference to the proposed consideration of the subject of architectural examinations, and the report thereof which had been entered upon their syllabus of that evening, that it would be impossible to take up the discussion at the late hour at which they had then arrived (ten o'clock), but that at their meeting on the 23rd instant he hoped they would be able to make considerable progress with the subject.

#### RAGGED SCHOOLS:

THEY SHOULD BE AIDED AND ESTABLISHED BY GOVERNMENT.\*

THE benevolent and able efforts of Miss Carpenter on behalf of Ragged and Industrial Schools at Bristol we have ere now brought to the notice of our readers. From the titles of the tracts just quoted, it will be seen that she has of late been urging the dispensation to such schools of a full share of the School Aid given by Government under the superintendence of the Committee of Privy Council on Education; and we not only give our hearty approval to such efforts, but, as our readers, and those of "London Shadows" and "Town Swamps and Social Bridges," very well know, have ourselves dwelt on this point for years past, and before the importance of it was either generally recognized or often urged.

In the letter on the debate lately in the Commons, on Sir John Pakington's motion,—one moiety of which was "that Ragged and Industrial Schools, which are alone adapted to meet the wants of a considerable number of destitute and neglected children, do not receive the amount of aid to which they are therefore entitled,"—Miss Carpenter expresses the error or fallacy of Mr. Lowe's assertions and arguments in course of the debate, and re-urges the case in favour of Ragged Schools; as indeed is also done in her other papers under notice.

One strange objection felt by the Committee of Council on Education to giving efficient aid to Ragged Schools, as stated by their late vice-president, is that the doing so *might make them permanent institutions*, and that an officer of state ought not to take it for granted that there would be permanently a Ragged School class in the country, and therefore ought not to make provision for it!

Do the Committee of Privy Council on Education then anticipate that "the poor" are about to "cease from the land?" or are they millenarians, and expect, with Dr. Cumming, that all these evils are to be remedied in 1867?

"Surely," says Miss Carpenter, evidently surprised, "this is not the principle on which the government of

\* Letter on the Debate in House of Commons on Ragged and Industrial Schools. By Mary Carpenter. Bristol: Arrowsmith, printer.

Abstract of Paper on Educational Help from Government Grant to Destitute Children, read by Mary Carpenter, at British Association Meeting at Oxford, in 1859. The Relation of Ragged Schools to our Educational System, and their Claim to a full Share of Aid. By Mary Carpenter. Read at Bradford Meeting of Social Science Association, 1859.

Charge of Mr. D. Hill, Recorder of Birmingham, to Grand Jury, October, 1859. Arrowsmith, Bristol, printer.

our country is carried on! It arises from a wrong state of things unquestionably, that the Ragged School exists: it arises equally from a "wrong state of things" that the pauper class exists—that thousands of our countrymen and women annually find it impossible to obtain an honest living in England,—that the sanitary condition of our large towns is such as to perpetuate disease both of body and mind,—that crime is constantly committed, even in open day. And does the government of our country remain passive, and allow of the existence of dreadful evils, because these things *ought not to exist*—and does it not become a statesman to do something more than ignore them? Should he not rather grapple with each evil in such way as appears most for the good of society in general and for the individual concerned? Does not the Government provide in such way as seems best for the necessities of paupers,—aid in the emigration of those whose labour will find a better market in more distant parts of the empire,—grapple vigorously with the unwholesome condition of streets and alleys, and even of private houses,—and, with respect to the thousands of criminals who annually spring up afresh in our country, does it not withdraw them from society, feed and clothe them, and otherwise provide for them, even at the risk of appearing thereby to discourage the honest labourer, who has often a far more scanty fare for himself and family than the pauper and the felon? No Government does act on such a principle in other matters; why should it do so in respect to the "something rotten in our state," which poisons its very core—the millions of children who neither can nor will avail themselves of the higher educational establishments?

As long as the poor, the destitute, and the diseased exist, so long, it is to be feared, will there be ragged children; and so long as there are ragged children, so long will there be a necessity for Ragged Schools, and for Government aid to the benevolent exertions of the public on their behalf.

Ragged Schools occupy a definite, recognized, and now popularly established position between the National Schools on the one hand, and the Workhouse Schools on the other; and neither of these can ever occupy the field that is open to the Ragged Schools. The children of the poor who are not absolute paupers, but are either unable or unwilling to keep their children in decent and cleanly condition and send them to the National Schools, must either be left to grow up into precisely the most dangerous and criminal class of the whole population, or they must be educated in the "Ragged Schools," to which more respectably attired children should rather be directed from going than persuaded to go; for, if once the Ragged Schools become more "respectable," shame and pride and vanity will keep off the more ragged children from a sphere where they will be liable to "odious comparisons;"—and even a child of four years of age is quite old enough to appreciate such comparisons. There is much in a name; and the very name of "Ragged School" is of value in the retainment of the special character of this class of school.

Would Christ's Hospital, which was originally in fact a ragged school into which the very street sweepings of society were daily emptied, be at this moment occupied exclusively by the children of the "well-to-do," without a single "wild Arab" from the streets among them, had the name of "Ragged School" been from the first as unchangeably fastened on it as the quaint and antiquated clothing of the children educated in it has been? What is it that keeps the ragged children of the streets themselves out of the workhouse schools but the very names of "workhouse" and "panner," which stink in the nostrils of all parents who can keep either themselves or their children out of them? And right it is that it should be so. The name of "Ragged School" then, occupies a special, exclusive, and proper place among the rising or falling grades of educational establishments, and it is to be hoped will never be altered. Those who begin to feel a wholesome pride, prompting them to refuse longer to allow their children to go to the Ragged School, will forthwith send them to a National school. Those who have no such pride, but nevertheless dislike the name of paupers, must feel the Ragged Schools to be the proper place for their children; and whether they do so or not, it is so in fact; and they do allow their children to go to such schools.

Why should the Government affect to ignore the Ragged Schools? It is now too late to do so: they are an established and decidedly requisite institution, and ought to be made permanent, both by means of Government aid and by legislative Act; in which Act, moreover, the very name of them ought by law to be perpetuated and made unalterable.

**PHOTOGRAPHIC PROGRESS.** From Paris we hear that crowds are attracted to Mayer's photographic gallery on the Boulevard des Capucines, to see a full-length, the size of nature, exhibiting the Emperor of the French. This is the first full-length of natural size we have heard of: it is doubtless produced by the new process of enlargement to which we lately drew attention.

WIRE-ROPE TESTING AT LIVERPOOL.

A NUMBER of gentlemen interested in shipping assembled at the Corporation testing-machine, King's Dock, Liverpool, recently, to witness a series of experiments having reference to the relative strength of wire-rope, as adapted to ships' rigging. The following, according to the local *Courier*, is a tabulated statement of the result:—

	Giroin-ference.		Guaranteed strain		Breaking Point.	
	Inches.	Tons.Cwt.	Tons.Cwt.	Tons.Cwt.	Tons.Cwt.	Tons.Cwt.
Newall & Co. ....	4	29 0	19 15			
Ditto .....	3½	22 0	16 15			
Ditto .....	2½	11 0	7 15			
Totals .....		61 0	41 0			
Garnock, Bibby, & Co....	4½	24 8	25 10			
Ditto .....	3½	15 0	18 5			
Ditto .....	2½	7 8	8 15			
Totals .....		47 2	53 10			
Whaley, Barrows, & Penton	4½	34 0	21 0			
Ditto .....	3½	20 0	18 5			
Ditto .....	3½	15 0	14 0			
Totals .....		69 0	53 5			
Hutchings & Co. ....	4	19 6	15 0			
Ditto .....	3 11-16	17 0	11 15			
Ditto .....	2 9-16	8 11	5 0			
Totals .....		44 17	31 10			

A piece of wire-rope, made by Messrs. Newall & Co., 1½ inch, weighing 3 lbs. per fathom, was then tested, and broke at 5 tons: a piece of 4½-inch Manila rope, manufactured by Garnock, Bibby, & Co., was next tested, weighing 2½ lbs. per fathom, and broke at 8 tons 5 cwt.; showing that Manila hemp rope is stronger, weight per fathom, than wire rope.

DESIGN FOR CONNECTING THE POPULOUS QUARTERS OF SOUTH KENSINGTON AND BAYSWATER, AND THE DISTRICTS ADJACENT, BY MEANS OF A SUBWAY UNDER THE MIDDLE WALK IN KENSINGTON GARDENS.

AMONG the unpublished plans for metropolis improvements left by my father, the late John Martin, were several suggestions for connecting the Bayswater and Kensington sides of Hyde-park and Kensington-gardens. One of these suggestions was to convert the existing Ha-ha fence into a roadway, and another was to form a species of sunk-road across Kensington-gardens. A recent consideration of the latter project has caused me to devise a plan, which I now venture to submit to the public through the columns of the *Builder*, merely premising that all the drawings, &c., of the requisite details have been kindly supplied to me by Mr. Ignazio Bonomi, who was formerly in extensive practice as an architect, and as engineer for the county bridges of Durham. The drawings have been made several months.

ISABELLA MARY MARTIN.

The point selected for the subway, is the most direct and shortest line between the Usbridge-road and South Kensington. Being only about 1,100 yards long, or five-eighths of a mile, it affords a commodious substitute for three miles by Park-lane, or two miles, with two turnpikes, by Church-lane, Kensington,—two narrow and crooked streets, which at present form the only lines of communication between the north and the south sides of Kensington-gardens and Hyde-park. At an average speed of five miles an hour, the subway would be passed through in eight minutes.

The subway is intended to be always open for general traffic like any other road or street, and will thus provide for constant communication with the London railway stations, where trains are arriving and departing at almost every hour of both day and night.

Notwithstanding these advantages the traffic will be entirely unseen, and the surface of both Hyde-park and Kensington gardens will remain undisturbed, excepting for the formation of the entrances into the subway next to and within 40 yards of the Usbridge and Kensington roads. The park and gardens are besides not rendered accessible at other than the present gates, and at the regulated times of admittance, as the railing bounding the quadrant entrance-roads excludes access from without.

The subway is proposed to be about 30 feet wide, and the arched roof 2 feet beneath the sur-

face level of the middle walk. The road is to be divided down the middle the whole length by a line of cast-iron columns and arches, or stone columns and brick arches, to support the roof. On each side of the columns are the footpath and carriage-road, edged with cast-iron or granite terraces for the wheels, one road being for carriages entering, and the other for carriages going out. The subway is entered from the main road by inclined quadrant roads sunk in the narrow strip of land between the footpath and the outer fence at each side of the gardens.

The rise of the surface of the park and gardens at about 40 yards respectively from the Usbridge and Kensington roads, equals at least 4 feet, and thus affords, by a gradual sinking of 12 feet in the quadrant roads of approach, a clear height of 1½ feet in the subway for vehicles, and 2 feet above for the arched roof and gravel.

The subway will be ventilated by gratings, which also light it by day; by night, gas will be used. The higher part of the middle walk is at about 150 yards south of Bayswater, from which the level slopes both ways so as to afford the means of draining off any percolating water into the street-drains at the two ends, and the construction of the subway is adapted for adjusting its level to the general level of the surface.

The subway does not interfere with any private property, nor with drains and pipes: the work can be effected in a short period, and with small amount of inconvenience, the cutting as it proceeds being closed in with its arched surface, and gravelled over.

The estimated cost of the entire work would be 38,000*l.* or 40,000*l.* if cast iron pillars and beams are used; but only 30,000*l.* if stone pillars, with brick arches down the centre.

It does not appear that the scheme could be carried out by a company, because the returns would have to be obtained by tolls, which are totally unsuited to the internal traffic of the metropolis. As the communication has been long required and in some degree requested, and the necessity for it is daily increasing, owing to the augmentation of the population in the important districts which it would unite, the undertaking may be considered of such general and public advantage as to deserve to be paid for by the public or parishes and authorities concerned with public improvements, for it must be remarked that the road in question is for general traffic at all periods of day and night, and for all classes.

Supposing the subway to be accepted and substituted for any contemplated roads through the park and gardens, the cost of such roads with the lodges and gates of access might be applied as a contribution to the subway by the Commission of the Board of Works. A notable saving would be the consequence in the yearly repairs of park roads, and in the salaries of the lodge and gate keepers.

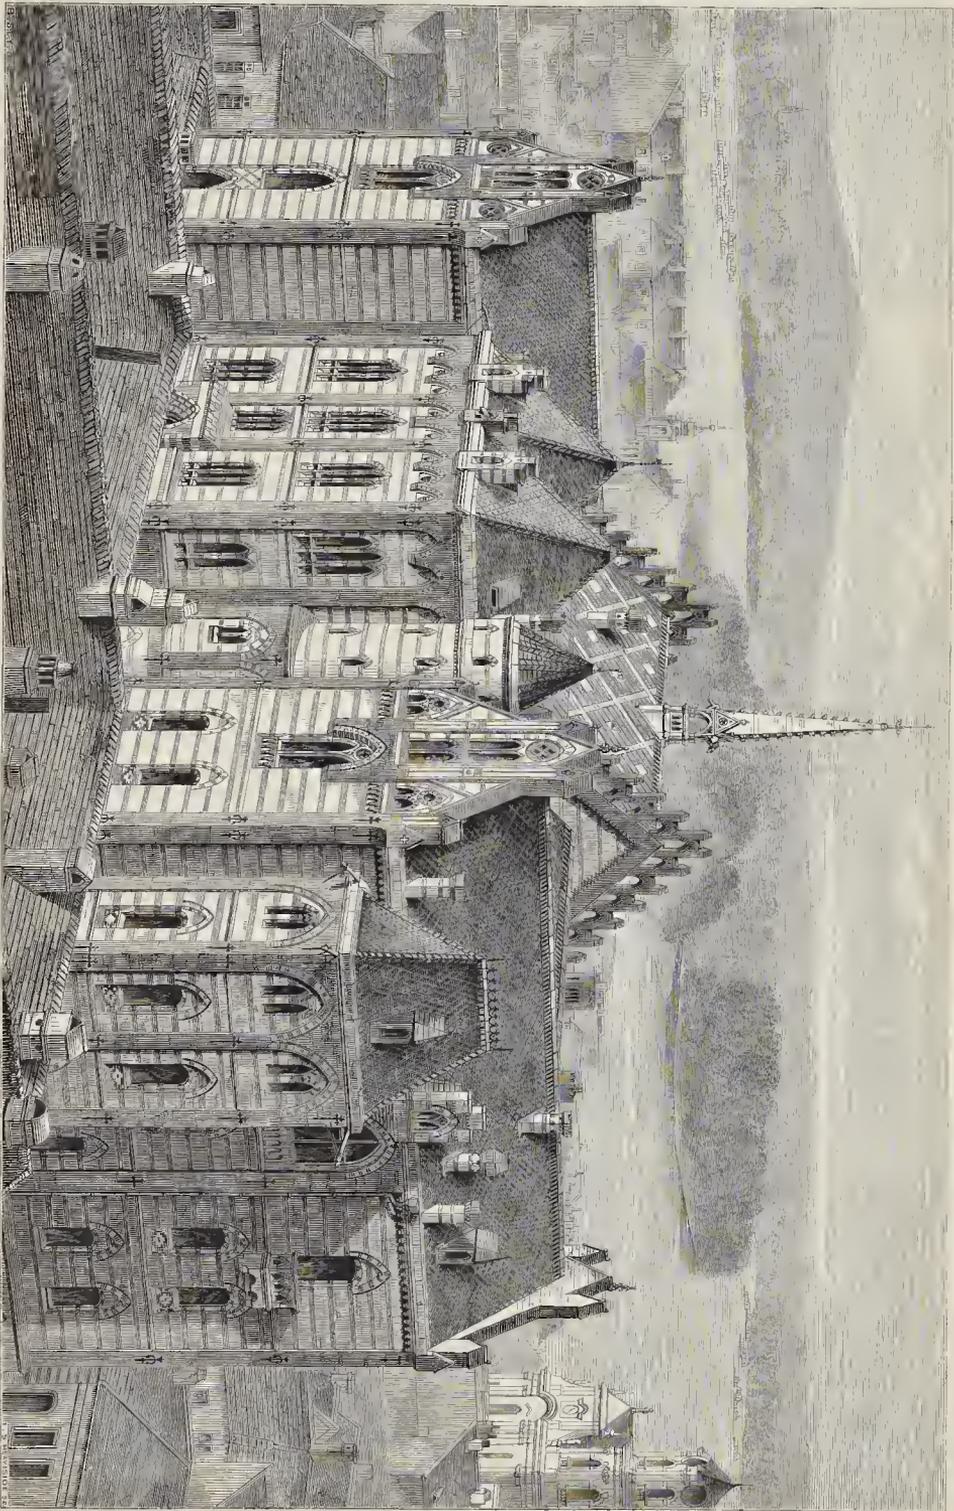

The adjoining parishes of Paddington, Kensington, St. George's, St. Margaret's Westminster, Chelsea, and the Brompton district would be more especially benefited, and the wear of the roadways east and west of the park and gardens would be much diminished.

The Metropolitan Board of Works would, no doubt, deem the communication of sufficient public importance to make arrangements for engaging in the undertaking.

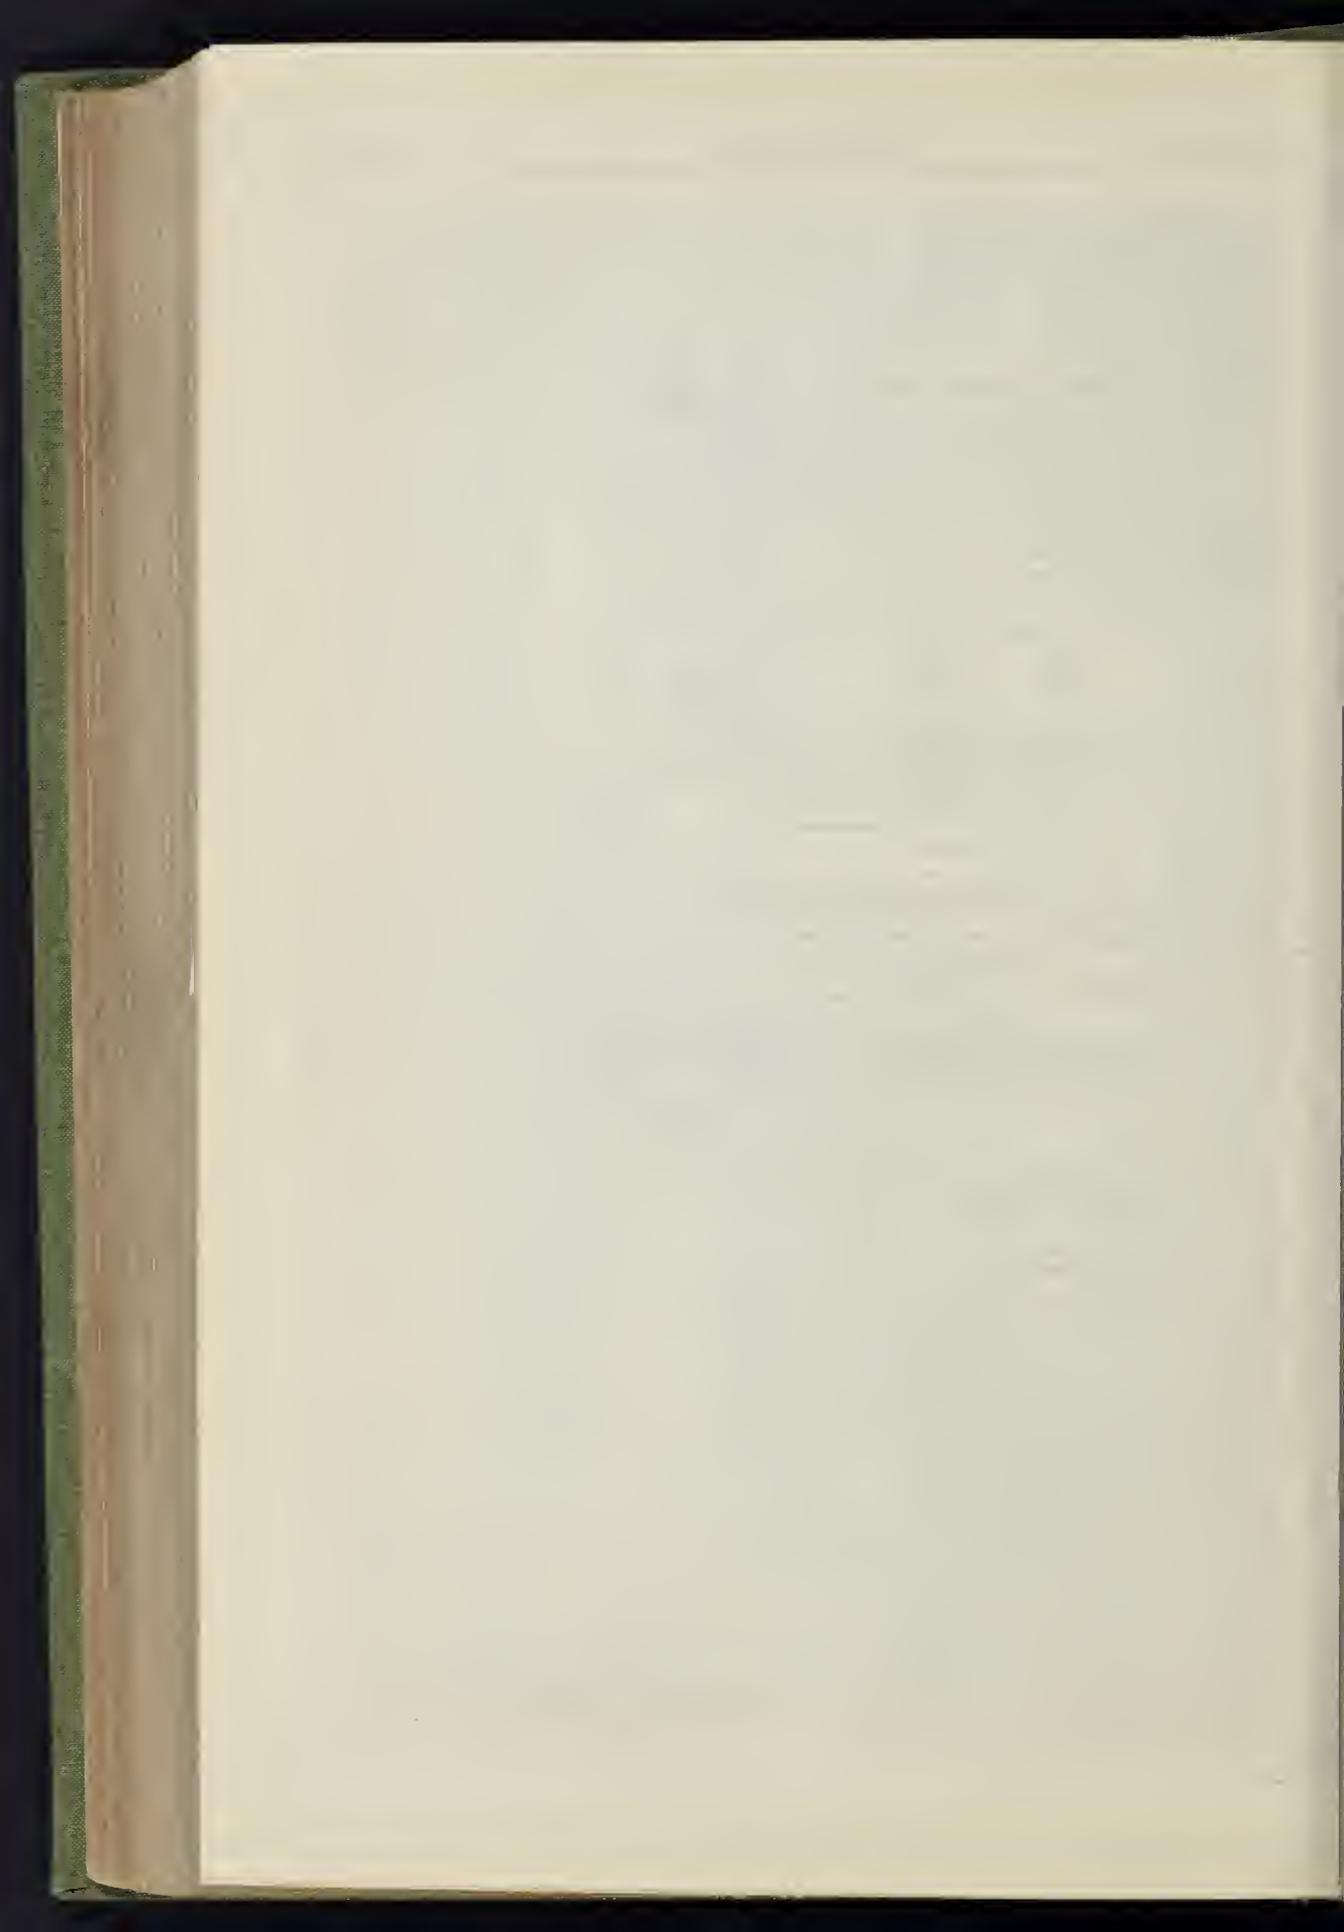

Impressed with the necessity of making the subway adequate for future as well as present requirements, and to avoid the necessity for a similar undertaking, possibly at no great distance of time, it seems advisable to provide a double carriage way for passage in each half of the width. The additional cost is estimated at 7,000*l.*

\*\*\* A means of communication always open between the two districts separated by the Park and Kensington-gardens has long been a crying necessity. Miss Martin's plan meets many of the objections made to the accomplishment of this object, and demands immediate and careful consideration. Miss Martin has, moreover, a claim of no ordinary kind upon the public. Her father, the late eminent painter, John Martin, devoted money, genius, and time for long years in the preparation of designs for the embankment of the Thames and other great metropolitian improvements, some of which have been carried out, and others will be, without the slightest return to Mr. Martin or his representatives. In all these efforts, as we know personally, his daughter was his devoted and loving assistant, acting as his amanuensis and right hand. Without any reference, however, to this, but entirely on the merits of the plan, we again commend Miss Martin's design, for connecting two very important districts, to the careful and considerate attention of the authorities and the public.

THE REAL-SCHOOL IN PESTH, HUNGARY.—PROFESSOR PETCHNIK, ARCHITECT.

### THE REAL-SCHOOL AT OFEN, OPPOSITE PESTH, HUNGARY.

The schools represented in our engraving have been erected in Alt-Ofen, adjoining Buda, a town of Hungary, on the right bank of the Danube. The design was made in 1857, and the schools were finished in 1859. The materials are red and white brick. The architect is Professor Petchnig. It is well situated on a height, and has a pleasing effect from the Danube, where the elevation has more unity. The architects of Pesth claim to be well acquainted with what is being done by English architects, through our pages. Dr. Henzelman, the well-known archaeologist, of Paris, a born Hungarian, has now the direction of the restoration of Villard de Honneour's church at Kaschan. Gerster is the architect under him, and the doctor will see the work is well done.

He will also be judge for the forthcoming competition for the new Academy of Arts in Pesth.

Pesth, as our readers will remember, situated on the left bank of the Danube, is connected with Buda by a fine suspension-bridge. It is about 136 miles from Vienna. Buda, the capital of the kingdom of Hungary, is a city of great antiquity. It was occupied by the Romans until the fourth century.

### CLASSES FOR INSTRUCTION IN ELEMENTARY SCIENCE, AND MECHANICS' INSTITUTIONS.

On the 1st instant Mr. Buckmaster delivered a public address at the Banbury Mechanics' Institution on the advantages and aid given by the new Science Minute to evening classes in connection with Mechanics' Institutions. Mr. Samuelson occupied the chair, supported by a number of gentlemen who have long taken a deep interest in the educational institutions of the borough. A discussion took place, in which Mr. Beale, Mr. Samuelson, Mr. Cadbury, Mr. Morrison, Mr. Roles, and others took part, when the following resolution was unanimously adopted:—"That in the opinion of this meeting the Science Minute of the Department of Science and Art is deserving the support of the evening classes in Mechanics' Institutions."

On the following evening Mr. Buckmaster addressed the workmen employed by Mr. Samuelson. One of the large workshops was extemporized for the occasion, and there was rather a large attendance of working men. With the exception of the persons on the platform, all were genuine working men. Mr. Samuelson was in the chair. He explained the reason of their being called together on so short a notice, and the deep interest he felt in every thing which tended to make men better than what they were. From what had taken place at the meeting last evening he was most anxious that the working men should have an opportunity of discussing this question of instruction in elementary science. It appeared to him that the Government were very willing to help those who were willing to help themselves. Mr. Buckmaster then explained that the object of the Minute was to assist the industrial classes in procuring instruction in those sciences which bore directly on the industrial resources and prosperity of the country, viz., practical, plane, and descriptive geometry; mechanical and machine drawing, building, construction, or practical architecture; mechanical physics, applied mechanics, experimental physics, inorganic chemistry, organic chemistry, geology, mining, zoology, human physiology, and botany.

To understand the conditions upon which aid is given, let us (he said) suppose a class in any of these subjects in a mechanics' institution or evening school, and the teacher holding the lowest, or third-class, certificate, and to which a yearly value of 10*l.* has been attached. In order that the teacher may obtain the benefit of his certificate, he must give forty hours' instruction in some subject, aided by the Department, to a class of pupils not under twelve years of age. This class will be examined; and, if only three pass, the teacher will receive his certificate allowance. In addition to this allowance, he will receive for every pupil who obtains a Queen's prize the sum of one, two, or three pounds, as payment on results. The amount which the teacher may receive under this head is only limited by the number of successful pupils. The standard of examination is low, and only such as justifies the examiner in reporting that the instruction, so far as it has gone, is sound. The examinations are not competitive: every teacher who obtains the necessary number of marks will obtain a certificate of the first, second, or third grade. The pupils of these science classes are encouraged by Queen's prizes, which consist of

suitable books, selected by the pupil or his friends, up to an amount which is determined according to the grade in which he passes. It will be seen at once that the chief feature of the Government scheme is to pay on tested results: how these results are obtained is rather a secondary consideration. The plan of assistance does not interfere in the slightest degree with existing institutions or schools, but rather stimulates them to greater usefulness. I know it has been said that the prospect of rewards and prizes is not the proper motive for seeking knowledge. Perhaps not; but with the mass you must have some definite and clearly-defined object which they can understand, and which they believe to be within the grasp of a reasonable effort. After all, rewards are not so bad: the heaven and hell of all Christians are based on this idea. Apart from the material advantages of knowledge, it is well when men seek knowledge for its own sake. But how difficult it is to master the elements of one single department of science! It is especially difficult for working men; but the same spirit which I have seen in times past, which has enabled you to labour patiently under great trials and privations, will, if properly directed, enable you to pass through the "wearisome bitterness of learning." Let what has been accomplished give us courage; and, if we are disappointed in the result, let us never fear the interests of humanity are safe under the eye of a Provident Providence.

The Rev. H. Back and other gentlemen addressed the meeting; and three workmen, Messrs. Manwaring, Holmes, and Cornes, are making arrangements to go to South Kensington, to be examined for the teachers' certificate in science, so that they may give instruction in the evening classes connected with the Britannia works. This is perhaps the first instance of working men taking up a question of this kind.

### SKINNING METROPOLITAN BUILDINGS.

At the present time this process is going on in various parts. Buildings of comparatively recent date have become so begrimed with soot, and the beating of the weather, or are so decayed, that scaffolding has been erected, and the structures are in the way of being chiselled from top to bottom.

The Scotch Church in Regent's-square, Gray's-inn-road, has been treated in this way. It seems that about the eighth of an inch over the whole surface has been cut away, and now the front looks like that of a new building. Satisfactory as is the present appearance, it is not desirable this process should be often necessary.

On another church in this square, which has been erected about the same time as that just mentioned, an examination has been made of the portico and facings. The state of decay is remarkable. In some parts the futings of the columns have entirely disappeared; and in other parts, the surface is rotten to a considerable depth. This rapid decay is a serious consideration. We ought to know more about stone than we do.

### PRINCE ALFRED'S VISIT TO THE CAPE.

YOUNG and inexperienced in worldly affairs as the two elder princes of the Royal Family of England are, their conduct on making what may be called their first public appearance has been unexceptionable, and must have had an immense influence in promoting a respect for royalty all the world over. As for the parents of the young princes themselves, the dignified yet affable and gentlemanly bearing of these their young sons,—not seldom in tedious, harassing, and trying circumstances,—has constituted a triumph of social and educational training with which they may well be pleased. The demeanour of the Prince of Wales in the United States was of no inconsiderable importance in an international view. Had even a vestige of undignified, of ill-natured, or of disrespectful conduct been displayed, under any circumstances, however trying, the whole tide of feeling might have been turned against us all, in the States, as if the nation were responsible. As it is, the good feeling between us and our Transatlantic consins has been decidedly enhanced by the well-trained and charming demeanour of the young prince. And this was equally the case in our own colonies,—in Canada with the Prince of Wales, and at the Cape of Good Hope with Prince Alfred—of whose visit our more immediate purpose at present is simply to take a professional note.

Among the events in Prince Alfred's visit were the laying of the first stones of the projected breakwater in Table Bay, the laying of the first

stone of a sailors' home (site given by Prince Alfred and the Governor, on Government property), and the opening of a public library and museum. The prince was feted and received (as was his brother in America) with the utmost enthusiasm, both by civilized and by savage. The Kniffrs and other aborigines vied with their less primitive brethren in the expression of loyal feeling towards the young "Ikosi," or Prince—a term, by the way, very curiously suggestive, though in Africa, of the ancient "Incas" of the American continent. Besides a ball, a concert, &c., there was an illumination, and the Prince was honoured by a formal body-guard of horsewomen, of whose (gallant) attentions (shall we call them?) the young midshipman appeared to be very proud.

The Cape Colony is making progress. One of its most recent steps in advance is the establishment of a penny post within municipal limits, with deliveries three times a day; and an extension of the English money-order system to the colony is contemplated.

### THE POLYTECHNIC INSTITUTION, REGENT-STREET.

THIS popular place of instructive amusement having fallen into the hands of a new company since the failure of the principal staircases—the consequences attending which are familiar to every one,—the new management have set themselves to work to re-construct and re-model a considerable part of the premises, with the view of rendering greater accommodation to the public.

The portico which formed the entrance to the building has been removed, the entrance considerably widened, and a shop constructed on each side, in that portion of the front premises which was formerly occupied by the officers and the vestibule of the Institution. To effect this, several walls and partitions have been cut away, the walls above being carried upon iron girders: the central corridor which was formerly constructed with stone paving on wood joists, is now paved with stone, on Fox & Barrett's fireproof floor, and access is obtained to the principal staircase by a broad flight of stone steps. The shops have plate-glass partitions next the corridor, and one of them has the convenience of a basement, with direct communication by means of a spiral iron staircase.

Great pains have been bestowed on the reconstruction of the principal staircases. The whole of the old steps, excepting those of the top flight, leading only to a gallery, have been removed, and new solid steps of Parkspring stone have been employed in the place of feather-edge Portland steps, formerly used. Under all the landings cantilevers have been fixed, and the security of those over the principal entrances to the exhibition has been insured by the upper ledge passing through the wall and being bolted down on the inside face. A wrought-iron string has been fixed under the outer edge of the upper flight, which is composed of old steps, and is supported by iron cantilevers, bolted at one end and well tailed into the wall at the other. The security of the staircase has also been increased by fixing cast-iron stays on the outside of some of the balusters, and also by fixing wrought-iron guards on the handrails at the landings, to give additional height.

A separate entrance from the principal staircase to the large side theatre has been constructed, with solid steps, up and down, and fireproof landings: by this means the access to, and the egress from, this theatre are materially assisted.

The engine which formerly stood in the entrance-hall has been placed in the great hall of the Exhibition. The floor of the gallery at the western end of this hall has been reconstructed, with wrought-iron riveted girders, the original construction having shown signs of failure. The staircases at this end have been re-constructed of Parkspring solid stone steps.

A new stone staircase has also been formed from the gallery of the Exhibition to a room at the back of the screen in the large side theatre; this room being made more available than heretofore, with additional light and new fire-place. At the extreme end of the building a small theatre has been remodelled and converted to the purposes of a picture gallery.

The management of the Institution having incorporated with the original undertaking an educational department, the front portion of the building above the ground-floor has been devoted to that purpose, and class-rooms have been formed for carrying out that object.

The laboratory, which has been a growing feature of the establishment, has been removed from its original *locale* in the basement, and placed in a well-lighted apartment off the principal stair-

case, and has every appliance attached to it which can make it an efficient laboratory.

The whole of the building has been thoroughly restored and painted. The works have been executed, under the direction of Mr. T. H. Wyatt, by Messrs. Lougnire & Burgo. The coloured decorations throughout have been carried out under the direction of Mr. Phené, the managing director.

We shall have another opportunity to speak of the entertainment provided and some of the things exhibited, but we must at once express a hope that a greater power of management exists in the Institution than was exhibited on the night it was opened for a private view. Unless it be so, the result will not be satisfactory. We say this by way of warning (not of complaint), and in the interest of an institution the success of which we desire.

#### WASTE HEAT USED UP, AND SMOKE CONSUMED, ON ECONOMICAL PRINCIPLES.

UNDER this heading we have occasionally called public attention to Mr. Hands's patent, as a promising mode of carrying out a suggestion long before made in the *Builder*, that waste heat, as of kilns, should be turned to account.

We hear, as to the manufacture of bricks, that some of the old brick-yards (where they are incapable of working above four months in a year with safety) are being transformed into factories, where they can make, dry, and burn bricks all the year round by his mode, which involves extracting the moisture from the centre of the newly-made bricks, tiles, or pottery, before the surfaces of the ware are allowed to incrust. Abroad, too, we are told that men are turning their attention to this invention. The *Journal des Mines*, in speaking of them, says Mr. Hands not only burns the smoke, and so effects a saving in fuel, but he obtains another result, which is this,—the articles dried by this principle never break in the kiln, for the heat is evenly diffused over the drying room, which is perfectly shut up, and free from draughts. The combustion of the smoke creates so strong a draught in the heated passages, that openings are made in them, through which the surplus vapours proceeding from the bricks or pottery are carried off.

Some gentlemen from Huddersfield, after going to his office, 5, Holland-street, Blackfriars, inspected his system in operation, at the works at Sudbury, a few days ago, and found some of the kilns were burning, and others were being emptied, and at the same time the process of drying the newly-made bricks was kept up with the waste heat from the kilns. They have since determined to erect rooms on his system. Other evidence has reached us of the gradual adoption of the principle. The system appears to be very simple, and the result economical.

We hear that Mr. George Jennings is extensively working this patent at his Pottery-works, Poole, Dorset, and that with great satisfaction to himself.

#### THE STREET TRAMWAY MOVEMENT.

At Birkenhead a certain class of the inhabitants are conscientiously object to the tramways, because they facilitate motion on Sundays; and they got up a memorial to the local Board of Commissioners on the subject, insisting—not that the tramway omnibuses should be prevented from running on Sundays but—that the tramways should be torn up altogether! Could anything be more preposterous and absurd in the shape of rational inference? Yes, there is one thing still more so; and that is, that another reason given for removing these very tramways is "that the facility given to the public by the street cars tends to induce parties to visit Liverpool in the way of marketings!" Were there a vestige of sanity in this idiotical inference, it is time the Londoners were astir to induce the Legislature to authorize the tearing up of every railway centering in London! Surely this memorial is a mere cunning dodge of that acute Yankee, Mr. Train, to enhance the merits of his tramway system? or is it an extract from *Punch*? The worst of it is that, while Mr. Train is assured, as he states, that, if he were not to run his cars on Sunday, the objections to leading would altogether cease; the foremost and most ostensible objection is pretended to be "the facility given to the public"—to run from Birkenhead to Liverpool,—but not (we presume) from Liverpool to Birkenhead—while the real objection, with its absurd inference, modestly appears, by a pious fraud, at the tail of the memo-

rial, like a lady's postscript, which is of more importance, in the eye of the writer, than the letter itself.

Mr. Train, we should suspect, whatever he has the merits of his system, could not well desire or require any more efficient promoters of it than these memorialists seem to be. And that they are promoters would appear from the result, according to the latest intelligence, which is that they have aroused a feeling the contrary of what they desired; and that the tramways are to be extended in Birkenhead.

The Marylebone vestry have resolved, by a large majority, to instruct their Paving Committee, in reference to the subject of paving the roadway of a certain part of Oxford-street, to take into its consideration the propriety of themselves laying down stone tramways within the same limits.

The tramway movement is also making active progress in Lambeth, Shore-ditch, and other districts of the metropolis.

#### THE LOCAL BUILDING REGULATIONS AT DONCASTER.

THE Doncaster council have adopted a series of bye-laws as to new streets, buildings, sewerage, &c., which, according to the local *Gazette* of 9th inst., which gives an abstract of them, have been confirmed by the Home Secretary. Every new street, not being a carriage-road, must be at least 30 feet wide, and where more than 100 feet long, the local Board of Health have the option of determining whether it shall be made into a carriage-road or not. The walls of every new building must be of such thickness as the Board of Health approve of, the foundations to rest upon solid ground, concrete, or other solid substructure. The external or party-walls to be of stone, brick, or other solid and incombustible substance, unless otherwise allowed where no danger of fire is apprehended. No finish or dowerwork shall be placed within 4½ inches of the inside face of any chimney or flue, and no openings shall be made in any chimneys or flues, nor shall pipes be fixed for conveyed smoke, heated air, steam, or hot water, except in manner approved of by the Board. Every dwelling-house to be erected shall have, either at the rear or side, 150 square feet free from any erection whatever, and the distance across such open space and the opposite property shall be 10 feet at least. If two stories in height above the level of such open space the distance across shall be 15 feet; if three stories, 20 feet; if more than three stories, 25 feet. Every new public building or school, and also every shop or factory, now erected or to be erected, shall be supplied with the means of ventilation to be approved of by the Board. With respect to the drainage of buildings, to water-closets, privies, ashpits, and cesspools in connection with buildings, the closing of buildings unfit for human habitation, and the prohibition of such for habitation, the clauses are somewhat numerous, extending from the 8th to the 26th.

#### CHURCH-BUILDING NEWS.

**South Hinksey.**—The parish church of South Hinksey, after having been closed for three months, for the purpose of restoration, has been re-opened by the Bishop of Oxford. The edifice was first built in the thirteenth century, but the decay of time, and the so-called taste of the last century, had almost obliterated the earlier features of the structure. These features have, however, been brought out again by Mr. C. A. Buckridge, architect, under whose direction the whole of the works have been executed by Messrs. Young & Co., of Oxford. The interior of the nave and tower has been restored, and fitted with open fittings; whilst the roof (which before had a very unsightly appearance) is now uniformly covered with Stonesfield slates.

**Abchurch.**—The new Baptist chapel has been opened. It was designed by Mr. James Cranston, architect, and erected at a cost altogether of about 900l., by Mr. W. Showell, builder, Birmingham. It is in the Gothic style of architecture.

**Brecon.**—A numerous meeting has been held at the Sbir Hall in this town, to consider the propriety of restoring a portion of the Priory Church. The Marquis Camden had offered 1,500l. towards the restoration of the chancel, provided 2,000l. were raised for the tower and transept. The chair was occupied by the Bishop of St. David's, and among those present were the Marquis Camden, the Earl of Brecknock, Sir Thomas Phillips, Archdeacon Davies, and Mr. Scott, the architect, who addressed the meeting, but presented no formal report. He said what they ought to do, in the

first instance, was to look to the main security of the building. The outer walls were substantial and firm, but the foundations wanted examining and under-pinning. The roof of the tower would have to be made new, the pointing attended to, the walls internally cleaned, and the accumulation of whitewash removed, so as to expose the fine old grey stone of the country; the roof of the transept was much decayed, part to be restored to its proper height. The floors would all have to be taken up, and especial care taken in relaying and replacing those monumental memorials of the past of which there were so many. The screen dividing the chancel from the nave would have to be removed, in order to give the fullest effect to the interior. The meeting resolved to meet the Marquis Camden's views by raising the sum required, and of this sum 1,250l. were subscribed at the meeting.

**Holme Pierrepont (Notts).**—The church here has been recently refitted and partially restored, at the expense of the late Earl Mansvers, and under the direction of Messrs. Hine & Evans, architects. The square box pews have been removed and open benches substituted. The family pew of the Earl, with its armorial hearings and other carved and gilded ornaments, has not been spared, and the family bench is now as one of the rest. The works have been executed by Mr. Joseph Hill.

**Lichfield.**—The choir of Lichfield cathedral has been re-opened, the stonework having been completed. The entire edifice will not be re-opened until the whitewash has been removed from the nave. There are six additional figures placed in niches in the choir, representing St. Peter, St. Philip, St. Christopher, St. James, St. Mary, and St. Mary Magdalen, which are the gifts by collection of several ladies and gentlemen. The new organ lately erected in the cathedral was built by Holditch, of London, and presented by Mr. Josiah Spode, of Hawkesyard. It is supplied by three pairs of bellows, with double feeders, requiring three men. The organ consists of three rows of keys, and a large independent pedal organ, the compass of the manuals being from CC to F in alt. The total number of great organ pipes is 1,056, of swell organ pipes 828, and of choir organ pipes 312; the pedal organ contains 211 pipes. The total number is 2,507 pipes and 60 stops. The pedal organ has a compass from C to E; and the large 32 feet CCC pipes are laid down.

**Melbourne.**—The church here has been restored, at a cost of 2,000l., and re-opened. During the restoration there were discovered many traces of its having been on fire, and for a long series of years the nave seems to have been roofless. In restoring it care has been taken not to cut away or injure any of the older work, and the new has been added in a style of architecture corresponding with the old. Mr. Scott has been the architect, and Mr. Hall, of Nottingham, the contractor.

**Birmingham.**—The new church of St. Barnabas, in Ryland-street North, has been consecrated. The edifice is in the Early Decorated Style. The architect was Mr. Bourne, of Dudley, and the builder, Mr. Melson, of Birmingham. Provision is made for 850 persons. The dimensions are, length, 80 feet; width, 44 feet 4 inches; height, 50 feet; and side walls, 20 feet.

**Woolton.**—The small Roman Catholic Church of St. Mary just erected at Much Woolton has been opened with the usual solemnities by the (R. C.) Bishop of Liverpool. The edifice is situated on a slightly elevated plot of ground. It is in the Early Geometrical style, and seats 650 persons. At the east end, the communion-rail, which is 46 feet in length, is brought 6 feet within the chancel arch. The church is composed of nave, chancel, side chapels, and transept. The estimated cost was 2,203l. Mr. R. W. Hughes, of Preston, was the architect; and the contractor, Mr. Hill, of Woolton; sub-contractors, Messrs. Walker & Co., Nicholson, and Bromley. The carving work was executed by Mr. Gellowski, of Liverpool.

**Manchester.**—The foundation stone of a new Wesleyan Chapel has been laid on a plot of ground known as Pooley's Park, fronting City-road, and near to Stretford Old-road. The chapel will be in the Early Pointed style, with stone dressings, and be capable of seating about 800 persons. The frontage to City-road will be 60 feet, and the interior of the chancel 72 feet by 38 feet 6 inches; besides the semicircular apse at the end, in which the communion will be administered. The roof will be constructed so as to gain the effect of the ordinary steep-pitched church roof; columns will be avoided. The gallery will traverse the sides and across the front of the chancel, the body of which will be lighted by three-light windows under the gallery, and above by circular cusped

windows, instead of the usual long windows, stretching nearly from floor to ceiling. The chancel will be lighted by three cusped lancet windows. A tower and spire are to be raised, the extreme height of which from the ground will be 100 feet. The work will be executed from designs by the architects, Messrs. Haley & Sons, of Manchester; and the contract has been entrusted to Mr. Warburton, of Harpurhey. A number of the sittings will be free.

**Sheffield.**—The new church, erected at Solly-street, and dedicated to St. Luke, has been consecrated by the Archbishop of York. The church is a Gothic structure, in the Flowing Decorated style, the arrangement of the plan being a nave with north and south aisles, and an internal chancel. The ground is considerably elevated, and the approach to the principal entrance is by a stone flight of steps. The plan provides for a spire to be erected at the corner adjoining Solly-street and Garden-street. The height of the spire will be 125 feet. The total length of the building is 74 feet, and it is divided into a nave, 40 feet by 24; chancel, 34 feet by 24; south aisle, 58 feet by 18; and north aisle, 56 feet by 11. It accommodates 700, about half of them free. It is intended to erect galleries at some future period over the aisles. The cost of the building in its present state is 2,500*l.*, all raised except 300*l.* It will take about 700*l.* more to complete the edifice. Mr. James Mitchell is the architect.

**Hovingham (Yorkshire).**—The church of Hovingham has been rebuilt and restored by Mr. Marcus Worsley, as a memorial of his deceased wife, and re-opened for divine worship. The church consists of a chancel with north aisle, and a nave with north and south aisles. The chancel and nave have been entirely rebuilt, the original character of the edifice being maintained. The old Norman tower has been repaired, and a new roof of stone placed upon it, surmounted by a plain cross. The roof of the chancel is open-timbered and unvasecoated: that of the nave also shows the rafters, which are stained. The floor of the chancel within the communion-rails is laid with mosaic tiles, and the remainder of the chancel floor is paved with self-coloured tiles. Mr. Hawkins, of London, was the architect; and Mr. Peale, of Malton, the contractor.

#### SUBWAYS FOR GAS AND WATER MAINS, REGENT STREET. LOSS OF GAS.

UNDER this head in the number for the 13th ult., the *Builder* published an account of an effort then being made by the Vestry of St. James's, Westminster, to bring about the formation of an accessible subway through Regent-street, for the deposit of a simplified system of the necessary gas and water mains, of which under present arrangements there is in the street a complex accumulation of no less than nineteen lines. The project had its immediate origin in an intimation the Vestry received from the Chartered Gas Company of their intention of breaking up this street for the purpose of taking up two of their mains, and the replacing them with others of greater calibre, for extending their business operations to distant quarters. The Vestry, desirous of availing themselves of the opportunity here presented of carrying out, in conjunction with this work of the Gas Company, the construction of such a subway, entreated the directors to delay for the moment their proposed operations in Regent-street; holding out, as the project in contemplation did, a probability that the mains might at once be laid in that way. But the company rejecting all overtures on the subject, proceeded to break up the street in defiance of Vestry interdiction. Whereupon the Vestry, actuated, not by a spirit of obstruction, but merely by a desire to gain time for maturing and giving practical effect to their scheme, resolved on taking a stand in vindication of its controlling powers in these cases (Metropolis Local Management Act, clauses 109, 110). However a bill filed in Chancery, and an injunction moved for, to restrain the Gas Company from going on, has been unsuccessful, Vice-Chancellor Kindersley ruling that a Court of Equity ought not to interfere unless the public interest suffered, which he considered it did not in this case, as it was manifestly for the interest of the public that the gas supply should be increased.

The Vestry, dissatisfied with the equity decision, and unwilling to leave any proceeding that promised a chance of success to its object untried, and, backed by the unmistakable clearness on the point, of the restrictive powers conferred by sections 109, 110, and 114 of the abovementioned

Act, recommended that, of procedure by summons for recovery of penalties; but, in consultation with eminent counsel, so much importance seemed to attach to the probable influential operation of the Vice-Chancellor's recent decision on the case, on magisterial judgment, as to render the attempt at proceedings in that way futile. As the result of this same consultation, an effort is now being made to so apply the powers of the 98th section of the same Act as will secure such a mode of carrying out the unexecuted portion of the gas-work in progress as will prepare for the ultimate introduction of a sub-way; but, in the mean time, the work of laying down the mains is being pushed forward with all haste, and in a few days more, so much will have been completed, that even though success attend this action, little advantage will be secured to the object in view. Indeed, it is now conclusive that the opportunity of forming a sub-way in Regent-street is finally gone by. The difficulties to the future execution of the project will be so enormously increased by the effect of the work now going on as to render any attempt hereafter to accomplish it, as a parochial undertaking, perfectly hopeless. And thus an enlightened local effort to preclude the establishment of a great metropolitan requirement has become abortive.

In a subsequent communication, having reference to the same subject (see p. 678, *ante*) allusion is made to Professor Spencer's report to the New River Waterworks Company on the corrosion of iron mains from the effects of gas leakage. This report contains further matter of so much moment to the London public at this juncture as to induce one more communication on the subject, founded mainly, it must be observed, on the deductions put forth in that document.

In the metropolitan supply of gas, it would seem that nearly one quarter of the entire manufacture is unaccounted for: in other words, that the gas companies receive pay for only three quarters of the stock they produce; this loss being occasioned by the various processes of condensation, defective meterage, fraud, and leakage.

After giving full allowance for loss from all other causes, that from leakage alone Professor Spencer sets down at 630,000,000 cubic feet per annum. That is, a quantity of gas equal to one-tenth of all that is burnt in London escapes from the mains, and is absorbed into the street earth, giving that blackened appearance and gas odour always observable in the subsoil of leading streets, wherever turned up. Were this immense loss of gas—which in value is equal to a dividend of 3½ per cent. per annum on the entire subscribed capital of all the thirteen metropolitan companies—a mere matter of "profit and loss," the circumstance would be of little interest to any but gas shareholders themselves. To the London public, however, it involves consequences most serious. (See the *Builder*, Oct. 20.) The joints of the mains are the outlet of this fearful escape. And Professor Spencer's arguments makes it pretty clear that this arises mainly from defects inherent to the mechanism of the joint now in universal use; and that it is the thing that it is now especially sought to bring under notice.

Gas mains and water mains are formed of a series of iron tubes of about 9 feet long, each tube having one widened end forming a socket, the other end being narrowed; and in laying, the narrow end of one tube is passed about 4 inches into the socket end of the next, just as the jointing of a flute or clarinet; and just as the joints of these instruments are not air-tight until wrapped with cord, so it is with the pipes for the conveyance of gas. The small end of the tube is less than the socket into which it goes, and when placed on concentrically, leaves a space of half an inch or so all round. Into this interstice a piece of hempen rope is pressed tightly, similar to the process of calking the seams of a ship; and the orifice of the opening is then plugged with a molten lead. As left by the workmen, this joint is probably generally gas-tight, and if it remained in the state as finished, there would be little to complain of; but it would seem every joint soon becomes more or less leaky, the fitting appliances (hemp and lead) being insufficient to the permanent retention of the gas. Thus, first, as to the hempen calking portion of it: if the hemp could be retained in a moistened and swollen state, as is the case in its similar employment in the jointing of water-mains, it might be successful to its intent here; but the nature of the contents of the gas-mains, on the contrary, is to dry and shrink the hemp, and, however tightly the calking may have originally been performed, the gas after a while freely permeates it. And, secondly, as respects the leaden plugging, the failure of this is attributable

to the contraction and expansion of the metals, by the alternations of cold and warmth. Of course iron pipeage for gas, though situated some two or three feet beneath the surface, is subject to this same universal law. It is a well-known fact that the iron rails of a railway expand in warm weather, on which account a space of about a quarter of an inch is seen to be always left between the ends of each rail. In warm weather the iron tubes of the Britannia-bridge measure several inches in excess of what they do in extreme winter, for which contingency ample provision is made at either end. Although what is just said applies to longitudinal expansion and contraction only, yet expansion and contraction of metals takes place also laterally in the same way, and hence, more particularly, the disturbing effect on the joints of gas-mains. For example, take the joint of a gas-main that has been laid during warm weather, when its diameter and length are at their maximum; as soon as the coldest weather sets in, the size of the main, including the joint, will have reached its minimum. But in its progress from one extreme to the other, it is evident that the joint must undergo disturbance; even though the lead and iron should expand and contract in an equal ratio: this latter, however, is not the case. Lead is but little acted upon in this way: its expansion and contraction as compared with cast-iron is only as 1 to 3. Thus, however tightly lead may be driven into the interstice of the joint originally, the joint subsequently becomes liable to disturbance from the operation of this law. Remembering, too, that there is no chemical adhesion between the iron and the lead, as in soldering, the joint being altogether mechanical.

It will now be obvious that a chief defect of the lead and iron joint for gas-mains arises from this important physical difference in the nature of the two metals. Notwithstanding the disturbance to which this joint is subjected by every change of temperature, it is clear that if the metals composing it contracted and expanded in equal ratio, less injury would arise in practice. But it is thus—the lead and iron are each contracted to a minimum in winter; but as the contractile power of the lead is not equal to that of the iron, it is obvious that the latter, in contracting, will press the softer metal into a less diameter than it would have assumed naturally. On the return of warm weather, when the iron portion of the joint becomes expanded to its original diameter, that originally belonging to the lead is necessarily covered, consequently, space is left between the iron and the lead sufficiently large to allow of the constant escape of the gas complained of.

According to ordinary ideas of space, openings in themselves so minute as are here implied, may appear inappreciable in practice; yet, taken in connection with the extremely subtle nature of gas, more especially best gas, they are far from being so. It is a well-known fact in chemical practice that apertures sufficient to exclude air and water will not exclude gas. A cracked receiver, for example, will hold water tightly enough, though it will allow gas to escape freely.

The fact of this mode of jointing gas and water mains, continuing to this day precisely the same as has been in use in the metropolis ever since the time of the first application of iron to the purpose, nearly fifty years ago, considered in connection with the fact of the joint being notoriously defective, naturally suggests the question,—has the working in iron, which has made such wondrous advance in the past half century, done nothing to the improvement of gas mains? The metropolis answers no; but Liverpool, Manchester, and Leeds, say yes. Gas mains with joints denominated "bored and turned" have for some years been in use in these great towns, with the most successful results, which a few recorded facts from Liverpool, where they have been long employed, sufficiently demonstrate.

The tubes for the mains, with the joint here referred to, are planned with their diameter a little larger at one end than the other. After the casting, the tubes are subjected to a finishing process: this is, a few inches of the interior of the larger ends are bored and ground, which is, in effect, like preparing the neck of a bottle to receive its stopper. The exterior of the smaller end is then lathe-turned, and fitted into the interior of one that has been previously bored. Thus the small end may be looked on as a stopper made without difficulty to fit into the neck of its fellow, every joint being so finished and completed in the foundry as at once to fit air-tight with precision and accuracy, after which each pair is numbered, so that in laying the respective pieces may be joined together without mistake. A coating of unctuous cement is applied to the ends on laying.

Since the adoption of this species of joint in Liverpool the loss on the manufacture of gas from all causes together has been reduced to 11 per cent. as against 22 per cent. in the metropolis, which low rate has been by degrees arrived at apparently just in the ratio that the replacing of the old pipeage by the new has progressed. And it has been observed that, in places where the old pipes have been long disused, the street earth has become comparatively without the odour of gas; as also that the water, the mains of which lie side by side with those of the gas, is now in no way affected.

Nor is the fact of the rapidity with which a line of main on this construction can be laid, underscoring of notice,—a rapidity, it is reported, equal to keeping pace with the most expeditious opening of the ground by one set of men, and the filling in behind by another.

At the present moment the metropolitan gas companies are each, to a greater or less extent, renewing their trunk mains in much larger calibre.

These prodigious pipes are being put together precisely on the same faulty principle as heretofore, a circumstance which suggests the question—apart from the consideration of subways,—are the gas companies doing justice to the public in their thus persevering in laying down these defective conduits? In the full knowledge, at the same time, that more perfect constructions are practicable at a little additional cost; and thus perpetuating the existence of one of the most fearful nuisances the metropolis is subject to.\*

Take the Regent-street case as an example; here two 10-inch mains are being removed, and replaced with others of 20-inch diameter. Now it is a principle in hydraulics that a tube twice the diameter of another will permit the passage of five times the quantity of liquid of the lesser one (the same law, it is presumed, applies in the case of gas); hence it follows as a certainty, that from this ten-fold increased flow of gas through the street, there will be at no distant period, when the new joints shall have had time to become leaky—the inevitable consequence of their “make,”—a corresponding increased escape of gas into the subsoil of the road. By no means an agreeable prospect for Regent-street. It is, however, a verification of the old adage, that “that which is everybody’s business is nobody’s.”

F. C.

#### ENGLISH SCULPTORS AND THE “CEUR DE LION” STATUE.

SIR,—Your remarks of last week on Baron Marchetti’s “Cœur de Lion” statue have been welcomed by all having the slightest regard for that impartiality of criticism demanded of the public journalist, which same measure of justice, much to the regret of honest minds, appears to be at times ignored in columns but too readily opened to any disparagings of our national character as artists.

You observe with truth, “this work has been greatly overpraised,”—an opinion, I am sure, held in common with all liberal men, who, whilst admitting whatever merits it may possess, must protest against the false tone and invidious feeling characterizing much of its criticism, as being not only insulting to Englishmen, but tending to foster most pernicious influences in the public mind. Is it that the writers of these glowing praises, sickeningly eulogistic on the one hand, and invidiously detractive on the other, are themselves striving for favour in high quarters by the back stairs? or is their estimate of our national art-capacity and patriotism so low as to lead them to believe that, in the desire to honour our illustrious dead, or embellish our public places with works worthy of a nation foremost in the ranks of time, we, Englishmen of the nineteenth century, are to cower under the humiliating sense of self-abasement, and, from convictions of incompetency, accept with grateful thanksgiving the production of a foreigner, whose works have, over and over again, been arraigned

\* Not yet, perhaps, should it be concluded that even this “bored and turned joint” is the very best thing that can be had for the purpose. A matter of such vital importance to the public, and pecuniary interest to the gas shareholders themselves, when the great works now in progress were about to be undertaken, ought to have instigated some effort on the part of the directors to the finding out of the most perfect construction for the purpose. A premium of £1000, offered for the most approved plan of gas main, would have put in motion—the elucidation of that point—all the inventive genius of the world in that line. The new Gas Act, just passed, by assigning companies, at once puts an end to the competition or rivalry in any way, and there is now nothing to prevent them, in such proceedings as that now suggested might have been carried out for 1000. per company.

at the bar of professional opinion, and notoriously found wanting? If such are the doctrines of our self-elected censors of art, the sooner they descend from their pedestals the better, not only for their own credit, but especially for the cause, which, while pretending to serve, they in reality damage.

Why, sir, the very journal whose influence the public is taught to hold as paramount, in at once directing and reflecting English taste and feeling, unhesitatingly tells the world we cannot make an equestrian statue, and therefore have cause for congratulation in having one made for us. Is the writer in the *Times* unconscious of the existence of Mr. Foley’s “Lord Hardinge and Charger,” or aware of its merit? Has he, in the face of such a fact, the bravery to taunt us with incompetency for such subjects? This work alone is more than enough to vindicate our national honour, and not only does it overwhelmingly refute any such malignant aspersions, but will hereafter serve to mark the school and age of its production.

In common honesty, then, let us “render to Cæsar the things that are Cæsar’s,” and, since the “Hardinge” statue demonstrates, beyond all doubt, the Englishman’s capacity for such achievements, we cannot stand coldly by and see the laurels of Fame wrenched from the brow of Genius, to wither in the uncongenial grasp of propped up mediocrity.

Among the various works to which the “Cœur de Lion” has been compared, is Kiss’s “Amazon,” and nothing could be more ill selected, there being no point of similarity in common between them. The “Amazon” is a fine example of the most complete concentrative unity in idea, design, and execution, whilst the “Cœur de Lion” is but a patchwork of incompatible isolations: the fore and hind parts of the horse appear to belong to different animals, or at best to an animal in different actions, the back parts being at rest, while the fore parts are in motion. As regards the surface manipulation, the modelling is most unworkmanlike. Altogether the work is unworthy its purpose, and must be viewed rather as a warning than an example, whilst the attempt to foist it on the public as a standard for English imitation can be met only by the earnest protest of all capable of appreciating such effort. X. Y. Z.

#### A CAUTION TO CARPENTERS.

SIR,—A carpenter of the name of Wm. Bachelor worked five days for Mr. Rudkin: he was paid the usual rate of wages, 5s. per day for an ordinary workman. He was told after dinner on Saturday that his services would not be required after that day, and to take his tools away with him, which consisted of fixing tools, which perhaps weighed 20 lbs. or 25 lbs. in the whole; he neglected to do so, and went to the job on Monday morning to fetch them, for which he wanted to be paid for a quarter of a day, after having had sufficient notice to take them with him when discharged. He then took out a summons for an additional 6d. per day, the wages given to superior workmen, as well as for the quarter he demanded for grinding on the Monday morning, which amounted to 3s. 10d. Of course a verdict was found for his employer, the defendant; and the plaintiff was ordered to pay his employer and his foreman, for appearing against so unreasonable a demand, 5s. each. The earliest insertion will much oblige.

E. COWARD,  
(for T. RUDKIN).

#### SCENERY AND THE STAGE.

At *Her Majesty’s Theatre*, “Robin Hood” still fills the house, and in many respects deserves to do so. It is to be regretted, however, that its production was not superintended by some competent person. The “getting up” is beneath criticism. For example, Robin Hood flourished in the reign of Richard of the Lion Heart,—the twelfth century,—the king is spoken of more than once in the opera; and yet we have in the second act an apartment specifically and ostentatiously of the fourteenth century, while the steps and terrace of another scene at the end of the opera belong to the sixteenth or seventeenth century. Mr. Sims Reeves is singing magnificently in it; and Mrs. Lemmens Sherrington has exceeded the expectations of those who expected much from her. This lady is a great acquisition to the lyric stage.

*Royal Italian Opera-house, Covent-garden.*—Mr. Harrison has produced Mr. Edward Loder’s opera, “The Night Dancers,” which contains, as the public know, some very pleasing music, and enables Mr. Henry Haigh to show that he has

improved greatly, and is now a charming singer. Madame Palmieri sings much of the music very well, and would do it better if some kind friend would lead her to show that she really understands what she is doing.

In the new drama, at *Drury-lane*, “A Tale of the [Rebellion of] ‘45,” besides some very spirited representations of the “March to Finchley,” and another of Hogarth’s pictures, Mr. Beverley has produced a novel and very clever moonlight scene, with flying clouds, which obscure and pass the moon, with admirable effect, and which would he even improved if the movement were a little less rapid. The piece is interesting, and Mr. Webster and Mr. J. L. Toole (in a Robson part) act admirably.

#### THE ARCHITECTURAL EXAMINATION QUESTION.

##### LIVERPOOL ARCHITECTURAL SOCIETY.

On the 6th, a meeting of the associates and students of this Association was held, to take into consideration the plan proposed by the professional members with regard to the question of “Architectural Examination,” laid before the Society by the Royal Institute of British Architects, and for the purpose of framing a memorial, to be presented to the Institute, informing its members of the opinions of those who, by the Liverpool Architectural Society, are excluded from voting on professional matters, yet on whose shoulders the whole weight of the proposed examination falls. Mr. Wm. Audsley presided. Several gentlemen having addressed the meeting at some length in condemnation of the proposed examination for a diploma, Mr. G. A. Audsley moved, and Mr. Doyle seconded, a resolution to the effect that the decision come by the Liverpool Society at their next meeting was, as just, and that, if it were not reversed, the associates, students, and professional members would memorialise the Royal Institute of British Architects to negative that decision.

#### DECISIONS UNDER THE METROPOLITAN BUILDING ACT.

##### BUILDINGS ON WHEELS.

At the Clerkenwell Police Court, on Friday, the 6th inst., Mr. Cases, of Ackerly-row, Islington, was summoned by Mr. Godwin, the district-surveyor of South Islington, for not amending certain irregularities committed in erecting a workshop, used as a wheelwright’s, in the rear of No. 6, Ackerly-row. Several shops had been erected at the end of the back gardens of this row, having a frontage in a Lower-road. The building in question was erected on a vacant space between two recently-built shops, having a frontage of about 29 feet 6 inches, and a depth of about 23 feet 6 inches. The defendant had covered over the area with a circular roof of boarding, pitched with gutters on each side, about 15 inches wide, also of wood sawed pitch. The roof was supported by four uprights on each side, resting on plates upon the ground, beneath which were some small wheels, and had one upright in the centre, resting on the ground. The front also was partly enclosed with woodwork.

The solicitor, on the part of the defendant, maintained that it was not a building contemplated by the Act, but merely a booth on wheels, so erected in order that it might be removed at the end of the term, with no intention to evade the Building Act.

It was held by the district surveyor that even with the small wheels attached it could not be removed without being taken to pieces, and the front part being taken down.

The defendant replied that it could be removed in two pieces.

The magistrate (Mr. D’Eyncourt), after a very patient hearing, said he was perfectly satisfied that it was a building not erected in accordance with the Act, and dangerous to the public, and he would make an order that the irregularities be forthwith amended.

##### BUILDERS’ ACTIONS.

*Ormes v. Beadel.*—This appeal, in the Court of Chancery, before the Lord Chancellor, from a decree of Vice-Chancellor Stuart, was argued a few days back, and stood the case until the end of the term, with no intention over for judgment. The case made out by the pleadings was that the plaintiff, a builder, in August, 1858, signed certain conditions, whereby he agreed to erect a house for one of the defendants, Alfred Copland. One of the conditions of the contract stated that if the works did not proceed with such progress as the architects, Messrs. Beadel, Son, & Cancellor, of Chelmsford, might consider necessary, they should be empowered to purchase materials and employ such workmen as they might consider necessary, and deduct the costs from any money due to the contractor. The whole of the money for the erection (with the exception of a sum to be retained for six months) was to be paid to the contractor, during and upon the completion of the work, on the architects’ certificate. The building was commenced; and, after two months, amounting to 25s. had been paid on the architects’ certificate, the plaintiffs’ agents, the architects, refused to give another certificate. Ormes made several applications, both to the architects for a certificate and to Alfred Copland for the money, but without success. The defendants then applied to the court, and the architects’ workmen not having been paid, all their wages were to the architects’ office to make another effort to obtain money, and he was followed there by the workmen, who were clamorous for the money, but he prevented his leaving the office until the wages were paid. Ormes then, at the dictation of the architect, signed a letter, dated the 11th of December, 1858, whereby, in consideration of 50l. then paid to him, he agreed to pay the balance of the sum being due to him; he gave up his contract, and agreed that the works should be paid for at a valuation. The bill was filed by Ormes to set aside this last agreement of December, 1858, on the ground that the plaintiffs’ agents, the architects, had obtained that the plaintiff’s signature to it had been obtained under such circumstances as that he was not bound thereby, or the subsequent proceedings thereunder.

From the defendants’ appeal, the following appeared:—Mr. Malins and Mr. Osborne were for the appellants;

Mr. Bacon, Mr. W. D. Lewis, and Mr. Drace supported the decree.

The Lord Chancellor on the 7th instant gave judgment and said there was no feature in the case which rendered the decision of the court below incapable of being supported. It appeared from the evidence that the plaintiff was fully aware of the nature and effect of the agreement of the 11th of December, 1858, at the time he executed it; that he voluntarily entered into it, and subsequently acted upon it. For these reasons the plaintiff was precluded from now asking to be relieved from its operation, and therefore the decision of the court below must be reversed and the bill dismissed.

**COMPENSATION TO WEEKLY TENANTS.**

An application was made last week at the Marylebone Court-house, before W. Griffiths, Esq., and Valentine Knight, Esq. (the presiding magistrates), by Mr. Pook, of Basinghall-street, on behalf of Mr. Bolin, a baker, residing at the corner of Chapel-street, Edgware-road, for compensation, in consequence of his premises being required by the Metropolitan Underground Railway Company.

Mr. Burchell, who appeared for the company, opposed the application, on the ground that the claimant was merely a weekly tenant, and therefore not entitled, under the Lands Clauses Consolidation Act, to compensation. He examined Mr. Withall, surveyor, and other witnesses, in support of his contention.

Mr. Pook argued that where a tradesman had been conducting a profitable business for some years, and even where there was no written agreement for a yearly tenancy, the uncertain nature of the tenancy made it a yearly one. In support of this view Mr. Pook cited several cases from well-established authorities, and called Mr. Pook, the auctioneer, and other witnesses, whose testimony, he contended, was conclusive upon the point.

The court having been cleared, after an hour's deliberation the magistrate decided that the claimant was entitled to 17*l.* as compensation.

**Books Received.**

*Useful Information for Engineers.* By WILLIAM FAIRBAIRN, LL.D., F.R.S. Second Series. London: Longman & Co. 1860.

The first issue of this important and valuable work was peculiarly successful, and this has led to the publication of the present volume, which contains various original papers not before printed, or not easily accessible to ordinary readers.

In a discourse on the education of working men, Dr. Fairbairn has shown what a wide field is still open for talent, combined with industry and self-reverence, in the attainment of distinction in science and art. In the papers on the Collapse of Tubes, a law of resistance determined by experiment is laid down—the law that “the resistance is inversely as the length of the tube exposed to pressure.” In the paper on the resistance of glass globes and cylinders to collapse from external pressure, and on the tensile and compressive strength of various kinds of glass, the author has sought to confirm the previous experiments on wrought-iron tubes, by experiments on a perfectly homogeneous material. On the influence of temperature on the cohesive strength of wrought-iron forms the subject of another paper, recording Dr. Fairbairn's experiments on that important subject.

For some part of the paper on the compressive strength of brick and stone, intended for the guidance of the architect and engineer, we must endeavour to find room in an early number of the *Builder*: in calculating the strength of piers, walls, and other structures, the results, the author confidently states, may safely be relied on.

There are also lectures on the machinery employed in agriculture, urging on the farmer the value and necessity of machine culture;—on the rise and progress of civil and mechanical engineering;—and on iron ship building, showing the disastrous consequences of construction on erroneous principles, and that numbers of iron vessels are perfectly unseaworthy; no wonder, therefore, they so often and so suddenly break up and sink.

Altogether, this volume forms a very important addition to our standard scientific treatises.

“The Year 1800;” or, *The Sayings and Doings of our Fathers and Mothers Sixty Years ago.* Compiled by F. PERAZZI, author of the “Chart of the Navy of Great Britain, from the earliest Period of History.” London: Thomas Sanderson, Fleet-street.

MR. PERAZZI, by putting together extracts from the newspapers and magazines of one particular year, has formed an interesting delineation of the manners and habits of our immediate ancestors, by which the reader may be able to judge of the advances made in the political and social condition of the people at the present time.

The compilation has been made from upwards of 1,000 different newspapers, printed during 1800, and contains a variety of curious advertisements, together with selections of articles on most of the political and domestic topics of the

period, arranged according to their subjects, and comprising home and foreign politics; Parliamentary proceedings; naval and military intelligence; magisterial and judicial cases; the fine arts; the theatres and amusements; sporting news; the *haut-ton* and prevailing fashions; the *faciæ* of the day; comprehending a variety of miscellaneous matter from which much information may be obtained of the public and domestic life in England at the conclusion of the past century. Gas, locomotives, electric telegraphs, and free trade were then unknown.

Mr. Perigal has classified his extracts so that the book really gives a readable view of the condition of things in 1800.

**Miscellanea.**

CARDIFF.—It having at length been resolved to demolish the present town-hall at Cardiff, the materials have been sold by auction. The first bid was only 20*l.*, and it was with considerable difficulty that the auctioneer obtained 100*l.* for the whole with the exception of the clock, which, however, has not kept time for the last 150 years. The auctioneer sold the old hall contained at least 20,000 superior bricks, and a large quantity of lead.

EDINBURGH.—Designs for a new Free Church in Pilgrig-street, by Messrs. Peddie & Kinmar, architects, have been adopted, and operations will be commenced at Whitsunday next. The style of the new church is Gothic, with a French tone in the composition, and the prominent parts of the design are a tower and spire nearly 150 feet high, and gables pierced by large and characteristic windows. As the site of the edifice is a space acquired on the north side of Pilgrig-street at its junction with Leith-walk, it is intended to give effective frontages to both streets. The principal entrance will be from Leith-walk, and the church will be seated for between 700 and 800 persons.

A CASE AS TO AN ARCHITECT'S CHARGES.—*Prideaux v. Middleton*, in Birmingham County Court.—Plaintiff, who retained Mr. King, was recently landlord of the Acorn Inn, Temple-street; and defendant, for whom Mr. Robinson appeared, is an architect in the same locality. The action was brought to recover a sum of 16*l.* 13*s.* 4*d.*, for rent of premises in Temple-street (adjoining the Acorn Inn), due from Mr. Middleton to Mr. Prideaux. A set-off for 10*l.* was pleaded by the defendant, for professional services rendered by him to the plaintiff, under the following circumstances:—Mr. Prideaux had been tenant of a farm upon the Perry Barr Hall Estate, under Lord Calthorpe. By arrangement made, a farm cottage, or cottage *ornée*, was to be erected at the cost of the owner, and Mr. Pashby, architect, of Birmingham, had made plans of the building. According to the statement of the defendant, he was commissioned to make another set of plans, or complete Mr. Pashby's, for the house upon the farm in question, and did so, together with the usual working drawings and specifications. For this he had charged the sum of 25*l.*, and of this Mr. Edwards had paid him 15*l.*, leaving the 10*l.* which formed the set-off pleaded. From circumstances which did not transpire, Mr. Prideaux left the farm, the buildings had not been erected, and Mr. Prideaux, leaving also Birmingham and becoming a timber dealer at Topsham, Devon, sought to settle matters with his tenant, the present defendant. Mr. Edward Holmes, architect, was called to speak to the charge made for the plans as to the Perry Barr farm buildings as executed by the plaintiff, and in his opinion the same were fair and reasonable. Had the architect been employed to superintend the erection of the buildings, the charge for the plans would have been included in the usual per centage paid upon the superintendence of the building. This, however, had not followed, and thus Mr. Middleton was entitled to the 2½ per centage charged for the plans upon the estimated cost of the buildings. After hearing the respective advocates, his Honour, in giving judgment, appeared to place much stress upon the fact admitted by plaintiff, that some conversation as to his paying for the plans, or at least a portion of their cost, had evidently taken place between him and the defendant. After due consideration, he had come to the conclusion that the plaintiff was liable for the 10*l.* claimed on account of the plans and the verdict would therefore be for the defendant, with costs. Of course the above decision did not affect the 6*l.* 13*s.* 4*d.*, paid by defendant into court, which will be handed over to Mr. Prideaux.

PROPOSED MECHANICS' INSTITUTION IN LEEDS: COMPETITION.—In response to the advertisement issued by the committee, twenty sets of plans have been sent in: the estimated cost of carrying out each design, with two exceptions, is 13,000*l.* In two cases that sum is exceeded by about 1,000*l.*

THE WORKS OF MR. FAED.—Messrs. Agnew & Son have gathered together ten works of Mr. Thos. Faed, in their gallery, 5, Waterloo-place, Pall-mall. The collection includes “The Mitherless Bairn” (one of his best pictures still),—

“Oh! speak him nas harshly; he trembles the while; He bends to your bidding, he blesses your smile. In the dark hour o' anguish the heartless shall learn, That God deals the blow for THE MITHERLESS BAIRN.”

also “Conquered but not Subdued,” and “His Only Pair,” exhibited at the Royal Academy in 1860. Grace and sweetness characterize all these pictures; but we doubt if they gain by massing. A glass of Hermitage is pleasant at dinner; but if there were nothing else on the table it would be less agreeable after a time. A charming engraving of “The Mitherless Bairn” has been made by Mr. Cousin.

COPYRIGHT OF DESIGNS, AND THE METAL TRADES.—The Birmingham Chamber of Commerce has presented a memorial to the Commissioners of the Treasury, praying that the scale of fees now charged for registration of designs, under the 5th & 6th Vic., cap. 100, the 6th & 7th Vic., cap. 65, and the subsequent statutes amending these lists, may be revised, and that the fees for the registration of designs of articles composed wholly or chiefly of metal may be reduced from 3*l.* to 1*l.*, and that the fees for registration, under the 6th & 7th Vic., cap. 65, may be reduced from 5*l.* to 1*l.* The official reply is, that the Lords Commissioners of Her Majesty's Treasury have signified to the Board of Trade their approval of the reduction of the fee on metal designs from 3*l.* to 1*l.*, but that there does not appear to their Lordships to be sufficient reason to justify the reduction of the fees on the registration of useful designs.

TOWN REFUSE.—A pamphlet has been published by Whitaker & Co., of London, and Leng, of Hull, on “A proposed new Mode of Collecting the Animal, Vegetable, and other Refuse of Towns, and the converting it into Composts for Agricultural Purposes, under the direction of Local Boards of Health.” There is also a supplementary article containing suggestions for converting farmyard manure into compost for drilling in with seeds. The refuse, such as street and market sweepings and horse-droppings, garbage, night-soil, and dustbin refuse, it is proposed to collect, along with purchased mixtures of cow and horse dung, into large towers, placed two or three miles out of a town, upon a line of railway, and ascended to by a summit level leading to the tops of the towers, into which the matter is to be dropped, with the aid of a substitute for hoppers, so as to produce various mixtures, to be turned over afterwards and worked into composts under cover, and sold in a dry state to farmers. The author of the project confesses himself to be but an amateur, who offers the suggestions for the consideration of practical men.

POUNCEY'S PHOTOGRAPHIC CARBON PRINTING PROCESS.—The claims of Mr. Pouncey, of Dorchester, to some more adequate remuneration than he has yet received for his useful process of carbon printing in photography, so long a desideratum, are urged in the *Dorset Chronicle*. In the course of the article the writer says,—“We ask a candid comparison of Pouncey's two leading directions already quoted, with the two following items in the ‘practical details’ of Sir Henry James, and confidently challenge any one to say whether they are not identical.—‘A solution of gum arabic is prepared by dissolving three parts by weight of gum arabic in four parts of distilled water. Boiling water is then saturated with bichromate of potash, and one part of the solution of gum arabic is mixed with two parts of the solution of bichromate of potash, both being kept at a temperature of about 200 degrees.’ Having seen thousands of impressions produced from glass negatives by Mr. Pouncey himself, we can assure our readers that the Southampton process is throughout nothing else (for it signifies not that Pouncey transfers to stone and James to zinc) than that long previously pursued in Dorchester, and which it often struck us our simple-minded townsman was little other than connosed to reveal and surrender for the most inadequate consideration—(Mr. Sutton says he received it all about 80*l.*). If, however, an improvement of such immense importance, in peace and in war, has been avowedly taken from Mr. Pouncey and introduced into a great Government department like the Ordnance Survey, the matter cannot rest there.”

**FOUNDATION OF NEW HOTEL, SHEFFIELD.**—The ground on which the hotel is about to be built being all artificial to a considerable depth, large masses of rough rock, brought from the neighbouring quarries, are being built up, and cemented with hydraulic mortar, forming a platform of solid (though artificial) rock, weighing upwards of 2,000 tons. This layer is to be 4 feet thick, spread over the entire area to be occupied by the hotel, and upon this the superstructure will rest.

**THE PEACOCK MEMORIAL.**—It appears that the subscription raised to promote a memorial of the late Dr. Peacock, the Dean of Ely, amounts to the sum of 3,565*l.*, inclusive of 1,000*l.* given by the dean and chapter. It is proposed to apply the subscription to the further adornment of the "ancient and beautiful house" with which the late Dr. Peacock's fondest associations were bound up, and the restoration of the lantern is to be accordingly undertaken.

**EXPLOSION AT ST. MARY'S CHURCH, OXFORD.** St. Mary's Church, about two months since, began to be under repair, for the purpose of laying down the hot-water apparatus, to keep the church in a proper state of warmth. The boiler exploded one Saturday noon, and caused sad havoc. The vice-chancellor's and proctor's seats were blown to some distance, almost into splinters, while some of the seats of the heads of houses were nearly demolished, and those of the ladies were much injured. So great was the explosion that no fewer than thirteen windows are greatly damaged, some being entirely destroyed, and others partially so. The large window over the western entrance has had even the lead surrounding the stonework forced from it.

**BIRMINGHAM ARCHITECTURAL SOCIETY.**—An ordinary meeting of this society was held on the first Thursday in the present month. There was a good attendance, and the following gentlemen were unanimously elected as honorary members:—Sir Francis E. Scott, Bart., and Messrs. S. Timmins, J. T. Bance, and A. Davidson. A paper was read by Mr. W. Harris, "On the Application of Colour to Architecture," in which he advocated a far more extensive use of colour in both exterior and interior decoration than it was at present the practice to employ. He differed from those gentlemen who upheld the use of the same materials in the interior of a building which served excellently for producing coloured decoration on the exterior. He thought that stone, and bricks, and tiles, had a harsh effect about them, which disqualified them for producing interior decoration. He thought that in interiors the actual materials should be concealed, and the decoration adopted not be suffered to depend in any way upon the materials employed in the structure of the building. A discussion followed.

**ARTESIAN WELL AT SELBY.**—At a recent meeting of the Yorkshire Philosophical Society, reported in the *York Herald*, Mr. Noble read a communication from Mr. John Turner, of York, containing an account of the sinking of an artesian well at Selby, from which it appears that the town of Selby being very inadequately supplied with water, it was determined to sink an artesian well, and the borings for this purpose began on December 8, 1853, and were continued till April 1, 1854, when an abundant supply of soft-water was obtained. The engineer of the works, Mr. Linton, has furnished a precise account of the strata through which the boring passed, with the depth at which they severally occurred. At the depth of 75 feet the new red sandstone rock was reached. All the remaining borings were through this stratum. An abundant supply of water having been obtained at the depth of 330 feet, the boring was not carried farther. Mr. Linton says that the new red sandstone has been bored in the neighbourhood of Selby to the depth of 370 feet, but that the strata which are supposed to lie beneath it have never been reached. The flow of water is not uniform, and the well stands the highest at noon and at midnight. The figures indicate the distance from the top of the well to the surface of the water, consequently the water is highest when the figures are the smallest:—

	Fect.	In.
6 a.m.	9	53
12 noon (highest)	8	63
6 p.m.	9	6
9 p.m.	9	0
12 midnight	8	9

Mr. Linton says that at first the variation in the amount of the flow was much greater. It would be desirable that further observations should be made, in order to ascertain that the difference is really constant.

**GAS: THE OUTGOING TENANT'S ARRAREAR QUESTION.**—The gas companies, it appears, are likely to be checkmated on this question under the new Act, 23rd & 24th Vic., cap. 125, entitled "An Act for the better regulating the Supply of Gas to the Metropolis," a summons having been granted at the Thames Police-court to a tradesman in High-street, Poplar, against the Commercial Gas Company, Stepney, for refusing to lay on the gas in his house. Mr. Self admitted that under the Act, the Company, if convicted, would be liable to a penalty of 40*s.* a day. The attempt to compel one man to pay the gas debts of another or he shall be himself supplied with gas is a most iniquitous one, which no gas company would dare to make were it not that they take unscrupulous advantage of their absolute or relative monopoly. As well might a butcher insist that a new tenant in a house shall pay the debt due to him by a previous tenant or he will supply the new tenant with butcher's meat. Had the butcher a monopoly of the business such might be the perverse and immoral influence of this position on his conduct that he too might be induced to insist on so unjust an act; but the wholesome dread of rivals in a trade has wonderful influence in keeping tradesmen and manufacturers out of the way of iniquity and extortion.

**TENDERS**

For finishing six houses in Cambridge road, Islington. Mr. H. Dawson, architect:—  
Turner & Sons.....£2,975 0 0  
Grime & Co.....2,960 0 0  
Hollins.....2,852 0 0  
Henshaw.....2,738 0 0

For a villa on the Copenhagen estate for Mr. J. E. Bradford. Mr. Jasper Cowell, architect:—  
Hale.....£2,179 0 0  
Macey.....1,748 0 0  
Keys & Head.....1,687 0 0  
Newman & Mann.....1,655 0 0  
Batterbury.....1,549 0 0  
Wheen.....1,431 0 0

For alterations, &c., at 39, Upper Bedford-place, Russell-square, for Mr. J. Solomonus. Mr. N. S. Joseph, architect:—  
J. & W. Crossweller.....£398 0 0  
King.....379 10 0  
Newman & Mann.....339 0 0  
Rolfe.....295 14 0  
Stone.....238 0 0

For repairs to a house and premises, No. 25, Bedford-row, for Mr. Salmon. Mr. Joseph Levensder, architect:—  
Stephens & Latta.....£268 0 0  
Aldridge.....161 8 0  
Brake.....139 0 0  
Clements.....119 0 0  
Sutton.....119 0 0  
Green & Son.....111 0 0  
Bryan Helm.....55 0 0

For new Congregational Chapel and School, Stratford, near Manchester. Messrs. Poulton & Woodman, architects:—  
Hollins.....£2,142 0 0  
Buxton.....2,109 0 0  
Young & Co.....1,950 0 0  
Clark & Jones (accepted).....1,859 0 0  
The old materials of present building in each case calculated to belong to the contractor.

For works to be done in alterations at 111, London premises, Nos. 18 & 19, Farnham-street, for Messrs. T. Simpson & Co. Messrs. Tiltott & Chamberlain, architects:—  
Fish.....£289 0 0  
Canon.....355 0 0  
Wills.....547 0 0  
Weston.....510 0 0  
Anley (accepted).....456 0 0

For works at Ousewetry Cemetery. Mr. Hans P. Price, architect, Weston-super-Mare. Quantities not supplied:—

	Contract		Contract		£. s. d.

Notley (accepted).....343 0 0

**TO CORRESPONDENTS.**

S. L.—A. J. K. (without any sympathy with "an architect" who tenders in competition, and executes a building from his own designs, he would be entitled to charge for the drawing and specification, in the absence of any agreement to the contrary, but certainly not for superintendence).—G. F. T.—Birmingham (the proposition to take the snaker out of churches into a general sewer or the existing sewer has been made before).—R. L. (only to Mr. Wade, publisher, Holborn).—W. H.—Palmdo. A. M. (shall bear it).—J. O. V. P. (next week).—W. S. A. (ditto).—S. R. P. (ditto).—A Subscriber (ditto).—T. R. S. (ditto).—M. W. (if the gate is made *à l'ouïe* with the fire-day or otherwise, the whole of the bottom may be covered).—O. H.—B. T. R. S. (is in type).—C. B. A.—J. B.—C. G.—T. R. T. G.—W. R. M.—R. & B.—T. M. (in type).

**NOTICE.**—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher."

Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

**THE PERFECTION OF MECHANISM.**—"In short, all the improvements for our convenience and comfort, dating from a state of barbarity to one of high civilization, are but the cumulative results of inventive ingenuity; and in no instance is this more clearly seen than in the history of those beautiful inventions which have from time to time been brought to bear upon the science of Horology. Trace its history from the time of the Romans with their clepsydra or water-clock, and Alfred with his candles, from hour-glasses and sun-dials, down to that miracle of ingenuity 'The Watch,' and see how improvement has succeeded improvement, until at last those now manufactured by Benson, of Ludgate-hill, London, have been characteristically described as 'the perfection of mechanism.'—Standard.  
Benson's Illustrated Pamphlet, post free for two stamps, is descriptive of every construction of watch now made. Watches safe by post to all parts of the globe."—Advertisement.

**ADVERTISEMENTS.**

**MR. WILLIAM ELLISON,** CONSULTING SURVEYOR, late of STAINSBY-ROAD, Has taken Office at 13, FENCHURCH-BUILDINGS, FENCHURCH-STREET, E.C. Where he continues to advise BUILDERS on BREACHES OF CONTRACT, DISPUTED ACCOUNTS, &c.

**ARCHITECTURAL ASSISTANCE.**—A. Every description of Architectural Drawings, Plans, Elevations, and Sections, SURVEYS, LEVELLING, TENDING, ESTIMATES, and all descriptions of Professional Assistances RENDERED.—Apply to E. DASSSETT REELEN, 3, Upper terrace, Islington, N.—City Office, 24, Finsbury, E.C.

**TO ARCHITECTS AND OTHERS.**—Compilation, Working, and Detail DRAWINGS, Suggestive SKETCHES, PERSPECTIVES in Outline, Colour, or Etching, from notes or sketches, SURVEYS, LEVELLING, TENDING, ESTIMATES, and all descriptions of Professional Assistances RENDERED.—Apply to E. DASSSETT REELEN, 3, Upper terrace, Islington, N.—City Office, 24, Finsbury, E.C.

**ARCHITECTURAL PARTNERSHIP.**—An Architect holding a well-established business in a provincial town, has a VACANCY for a JUNIOR PARTNER in a position of ability indispensable.—For particulars and terms, address, W. D. Office of "The Builder."

**YOUTH WANTED, in a Jobbing Builder's Office.** Must write a good hand, and be quick at accounts. One who has been used to a good penholder business preferred. Business address, 10, Old Bailey, London. Age, salary, &c. to E. R. E. 11, Baker-street, Lloyd-square, W.C.

# The Builder.

VOL. XVIII.—No. 929.

Edinburgh.—Holyrood Palace.

**AVID**, King of Scotland, who appears to have been as devout a prince as his great namesake, the Israelitish poet-king, was out hunting one day, when he was suddenly attacked by the infuriated stag he was pursuing. He would probably have perished but for the ready aid that monarchs appear always able to command. A knight rushed to the rescue, and King David lived to found an abbey upon the site of his perilous adventure. This pretty tradition, redolent as with incense from the censurers of gratitude and piety, is borne out by the armorial device of the abbey and adjoining burgh of Canongate,—a cross between the antlers of a stag,—although there is not wanting a different version of the story, which ascribes the escape to miraculous agency. The monastery thus founded was called

Holy Rood Abbey, on account of the incident having occurred on the festival day of the Holy Cross, and was held especially sanctified by virtue of the possession of a small black fragment of the true cross,—a legacy bequeathed by Margaret, the grand-niece of Edward the Confessor, to her son, King David. We read in the old Scottish records, that the good prince sent to Flanders and France for “the great crafty masons” under whose hands the structure arose; and that the marshes around were subsequently drained and the cemetery walled by the “pleasant, devout, affable” Abbot Elias. Here for upwards of four centuries, through various vicissitudes, the brotherhood dispensed charities and hospitalities,—now impoverished by the ravages of Edward II., afterwards burnt out by Richard II.,—now sheltering a Scottish queen, who gave birth to twins within the precincts of the monastery,—then assisting in the ceremonies attending royal nuptials, coronations, and burials. The marriage of the French princess, Mary of Guelders, and that of Margaret, the Danish princess, were both celebrated within the abbey church; as were also the celebrated nuptials of the English princess, Margaret, with James, the hero of Flodden. Every trace of this religious house has disappeared, except the nave of the abbey church, which, under the name of Chapel Royal to the palace subsequently erected by later kings, has been preserved. Most of our readers are familiar with its picturesque ruins, its tower arch, filled in with decorated tracery to form an east window; its *flou-de-lis*, the broken columns, the pinnacles of the buttresses peeping over the crumbling wall of the north aisle, and casting slender shadows on the incised slabs with which the nave is paved: for who is there that has visited Edinburgh that has not examined, with lingering curiosity, the storied stones of Holyrood Chapel?

The adjoining palace was commenced by that flower of Scottish chivalry and romance, James IV., for the reception of his English bride, the high and mighty Princess Margaret, described by Marchmont Herald, when distributing largesse on her wedding-day, to be “Queen of Scotland by the grace of God, and first daughter engendered of the very high and mighty prince, Henry VII., by that self-same grace King of England.” Their son, James V., continued the work that the battle of Flodden arrested, and under his auspices the palace became “*amplissimum et superbissimum*.” But before Holyrood became the residence of

the beautiful queen whose association with it has paled the memory of the pious founder of the abbey, and that of all the princes and princesses whose names would have otherwise invested it with romantic charms, it was again veiled with scaffolding, having been much injured by the Earl of Hertford’s army in 1543. The towers at the north-west angle of the present building are part of this ancient palace, and contain the suite of rooms once occupied by Mary. Her bed, her baby’s cradle, her workbox, the almost tintless tapestry, seem to be all toned down to the sad hue of her fate. We can realize the supper party which was disturbed by the sudden lifting of the arras, and the entrance of Darnley and his followers on their errand of murder—the lovely queen’s revengeful threats, albeit spoken in broad Scotch, as her “chalmier chield,” Rizzio, was dragged from her presence with her husband’s dagger sticking in his back,—her tearful and stormy audiences with Knox, the Reformer,—the anguish, horror, and despair with which her breast must have been torn by the vicissitudes of her fortune. But where are the bright chambers where she and her four Maries, the Ladies Fleming, Seaton, Livingstone, and Beaton, danced before her guests disguised in male attire? Where was the window through which the queen listened to the serenade of violins and “little rehecks,” with which her citizens welcomed her from France? Surely nothing joyous ever existed here!

We are so accustomed to associate King Charles with Whitehall, more particularly, perhaps, with a certain window facing the Treasury, that it is not without effort that we bring ourselves to look upon some portions of Holyrood as being built under his direction. He was crowned in the nave of the abbey church, then called the Chapel Royal, for which ceremony considerable renovations were effected, in testimony of which a tablet was inserted in the external wall over the main doorway, thus inscribed:—

HE SHALL BUILD ANE HOUSE  
FOR MY NAME, AND I WILL  
STABLISH THE THRONE  
OF HIS KINGDOM  
FOR EVER.

BASICAM HANC SEMI  
RUTAM CAROLUS REX  
OPTIMUS INSTAURAVIT  
ANNO DOMI  
CIB, 1633XIII.

Charles II. rebuilt the palace of his ancestors from the designs of Sir W. Hamilton, retaining the strong tower in which his great-grandmother, Mary Queen of Scots, resided, in the north-west angle of the new building, and continuing the use of the remains of the abbey church as the Chapel Royal. The new design was, of course, in the Palladian style; but the original architecture was preserved in the towers in question, as well as in a lodge known as Queen Mary’s Bath.

After a long season of neglect, Holyrood was once more lighted up for the festivities and rejoicings in 1745, when the Pretender held his court there, only to be made more ghostly than ever in the gloom and desolation that followed. In 1850 the echoes were awakened with sounds of hammers and chisels,—the preparation notes for the reception of our Most Gracious Queen, who since that period has annually brightened Holyrood with her presence and that of her admirable family.

The street scenery of the old part of Edinburgh is as picturesque as the purple hills, melting link-ways into a sea prospect, with which it is environed. The immense rock rising out of the heart of the town, crowned by the Castle with its old-world history; the innumerable wynds, close alleys containing the quaint mansions of the ancient nobility, sometimes ornamented with Latin, sometimes English inscriptions; here a cannon-ball left half embedded in the wall; there a ducal coronet, with supporters, rudely carved over a doorway; here a gable semi-hipped side by side with overhanging eaves and projecting stones; the streets of tall houses, some of them fourteen stories high, with their steep step-

gables,—all over-shadowed by the mighty crag, fantastically called Arthur’s Seat, form as strong a contrast to the wide, colourless streets of the new town, as the quilled ruff round Queen Mary’s throat does to the smooth neck-gear of our modern belles. Of late years a very laudable attempt has been made in the old city to maintain in the architecture the characteristics for which it is peculiar.

The National Security Savings Bank and Offices of the Free Church of Scotland, now erecting on the site of the recent conflagration on the head of the Mound, grouping boldly with the towering houses up the ascent into the Lawn Market and the new Cockburn-street, are conspicuous examples of this spirit. The last we illustrated a few weeks ago. Of the former, in North Bank-street, at the head of the earthen mound, we now give an engraving.\*

These buildings are near to the Free Church College, and occupy half of the site of that immense and lofty tenement which was destroyed by fire a few years ago. This ancient pile was a striking feature in the dark grey mass of the old town leading up to the Castle. The addition of it still stands, attracting the admiration and wonder of strangers visiting the city, who count with curiosity its nine or ten “flats,” approached by one common stair, the height being to the attics about one hundred feet. On the right hand in the illustration is one of the old steep doses or “wynds,” leading up to the Lawn Market.

Although we cannot but regret the fate of the ancient building, the new design in its place forms an attractive and pleasing subject, especially as seen from Princes-street, where the varied towers, turrets, and pinnacles, tell effectively against the sky. Owing to the area of the new erection being strictly limited and other conditions, the front was restricted as much as possible to a flat unbroken elevation, allowing no hold projections to give light and shade, and, therefore, surface decoration was employed in the dressings of the doors and windows until the roof was approached.

The style adopted is the “Scottish Baronial” of the sixteenth century. The Savings Bank offices are entered by the centre porch, and occupy the whole of the ground floor and the greater portion of the first-floor. The remainder of the building, entering by the doorway on the left, is appropriated as a Presbytery hall, library, and offices, in connection with the Home and Foreign Missions, and other schemes of the Free Church of Scotland. Over the windows of these are the armorial bearings of some of the most celebrated divines of Scotland,—as Wishart, Melville, Hamilton, Chalmers, Thomson, and Welsh. Above these rooms is a dwelling-house for the librarian and keeper; and in the upper floor and attics are the apartments of students attending the college.

The architect is Mr. David Cousin, who is the architect and superintendent of works for the city of Edinburgh.

The Commissioners of Her Majesty’s Woods and Forests have been making various alterations in and around Holyrood Palace; and in these, it appears to us, they have altogether ignored any national aim. In the new lodges to the palace they have produced *fac similes* of those recently erected in Regent’s-park and Hyde-park. With the picturesque lodge in view by which the murderers of Rizzio made their escape, with its conical roof, and cunning and characteristic turrets before them as a guide to the style historically required by the site, the Commissioners have preferred their stereotyped London park lodge. The French Empress, journeying through Scotland, and noting with appreciating regard the peculiarities of the land of her Scottish forefathers, will scarcely be gratified by these.

Among the improvements the Commissioners have effected are the removal of the iron railings from the east side of the palace, and the extension of the grounds by their re-erection on the southern side, by which arrangement the open space before the principal front can be closed in with gates when required. The new carriage-drive through the park is also

worthy of praise; but the new fountain ornamenting the approach to Holyrood from Canongate is not so satisfactory. When it was first proposed to reproduce the Linlithgow fountain here we protested against it in the interest of the art of the nineteenth century, and now that the proposition is carried out there are very few who will not wish that our objections had been listened to. If the design of the old fountain had been good, we should still have protested; but this is not the case. It is a confused and miserable mixture, ugly in outline and puerile in detail,—a pyramidal array of small figures in niches and otherwise, surmounted by a huge stone crown;—the water supply, mere spouts, falling from lions' mouths into a disproportionately small basin. In the second range we have, amongst other representations, Rizzio playing on a flute; John Cunningham, the old town-drummer of Linlithgow; and Queen Mary with a sceptre; and in the third range heads of Edward I., the Dunfermline Abbey fool, Oliver Cromwell, Shakspeare, and so on. The various constituents are of all scales; the lions' heads are as big as men. In short, it is an abomination, and deserves no more words. The supply of water to it has been made the means of further injury. The semicircular belt of rocks, called Salisbury Crags, dwelt upon with delight by the great author of "Waverley," as the spot of all spots whence to behold the rising or setting of the sun, has been selected by the Commissioners as the site of a reservoir, from which a pipe conducts water to the fountain. The beauty of rock scenery consists as much in the time-gotten tints it presents as it does in a certain wild, rugged aspect; and these cannot but be impaired by the breaking up the surface for the building of this reservoir. It is described as 45 feet square and 12 feet deep; it is divided into five compartments, laid with Caithness pavement lined with masonry, and has cost from 400*l.* to 500*l.*

It is understood that stables and coach-houses are to be erected for the Queen's use opposite the palace of Holyrood. The ordinary entrance to the stables will be from the Horse Wynd; but in the centre, and opposite the Palace gate, there will be an arched gateway for her Majesty's carriage to enter the great square. The facade of the new buildings, as seen from Holyrood, will be, it is said, somewhat in the Scotch baronial style, and in keeping with the architecture of the palace itself. Plans for the structure have been prepared by Mr. Matheson.

In another part of the city, the gardens of South Lauriston House, we may mention, by the way, a large building, Domestic Gothic in style, has been erected for the residence of the Sisters of Mercy. It is of considerable size, and has a tower next the new street, Lauriston Gardens. Mr. David Cousin is the architect, and Mr. William Matheson the builder.

In this monumental city,—this remarkable and striking union of the old and the new,—closes open in all directions into fine wide streets; closes where the houses nearly touch, and scores of families lie huddled together; closes where fever dwells and criminals are reared. We may have another occasion to speak on the subject.

As the great majority of tourists from the south, visiting the royal house of the Scottish dynasty, arrive in Edinburgh by the railway, it may not be useless or out of place to mention here that they will not be very favourably impressed with the national neatness, from the signs of neglect, the rust, the dust, that will meet their view when they alight in the railway station. Nor will they find anything conducive to an equable frame of mind in the embarkation of slaying horses from the passenger platform; or in the leisurely manner in which the somewhat small lift transports luggage from one level to another, unquickered by the ringing of the starting-bell, or the whistle of the guard.

If, however, they should chance to travel between Edinburgh and Berwick, and it be such a day as that in which we happened to do it, all annoyances will soon be forgotten. The sea was flashed with purple and green, the sky

was blue without a cloud, and the air was as exhilarating as champagne, without any headache for the next morning.

## FROZEN POETRY.\*

THE new state of things produced by the break up of Rome, described in the previous paper, gave birth to and elaborated a new art—all its own; whether viewed from the vasty dome of St. Peter's at Rome, or the fairy-like aisles of York Minister, or the Cathedral of Wells,—two seemingly distinct and opposite forms of art, yet which possess in common all the attributes of beauty. With the latter or Gothic art, we shall conclude our poem—with the former our sixth canto; and this cannot be better done than in the words of a great living poet, Alphonse de Lamartine. "St. Peter's [says he] is the work of an idea, of a religion, of the human mind in its entire extent, at one period of the world. It is no longer an edifice destined to contain a vile people which we are considering. It is an edifice destined to contain all the philosophy, all the prayers, all the grandeur, all the thoughts of man. The walls seem to rise and swell out, no longer in the proportions of a nation, but in the proportions of God. Michelangelo alone has understood Catholicism, and has given to it, in St. Peter's, its most sublime and complete expression. St. Peter's is truly an apotheosis of stone, a monumental transfiguration of the religion of Christ. Michelangelo is a philosopher in his conceptions. St. Peter's is philosophical Christianity, from which the divine architect banishes superstition and shadows, and into which he introduces space, beauty, symmetry, and floods of unextinguishable light. The incomparable beauty of St. Peter's at Rome consists in its being a temple which may be used by all worshippers—a god-like temple, if I may venture to employ that term in relation to stone. It seems destined to clothe the idea of God in all the splendour of which it is capable. Were Christianity to perish, St. Peter's would still remain a universal, eternal, and national temple of whatever religion should succeed to the worship of Christ, provided that religion were worthy of humanity and of God! It is the most abstract temple which the human genius, inspired by a divine idea, has ever constructed here below. When a visitor enters it, he knows not whether he is entering an ancient or a modern temple: no details obstruct the eye, no symbols distract the thoughts: men of all creeds and sects enter it with the same respect. They feel that it is a temple which can only be inhabited by the idea of God, and which no other idea could fill. Change the priest, take away the altar, pull down the niches, carry off the statues; nothing is changed—it is still the house of God. Or rather St. Peter's is in itself alone the grand symbol and type of that eternal Christianity which, possessing in its *morale* and in its holiness the germ of the successive developments of the religious ideas of all ages and of all men, expands along with human reason in proportion as God develops it, holds communion with God in the light, spreads wide and towers aloft in the proportion of the human mind, as the latter expands increasingly, and collects all nations into the unity of one adoration, every day more and more rational; shapes out of all divine forms one God alone, and out of all nations one only humanity. Michelangelo is the Moses of architectural Catholicism, and as such he will one day be understood. He has erected an imperishable ark for future times, a Pantheon of Reason, purified and rendered divine.

Our seventh canto is dark and shadowy throughout. It treats of temples without hieroglyphs, without sculpture, without painting, and for the most part without ornament of any description, save the wild moor, the bleak plain, the barren weird rocks, the dashing falls, the solemn oak forest. Yet it is highly interesting to ourselves, filling the mind with vague dreamy imaginations; the subject being the monolithic temples of our ancestors—the Druids.

"Darkness surrounds us: seeking we are lost  
On Snowden's wilds, amid brigantine coves,  
Or where the solitary shepherd roves,  
Along the plain of Sarum, by the ghost  
Of Time and shadows of Tradition, cross;  
And where the boatman of the Western Isles  
Sticks his course,—to mark those holy places  
Which yet survive on bleak Iona's coast;  
Nor these, nor monuments of eldest fame,  
Nor Palestine's unforgotten lays,  
Nor characters of Greek or Roman fame  
To an unquestionable source have led:  
Enough—if eyes that sought the fountain-head in vain,  
In vain upon the growing rill may gaze."

We have hitherto found that the study of the

\* See pp. 709 and 716, *ante*.

past is not necessarily dependant on written histories: indeed, were it otherwise, our knowledge would too often be scant indeed. Certain it is, we possess no definite records of our ancestors; yet abundant remains lie around us from which peculiarly interesting information has been obtained. Of course it is not to be expected that we shall ever reach the fountain-head of our history. The works of man in the earliest ages of the world may be buried beneath the veritable "drift," or lie beneath the hills and river; but we can only trace our ancestry to the period indicated by the barrows, stone circles, and earth-works, of Salisbury Plain. It seems pretty certain that about the time when Jacob was taking his journey into Egypt to see his son Joseph, the Celts were crossing the Channel that divides us from Gaul, and peopling the dense forests and swamps of our island; and their priests, the Druids, were fashioning the symbolic circles and raising the massive trilithons on our moors, downs, and forests, about the same time that the priests of Isis were, on the banks of Nilus, consecrating the proud monuments of Thebes, and the great lawgiver of the Jews was setting up the pillars of the twelve tribes in the wilderness of Sinai.

They who have visited the wondrous temples of Stonehenge and Avebury will bear me out when I say the effect they produce on the mind is most thrilling. Sublimity was certainly attained by the monolithic builders. Feelings of wonder and awe even now transfix the mind completely; and especially is this the case at Stonehenge—the *chorea giganteum*—and perhaps the most remarkable Druidic temple in the world. One feels that the tradition of Merlin, the magician, having brought the stones from Ireland, is but a poetical homage to the greatness of the work. Its appearance on approaching it is august in the highest degree; and once inside the magic circle the deepest feelings are aroused by them—shall I say, tragic—interest of the spot, and the mystic imagery the associations call up. The circle within circle, the avenue, the trilithic details, are all significantly symbolic: here the arch Druid, with bold, majestic mien, his long white beard flowing in the wind, invoked the God of the thunder-cloud and the tempest—the God of love he did not know,—and herein he celebrated those rites, deep and mysterious, which his forefathers brought from the far East,—

"Screams round the arch-Druid's brow the sea-mew,  
while  
As Menai's foam; and towards the mystic ring,  
Where augurs stand, the future questioning;  
Slowly the cormorant aims her heavy flight,  
Portending ruin to each hateful rite,  
That in the lapse of ages hath crept o'er  
Diluvian truths and patriarchal lore."

The sanctity of the mistletoe, the watchfires of spring, and summer, and autumn, still retain their traces amongst us, and our Sun-day and Moon-day still remind us of the untoward worship of our forefathers; and from the stone circles set up by Joshua at Gilgal to the circles set up at Stonehenge by the Druids, and maybe not far apart in point of time, the same principles are detected—*religiones interpretantur*.

In opening our eighth and concluding canto, which, as I intimated before, will treat of vertical art, I cannot do better than quote the words of that profound German thinker, Schlegel:—"The wonderful architecture of the Middle Ages," says he, "displayed itself in the richness of an inventive imagination, as so many splendid monuments in Germany, England, a part of France, Venice, and the north of Italy, can attest. The style of the Byzantine churches was the first and principal model of this Gothic architecture, though a fantastic monument of Arabic architecture may here and there perhaps have had some influence in its formation. The elaborate and orate style, and the fantastic singularity of this architecture, breathe the true spirit of the Middle Ages."

Gothic art is incontrovertibly *par excellence* the art of Christianity. All the great Pagan empires of old had their peculiar styles of art along with their mythologies, and which arose out of their own idiosyncrasies. The Hebrews, too, in the zenith of their power, were as peculiar in their architecture as in their religion: indeed, it is certain that the necessities of the religion of the nations of antiquity gave birth to and elaborated the fine arts: architecture, painting, sculpture, poetry—they are all a reflex of the religion they sheltered, adorned, and praised. Is there then anything remarkable that the best of all the religions that have swayed the hearts of the human race should give birth to and elaborate a style of art all its own?—and that that style of art should be a reflex of the religion which gave it birth? To call this art *Pagan* is a libel upon common

sense: it never was nursed in Rome or by the Popes: it belongs to no sect or party: it is, as all real art must be, universal. Especially adapted to ecclesiastical architecture, which is indeed very natural (quite as much as Solomon's temple and the Parthenon were to their several religious forms and services), symbolism is the very soul of Gothic art. There is nothing new or remarkable in this. All art is symbolic, and symbolism is the life of art: without symbolism art would be like the dry bones of Ezekiel's vision. Symbolism in true art never detracts from the reality nor sets aside the end in view. Lamartine says there is no symbolism which distracts the mind in St. Peter's, thereby inferring that in Gothic art there is. Now this remark is only true so far as *distracting* the mind goes; for this very St. Peter's is one of the sublimest symbolic poems upon the face of the earth: it embodies under other forms the same great truths that Gothic art does, and many minor things that Gothic art does not: St. Peter's is, in fine, a synopsis of the Papacy: Gothic art is a synopsis of—not any one sect, but—of broad Christianity as a whole. The very essence of Christianity is symbolism: all its great truths are conveyed to us in symbols: its praises are sung in symbols as well by the lisping infant as the hoary saint: much of its prayer is uttered in symbolic language: its great Founder taught His disciples and the multitudes in symbols; the books of Isaiah, of Ezekiel, and the Apocalypse, are full of the sublimest symbolism: the Song of Songs is a splendid symbolic poem: the minor prophets sang their words of reproof and promise in the language of symbolism: it forms the most beautiful and soul-stirring of modern preaching: in fine, without its symbolism, Christianity would be dry and prosy. Tell me, is there anything surprising or to be objected to in the symbolism of Christian art, seeing what Christianity is in itself? In Christian art symbolism attained a luxuriance and pliability never before acquired. Planned upon the Cross and reared towards heaven, emblematic of the hopes and aspirations of the race; its triangular details, typical of the Trinity; its aspiring vertical lines, reminding us of the Resurrection; the windows, symbolical of the light that has come into the world; the various sculptures, all pregnant with symbolic truth—all this has a deep and solemn meaning. Nobly and powerfully has Gothic art attained her ends; and wood and stone, fashioned with fastidious art, have fascinated every lover of the beautiful, the grand, the true, the ennobling, the sublime. Indeed, I—

— "love the high embowed roof,  
With antique pillars massy proof,  
And sturdied windows richly light,  
Casting a dim religious light,"

for the associations they call up. Yet I do not love "a dim religious light." Gothic art does not call for that, nor for devils in stone and paint, nor mythical monsters, nor representations of startling distorted countenances writhing in horrors of purgatory or something else as had, often, as in Chester Cathedral and elsewhere—the *tooth-ache*; nor for disgusting loathsome animals: all this meaning suited the age of monkdom, when penance was the order of the day; but now we require pure majestic beauty, chastity of design, a sacred elegance, a holy grandeur,—and these are emphatically characteristic of Gothic art. It is true there are many old-fashioned country gentlemen brought up and educated in the wonderful luxuriance of one ideal, either Greek or Roman, as the case may be, who cannot see beauty in any other,—perfectly correct in what they say of the splendid harmonic beauty of their own ideal, but equally wrong in their aspersions on another form of art. Horace Walpole said that "One must have taste to be sensible of the beauties of Grecian architecture: one only wants passion to feel the Gothic." Lamartine says that "the Gothic architects were sublime barbarians." Let me ask any one who may have a high taste for the beautiful, and who has seen the exquisite conceptions of York Minster, Salisbury, Lincoln, and Wells Cathedrals, if such aspersions can be true? Who, I wonder, was the greatest "barbarian," the beaten designer of the Parthenon, or the Christian designers of York Minster? Enter with me any one of our cathedrals, such as Salisbury or Wells. How grand—how majestic—how sublime! An air of solemn grandeur seems to be diffused over all the scene, and we breathe it: insensibly we feel a reverential awe stealing over us, and we seem conscious of the presence of something more than mortal, and the mind finds the chastening influence, and becomes grave and solemn; and, in spite of ourselves, we feel that it is a place meet for the Duty to honour with His

peculiar presence. Let us now change the scene to St. Paul's. We shall exclaim, "Beautiful and elegant, exceedingly! What symmetry and proportion prevail throughout! What a singularly beautiful effect the handsome columns and the elegant roof produce! Observe the fine effect produced by the sublimity of the towering dome, the harmonious blending of the colours, the richness of the gilding, and the solemn arcades! We cannot but admire! It is in very deed a magnificent creation of genius!" Wherein is the difference? The answer I must leave. It is not right artistically to call Christian art superior to the Classic, or the Classic superior to the Christian, for in many respects they are each superior to the other. Both are embodiments of chaste intellectual majesty, of beauty, sublimity, and grandeur. Both rise nobly from the earth, expanding the intellect, dilating the soul, and filling it with ennobling sensations. The one is a grand epic poem, the other equally grand in its poetic imagery and rhythmical consonance. Each is pregnant with the sublimest lessons, and each will cause all rightly-constituted minds to lift up their hearts in thankfulness to Him who has endowed man with such a marvellous variety of powers.

"What great power doth waken feeling  
In your column'd hall so high?  
Is it the dim shadows stealing  
Into deeper mystery?  
Or the golden sun revealing  
Forms of light and symmetry?  
Is't the vernal hand of Time,  
With his choicest tints adorning?  
Or the vapours of our clime,  
Crowning with the dews of morning?"

No, nor

"Yet in olden legends lie,  
Nor in heathen symmetry,  
The spirit-moving power,  
But in thoughts that never die—  
Thoughts that have their birth on high  
In a holy hour."

FRANCIS DRAKE.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The ordinary general meeting of members was held on Monday evening last, at the house in Conduit-street. Mr. G. Godwin, V.P., occupied the chair.

The minutes of the last meeting having been read and confirmed.

Mr. T. Hayter Lewis (honorary secretary) announced the receipt of a number of donations to the library, of which the following are the most important:—A piece of curious mosaic pavement (15 inches square), representing one of the dogs of Diana hunting, from the site of the ancient city of Heliocarnassus, presented by Mr. J. W. Walton; a portion of a bird's-eye plan of Paris, showing the buildings around the Louvre, Tuileries, and Palais Royal, commenced 1734 (engraved 1739), presented by Mr. J. W. Papworth; a volume of engravings published by the Royal Society of Antiquaries, presented by Mr. Octavius Mansard; the new part of the Architectural Dictionary, including the letter F, presented by the Architectural Publication Society; the portrait of a "Fellow" (a very clever water-colour drawing by the late J. Hollis, A.R.A.), presented by "An Associate;" and the Ganges Canal Report, containing a great quantity of local information relating to prices of labour, material, &c.; and descriptions of certain improvements on the well-sinking principle as applied to the construction of the piers of bridges in unfavourable localities; and also an account of the simple but efficacious means, by which bridges in India have been protected against the devastating effects of mountain torrents.

Mr. Penrose (honorary secretary for Foreign Correspondence) called attention to a drawing of the new Roman Catholic Cathedral of New York (Messrs. Renwick & Rodrigues, architects), said to be capable of holding 14,000 persons. Mr. Penrose remarked, that whether a building of such size (300 feet long by 121 feet wide) could contain so large a number of worshippers or not, still that the building was a most important work, and that the Institute was indebted to the architects for their courtesy in forwarding the drawing.

The Chairman in bespeaking the thanks of the meeting to the donors of so many valuable contributions, spoke, with reference to a plate in one of them, of a recent correspondence respecting certain indentations found in the inside of a Roman well in Oxfordshire, and in relation to which various speculations had been indulged in. He observed that in the Greek cistern, shown in the plate, the same object appeared to be aimed

at by adopting an opposite principle; for, instead of indentations, a stone was made to come out in a spiral manner, in order to assist the person descending or ascending the well. With regard to one of the donations announced, namely, the last volume of the Architectural Dictionary, he begged to remind the members of the Institute that it had now reached the letter F, a sufficient assurance that the work would be completed. He hoped, therefore, that no member of the profession would hesitate to subscribe for a work so useful and so essential to every architect.

Mr. W. Burges then read a paper on "Architectural Drawing," which we print on another page.

At the conclusion,

Professor Donaldson observed, that they were much indebted for the very erudite, and, he might add, amusing paper with which Mr. Burges had favoured them. Some points, however, were raised in it which were of a debatable nature. He stated, for instance, that Harold sent to Flanders for architects, as if there were no architects in this country who could design, or men who could build.

Mr. Burges said, that Edward sent to Normandy for architects there could be no doubt whatever.

Professor Donaldson said that, with regard to the Weir collection of drawings at Lille, he had called the attention of the Institute to them in the year 1853, and had, after minute inspection, expressed his opinion that those alluded to were not by Michelangelo (as Mr. Burges seemed to think) but were the work of Vasari. Such was his deliberate opinion, but he admitted that the subject was open to discussion. He recommended the members of the Institute to obtain access, if possible, to the important collection of drawings by Italian architects of the thirteenth and fourteenth centuries, preserved at the Duke of Northumberland's, at Chiswick.

Mr. Burges replied, that the hands were put in with great anatomical fidelity, whereas the fact was that, in drawings by Vasari, these were drawn in a very clumsy manner.

Mr. Digby Wyatt agreed with Professor Donaldson in his opinion of the Lille drawings. They were wanting in firmness, and did not carry that sustained attention to the end, so noticeable in the drawings of Michelangelo. He expressed his regret that Mr. Burges had not referred to the Holbein drawings, which combined a firmness of line and a beauty of expression not always attained in such works. The practice of drawing in thin lines originated with the Anglo-Saxon illuminators. This style was subsequently initiated in France. In Italy, however, another principle obtained; Leonardo da Vinci had left the most beautiful sketches, showing how he excelled in broad, firm lines, and how he could mark the light and shade which floated in the fancy of the draughtsman. It must not, however, be supposed that we were indebted exclusively to foreign schools for beautiful architectural drawings. We could congratulate ourselves upon the possession of those of Inigo Jones, who was not only excellent in landscape, but in figures. Then, descending to more recent times, many specimens remained of drawings by the Adamsons, who had remarkable power as draughtsmen. This was a subject upon which he felt there was no reason to apprehend a declension. On the contrary, he felt that we were rapidly returning to that happy facility in drawing, without which it would be impossible to produce truthful or expressive delineations; and if we went on improving in like proportion in the other departments of art, we would inaugurate an epoch of rare perfection, alike creditable to the age in which we lived and the country in which we laboured.

Mr. Seddon remarked that the object of the paper read by Mr. Burges was to introduce a former mode of drawing. The question was, how was this desideratum to be attained? It seemed to him that the real origin of fine line drawing was to be traced to the invention of India-rubber. If that commodity were tabooed, it might be possible to introduce a firmer and more nervous system of drawing.

Mr. Papworth inquired whether Mr. Burges would have any objection to draw what he called a "moderately thick line," for that was a point upon which people might differ. There were some who thought thick and thin lines were desirable in order to show exactly that which it was intended to represent. In fact, the draughtsman could not accomplish this without showing a thick line and a thin line, and occasionally the much-abused shadow. The very thin style of outline observed in the drawings of the architects of the latter portion of the seventeenth and beginning of the

eighteenth centuries took root early in Italy, and then spread to France, although he was bound to say that he could point to a series of drawings for every year for seventy years, which left nothing to be desired by the architect of the present day. With regard to the Adamsses, they drew with a strong, fine line, but they also used thin lines, because they found it would be impossible to convey an accurate idea of their works without such use.

Mr. Street said it seemed to him that every architect drew more or less in his own manner, without reference either to the elder Pugin or to Willars de Honecourt. What the architect really wanted was to produce drawings which a builder could carry out. The drawings of the elder Pugin, for instance, showed precisely what he wished to be carried out. The question, therefore, in his (Mr. Street's) opinion, was one of style rather than of drawing. Another fallacy dwelt upon by Mr. Burgess was the supposed use of Indian-ink in architectural drawings. He could not tell what other gentlemen might do, but for his own part he could only say that he was unable to do more than get in his drawings in pencil.

Mr. D. Wyatt said he did not wish to be understood as condemning the use of shadows (as Mr. Papworth seemed to infer); on the contrary, he considered them most useful.

Mr. Penrose said that the observations of Mr. Papworth did not dispose of Mr. Burgess's argument. It was desirable that the best school of drawing should be pointed out to the student; and Mr. Burgess had done good service in pointing out Michelangelo as the most exalted master that could be followed. The best collection of his drawings was to be found at Michelangelo Taylor's Museum, at Oxford. He (Mr. Penrose) had examined them there six or seven years ago with great pleasure, and he hoped some profit. The drawings preserved at Bologna were also very interesting, and he had examined them for several hours. Those of Palladio had moderately thick lines. When he said "moderately thick," he meant that eight such lines would go into the eighth of an inch. The principal elevation was 3 feet long by 3 feet 6 inches wide, so that they were quite in proportion to the drawing. Unfortunately, Palladio was no sculptor. He could not draw the human figure; but if he could have done so he would have been all his most enthusiastic admirers represented him to be. With regard to the use of India-rubber, he did not think there need be any apprehension on that score, for he had not seen for the last few years a single pencil whose marks would rub out. He believed that the use of fine lines was to be traced to the practice of following French engravings, the lines of which were so fine that the majority of them could not be discerned without a microscope. He was of opinion that a firm line was better than a thin one, and he thought that any person who studied out of doors would necessarily fall into the natural style, because he would endeavour to portray the building before him as it really was. If the natural style were followed there need be no apprehension of getting into the practice of making the lines either too thin or too thick.

Mr. Kerr thought it was a question of style. There was, for instance, Gothic drawing and Classical drawing. In classical times, or quasi-classical times, the style of drawing was of a classical character; the lines were fine, the shadows were indicated, and the work of the draughtsman was refined, polished, and minute. Now that the style had become changed into the picturesque and the romantic, the drawings were found to be also picturesque and romantic. It was only necessary to point to the drawings of Mr. Burgess himself, and other gentlemen of his school (no doubt most meritorious works), to perceive that they were part and parcel of the intellect of the man which he followed, not arbitrarily nor by choice, but inevitably as a master-idea in his mind. The object of an architectural drawing was to present in outline what was to be executed in the solid; and the way to do this was to make a moderate line according to the scale of the drawing, which would represent honestly and faithfully the object to be delineated. Such was a plain, substantial, honest drawing; but when the architect got out of that and plunged into picturesque Gothic or classical, he gave expression to that which was really the individual intellect or idiosyncrasy of the mind. He agreed with Mr. Burgess that a firm nervous line was to be encouraged, for nervousness might be thrown into the most delicate drawing. Moreover, the present age was a nervous age, and it was part and parcel of the spirit around us.

Mr. White protested against the assertion that the picturesque was solely applicable to the Gothic

school, or a great element of it, or that grace and beauty were to be found in classic architecture alone. He believed that grace and beauty were common to both styles, and that it was much more a question of southern and northern than of Gothic and classical, and that thickness of line depended more upon the finish intended to be given than to the representation of any particular style of architecture.

Mr. Ferrey said he did not consider any defence of the late Mr. Pugin necessary in that room. Mr. Pugin appeared to have used back-lining from what he had seen in France. Mr. Pugin was a Frenchman, and naturally fell into that error. He would not discuss whether the line ought to be the sixty-fourth or the eighth part of an inch, but it should be the clear expression of the form to be hereafter executed. As little picturesqueness should be introduced as possible, as the object ought to be presented before the client and the builder as nearly as could be in the shape in which it was to be carried out. He objected altogether to back-lining.

Professor Donaldson differed from Mr. Ferrey on that point, for it would be impossible to represent what a thing would be when executed by drawing lines all of the same thickness; for, unless the back lines were put so as to show what was shadow and what light, the whole would resemble a piece of inlaid work, or he like the elevation of the Cathedral of Florence. He should have liked the directors of the School of Art at South Kensington to have heard the discussion of that evening, for there the students all copied a rigid, hard metallic line, devoid of all sentiment whatever.

Mr. Papworth agreed with Professor Donaldson that it would be impossible to give a correct impression of what a building would be in the solid, if all the lines of a drawing were precisely of the same thickness.

Mr. Street said that had draughtsmen generally put in back lines to conceal had drawing.

The Chairman, in closing the discussion, said he was glad it had been left to him to propose a vote of thanks to Mr. Burgess for his interesting paper, in which he had displayed his usual research, and imported into it those touches of sarcasm and gaiety which, when dexterously applied, lent light to the least inviting subject. In the course of his observations, he had playfully alluded to deceptions practised on a client as "allowable." This might have been the case in years gone by, but the architects of the present day would, he was convinced, never forget that they were gentlemen and men of honour, and would feel it to be a disgrace wilfully to deceive a client. There were some points referred to by Mr. Burgess which of course were open to discussion. For his own part, he admitted that he could not wholly agree with him in his sweeping condemnation of all "crochets and fizing;" for he was afraid if they were to admit the correctness of that as a principle, they would get into a plain and bald style of architecture, which it would not be desirable to encourage. The subject which Mr. Burgess had chosen for his paper gave ample scope for many interesting details with reference to ancient drawings. There was, for instance, a very interesting fourteenth-century drawing at Liege. A curious history also attached to the original drawing of Cologne Cathedral, which was no doubt familiar to most of them, and from which it appeared that one portion of it was found at Darmstadt, forming the bottom of a corn-sieve, while another portion was discovered in some distant part of the country, and both were ultimately united, after a separation of many years.

A vote of thanks having been passed unanimously, the following gentlemen were, on ballot, elected Fellows of the Institute:—Mr. John B. Waring, 22, Edward-street, Portman-square; Mr. Frederick Lett, 36, Essex-street, Strand; and Mr. Edward H. Martineau, 24, Lincoln's-inn-fields. Mr. William Potheringham, of 2, Queen's-terrace, Holloway, and Mr. B. A. C. Herring, of 1, Danes'-inn, Strand, were elected Associates. At the next ordinary meeting of the Institute, on the 3rd of December, a paper will be read by the Rev. Mackenzie Walcott, "On Church and Conventual Arrangements."

THE OXFORD ARCHITECTURAL AND HISTORICAL SOCIETY.—A meeting took place on Wednesday, the 14th, and was the first held since the change in the title of the society, which was made last Term, and by which the scope of its labours were enlarged. The usual business of the society being concluded, a discussion took place "On the Connection of History with Architecture."

#### ARCHITECTURAL DRAWING.\*

In giving the usual paper which is very rightly expected of every new member of this Institute, it is not without some little misgiving that I have selected the subject of architectural drawing. I feel that I ought rather to have tried my hand upon one of those stock subjects, viz., architectural colour and mosaics, on which so much is to be said, but which we have seldom or never the means of putting into practice, either from the disinclination of our clients, as in painting, or from the want of materials and special artists, as in mosaic. In the meanwhile, whenever we do get the opportunity, the result is generally a failure, partly because no rules will ever teach a man the value of one tone of colour as compared with another, and partly because we require in this case to be taught by repeated failures as to what combinations of colour look well, and what look ill. Under these circumstances, therefore, it has struck me that it may be more useful to bring together a few notices of a much less ambitious branch of the arts, but which, however, is of the most vital importance to us architects, inasmuch as it exercises more or less influence upon the design of the building itself; and we all know that although the building is but the skeleton for the additions of painting and sculpture, still, if that skeleton be bad or deformed, no satisfactory result can ever arise, even with all the painting and sculpture in the world. I venture to assert that the manner in which a man draws does and must affect the nature of his design more or less. Thus, if he uses strong thick lines, he will, in all probability, be induced to make his design massive and simple, and not give way to the vanities of crochets and pinnacles, because he will find that he has hardly got space to get them in. He likewise sees his design in its most severe and unfavourable light, and ten to one the building will turn out much better than the drawing, to the advantage of every one concerned. If, however, the architect draws in a moderately thick line, and puts in the stone joints and etches the walls (I am now speaking of elevations, &c.), he simply deceives not only his client, which is partly allowable, but still worse, himself, for the building is almost sure to come out worse than the drawing, the joints, roughnesses, &c., not, of course, showing in new work. As to the third style of drawing, with very fine hair-like lines, relieved by what is termed back lining, whereby small fillets are made to look like hollows, and hollows like fillets,—this style, in fact, is scarcely worth mentioning, for it means nothing, and hardly anybody employs it in the present day; and, indeed, one is almost tempted to believe it to have been invented by some instrument-maker. I may likewise observe that it was generally employed in the worst days of architecture.

And now concerning the way in which our ancestors drew. It is generally believed that very few drawings have come down to us from the Middle Ages, but, thanks to the labours of the French and German antiquaries, we have now a very fair catalogue of drawings of all ages, besides published *fac similes* of a tolerable proportion of them. In the Dictionary of the Architectural Publication Society, under the word "drawing," will be found an enumeration of the more famous of these, to which might be added the very numerous designs and drawings scattered up and down in the collection of MSS. and prints of the various museums in Europe. Instead of going through the whole list given in the "Architectural Dictionary," the great majority of the drawings mentioned in which I have not seen, and which I should have to describe second-hand from hooks, or else to confine myself simply to noticing the fact of their existence, I propose to touch upon those, the *fac similes* of which are published in books within every one's reach, and upon others which I have seen and examined myself at leisure.

I believe nothing whatever is known of the architectural drawings of the Greeks and Romans. The "Lapides Capitolini," containing a plan of Rome, are simply inscribed on marble, and formed anciently part of the pavement of the Temple of Romulus and Remus. The light and beautiful architecture painted on the walls of Pompeii was never, that I know of, resolved into real materials. Our series of drawings then opens with the plan of the Monastery of St. Gall, now preserved in the library of that establishment. It was first published by Keller, at Zurich, in 1844, and republished two-fifths of the real size in the fifth volume of the "Archeological Journal," p. 87, with a most excellent notice by Professor Willis.

\* Read by Mr. W. Burgess, as elsewhere mentioned.

The plan, which is drawn in thin red lines upon a large sheet of parchment, with inscriptions all over it, showing the uses of the different parts of the building, was sent, as one of the said inscriptions informs us, for the use of the Abbot Gospertus (who began to rebuild the church and monastery in 829), by some anonymous friend, who is supposed, with some reason, to have been Eginhard, the son-in-law of Charlemagne, and who held the office of prefect of the royal buildings. However this may be, the plan presents us with a very complete monastery, with its great church and accompanying buildings. The red line not only seems to mark the external and party walls, but also to indicate the furniture, such as benches, tables, stoves, &c., requisite to each building. The plan as Professor Willis very properly remarks, is not done to scale, but certain figured measurements enable us to form some idea of the sizes of the various parts. The church would appear to have been a most noble building, with two apses and their paradises or semicircular walks. The western one was further enriched with two circular towers.

The winding stairs of these latter are shown as gradually winding round from the circumference to the centre, like a section of a snail's shell. It is doubtful whether a common winding staircase is thus represented, or whether it was really an inclined plane which went from the circumference to the centre, and so on to an upper chamber, where there was an altar, in one case dedicated to St. Michael, and the other to St. Gabriel: there would, supposing the latter supposition to be correct, be space to hang the bells in the space between the novell and circumference in the upper part of the tower. The ornamental finial at the top is shown on plan as finishing the novell.

The arches of the cloisters and the crosses of the altars are shown by elevations in their respective places on the plans,—a mode which still obtains in Turkey at the present day, among the distinguished native architects who have the honour of working for his Imperial Majesty the Sultan, so little have things changed in the East. Another peculiarity in the St. Gall plan is, that sundry squares are drawn in the middle of courtyards and of buildings. These, as Professor Willis suggests, may be either indications of the classic atrium with its uncovered unpluvium, or a sort of upper lantern rising above the roof, and giving light by means of clerestory windows; both these explanations are very feasible, and both probably were intended in the original. Lastly, Eginhard, or whoever was the architect, wrote certain explanations in Latin verses on various parts of the drawing. Fancy that most matter-of-fact production, a modern plan ornamented with metrical directions to the builder.

The next drawings to be noticed are those incidental pieces of architecture which occur in the Anglo-Saxon MS., in which the British Museum is so rich. It is true that they are generally ill-drawn; but still they show us enough to enable us to draw very valuable conclusions as to what Anglo-Saxon architecture really was, and to refute the generally-conceived idea that both architecture and history began in England exactly in the year 1066. Mr. Wright has contributed a most interesting paper on the subject in the first volume of the Transactions of the Archaeological Institute. In it he shows that the triangular arches, and the baluster shafts, which are now recognised as Anglo-Saxon features, occur equally with representations of domes, and carved capitals, pinnacles (not crockets), and iron work, which antiquaries are generally unwilling to acknowledge as belonging to the time before the Conquest, as if the countrymen of Alfred and Edgar, both great and powerful kings, should have been unable to carve a capital or use a chisel, when they were renowned all over the world for their manuscripts, jewellery, and embroidery. I suspect the fact is, that the history of architecture has been lithero written in far too scientific a manner; and because the art exhibits a general progress and decline, people have believed that sundry processes were unknown at certain periods; when, in fact, almost all the essentials of buildings have remained the same since the first ages. Thus, because Gervase says that the work of the old cathedral at Canterbury was done with an axe, and the new with a chisel, we are to suppose that the Saxons had no chisel, and no carved ornaments. Now the MSS. distinctly show us elaborate capitals which

must have been done with a chisel; and no one can for a moment imagine that so useful and obvious an instrument could ever have been lost even in the most barbarous countries, much less so among the civilized Anglo-Saxons. We owe also to Mr. Wright the first doubt as to the date of Waltham Abbey church. Hitherto most antiquaries believed it to be of the date of Henry I.—first of all, because it was like the architecture of that time; secondly, because the two queens of that king were great benefactors to the establishment; and thirdly (and here was the rub), because it was more ornamented than any known contemporary Norman or Saxon building. As if Harold, the richest and most powerful man in England, could not have given orders for a rich building to be erected, or had not the funds to carry it out. I do not deny that he might have employed foreign workmen, but it by no means follows that these foreign workmen must have come from Normandy. Harold and his family were very properly anti-Norman, and it is just as likely that he got his workmen from Flanders or some other part of the Continent as from Normandy.

The next document I shall bring forward is a view of the church and monastery of Canterbury, contained in the magnificently illuminated Psalter of Eadwin, now preserved in Trinity College, Cambridge. This very curious drawing, which is made to do duty both as plan and elevation, has likewise received the elucidations of Professor Willis, to whom I may venture to say the literature and some parts of the practice of our art owe more than to any one else. The way in which the plan and perspective are made to co-exist is by making a vanishing point in the centre of each court, so that there are three or four of these vanishing points in the drawing. The two towers, which we saw in the plan of St. Gall here reappear, although in different positions. All the water-courses and drains are shown, and upon the whole, considering the very original perspective, it may be pronounced to be a very accurate drawing; indeed, Professor Willis tells us that wherever a building is shown on this plan, Romanesque work is more or less found at the present day at Canterbury. I have not been able to see the original of this drawing, but the notice in the "Vetusta Monumenta," where it is engraved, assures us that it is coloured. As a drawing it is curious, as showing the complete development of the practice of drawing elevations upon plans, as at St. Gall. I think, however, that we must consider this drawing of Canterbury more in the light of a survey for the purpose of showing the system of water-courses than as a document to be worked from. In all probability such documents would not be very common, and when the work was done the erasing knife of the writer would be brought into use, and the parchment or vellum, which was very valuable in those days, and which by the way is not very cheap in these, would receive a new employment. That this was the case we know from the discovery made by MM. Varin and Didron, in 1838, of the design for the west end of a cathedral, besides several details, and which they found under the writing of a manuscript containing a list of the deceased members of the chapter of the cathedral of Rheims. Now the last entry is 1270, and the drawings were executed in all probability some time before. They have, according to M. Didron's account in the fifth volume of the "Annales," been first sponged out and then scraped over, to obliterate the lines, and finally cut into leaves. However, enough remained to enable M. Didron, assisted by the late M. Lassus, to produce engravings of several portions, which will be found equally in the same volume of the "Annales." M. Didron assures me that the lines are very thin, which is not to be wondered at, considering the treatment they have undergone.

The principal composition shows a façade for the west end of a church, with the usual three portals, and the somewhat unusual feature of a large window above. It is either an unfinished production, or one for the use of the architect and his workpeople alone, for as little as possible is shown. Thus, only two or three crockets are shown at one side of each of the great pediments; no ornament or figure is shown in the vousoir; the left-hand corner is, indeed, more worked up, but the artist has made up for it by showing nothing at all on the right. The whole composition appears to me to want somewhat of severity, and I hope that it was sponged out, and never executed on this account. Another plate shows part of what M. Didron thinks is another portal, but which might possibly represent the return angle of the former drawing. It is remarkable, if really a portal, for showing the outer plane of the centre door as

filled with tracery; if this be really the case, it gives us an arrangement somewhat similar to that obtained in the west front of the now destroyed church of St. Nicaise, at Rheims. M. Didron thinks that the architect, being hard up for room, drew in the tracery of the window, but to a different scale to what the portal arch was drawn; but if even that were the case, a window would hardly have its centre light twice as broad as its side ones, which this has. Below this portal are three pieces of ornament, each drawn in between borders, composed of six lines each. What these six lines mean I am totally unable to decide, unless they represent in a sort of shading, the rounded edges of the houlds on either side of the great hollow in which they are placed; but I certainly cannot agree with M. Didron's suggestion, that they may be the lines of the musical scale, and as the outer parts of the ornament are occasionally drawn upon them, and of course go up and down, so we have a sort of architectural music.

Willars de Honecourt is the next on the list, the fac-similes of whose sketch-book are now in the hands of everybody. So much has been said and written concerning these drawings that I shall very much curtail my description of them, which would otherwise have been long, considering that these are the most perfect and the largest collection of the drawings of the Middle Ages which have come down to us; and first of all I must be allowed to claim Willars for our profession, as some attempts have been made to hand him over to the sculptors and painters, because, forsooth, he drew the figure too well and too frequently. There is one fact, however, which completely, as far as I see, upsets this theory, and that is this—the tendency of an artist, either painter or sculptor, or architect, would be to sketch details which would come in useful to him. Thus the painter and sculptor would draw parts of the human body, bits of costume, anatomy, &c., while the architect, on the contrary, would draw mouldings, capitals, foliage, &c. Now, in the sketches under consideration we do find the capitals, foliage, and mouldings, but we do not find studies of hands, of feet, of anatomy, &c.; but, on the contrary, there are a number of problems which would only be useful to a man engaged in actual building. As regards the drawing itself, the sketch was first made with a leaden or silver pencil, either of which would perfectly mark on the vellum. If the subject were an architectural one, the straight lines were ruled, and the circles put in with a compass, one end of which had a leaden point. These lines were afterwards gone over with a blackish brown ink, by means of the hand alone, no instrument being employed. Upon looking again at this MS. two months ago, I was struck more than ever by the extreme precision of the touch: there is no faltering or wavering, but the line is just as thick and as firm where it ends as where it begins. Again, in drawing things in small, mouldings and foliage became simplified so as not to break up the breadth of the composition. Clearness is got by hatching hollows where they occur, and the grounds of ornament, such as capitals, &c. The walls of the plans, however, are not etched, and we shall find this practice obtaining even in Hope's time, the majority of whose plans are not etched, although not devoid of colour. One would imagine that Willars might have etched them up with his leaden point as he often did his drapery; but nothing of the kind occurs. Another peculiarity of our architect was, when he copied any executed work, he copied it not as he saw it, but with variations of his own, and as he would execute it himself; thus the window at Chartres is considerably altered in order to get more space for light, while that at Lausanne is so much so that it can hardly be recognised. But with all his peculiarities, Willars presents us with a decidedly good style of drawing, and which, it strikes me, might eventually be developed into something much better than that in use of late years. I mean, that we should join our improved knowledge of perspective and of the figure to the energy, simplicity, and firmness of our confreres of the thirteenth century.

The fourteenth century affords us the drawings of the Cathedral of Cologne. These I saw some ten years ago, but as far as I remember I was told that the originals were in the architect's office, and that what I saw were only copies. It is very true that they, besides several others, have been published both in Germany and France, but I must confess that I should be sorry to deduce any theories as to thickness of line, &c., from the fac-similes made by the German, who have an admirable mode of publishing almost everything in the finest possible lines, exactly

\* See Willis's "History of Canterbury Cathedral." It is surprising that this book has not been more popular with the profession. It is the history of the building of a church, or rather of the choir of a church, during the very best period of art.

like Pugin's Specimens and other works of that period, thereby utterly depriving them of all vigour, and producing a very false impression.

The fifteenth century being nearer our own time, presents us, as might have been expected, with a greater number of drawings. First, we owe to Professor Willis the explanation of the legends attached to the section of mouldings from the door of the church of St. Stephen's, Bristol, made by William of Worcester in his Itinerary, preserved at Corpus Christi College, at Cambridge; but the most interesting to us as Englishmen, are those drawings for King's College, Cambridge, now in the Cottonian collection of the British Museum. The first of these shows the east and north sides of the chapel in perspective, *i.e.*, the north side is drawn parallel to the horizon, almost in elevation, while the lines of the eastern go to a vanishing point. The drawing is partially coloured, and is especially curious, as showing a small half-timbered building at the eastern end, with a niche containing a clock-face. The details of the architecture are very well made out, and there are ruled lines, like a modern drawing. No figures are shown in the niches, and the rain-water is carried off by regular pipes, as in the present day. Curiously enough, similar leaden pipes are to be found in those parts of the Cathedral of Beauvais erected at the end of the fifteenth century; but in this latter case they are elaborately finned with powderings of *fleur-de-lis*, &c. Although this drawing has a look of having been subject to a great deal of wear and tear, and looks just as if it had really been used by workmen, I am afraid that its general appearance has the look rather of the sixteenth than of the fifteenth century. Another drawing shows us the tower intended to have been erected close to the same building. As an architectural composition it is of no great value, having several stages, with a small window in each, and an octagonal buttress at each angle, which buttresses finish in spirelets. The drawing is executed in ruled black lines, and has a wash of blue colour, more or less deep, all over the building. The hollows of the mouldings are not blacked in, but etched, which is the next best thing, although rather a dangerous one; for a contractor on one occasion actually mistook the etched hollows in a drawing I gave him for dog-teeth, and estimated them as such. Of course, when the amount had to be deducted from the estimate, the dog-tooth ornament was not allowed too much for. I should mention that this drawing of the tower of King's College is in perspective, although of a very unsatisfactory kind, for, among other things, the whole of the four spires find themselves at the same level at the top of the drawing. Another design, of about the same period, is that for a gallery for Henry VIII.; this, likewise, is in perspective, and runs diagonally across the page. It is drawn with the free hand in black ink or pigment, but one or two of the longest lines have been ruled. It is likewise shaded up in black, and locally coloured with thin washes, like those I shall presently notice in Albert Durer's works. It is a very careless drawing, and the style is a sort of bad Germanized Renaissance, with baluster columns, &c.

A later drawing is contained in the same collection, the date of which would probably bring us to Edward VI. or Mary. It is the facade of a house, almost in what is now called the Italian style, but with Renaissance details. The perspective is very fair, the vanishing point being in the middle of the building, so as to show the projecting wings and the external staircases in perspective. The composition, also, is by no means deficient in picturesque quality; but we can hardly praise the colouring, which, with partial shading in black or gray, presents us with a bright body-colour cobalt roof, and bright vermilion cements to the windows.

Before leaving the MS. Room of the British Museum, I must notice one or two drawings there deposited. The first is a design in perspective for a large and complicated tent. The plan may be described as like that of Canterbury and other cathedrals, *viz.*,—a cross with two transverse. The drawing is made in black lines, is tinted up with yellow. The book known as Aug. 3, Cotton, presents us with several other tents, and a Renaissance fountain, the latter also in perspective, and tinted up with black or gray. It is likewise valuable to the artist as presenting him with several very large coloured figures of the costume of the time of Henry VIII.

The third drawing is a design for the tomb of Henry VI., which Henry VII., who revered him as a saint, had, it appears, intentions of erecting at Windsor. The execution, however, does not

appear to have come off. The design is in bad perspective, as usual, but drawn very carefully, and probably with a ruling pen. The circles and arches also appear to have been done with a bow pen. The ink is a sort of dark sepia; it is also shaded very neatly and carefully with the same. There are no figures shown in the niches, and the line of impencetration above is distinctly shown, whereas in some of the German drawings, if we may believe the engravings, the mouldings in similar cases are simply drawn as ending in nothing.

The Society of Antiquaries have published also in the "Vetusta Monumenta" the drawing representing the funeral of Abbot Islip. This very curious roll of vellum, which is now preserved in the Herald's College, is of great value both to the antiquary and to the architect, inasmuch as it presents us with sundry views of the interior of Westminster Abbey before the Reformation. The lines are thin and the execution delicate. From it we learn what statues adorned the altar-screen, and what statues were placed above it. The dossal, exactly the most curious part, is represented as being covered up; but the brackets on the pediment of the wonderful tomb of Amya de Valance are shown to have supported angels. Again, the blank wall space in the chapel over Islip's Chantry, where now the waxwork is deposited, had a large picture of the "Last Judgment," and another part of the roll presents us with the screens, now destroyed, which divided the chapels of the north transept from one another. Nothing can be made better than the drawing both of the architecture and of the figures in that roll. I may mention as another proof of the value of documentary evidence relating to the same building, that the manuscript life of St. Edward, written in the thirteenth century, shows us what figures were placed on the twisted columns at the western end of the Confessor's tomb. It appears that they supported statues, and if we may believe the MS., coloured or enamelled statues of the king and St. John.

I must now take you to the Print-room of the British Museum, to examine the drawings of two of the greatest artists the world has ever produced, for we shall here find drawings made by the hands of both Albert Durer and Michelangelo, both great in all the three arts, as I hope some day may be the case again with our profession. This day, indeed, will not come in our lives, but still we must do our best to help on the good time, and instead of fame take the consciousness of having done our duty, as the reward of our exertions. First, of Albert Durer, for he closes one great period of art. In the Print-room is a very large square folio volume, nearly filled with drawings by this master; at all events, they are attributed to him, although I have always had my doubts how ever Albert Durer, although aided by great industry and a scolding wife, could have got through even one-half of the work attributed to him. His drawings are done in moderately thick lines, either with black or dark brown ink, and betray most certain traces of compass points, ruling-pens and bow pens. The first drawing I shall notice is the plan, looking down from above, of a most complicated fountain or pinnacle; there are pinnacles and pediments with an S-shaped plan, and, indeed, it resembles the almost impossible architecture that Israel Van Meekin designed on paper, and Adam Kraft executed in stone.

There are a great many compass-holes in this drawing, as if it had been pricked off. It is most carefully done, and the sections of the mouldings have the beads turned in with the bow pen. The lines of operation, such as the centre lines, are simply scratched on the paper, as it does not appear that they had means of crasing the lead lines. We shall see John Thorpe doing the same thing. Another drawing represents a tomb, evidently Italian, beneath a vault, supported upon four pillars. This drawing is done in black, and elaborately shaded with the same colour mixed with white; the lines are ruled.

There are likewise designs for sundry pieces of jewellery. These are outlined in black or dark brown, and then very slightly coloured with light washes of colour, the raised parts being left white. One design would appear to represent a large vase or fountain of the most elaborate description. From it the various figures pour out streams of liquid, which, as it is coloured red in one case, I suspect to represent wine. There are two hands a little below the middle which hold out cups similar to those attached to the drinking-fountains of the present day, to receive the noble juice. Indeed, this design would make a most charming drinking-fountain if executed in copper

and enamelled, or, indeed, even in stone, painted; and I should be very much inclined to recommend it to the notice of the Drinking-fountains Association, whose designs certainly, to say the least, afford some margin for improvement. But to return to Albert Durer. Three or four leaves of the book are occupied with a coloured design for baluster column covered with arabesques; the drawing is most vigorous, and the colouring leaves nothing to be desired. The other drawings are more remarkable as curiosities than as having relation to architecture. Thus there is the figure drawn from the model which he afterwards used in his beautiful plate of Fortune. The original figure is covered over with squares drawn with a sharp point, evidently for reducing or enlarging it. At page 143 is a bird remarkably like the dodo, and further on a full-size elevation and plan of a shoe of the period,—a most valuable drawing for the writer on costume. Durer, in fact, appears to have had all the conveniences and appliances of modern times as regards his architectural drawing; but it is evident that his bow pen was none of the best, as his circles are the least neat parts of the drawings.

Now for Michelangelo: the British Museum is not very rich in the architectural drawings of this master, yet it will probably be better to go through them as they are more accessible to the student than those in other collections would be. They are for the most part sketched on with common ink, which has now turned brown, with a common pen, and drawn right off by hand, the circles being put in auyhow. Some of them may probably have been first of all scratched in with charcoal, but we have no traces of it: one of them, however, has evidently been inked in upon something resembling chalk, or very black soft pencil. The drawings, even the details, are exceedingly rough, and if ever worked from, must have been drawn out on a board by a pupil, and afterwards corrected by the master. They consist of all sorts of subjects, windows, capitals, entablatures, &c., but none of any great interest. The Musée Wear, at Lille, is the place one must go to who wishes to see what the architectural drawings of Michelangelo are really like. It appears that Wear got hold of a sketch-book of Michelangelo's, very similar, in fact, to that of Willard de Honecourt, and it is this book, cut up, and framed and glazed, which constitutes one of the riches of the Lille Museum. The book contains architectural studies from the modern contemporary edifices—from those of Bramante and Brunelleschi, studies from classic buildings, and his own compositions, including the facade of St. Lawrence, and the plan of the vestibule of the Laurentian Library; and, lastly, directions for casting artillery. It is curious to compare this latter with the trebuchet of Willard, so excellently described and elucidated by Professor Willis. I find the following notes in my copy of the Wear collection. These drawings are executed in brown ink, with the help of a common straight-edge. There are no cross-hatchings, and though the plans are tinted, they are done so in a very careless manner. Very often no straight-edge is used, and the lines are drawn in by hand. Lines are also often drawn with a blunt point on the paper. The same institution also contains the *velum sketch or pattern book of Francia*. As many of these compositions are very small,  $\frac{1}{2}$  by 1 inch, and as they have the appearance of having been done for niello, it is not improbable to suppose that they were intended to serve him in his profession of goldsmith. One page contains ten Madonnas, each less than the other, the largest 1 square inch, and the least,  $\frac{1}{4}$  of an inch by  $\frac{1}{8}$ . There are also on the same page twenty-four portraits, eight of whom are Turks, besides several other subjects, such as children's games, &c.

This museum also contains a copy of the drawing attributed to Van Eyck, of which duplicates are to be found, if I remember rightly, both at Bruges, Cologne, and I almost think Antwerp. It represents a female seated in front of a tower holding a palm-branch and book; the tower is octagonal or hexagonal, and in process of being built: it is drawn on paper and entirely by the pen except in some of the dark parts, where a little colour is dragged on to assist the lines; there is no cross-hatching, but occasionally small dots are used to continue the lines; it is covered with squares, and I suspect it to be a copy.

We must now return to England. By the very great kindness of Mr. S. Smirke, who put himself very much out of the way to oblige me, I have been enabled to examine the drawings by J. Thorpe now preserved in the Soane Museum. As several of these drawings are already known by the *fac-similes* published by Mr. Richardson in his series

of Elizabethan architecture, it will not be necessary to enter into the subjects represented, and I shall only say a word or two upon the execution.

Thorpe appears to have had all the advantages which we have in the present day, except that he could not rub out his pencil, or leaden point. Thus, the centre lines are therefore done with a blunt point. His plans are very seldom etched, although there are one or two that are so treated; among them, a very curious plan of Henry VII.'s chapel showing all the screens perfect, as well as the site of Edward VI.'s tomb in front of that of Henry VII., which tomb was put up by one of his sisters and destroyed by the other. It is curious that I did not observe any cast shadows in the tinted elevations of Thorpe,\* or indeed, of any of those which I have been noticing; it being reserved to us moderns to make our drawings at once ugly and scientific. With Thorpe we take leave of the Middle Ages, and there propose to close this small notice, merely calling attention to the very valuable and clever volume of drawings belonging to our library, containing a large number of sketches washed in in sepia and Indian ink, apparently designs for scenes. Although belonging to the most *Rococo* period, yet they display a power of invention and design which would do honour to any age; and we can only regret that such good men should have fallen on evil times. We also possess a little sketch by Sir C. Wren, done like those of Michelangelo, with the free hand, with common pen and ink. At the end of last century, and the beginning of the present, the fashion was to make drawings in fine lines, tinted with Indian ink.

At the revival of Medieval art a favourite way of sketching was to outline in pencil, and tint up with Indian ink or sepia. Most of Mr. Blore's drawings are done in this manner, and are so surprisingly and minutely finished, that they give the idea of very clear photography. But before this the custom of offices was to make the drawings simply in thin lines, and then to back-line them,—a practice destructive of all breadth of effect, and absolutely perplexing to the eyes.

The elder Pugin's works are specimens of this style, which, I am happy to say, is nearly obsolete.

The younger Pugin brought the first change to the system in his plates, where, on the contrary, made things look too well by his marvellous etching; indeed, there is a fizziness and an action in all his plates which you look in vain for in the real thing. The present system of etching up a drawing is an offshoot from this style, and is, I am afraid, open to very nearly the same objection.

We have to thank competition committees for its use, who, forbidding the employment of colour, have obtained a much more seductive style of perspective; for I think I would any day back a good etched drawing against a coloured one.

But, of course, the success of a design in stone and mortar must depend upon the working drawings, for nobody sets out work or chisels stones from perspectives; and it is in these that I hope to see good strong, thick, bold lines employed, so that we may get into the habit of leaving out those prettinesses, which only cost money and spoil our designs. But, after all, no amount of architectural drawing would make a man an artist or an architect,—for they are one and the same thing,—unless he obtains a complete mastery of the human figure; and I would earnestly suggest whether this Institute could not aid the attainment of this end by having evenings when a model should sit and a good artist be engaged to correct the drawings. When the profession generally begin to draw the figure and make bold architectural drawings, and generally to think for themselves, instead of going to past ages and precedents, we may then hope to have an *Architecture*.

#### PROPOSED PUGIN MEMORIAL FUND.

On the principle of allowing both sides in matters of judgment to state their views, we give place to the following letter, which has been addressed to the honorary secretary of the Fund, by Professor Donaldson:—

"I am truly ashamed to have allowed your friendly notes respecting the Pugin Testimonial to remain so long unanswered, but I was in the country at the time the first arrived, and have been pretty constantly away from town ever since, and occupied in absorbing matters of business, so as not to have had the time to acknowledge them with the deliberation they deserved. I am much gratified by the proposal to be upon the committee; but, anxious as I have ever been to take

part in any project which had the sanction of an influential portion of my professional brethren, and the object of which might professedly be the promotion of our art, I feel that I must decline the honour you propose to me. It is proper and due to you and the earlier promoters of this testimonial, that I should frankly state the grounds upon which I do so.

I consider that Welby Pugin was a very distinguished and earnest artist; that he did much for our school; that he freed it from the trammels of merely following in the course of Medieval art as it existed in this country; and, by going to France and Germany, and seeking in the productions of those countries fresh hints and suggestions, new sources of beauty, and novel combinations of form and decoration, he enlarged the sphere of conception, and produced works of high merit. We must also recognize in him an artist's soul, filled with an enthusiastic zeal. Under this point of view I should heartily concur in a testimonial, even although there already exist a most fitting one in the chapel at Rainsgate and the statue erected by the love and devotion of his admirers. But, amidst all the admirable qualities of Welby Pugin, there existed a narrow-minded sectarian spirit. His love for art was limited to a superstitious devotion and worship of Medieval or Gothic creations. He was intolerant of every other class of aesthetic thought; he could not bear any other style that might be supposed to compete with it. He attempted to crush classic architecture with a relentless and consequently with a very unfaithful spirit, as witness his 'Contrasts.' He reprobated its study, and considered its productions as intolerable nuisances. This exclusiveness was an unhappy feature in his character, an obliquity of artistic perception. Now, this obliquity it is sought to perpetuate by the memorial proposed in your letter for the establishment of a travelling studentship, in confining its purpose to examine and illustrate Medieval architecture, sculpture, and painting, in the United Kingdom. This special form of the memorial is founded upon an aspiration of his uttered many years ago. Since then Gothic art has been more studied in this country than any other, and greater encouragement given to its followers than to those of the arts of any other period or style; and a large portion of our leading men are those justly eminent throughout Europe for their talents as Medieval architects. The limitation I conceive to be most pernicious, for it fetters the taste and narrows the judgment. The highest privilege of the artistic mind should be its perfect liberty, and the student should be allowed to drink at every fountain of inspiration. It creates the false idea of there being one point of view from which form, sentiment, and expression can be alone properly studied, and that out of it there can be no propriety of thought and conception. It confirms the notion, too sedulously inculcated already, of antagonism, contempt, and strife; whereas, the arts should offer a common platform of peace, harmony, love, and generous rivalry between the lovers of nature,—that is, those who seek by their works to transfer to their production the beauties, intellectual and physical, of the material world. It sows the seeds of permanent discord, and of a foregone conclusion. In my writings and my lectures I have studiously sought to do all honour to the glorious productions of the Medieval period, and to teach those under me to appreciate the beauties of art and science which abound in the wonderful edifices of Gothic architecture. In fact, my view of our art is a catholic and general one, and I cannot but regard with apprehension any movement tending to drive out of the field all styles but one. It would be as pernicious as, in painting, to select for exclusive distinction and honour pre-Raphaelism, and so to ignore those classes of historic art which Raphael himself, Michelangelo, Paul Veronese, Titian, the Carracci, and other great masters illustrated by their magic powers.

Entertaining these views of the proposed Pugin testimonial, I should be stupid and cowardly if I shrink from expressing the objections I have to it in the true interests of architecture.

THOS. L. DONALDSON.

\*\* It should be remembered that as the fund will be handed over for its application to the Royal Institute of British Architects, by whom Architecture in its universal sense is to be maintained and fostered, and who have already a fund to aid their medallists in pursuing their studies abroad, the Pugin Memorial Fund, for studies at home, will take its place as one of the means at the disposal of the Institute for the promotion of the study of architecture in all its developments and varieties.

#### THE PROPOSED EDUCATIONAL QUALIFICATION FOR ARCHITECTS.

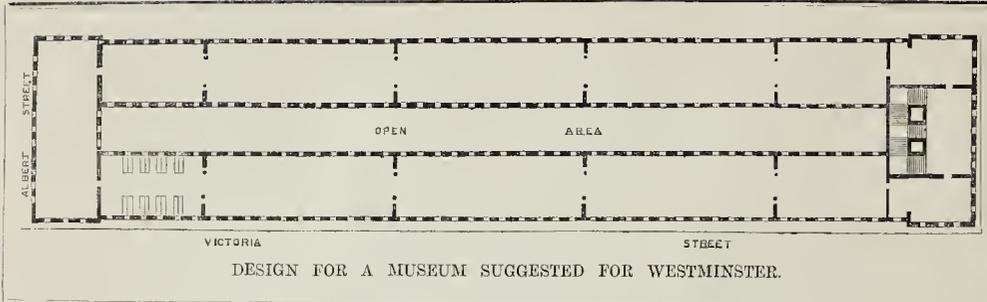

BEFORE leaving my first inquiry for the second,—that is to say, the general principle of the Institute proposal for its details,—it may be well to take up one point in transition, namely, whether the present seems to be the proper time for action. Is the condition of the profession suitable in respect of preparedness? Has the measure itself passed through a satisfactory preparatory course? If the profession is not ready, the measure must wait. If the measure is not matured, the profession must wait.

As to the condition of the body of architects, I am very hopeful that this may not be found unsatisfactory. Taking London alone, as the best criterion, we find about one thousand persons professing the craft, either as principals or salaried assistants. Make all allowance for irregulars: take away also those considerable classes of measuring surveyors and merely superintending surveyors ("practical men" so called), who are perfectly respectable in everything but their assumption, needlessly I think, of the superior name: eliminate also for the sake of argument those (some of them amongst our most responsible men of business) who profess and desire no other practice but that which arises out of dealings with property: there still remain, perhaps, three or four hundred gentlemen of good general education and social standing, together with a corresponding number of assistants, who are every one more or less competent to challenge the twofold test of a practical architect, namely, artistic design, and scientific construction. Now this is a goodly array of guild-brothers. Such a profession is entitled to public confidence; and it possesses it. Upon this basis of what is called respectability of practice, the present Institute has been established, and, by the exercise of the ballot for admission, has been successfully maintained. The introduction of an educational standard, whenever this shall be brought about, is a superseding of the present standard of so-called respectability; and we are now inquiring whether our organization is ripe for this advance,—whether our principles of craftsmanship are so far understood, not only by the few who are to lead, but by the many who are to support with their approval, as to be academically systematized for the more easy and thorough instruction of youth. This is matter for evidence; but at present I am inclined to believe that the result of evidence would be in favour of action.

If so, then what is the position of the measure before us as to maturity? I am afraid that some of our advisers, especially in the provinces, are under the impression that the proposal is entirely new and original, a sudden inspiration on the part of the last year's Council. But whether sufficiently matured or not, it is more matured than this. The readers of the *Builder* will remember, that for a good many years the question of educational reform has been kept steadily before the architectural public. In 1847, the demands of the students themselves for a better system of education led to the establishment of the well-known junior society, which still flourishes. Its object was to supply, for want of better, the means of mutual instruction. Several attempts have since been made to graft upon this institution something that should make it more academic, but without effect: certain proposals will also be remembered as having been offered to the Institute itself, with a similar view; still without effect. Again, not to speak of merely private suggestions, the establishment of a national Academy of Architecture has been publicly advocated in various shapes from the time of Mr. Bartholomew to the recent occasion, when the Institute took into serious consideration the position of architecture in the Royal Academy of Arts. Still, another endeavour dates from the publication by Mr. Fife, at the instigation of the junior society, of the famous Berlin curriculum. Such as these have been the chief stages of the movement. The last developed itself into what is called the "Diploma question," which fastened not only upon the professional mind, but upon the less accessible mind of the Institute, provoking long debate, until at length, discussion being "adjourned," the disquieting question, judiciously perhaps, if not quite constitutionally, was gently extinguished by the Council: the adjourned discussion never was heard of again, like the ship that sailed on a Friday.

The diploma question, as I argued last week, is based upon a radical error, the fallacy, namely, which would create a shadow signifying, before creating, the substance signified. The present

\* When I say cast shadows, I mean cast shadows sharply defined. There is often a cast shadow, but it is almost always shaded off.

proposal is a great improvement upon this. It provides the curriculum primarily, the diploma secondarily. Whether even now it is well matured, must be carefully inquired into; but if the principle of the "diploma question" is understood to be abandoned by the profession, and if the details of the present project will bear examination and amendment, I hope nothing else will occur to make it appear that the educational movement is otherwise than ripe for action now.

One more remark in passing. The organization of the Institute is such at present that no movement of any importance can hope for success unless it accords with the views of the council, so as in fact to be adopted as a council measure. There may be no positive harm in this, except that it is scarcely according to Hoyle; but at all events it renders it necessary that educational reform should become a council measure before it can be a successful one. To the credit of the council the "diploma question" never was adopted by them; on the contrary, they ultimately promoted its extinguishment. To their credit still, now that they come forward as movers in the cause, they appear at once to take the higher and more proper ground. Thus we find doubly. The cause possesses now the influence of our cabinet; and that influence, moreover, is put upon the right track.

Let me now proceed to a consideration of the scheme of the council as regards its details. If we should find it to be without fault it would be much more than in all the circumstances we are entitled to expect. If we find it to be capable of amendment let us be satisfied. This question of details is naturally divisible into two. What should we consider to be a complete system of instruction? How far is it possible or convenient to bring the agency of the Institute to bear upon it?

Perhaps every vocation amongst the so-called liberal professions has to be acquired in two forms, namely, practically, by means of assisting in the transactions of business; and theoretically, by pursuing a course of public or private study. Of office pupillage I need say nothing; the other branch is the matter before us.

The theoretical study requisite for the practice of the architectural profession is properly of two sections, the artistic and the scientific; under each of these categories I must necessarily be allowed to include much more than to some persons may at first be apparent. The artistic section of architectural education would embrace not only the delineation, design, and criticism of all that affects the fine-art of architecture directly, but a certain amount of knowledge of the subsidiary, supplementary, and even collateral fine-arts. The scientific section would embrace not merely what is called construction, but all physical science bearing upon matters of building, and the elements of mathematics to such extent as seems requisite for the application of these sciences: here also we may include the principles of the whole province of plan and such special matters of physical science as bear upon this. The practice of the measuring-surveyor, to some extent, in the bearings of law and usage in reference to building, and various minor matters of business which are more or less important to be understood, although not essentially architectural, must form a supplementary section. A good general education and an aptitude for draughtsmanship are of course essential preliminaries; and with the help of these I am prepared to assert that a complete curriculum can readily be determined which shall bring the whole of what I have now hinted at within reach of an average mind,—plenty of work to do, but nothing to fear. I wish I were twenty years younger, and had such a course of training fairly marked out for me. This cannot be; but the next

best thing is to help to mark it out for those who happily have not to wish for younger days.

I do not expect that the Institute can at once assume the control of a complete educational system. Indeed, I fully hold it to be prudent to creep before we run; and I clearly see that the introduction of an element such as this into our present organization must be a work of very careful and well-considered progress. But before the Institute is permitted to involve itself in any action whatever, the profession ought to take care to have this guarantee for success, amongst others, that the promoters of the measure exhibit a thorough knowledge of detail. Now, for this guarantee we can only look to their published programme. If this be well systematized, we have reason to be satisfied: if it is more or less vague and complicated, we have more or less reason to fear. I take it then *verbatim*. "Pure and applied mathematics, land surveying, mensuration, geology, ordinary construction and materials, drawing, the styles of architecture, the history of architecture, languages, and chemistry"—this is for the elementary examination. "Such (subjects) as occur in professional practice with the general theories on which the detail of such practice is based; e.g., languages, architectural jurisprudence, the Building Act, sanitary requirements, the history of architecture, the theory of the beautiful, the analysis of the styles of art, architectural composition, the literature of architecture, the theory of the higher subjects of construction; e.g., arches, bridges, and domes, the application of iron, &c."—this, with a further development of the elementary list, is for the higher examination. I do not know exactly what may be the general impression produced by all this upon other minds; but if I were to pretend to be myself left in any other condition than that of a respectable November fog, I should not be speaking candidly. It would be too much to say that the gentlemen who portrayed this panoramic sketch of architectural knowledge, were themselves hazy as to its interpretation; but, before the profession can rely upon them for carrying it into practical effect, it is only fair to ask that they should put it into the form of what they may consider to be a systematic scheme, in which the characteristics of irregularity and uncertainty may be kept at least within modest limits. For the essence of the scientific principle of instruction lies in system; and if our students are led to think that the curriculum before them is not capable of being reduced to system, the result must be discouragement.

It is true that the programme above recited is followed by a proposition, "that a curriculum be prepared and circulated, giving a general outline of subjects for examination;" and here I am willing to understand it to be meant that in the "general outline of subjects" we should have a specific and detailed guide to the course of study which is before given in the general outline properly so called. But if the lesser and more brief system of generalities he slightly chaotic, what would the greater and more lengthy system of particulars be? I therefore venture to suggest that before the question comes forward again for debate, the promoters should carefully reconsider their programme, and lay it out in an entirely new form; otherwise I do not see how it can possibly become the basis of any intelligible understanding.

R. K.

**SOCIAL SCIENCE ASSOCIATION.**—The next annual congress will be in Dublin, in response to the invitation of the Royal Dublin Society, who have resolved "That it be referred to the honorary officers to consider and report upon the steps necessary to be taken in order to secure the most efficient reception of that body."

#### MUSEUMS FOR THE METROPOLIS. SUGGESTED MUSEUM FOR WESTMINSTER.

This plan we have engraved, made by Mr. William Bardwell, architect, was laid before the late Select Committee of the British Museum by Mr. Rigby Wason, who stated that fourteen acres of land in Victoria-street, Westminster, might be bought by the Government at 7,000*l.* per acre.

The plan shows a continuous gallery on each floor, 1,780 feet in length by 50 feet in width, and has exits and entrances at each end on the ground floor. The total length of the building is 800 feet; the length of the end galleries 155 feet; the width of the area 30 feet.

#### COURT OF LIEUTENANCY.

A NEW commission of Lieutenancy for the City of London has, by command of Her Majesty, just been issued. The following is the list of the new members named to supply existing vacancies:—

Sir Anthony de Rothschild, Bart.; Edward Huggins, Esq.; Francis Burton Ware, Esq.; Josiah Hale, Esq.; George Whiting, Esq.; Joseph Sebag, Esq.; Henry Hill, Esq., F.S.A.; James Duke Hill, Esq.; Angus A. Croft, Esq.; S. W. Silver, Esq.; J. W. Carter, Esq.; John Jones, Esq.; F. G. Moon, Esq.; Charles Kelson, Esq.; John Clark Lawrence, Esq.; A. J. Waterlow, Esq.; H. V. Vallance, Esq.; Lionel Lucas, Esq.; W. Tite, Esq., M.P., F.R.S.

#### RAILWAY MATTERS.

ENGINEERS are engaged in making the necessary surveys for plans to be deposited with Parliament in the ensuing session, for the construction of an underground railway, commencing at Regent-circus, Oxford-street, and terminating at the station of the Metropolitan Railway in Victoria-street, Holborn-bridge. The line will not pass under the principal thoroughfares, as does the railway now being constructed, but will take a route to the south of Oxford-street and Holborn.—Another new railway project, which excites some interest in the City, is a scheme for directly connecting the Bank and Charing-cross. This connection is not sought to be obtained by any street railway such as that proposed by Mr. Train, but by means of locomotive railway, passengers to be conveyed from Charing-cross to the Bank in about six minutes, in trains running at intervals of five or ten minutes during the day. The proposed railway will connect the Charing-cross line directly with the City by means of a bridge across the Thames at a point where the river is at the narrowest, about midway between Southwark and London bridges, and carry the line thence to the back of the Mansion House, or to Cannon-street. The distance from a point immediately behind St. Saviour's Church, Southwark, to Cannon-street, is only about 800 yards. This is said to be practically the whole length that will have to be constructed in order to bring the Bank and Charing-cross within five minutes of each other.—A return has been issued by the Board of Trade, made up to the end of last year, showing the financial condition of the railways of the United Kingdom. The total capital raised is stated at 334,362,928*l.* It increases by several millions every year, part of the new capital being laid out in heavier rails, larger stations, and additional rolling stock, and the rest absorbed by new lines. The new lines opened in England last year were altogether greater in length than a railway from London to Durham, Lancaster, or Plymouth. The capital raised and spent by twelve companies exceeds 200,000,000*l.*; and three-fourths of it paid less than 5 per cent. in 1859; but 1860 is proving more auspicious.—There appears to be an unusual number of notices of application to Parliament next session as to railway extensions, junctions, branches, and other lines of railway throughout the country.

NATIONAL SECURITY SAVINGS BANK, AND OFFICES OF THE FREE CHURCH, EDINBURGH.\*

MR. DAVID COUSIN, ARCHITECT.

## THE GROSVENOR HOTEL.

It is not a very hazardous conjecture that upwards of nine-tenths of the visitors to London arrive by railway, and that of these fully three-fourths are domiciled at hotels, inns, taverns, or coffee-houses. Every veteran traveller knows—and more than that, feels—that properly to “take one’s ease at one’s inn,” it should not be far from the point of arrival and departure. As the train gradually pauses at country town after country town, the words “Railway Hotel,” or “Railway Inn,” are among the first to catch the eye; and, for the sake of proximity to the station, and saving trouble and expense in the transport and retransport of cumbersome luggage, the traveller will often cheerfully prefer inferior accommodation close at hand to superior accommodation at the same price farther off. It would almost seem that some perception of this fact prompted, until recently, the opening of the worst hotels and the dirtiest coffee-houses in close proximity to the metropolitan termini. The inquisitive and persevering traveller may easily satisfy himself as to the former general state of miscellaneous accommodation in such localities by wandering in the neighbourhood of the Waterloo-station, until fatigued with carrying his carpet-bag. There he will perceive an archaic state of things still existing in the present day; but elsewhere, except perhaps in the savage regions of Shoreditch, *non avens changi tot cœla*. Although excellent hotels have for some time been established near other stations—that, for instance, at London-bridge—it is only recently that the idea has occurred to enterprising minds to connect with the chief termini hotels equal to the demand of the traffic on the lines, adapted for the reception of the middle and the higher classes, and even more commensurate with the importance of London than the best “Railway Hotels” are with that of provincial towns. This conception, prosaic though it may be deemed by some, is one of those striking conceptions which distinctively mark the civilization of the age, so far as it is justly considered that judicious arrangements for bodily comfort and convenience are absolutely essential for healthy mental exertion and truly pleasurable enjoyment. But such colossal erections were beyond the means of single individuals. Public companies were formed, and soon the Paddington and the Great Northern hotels (not to mention the Westminster, as unconnected with a railway,) formed conspicuous and even palatial features in the varied architecture of London.

In the Victoria-road, Pimlico, and communicating directly with the platform of the Victoria terminus of the Brighton Railway, another *monstre hotel* is now in course of erection by the Grosvenor and West End Railway Terminus and Hotel Company. This structure bids fair to dwarf even the lofty mansions of Belgravia, and to rival, in extent, convenience, and lavish decoration, any of its predecessors. The plan is oblong, and presents two street frontages of the respective lengths of 262 and 75 feet, the height to the highest part of the roof being 150 feet. Some brief particulars of the general arrangement and construction can scarcely fail to interest our readers; and, as the works progress, we shall recur to the subject.

One of the most important points to be considered in the planning of extensive edifices destined for the reception of successive relays of strangers is that the arrangement shall be so devoid of complication as to obviate, as much as possible, the visitor’s hesitation in finding the respective apartments. This difficulty appears to be fairly met in the Grosvenor Hotel. Our remarks, it should be premised, apply, not merely to the actual state of the works, but to what is ultimately proposed. Immediately on passing the vestibule and entering the extensive hall, the harp presents itself on one side, and the porters’ room on the other, there being also, adjoining the latter, a lift kept constantly in readiness to convey travellers and their luggage to the upper floors. Beyond, from the centre of the hall, two wide and straight corridors lead, right and left, to private sitting and other rooms and offices, and are terminated, at one end, by a large dining-room for wedding and other parties, and a ladies’ coffee-room, and at the other, which may be considered as the bachelors’ end, by the gentlemen’s coffee-room, adjoining which, at the rear of the edifice, is a smoking-room. The latter are very spacious apartments, the coffee-room being 69 feet by 36 feet, and the smoking-room 39 feet by 23 feet; both are 18 feet in height. At the end of the hall, facing the entrance, the principal staircase is placed; and two servants’ staircases are concealed on each side. Above, on the first floor, an open

gallery extends round three sides of the hall, which is lighted from above; and the hotel is thus separated into two portions. The galleries on the right and left of the hall communicate directly with two corridors on each side, between which corridors principal staircases, forming somewhat novel features, are placed, the servants’ staircases now mentioned being carried up at the rear vertically from their original starting-places in the basement. It must be evident how greatly this distinct division of the structure in halves tends to obviate confusion, alike in the service of the establishment as in the visitor’s ideas of location. He has but to remember that he should turn to the right or left, and he is at home, or rather in the proper part of the hotel.

There are seven stories above the ground floor, the two first containing suites of drawing, dining, and bedrooms, and other accommodation for separate families, the remaining floors being appropriated chiefly for sleeping accommodation. In each wing a bath-room and room for attendants are provided on every upper floor, except the top-most one for the servants. Three internal areas light the corridors, staircases, and offices.

The service department in the basement, which is amply lighted, is, as may be imagined, on an extensive scale. The kitchen is 38 by 36 feet, and the wine-cellar and coal-cellar are little inferior in area, the other rooms and offices,—bakery, pastry-room, plate-room, larders, stores, house-keeper’s room, servants’ hall, female servants’ room, visitors’ servants’ dining-room, engine and furnace house, &c.,—being also of proportionate dimensions.

Altogether the hotel forms, as it were, almost a little town under one roof, the number of apartments, exclusive of various closets, &c., being close upon three hundred.

The construction throughout is of a very substantial description. On account of the loose character of the soil, and the immense weight to be placed upon it, 22,000 cubic yards of concrete were used in the foundations. The concrete is 10 feet in thickness throughout the whole space built upon, the lower part of the bed, to the height of 3 feet, being formed of Portland cement and Thames ballast in the proportion of one of the former to nine of the latter; but the ordinary concrete extends to the depth of about 35 feet below the main walls. It has been deemed sufficient to make only the approaches and corridors fire-proof: these are paved with Portland stone on brick arches, and the staircases are of the same stone. The divisions of all the apartments are of brickwork, to prevent the passage of sound and fire, wood partitions being excluded. Stirling’s patent toughened iron is adopted, and wrought iron plate and box girders are introduced over the iron columns and in other places. The curves of the roofs are formed with three thicknesses of 1½-inch deals, with rafters and ceiling joists notched on: thicknesses of deals are in other instances substituted for solid beams. Lead is the covering material of the roofs, and a point often neglected is specially enforced, viz., turning the open sides or laps from the south-west, west, and south, wherever practicable.

The hall, corridors, &c., are heated by means of hot water, the pipes being placed in channels formed with bricks on edge on the arches under the paving. The latter is related for continuous iron perforated plates of ornamental design, running along both sides of the corridors and surrounding the hall. For the disposal of foul air, flues are led to a small shaft in connection with the furnace room, where a draught is created. The fireplaces are supplied with air by means of 3-inch glazed stoneware tubes, jointed with Roman cement and communicating directly with the outer atmosphere by means of air bricks; and thus draughts in the rooms towards the fires are obviated. The internal openings are at both sides of the fireplaces instead of below, and admit of regulation.

The elevations are designed in a bold and vigorous style,—a modification of the Florentine-Italian, similar to the edifice at the junction of Chancery-lane and Fleet-street.\* Bath and Portland stones, Portland cement mouldings, and Suffolk white bricks are the facing materials. The ground-floor street-fronts, of Bath stone, are arched and rusticated; and, extending from the respective key-stones, some of the largest swags in London will be carved. Above, the arched windows have pierced and foliated Bath stone hoods; and between these, on the first floor, which has a continuous balcony, are recessed circular medallions, to be filled with busts by Mr. Dayman. The roofs

are curved: that in the centre is flat on the top, and those at the ends rise to a considerable height, and are surmounted with cupolas. At the rear, the elevation, where it appears above the railway station, is similar in character to the principal front.

Internally, the hall, corridors, and principal apartments will be elaborately decorated in plaster, Keene’s and Martin’s cements: several of the walls are to be covered with diapered work, and scagliola columns will be introduced. The chimney-pieces for the chief apartments will cost from 30*l.* to 50*l.* each.

The site belongs to Mr. Kelk, by whom the works are being carried out from the designs of Mr. J. T. Kowles. Mr. W. Hemsley acts as clerk of the works, and Mr. W. Heru is the builder’s foreman. The estimated cost of the erection is, we understand, about 100,000*l.*

## LIVERPOOL ARCHITECTURAL SOCIETY.

## ARCHITECTURAL EXAMINATIONS.

At the ordinary meeting, held on the 14th instant, Mr. James M. Hay in the chair, the hon. secretary reported that he had received a letter, enclosing two resolutions, which were passed at a meeting of the associate and student members in the previous week, first, “That a vote be taken as to the desirability of an architectural examination of any kind.” For the examination, one; against, fourteen. Second resolution: “That we acquaint the members of the society with our decision, and request them to withdraw their late resolution of approval. Failing, a memorial to be forwarded to the Royal Institute of British Architects, to be signed by the associate students, and those architects who are against the movement; acquainting the Institute that they object to anything like an architectural examination being established.” A communication in answer to the resolution was requested to be sent before Friday.

The chairman observed that it was quite out of order to request the society to rescind a resolution which had been passed after public notice had been given that the subject would be discussed. The first resolution could be properly accepted as an expression of opinion, but the second was out of order. The duty of the associates and students was to have memorialized the society, and it would then have been a question with the society whether they would send the memorial to London as an expression of opinion.

The memorial was discussed at some length; some of the members expressing an opinion that it was not courteously couched. Mr. Howard supported it, and said three professional members were dictating to the whole of the society. Mr. Boulton said a statement in the memorial was not correct, and that he did not wonder, after the spirit they had shown, that the students and associates were afraid of an examination. Their minds were manifestly extremely inexact.

Mr. Audsley explained that the resolution was not intended to convey any threat; but as it was viewed in that light he would, on behalf of his brother, withdraw the whole communication, and it could be re-written, and sent to the society at the next meeting.

After some further conversation, the letter from the students and associates was withdrawn.

## PROPOSED UNION OF INSTITUTES.

The hon. secretary read a letter from Mr. O’bry, secretary of the Northern Architectural Association, Newcastle, enclosing a resolution of that body, recognising the desirability of a general alliance of the institutions of architects, in order that combined action might be taken, if any question should arise affecting the interests of the profession.

Mr. Bout proposed the following resolution, which was seconded by Mr. Hay, and carried:—“That the receipt of the communication from the Northern Architectural Association be acknowledged, and that the secretary be requested to say that the members of this society will be happy cordially to co-operate in the attainment of the proposed objects, so far as they may prove to be feasible; and that the letter be referred to the council of this society for their consideration and report, upon the best means of realising the proposals of the Northern Architectural Association.”

It was announced that Mr. Milner had given a prize for the best design for a door for his safes, to be competed for by the students.

## THE HISTORY OF ARCHITECTURE.

The paper for the evening was “An historical and critical Review of the various Styles of Archi-

\* Described and illustrated in vol. xiii. p. 389.

ecture that have been practised in the world from the dawn of art to the beginning of the present century," illustrated by a coloured chart of the history of architecture; by Mr. Samuel Higgins.

He commenced by saying, that though the secretary's circular promised an independent paper, illustrated by the chart, he had thought it best to reverse their relationship, and make the paper an illustration of the chart, which latter represented the origin and various successive transformations of the architecture of the Greeks, involving the rise, chronological sequence, relationship, &c., of the principal styles that have been practised from the dawn of art to the present time. It was embellished by various chronological tables,—one of the great ruling powers; another, of the principal architects; a third, of the great typical edifices in each style; and a fourth, of great events having an influence on architecture, which latter he had found so numerous as to show that, if the history of architecture was not identical with the history of the world, it was at least an appendage to human history, and organically developed out of it.

He began with the Egyptian style, the origin of which was lost in the night of time beyond the ken of historic record. To it belonged the oldest buildings on the face of the earth, irrespective of the pyramids, which, though sublime objects, could scarcely be considered as architecture at all. Unlike the subsequent styles, which invariably manifested progress for a certain portion of their career, the course of Egyptian art was one of decline; the oldest buildings being the greatest and purest in style. The Temple of Karnak was the oldest of temples, and perhaps the sublimest building ever reared by human hands. The Egyptian and Assyrian were the Asian and Eve of the architectural styles of the world. The Egyptian gave to the Greek some of its most beautiful elements and sublime characteristics, and showed forth the Doric order, while the Assyrian suggested the Ionic.

After describing the Assyrian style, which was chiefly illustrated by palaces, the remains of which had been, within the last few years, dug out of the earth, he went on to the Persian—a style almost identical with the Assyrian, and which continued to flourish at Passargadae and Persepolis, till the fall of the Achaemenian dynasty and conquest of Persia by Alexander the Great.

The style of the early inhabitants of Greece was the Pelagic, which, under the Dorians, was there mingled with Egyptian and Assyrian elements till it grew into the Hellenic, or true Greek, the first appearance of which was at Corinth, under the Cyclades, in a form almost as massive as that practised in the valley of the Nile. This originated the archaic age of Greek art, which was followed by the middle age of Pericles. Of the style, as it existed at this time, he would only say, that every increase of knowledge went to confirm the belief that it was the most pure, noble, and perfect architecture that ever existed in any form in which the most intellect and refinement of feeling was embodied, and that involved the sublimest graces and excellencies ever expressed in stone. The noblest example of the style—the Parthenon—embodied the most perfect beauty and æsthetic perfection of form and detail within the same compass than any other building in the world.

The period at which such architecture was produced, both Classicist and Medævalist must almost be the most illustrious epoch to which we could point in the history of architecture. As might be expected, it was otherwise illustrated; and the genius of architecture did not reach to so distinguished an eminence unaided, as it was aided by her sister arts; not only by sculpture and painting, which were then in their zenith, but by poetry and "Divine philosophy." The Homeric period of the Grecian epic was passing, at the time in question, but it followed close upon that of Pindar and the Greek lyric muse, and it was contemporary with the glorious dramatic era of Æschylus, Sophocles, Euripides, and Aristophanes; rendered still more illustrious by the pure doctrines and bright example of the greatest philosopher of antiquity, who was then living in Athens,—Socrates; while it heralded the philosophic age of Plato and Aristotle, and the no less brilliant era of Demosthenes and Æsopates.

The two styles, Greek and Etruscan, flowed together to form the Roman, into the defence of which, against recent depreciation, he warmly entered. The Roman style, in the time of Augustus, its great period, was practised from the shores of the Atlantic to the Black Sea and Persian Gulf, and all round the Mediterranean, save Egypt. With the exception of the Egyptian, it was the only style of the civilized world, and, notwithstanding all that had been urged against it, he thought it was not unworthy of its great extent of practice, as Paul's Cathedral, London, was Roman architecture as the Romans used it; and neither the Greek nor the Etruscan alone could have embodied such a composition, nor so Romanesque, in which the two styles were fused into one, in the manner in which the Romans should have united the styles, could have attained to half its grandeur.

After describing the style of the middle Persian Empire, which had an important bearing on subsequent styles, he entered on a description of the Christian career of architecture. Under the influence of Christianity, he traced the of all associations of Paganism, and its new requirements, the Christian Romanesque was generated, which style was no sooner formed than the Byzantine commenced its separation from that of Paganism, as Hope says, originated in a wish on the part of the architects' Com. stantople, after its separation from the Western Empire, of giving to the architecture of Christianity a form wholly different from that of Paganism. The Byzantine was the style of all nations of the Greek Church, or the remnants of Christian in the East, and did not embrace the faith of Mahomet. After giving a full description of the style which, in course of time, became and retained into several distinct branches, European Byzantine, Western Asiatic Byzantine, Armenian Byzantine, and Georgian, the latter coming down to the present time, he went on to the Saracenic group of styles, which were developed out of the Byzantine, viz., the Persian, the Syrian, the Egyptian, the Spanish, or Moorish, and the Indian and Turkish; of which styles he gave an interesting description, great influence through the medium of the Crusaders on the decorative development of the Gothic. It was devoutly to be hoped, for the sake of the general interest of architecture in the world, that the increased intercourse with Europe would not further interfere with the practice of these styles, and prove an extinguisher of so much

that was beautiful and poetic. Returning to the main stem of the history, he entered on the subject of the Gothic style. From rude attempts of the various tribes of barbarians, who overthrew the Roman Empire, to initiate the edifices of ancient Rome in Christian churches, an entirely new system was originated, called Gothic, which for a while was all one nebulous chaotic mass. But in process of time it consolidated, branched out, and grew with the faith which called it into existence, into the different countries of Europe, where it exhibited local varieties according to the character and energies of the different races who adopted it. As the vernacular languages of modern Europe pushed themselves through the Latin as the exponents in each particular country of the popular thought, so in like manner the Gothic styles of architecture made their exit from the Roman. Of these Gothic styles, the Lombard was the first that became formed into an independent style: the German was the next, which was the finest of the round Gothic styles, and the one most worthy to stand as the representative and typical style of the class. He described the career of Gothic in France, England, Spain, Belgium, Scotland, and Ireland, and traced them through all their different periods to the time when their course was arrested by the reformation and revival of Classical art and other causes. He meant no disparagement to the Gothic system when he expressed his belief that it never could have come to us, but through the artistic darkness and barbarism of the Middle Ages; for none but men who knew nothing of Classic canons of art, and on whom Greek and Roman tradition had no authority, could have made so bold a venture. The Gothic style which at the time was all but universal, as the Lombards and other Gothic tribes made in the sixth and following centuries. Reverence for their great predecessors did not never have suffered Roman artists to take sufficient liberties with the proportions of the Greek ordinance for the creation of a style so different in spirit and principle of composition as the Gothic. We were indebted to the advent of barbarism in the fifth century, which destroyed the civilization of the ancient world, and plunged Europe for ages in mental gloom, for the greatest system of architecture that had arisen since the Greek; and to the rise of a false prophet in the sixth century, who, by his doctrines by the sword, and carrying desolation over the fairest countries of the globe, for another, which, if not so great, was still more elegant and refined. He then traced the history of the Gothic style in the thirteenth century—Romanesque and mixed styles—such as the Sicilian, Italian, Gothic, Moresco, Neapolitan, and others; and then entered into an account of the revival of ancient architecture, the first dawn of which was in the thirteenth century, and traced the course of the modern Italian stream of art through the great period of the cinque secoli to the present time. In conclusion, he said he could not give so much attention to the subject as he was under the conviction that a knowledge of the development and history of styles was greatly assisting, if not absolutely necessary, to a right understanding of the principles of architecture.

Thanks were voted to the reader, and the publication of the paper and chart was suggested.

#### MASTER AND WORKMEN.

MESSRS. LUCAS AND THE VOLUNTEERS.

THE workmen, in Messrs. Lucas, Brothers', employment, belonging to the volunteer corps, to the number of nearly ninety, were invited by their employers to dinner, along with their fellow workmen, and various personal friends of the employers, on Tuesday last week, in a temporary dining-hall, prepared in the yard of Messrs. Lucas's works.

Mr. Charles Lucas occupied the chair, supported right and left by Sir S. M. Peto, bart.; Major-general Sir R. Daeres, K.C.B., R.A.; Colonel Wingfield; Colonel Hockley; the Vicar of Lowestoft, and various other gentlemen, both civil and military.

We do not propose to give a report of the meeting, our purpose being chiefly to quote some remarks by Sir M. Peto on the interference of third parties between masters and men. On this subject, Sir Morton, while responding to his own name in a toast, remarked that,

What he wanted to say to them was this,—Never let any one come between them and their masters. He did not wish to tread on tender ground, but he had very hard things said of him in London,—a great many things that he did not think he deserved. But it was because he believed he was the workman's best friend in telling the sure truth on all occasions, that he now said, if they let any one come between them and their masters, that confidence, which was something like the love of a husband and wife, would be destroyed,—the bloom would be taken from the fruit, and great injury would result. The reason why they got on so well with their masters, the reason that they had been so happy together, was that they had no strangers in Lowestoft stirring up mischief between them. He prayed them, as one of their best friends, to continue in this happy path; because he believed from the bottom of his heart, they might continue in it, for he knew their worthy chairman and his brother so well, that they would ever prize in their workmen that feeling which he had said began with the troublesome complaint (the Jack-plains fever) he referred to, and would be anxious to see them working their wayward waywardly. They wanted to see their workmen stepping the ladder as well as themselves, but they wanted to have the pleasure of stepping it with them apart from the interference of others.

The workmen present, it appears, were quite of Sir Morton's opinion, and have very strongly expressed their intention to follow his advice.

We may also quote a few further remarks by Sir M. Peto on the question of workmen's dwellings. In proposing the name of Mr. Lucas and his brother for a toast, he said,—

His friends were paying in the town of Lowestoft an annual amount of wages approximating closely on

40,000l. What did that do in a town like this, dispensed yearly? The amount of good it did in all its various modifications was scarcely to be credited. In the first place it kept every person employed by the firm, and most of them were the contented families. They had their houses which they had the pleasure of knowing were very different from the houses of workmen in London. He believed the great drawback to workmen in London was the want of suitable houses. He did not know how this question was to be met: it was one that presented itself alike to the workmen of London and Paris. However, that difficulty did not exist here.

The Chairman, in responding to this toast, took occasion to refer to Sir M. Peto's remarks as to the relationship between masters and workmen, and as to their own excellent understanding with their workmen, and the good fruits to all concerned.

He saw around him, he said, large numbers who had been in his and his brother's employ for thirteen years, and they had had the same number of men in their employ upwards of ten years, and who had never yet had to work an hour's short time. On the contrary, those who liked to do so had invariably worked overtime; and the lending men would bear out the fact that they had felt it their duty at times to take work at a loss in order to keep their old hands on. He did not wish them to believe that their trade had been a loss; but, on the contrary, it had been a profit beyond anything they could have anticipated. It was their desire, from the commencement, to become one of the first firms in London; and he thought he might say, without egotism, that they had become so. He could not express to them too strongly how much his brother and himself were indebted to their workmen for this result. There was one most delicate subject he should have touched on, but Sir Morton Peto had touched on it much better than he could do. It was anything between them and their employers, he would ask them to say what it was, and not to bring in a third party. He did not wish them to be shackled to him or any one else, but he wished them to use their own judgment, and to do what they thought right. If they did this, they might depend on it that they would retain their self-respect, and gain the respect of all around them.

On the subject of the mental and industrial education of the workmen's children, the Chairman also said,—

He believed there was no place in the world where a man could more easily obtain education for his children than in Lowestoft. He could only say to his workmen, when their children had been educated, and were in a measure of their hands, they (Messrs. Lucas) would be happy to take any of them, and apprentice them in any branch of the trade in which their parents might feel disposed to place them. They not only desired to do that free of cost, but they should also feel it their duty to pay them such wages as would relieve their parents from the great care they must necessarily have in supporting them.

"The Architects and the Profession" was a toast proposed by Sir M. Peto, coupled with the name of Mr. John Thomas, who was present. Of Mr. Thomas the speaker remarked that the first time he had the pleasure of seeing that gentleman, he was on a ladder, carving a lion's head on the front of a shop at Birmingham. The next time he saw him he was carving various graceful figures, with great effect, in St. Edward's Grammar School, Birmingham. Subsequently Mr. Thomas executed some works for himself; and on his (Sir Morton's) being, with his late partner, employed by the Government to erect the new Houses of Parliament, his friend Mr. Thomas took the whole of the sculpture connected with those edifices. He was now so much employed by the Queen and Prince Consort, that it was a matter of difficulty for him to get the necessary time for the rest of his work. Mr. Thomas had been able to do this, and surely there was the same path open to every one in this room. It was a happiness experienced by Englishmen that any man who had talent might have the opportunity, by perseverance and determination, of achieving similar success.

It was stated by Lieut. Lucas, in proposing "Prosperity to the Town of Lowestoft," that he himself remembered when the population was only 3,500 or 4,000, whereas now he believed it to be upwards of 10,000, a fact which spoke volumes.

#### THE PHILHARMONIC HALL, ISLINGTON.

On the eastern side of the Islington high road, close to the turnpike, and not far from "The Angel," a spacious house in front and an ungainly inclosed building seen at the end of a gateway at the side have long disgraced the spot. Under the direction of Messrs. Finch Hill & Parlane, architects, Messrs. Holland & Hanson have transformed these premises, for Messrs. Saunders & Lacey, the proprietors, into a handsome music-hall, with approaches, howling-alleys, and billiard-room. The principal entrance leading to the great hall is wide and commodious, and 40 feet long, at the end of which is the principal staircase, consisting of three flights, the centre leading down to the area of the hall; the two others lead to the balcony. Descending the centre stairs we reach the corridor, which is 100 feet long and 13 feet wide. It is divided into four bays by project-

ing columns, supporting semicircular arches. On the left of the passage are the billiard-rooms and American bowling-alleys; on the right is the music-hall, a well-proportioned room, measuring 100 feet long, by 43 feet wide, and 40 feet high. The balcony at the sides of the hall is arranged for two, and that at the end for five rows of seats, with a promenade behind. Above the form of the orchestra are private boxes, eight in number. The walls of the hall are divided into bays by pilasters, on the face of which are life-sized caryatides, supporting square blocks, round which breaks the entablature. The ceiling is divided into panels by hands formed by an open fretwork, which affords means of escape for the heated air. The orchestra is of a semicircular form, and is enriched by sculpture, gilding, and other decorations. All the interior decorations, in *carton pierre* and *papier mâché*, including all the ornamental work in relief, were executed by Messrs. White & Parby; the gaseliers by Messrs. Jones; and the ironwork was by Mr. G. Barrett.

#### NORTHERN ARCHITECTURAL ASSOCIATION.

THE quarterly meeting of this Association was held on the 20th instant, in the Old Castle, Newcastle-upon-Tyne. Mr. Green, vice-president, in the chair.

Mr. Oliver, the hon. secretary, read a letter from the secretary of the Royal Institute of British Architects, acknowledging the receipt of resolutions in favour of a diploma, passed at a previous meeting of the Association. Letters were also read from the Royal Institute of Scotland and the Birmingham Architectural Society, stating that the proposal for establishing an Architectural Alliance of the different societies throughout the country would be laid before the members of the societies named.

Mr. Watson then read an interesting paper on "The Practice of Architecture."

#### REMARKABLE GAS EXPLOSION.

ON Saturday last an explosion of gas took place in a small house, No. 1, Elizabeth-place, Wandsworth, which blew up the walls, and has necessitated the entire rebuilding of the house. It is stated that, through defective pipes, the gas had accumulated beneath the lowest floor in the front of the house. A woman and children were in the back room, where the floor remained uninjured, and they contrived to escape. The furniture in the house was blown to pieces. It is remarkable that a man and his wife, who were in the adjoining house, and were slightly injured, did not hear any explosion, though the neighbourhood were alarmed by it far and near.

#### CHURCH-BUILDING NEWS.

**Godalming (Surrey).**—The district church of Farncombe, near Godalming, has lately undergone enlargement and renewal, and has been re-opened. A north aisle has been added, corresponding with the other parts of the church. Two hundred additional sittings are provided, and a gallery has been erected for the use of the school children. All the windows of the church have been filled in with stained glass, supplied by Messrs. Powell & Son, of London. The architect was Mr. Scott, and the contractors were Messrs. Jackson, Shaw, & Co.

**Bathelston (Somerset).**—The chancel of this church has been rebuilt by the vicar, the Rev. T. P. Rogers, and re-opened. The stone work has been executed by Mr. Newman, of Bathford; and the wood work by Mr. Silver, of Maidenhead; whilst the carving was done by Mr. Earp, of London. The floor of the chancel is inlaid with encaustic tiles, by Mr. Godwin, of Lugwardine; and in the south-east is a memorial window to the first wife of the vicar, executed by Messrs. Clayton & Bell. The chancel has been rebuilt under the direction of Mr. F. Pready, of London, architect. In the rebuilding, the old stone work has been, as far as practicable, re-used; but being of two distinct periods, the architect has adapted the Earlier or Geometrical Decorated style. The debrased flat roof has been replaced by an open trussed roof of the same height and pitch as the original one, covered with the stone slate of the neighbourhood. The ultra-high pews have given place to low oak open benches. The benches and other parts in wood and stone work display a considerable amount of foliage and figure carving, and Messrs. Hardman & Co. have supplied a corona of brass.

**Leicester.**—A new clock for St. Mary's Church is to be erected by public subscription, promoted

by Mr. Joshua Underwood, with the concurrence and assistance of the vicar and churchwardens. It will strike the hours and chime the quarters on four bells, with a varied musical chime for each of the three quarters, and hour. It will have three dials, of 6 feet 6 inches diameter. The minute hands will move over each division at once instead of gradually, and enable the public to ascertain the time from the street, within a second, without waiting to hear the clock strike. Frame, 260 lbs.; wheels, barrels, and other brass works, 240 lbs.; moving weight of quarter-jack, 728 lbs.; hour weight, 501 lbs.; going-weight, 100 lbs.; total weight, without dials and hands, 1,829 lbs. The clock, says the *Leicester Advertiser*, will embody the several improvements of Mr. Losby's patent, and the works have been arranged throughout on the same model as he would employ for larger clocks than any yet constructed in Europe.

**Warrington.**—The parish church has been altered in the interior. The pews have been done away with, and nearly the whole area of the church thrown open, with free seats, to the people. The restoration of the tower and spire will be commenced as soon as funds can be obtained for the purpose, under the direction of the Messrs. Francis, architects, London.

#### FAILURE OF A POWDER MAGAZINE, WOOLWICH.

WHEN we mentioned, in October last, that a settlement had occurred in a magazine under construction in Woolwich Marsh, the contractor wrote for the name of our informant, and denied the truth of the assertion in so unqualified a manner, that we at once expressed ourselves willing to accept his assurance. It would seem, nevertheless, that we were correct, and the failure is now common talk. Thus we find the following in more than one of the London papers:—

"Reference having been made a few weeks ago to an alarming cleft which had made its appearance in one of the exterior walls of the newly-constructed magazine at Woolwich, the statement was hotly contradicted by authority; in some of the public journals; and, with a view of supplying all possible proof of the fact, the gap was cleverly plastered over, and temporarily obscured by what is officiously termed 'clocking the matter' in spite, however, of every precaution, the evidence very soon became again quite apparent, when suddenly the piers supporting the groins gave way, and the ponderous iron rafters, thickly inlaid with concrete and shingle, and covered with asphalt, composing the flat roof, together with the supporting brick wall underneath, now form a mass of ruins. From the present state of the structure throughout, it is apprehended that other portions may in all probability be insecure. The police are therefore strictly charged to warn visitors of the danger of their approach. The building is stated to have cost 7,500*l.*, and a discussion is likely to ensue as to the individual liability, the building having been constructed by contract from a draught furnished by the Royal Engineer department of the royal arsenal."

The contractor will probably think it becoming to explain the matter. We had no desire to attribute blame, but we have a desire to defend the correctness of our statements.

#### TRIBUTE OF RESPECT TO A NATIONAL SCHOOLMASTER.

IN this country the schoolmaster has been too little considered. In ninety-nine cases out of a hundred he has been allowed to pursue his laborious, tedious, and often thankless office with but little notice.

In many cases the salary of the schoolmaster and schoolmistress is not so much as that allowed to the agricultural labourer or the meanest mechanic; and yet what powerful workers are these men and women in connection with the welfare of the state! Of late a somewhat better spirit has been exhibited. It must be admitted that the schoolmasters and female teachers of the National Schools have, as a class, vastly improved. As an instance of a good change, we make a note of the death of Mr. Jessop, which took place a short time ago, after he had been master of the All Saints' National (boys') School, Islington, for a period of six or seven years. During that period, he in a most conscientious manner performed his duty. In spite of delicate health, this gentleman continued his exertions until he was stricken down in the midst of his scholars by the bursting of a blood-vessel. The body was borne to the district church, followed by a long procession of mournful scholars, teachers, and friends: the church was crowded in all parts; the incumbent read the funeral service; and, amid the sob of the assembly, delivered a warm and well-merited eulogium on the deceased. After this the mourners proceeded to one of the northern suburban cemeteries; and we noticed that as it passed along the Caledonian-road nearly all the shops of the tradesmen

were closed, and the window-blinds of the houses drawn as in the time of mourning for a near friend. Such marks of respect are gratifying to survivors, and will act as a stimulus to other schoolmasters rightly to perform their great mission.

#### TIMBER BRIDGE, BRITISH HONDURAS.

A TIMBER BRIDGE has been recently erected in the settlement of British Honduras, over the river Belize. It had been contemplated some years to erect a bridge of one span over the river (for which designs had been made); but, from the lowness of its banks, and the difficulty of making raised approaches, without interfering greatly with private property, the local government determined to adopt one of three arches, designed by the Colonial engineer, Mr. Baylis. The sum voted by the House of Assembly was 25,000 dollars, but the present bridge has been erected for 13,754 dollars. There is some novelty in the design: the centre bay is 50 feet in span; each of the side bays, 40 feet, and with slight rise, the angles formed by the struts and straining beams being less than is usual in such structures. The roadway is 20 feet wide. The bridge is built of timber little known in this country, viz.—Sapodilla wood, which is a close-grained, dense, hard wood, and weighs about 75 lbs. to the cubic foot. It grows abundantly in the vast forests of this region, and balks may be had 30 or 40 feet in length, that will square 12 to 14 inches, and cost in scantling, 2*s.* per cubic foot.

The old bridge, which was a beam bridge, resting on piles, was built of the same description of wood, and had been in existence upwards of forty years. Some of the timber, particularly parts of the piles, was sound and good on its removal, although it is a most trying climate for timber.

The piles of the piers of the new bridge were eased or sheathed with toughened cast-iron, which was fixed on and bolted to the piles, and these were driven into the bed of the river, and on the front of the abutments, after the sheathing had been put on. These effectually exclude the worms, as well as add stability to the structure.

The contract was obtained, and the work carried out by Mr. Connor (formerly of London), after an open competition. The other competitors were Mr. Lord, whose tender was 18,000 dollars, and Mr. Utar, 17,000 dollars.

#### EXHIBITION OF IRONMONGERS' ASSOCIATION.

THE Ironmongers' Association, of whose meetings our readers have at times heard, have opened an exhibition for a few days (at 76*a*, High Holborn) of inventions and specimens connected with the trade. Although it does not contain many things actually new, it deserves the attention of ironmongers and others who desire to see what is being done. Gibbons's knobs, wire-blinds, some Sheffield wares, Bulmer's gas-stove for bookbinders, Walker's patent stove, in which the fire-brick sides can be brought closer together, so as to reduce the fire, and the American brushes, are amongst the noticeable items. Messrs. Kenward, also, send some fair iron castings.

#### EMPLOYERS AND ARCHITECTS.

SIR,—A. employs an architect to build a church, which is opened say two and a half years, though unfinished as to pulpit and ornamental chiselling. B. is a sculptor who has done some little work for this church. A. happens to obtain possession of a statue of B.'s work which he finds in another county, and, wishing to mount it on a pedestal or column in the church in question, he writes to B., asking for a design, describing, as well as he can, the kind of church, to which he has sent, through the architect, what he had already done for it. B., however, writes back that diffidence with respect to the architect prevents his giving such design.

May I ask you if such is usual? If so, it seems to me to monopolize every out of a chisel or piece of glass in a church into the hands of the architect who began the church, thus preventing the paver for the church "picking up" what may strike his fancy elsewhere, or perhaps from encouraging some young artist from whom he may wish to order some little work.

#### A SUBSCRIBER

\*\* B.'s reply was correct and praiseworthy. Nevertheless, the employer can, of course, employ whom he will; good taste and good feeling alone controlling him.

## CONSTRUCTION OF FLAT ROOFS.

I HAVE noticed in your paper on several occasions lately notices relative to various modes of covering flat roofs with other materials than lead. If you can find room for the following particulars of a form of construction I have adopted, and which has now been executed about twelve months without any appearance of failure, they may be of use to some of your readers. The space covered is a dining-room ceiling, the joists of which are about 19 feet clear bearing, 9 by 3 inches, and 10 inches apart, with two rows of trussed bridging to make them perfectly rigid. About 2 inches above the underside of joists ribs are nailed to the sides, for the purpose of receiving 2-inch boards; on these rough boards the spaces between joists are filled in with sawdust to deaden sound; on the top of joists rebated 1½ boards are laid; these are covered with Croghan's asphalted felt, and upon this felt 9-inch Staffordshire tiles are laid, with painted edges and jointed in oil putty. It is important that the surface of each tile be perfectly level, or, rather, flat, so as not to hold water. This roof is in a very exposed situation, and it is used for walking upon and for plants, &c. Upon calculating the cost of the labour and materials used in lieu of lead, it is a little more than half that of 5 lbs. milled lead. A fall of 2 inches to 10 feet is given.

T. MERCER, Architect.

\*\* Such a mode of construction cannot be generally recommended, the risk of failure being considerable.

## WANTED! SOME CHEAP AND ORNAMENTAL WOVEN STUFF FOR CEILING OF ROOMS.

If your excellent paper, so widely spread among skillful manufacturers, will call their attention to this short note, I think that, with the many different kinds of raw natural material for cheap and thick cloth and matting, now brought to England from all parts of the world, some ingenious man will find a way to make ceiling covers, in place of the present ancient and barbarous lath and plaster; and that, like carpets on the floor, it will be put on in one piece, same size as the ceiling, and fastened to the joists by screws, with ornamental star-like heads; also which covers can be made thick, so as quite to deaden the sound of feet walking in the room overhead; also which can be taken down and cleaned, and put up again with little trouble; also on which agreeable skies, or patterns, in panels, in the Italian fashion, can be stamped or painted.

Surely some such kind of ceiling cover is wanted in many classes of rooms, and is likely to make the fortune of its inventor, and is therefore worth some trouble.

J. G. V. PORTER.

## EXPLOSION AT ST. MARY'S, OXFORD.

A REPORT on the cause of the recent explosion in St. Mary's Church, Oxford, by Mr. Siemens, of London, attributes it to gas accumulated under the flooring, where a workman had thrown down a burning match. The gas-main had been broken while laying pipes for the hot-water apparatus.

Sir,—In your last week's edition there was a short account of the accident at St. Mary's Church, Oxford.

As I happened to be at Oxford last week, I think it right to send you word that, from what I saw and learnt on the spot,—viz., the facts of the boiler not burst; the hot-water pipes broken straight across, as from an external blow; the gas-pipes old and honeycombed; and an overwhelming smell of gas previous to the accident; a light used by the gasfitters previous to the accident; the extensive character of the explosion, all the windows in the church being blown out, and the loud report,—the conclusion is inevitable that Mr. Rosser's low-pressure heating apparatus had nothing whatever to do with it, but that it was an ordinary gas or fire damp explosion.

F. C. PENROSE.

## ROADWAY AT KING'S CROSS.

Sir,—Allow me, through the medium of your paper, to call attention to the boon the Board of Works might confer upon the public by making a road across the new railway at King's Cross, opposite the Caledonian-road, thus making a direct way from the Gray's-Inn-road, and saving the present detour. The expense would be a mere trifle now all the houses are down; and, as anything improving the neighbourhood must be beneficial to the railway company, one would fancy they would gladly assist. To the market people it would be a very great benefit.

W. S. A.

THE AWARD, *RE MYERS & SARL & SONS.*

## COURT OF QUEEN'S BENCH (TUESDAY).

Before Lord Chief Justice Cockburn, the Hon. Mr. Justice Hill, and the Hon. Mr. Justice Blackburn.

An action was brought by Messrs. Myers, of York-road, builders, against Messrs. Sarl & Sons, silversmiths, of Cornhill. By arrangement, the action was referred to Master Norton, one of the Masters of the Court of Queen's Bench, who, after hearing evidence of most voluminous extent, made his award in favour of the plaintiffs, but, at the request of the defendants, left it to the Court of Queen's Bench to say whether the arbitrator was right in receiving parol evidence to explain a certain phrase ("weekly accounts") in the contract. The defendants, however, also moved the Court to have the whole matter referred back to the arbitrator for re-consideration.

Mr. Bovill, Q.C. (with him Mr. Tompson Chitty) now showed cause against the rule, and was also heard in support of the finding of the arbitrator. He said that the question raised in this case was whether the phrase "weekly accounts," in the contract, was a term of art. The objection raised by the defendants was, that no sufficient weekly accounts had been delivered by the plaintiffs. The question then was, whether evidence was admissible to show that the words were a term of art. The award found that they were a term of art, and that the accounts delivered were the words with which the contract was submitted for the opinion of the court were, first, was I right in admitting parol testimony to show the meaning of the term "weekly accounts," as used in the contract; and, secondly, was an arbitrator, in such a case, to be bound by an award?

Lord Chief Justice Cockburn said he did not find any ambiguity in the award. He understood the question was, was this a term of art; and, secondly, if it was, was it capable of being explained by parol evidence. At the moment you had ascertained that the words were not to be taken in their ordinary, every-day sense, but in an artificial sense, then you have a right to receive parol evidence. Was there any doubt about those words being a term of art?

Mr. Lush, Q.C. (for the defendants), said the question was, whether the arbitrator was right in admitting parol evidence to explain the meaning of a written contract.

Lord Chief Justice Cockburn said that would depend upon whether the words were clothed with a peculiar significance.

Mr. Lush said that weekly accounts were to be rendered by the parties of the first part to the contract to the work done thereunder, and the evidence proved that accounts of only half the work done were delivered. He, therefore, said it was in derogation of the contract, which was "to deliver weekly accounts of the work done."

Lord Chief Justice Cockburn said the fallacy seemed to be in supposing that the words used had a significance antithetical to the contract. The parties meant them in a different sense—in a sense different to their ordinary signification. If not so it was a very different matter.

Mr. Lush said the whole question was, whether, looking to the terms of this contract, the arbitrator was right in receiving evidence at all.

Master Norton explained, for the information of the court, that it was contended that the plaintiffs could not recover a large sum for additional work done which had not delivered "weekly accounts." It was contended for the plaintiffs that they did give "weekly accounts," and accounts were produced. The defendants then said those accounts were not "weekly accounts," and were not sufficient for the purpose, and it was contended I should hold they were not "weekly accounts." It was then proposed to show me that the accounts produced were "weekly accounts" used in the trade, and from thirty or thirty-five architects were called, of the highest eminence, who were all unanimous upon the subject. He called their attention to the accounts and asked if they were such "weekly accounts" as signified the exigency of the contract. It was unanimously held that "weekly accounts" was a term of art; and being such, the question was, were the terms of the contract satisfied?

Mr. Lush.—There was evidence on the other side.

Master Norton.—There was evidence on the other side, but what there was was very little, very contradictory, and very unsatisfactory.

Mr. Lush then proceeded to contend that the evidence received was not admissible. He asked, if a condition for weekly payments had been inserted, whether it would have been possible to call evidence of custom to explain away the meaning of the contract with regard to penalties. He relied upon the case of *Blackett v. Royal Exchange Insurance Company*, where it was held that the insurance of the ship, boats, furniture, and cargo, meant, the insurance of all the furniture and cargo. He applied this to the case under consideration for the purpose of his contention, that "weekly accounts of the work done" meant "weekly accounts of all the work done." Out of 1,400 extras, the accounts only showed about 300. He said the very object of the contract would be defeated. The object of the delivery of the accounts was in the event of any accident happening, that the present or any future architect of the defendants might know what was being done. He submitted that the term in the contract, "weekly accounts," must be read "weekly accounts of all the work done;" and that parol evidence was not receivable to show that by usage, "weekly accounts of part of the work done" would satisfy the contract.

Lord Chief Justice Cockburn said that the court were of opinion that the parol evidence was properly received.

Mr. Tompson Chitty then drew the attention of the court to the award, which he said he could not say for certain sketches, delivered by the defendant architect to the plaintiffs, and acted upon by them, were orders and directions in writing, under his (the architect's) hand, as in the contract mentioned. The direction was thus:—The arbitrator had awarded 2,050l., subject to be reduced by 1,075l., if the parol evidence was improperly received; and then to add 108l. 18s. 6d. if the sketches by the architect, handed up to the court, amounted to directions in writing under his hand. They were found to have been made under his direction, and by his order.

Lord Chief Justice Cockburn had no doubt they came from the architect, and it was a very proper question. The fact, however, of his not drawing them up in a more regular form left it open to say they were not within the terms of the contract, but it was a very unkindness and ungenerous objection.

Mr. Chitty then applied that the rule might be discharged, with costs.

Lord Chief Justice Cockburn, in delivering judgment, said he was of opinion that the course pursued by the

arbitrator was perfectly correct in point of law, and that the parol evidence was properly received. The duty of a court in considering a contract was to give effect to the intention of the parties. Although parol evidence is not admissible to control the terms of a contract, where the terms used merely indicate the intention of the parties, if the terms have no other than the ordinary acceptation, yet if the terms have not only an ordinary but a particular meaning in reference to the business, and it is obviously the true intention of the parties to interpret the words in their ordinary meaning, but in their particular signification, then they must be so construed. Therefore it has always been held that where terms have been used in a contract that have an ordinary, but besides a scientific and particular, meaning, those parties who have drawn up the contract with reference to that particular department of trade must be taken to have intended the words to be used, not in their ordinary, but in their particular sense. That was only acting upon the sound principle that a contract is to be interpreted and carried out according to the intention of the parties. It was only giving effect to that principle in this case, to give the words their particular instead of their popular sense; and it could only be by means of parol evidence that the particular signification of the words in the contract could be shown to be distinguished from and inconsistent with their ordinary sense. Having referred to *Sturton v. Ender* and *Illustration*, Lord Chief Justice Cockburn said that in the present case "weekly accounts" had been used by the parties, and that the parol evidence showed that "weekly accounts" of work has a peculiar signification in the building trade, and that it relates not only to a week, but to particular portions of a week. As to the case cited by Mr. Lush, he thought the doctrine there laid down had been carried to the extreme verge, and he did not think the case should be distinguished from the present upon the evidence that in this particular trade general terms were used with a particular meaning; and as to "weekly accounts" of work, that was taken as a general understanding, and was not considered as extending to the whole of the week. The terms are general, but there was no reason why evidence of usage should not be admitted to show it was not to all the week. He regarded the arbitrator's award as to be rendered, but only to that portion which was so in the understanding of the trade. His lordship having distinguished the case as cited by Mr. Lush, and pointed out the error in the reasoning of the present case, he observed, in conclusion, that true it was the parties here stipulated for "weekly accounts," yet he thought, even upon the authority of the case cited, that general terms may be restrained and specifications to the particular trade, and that in the contract. He, therefore, was of opinion that the evidence of usage was properly received by the learned arbitrator.

Mr. Justice Hill and Mr. Justice Blackburn concurred, for the reasons they stated. The rule was discharged with costs; the arbitrator's award to stand.

## TENDERS OF CONTRACTORS.

A POINT of some importance to contractors and others was decided in the Leeds County Court, on Monday last by Mr. T. H. Marshall, the judge. The plaintiffs were the contractors, and the defendant, Mr. G. A. Emmsley, was brought to recover the sum of 360l., being the balance due to the plaintiffs for the erection of some dwelling-houses by them for the defendant. Mr. G. A. Emmsley appeared for the plaintiffs, and Mr. Ferns for the defendant. It appeared that the defendant, in October last, being about to erect some dwelling-houses, submitted the plans and specifications to the plaintiffs, and requested them to give him a tender for the work, which they did in writing. The defendant afterwards accepted the tender verbally, and the plaintiffs executed the contract, and received the whole of the consideration of the contract, and the amount now sued for. Upon the tender of the plaintiffs being offered in evidence, Mr. Ferns objected to it because it was not stamped. He contended that the tender, having been accepted by the defendant, became evidence between the parties and required stamping as an agreement. For the plaintiffs, Mr. Emmsley submitted that the tender was merely a proposal by the plaintiffs to do the work for the amount specified, which the defendant had the option of either accepting or not, and that, as he did not accept it in writing, but verbally, the tender was not such a document as the law required to be stamped as an agreement. The question was argued upon except the amount now sued for. Upon the tender of the plaintiffs being offered in evidence, Mr. Ferns objected to it because it was not stamped. Mr. Ferns applied to the judge to grant a case to one of the superior courts upon the point, and his Honour consented.

## Books Received.

*A Walk from London to Fulham.* By the late T. CROFTON CROKER, F.S.A. Revised and edited by his son, T. F. DILTON CROKER, F.S.A. With additional illustrations, by F. W. FAIRHOLT, F.S.A. London: William Togg, 1860. This charming little book, rich in gossip and engraved sketches of things that have passed away, is founded on a series of papers by the late Thomas Crofton Croker, which originally appeared in "Fraser," and grew out of a chat with the conductor of this journal along the road here annotated. Alack! for the flying years! The neighbourhood has long been the resort of literary men, artists, and actors; and we get here notice, often too brief, of 350 persons more or less known in the world, and much antiquarian talk. Shaftesbury House, in Little Chelsea, as it was called, demolished to make room for the additional workshop for St. George's, Hanover-square, is illustrated very fully; and a whole chapter, the last, is devoted to a description of

the Pryor's Bank, Fulham, as it was when Mr. Baylis and Mr. Lechmere Whitmore held court there. These gentlemen had filled it with works of art, ancient manufactures, carvings, tapestry, and remnants of old places, tastefully gleaned, often from the lumber of brokers' shops; and many will remember the nights and days of piquant entertainment and unbounded hospitality enjoyed there.

Mr. Dillon Croker has performed his portion of the task with taste and skill, prefacing the "Walk" with a memoir of his father; and Mr. Fairholt has added some illustrations to those previously made.

### Miscellaneous.

**THE SEWAGE AND SEWERAGE OF BURY ST. EDMUND'S.**—The Home Secretary, according to the *Bury Post*, has signified his approval of Mr. Burns's plan for disposing of the Bury sewage, and has consented to the borrowing of 4,000*l.* to carry out the plan and complete the sewers.

**POISONOUS PAPER-HANGINGS.**—The Registrar-General's return of last week contains the following entry among the deaths:—"At Beresford Lodge, Highbury New Park, on the 3rd November, the son of an insurance broker, aged 3½ years, poisoning from arsenical exhalations from the green paper of a breakfast-room." There was a *post mortem* examination and an inquest.

**SOUTH WALES INSTITUTE OF ENGINEERS.**—A general meeting of this association has recently been held in Merthyr. The walls were hung with diagrams and sections explanatory of the papers about to be discussed. Mr. C. H. Waring, of Neath, also exhibited an improved safety-lamp for colliers, which he has just patented. The lamp, when locked, cannot be reopened without the light being first extinguished. The Institute discussed Mr. Heth Ogden's paper on "Improvements in Cupolas for melting iron suggested as applicable for Blast Furnaces," read at last meeting. Also Mr. Dorman's paper upon "The extent to which the mechanical power capable of being produced by the combustion of fuel is and may be utilized in the steam engine;" and Mr. Redington's on "The Longwork System." Papers were then read on a simple form of diagram for showing the motion of the valves in steam-engines, by Mr. Cope Pearce; on the Cornish engine, by Mr. Sims; and on his improved patent safety-lamp, by Mr. C. H. Waring. The members afterwards dined at the Castle Hotel, the President in the chair.

**METROPOLITAN BOARD OF WORKS: STOPPAGE OF MIDDLE-LEVEL SEWER.**—At the usual meeting of the Board last week, in reference to the stoppage of the works of the middle-level sewer by Mr. Roe, the contractor, a report was received from Messrs. Hunt & Stephenson, which stated that Mr. Roe had been paid more than he was legally entitled to under his contract. Mr. Carmichael moved that Mr. Roe, having failed to execute the contract with due diligence, and having declined to proceed with the works, the Board invite tenders for the execution of the said works from other contractors; that the specification he laid before the Board at their next meeting; and that their advertisements be issued soliciting tenders. The motion was put and agreed to.

**COMMUNICATION IN RAILWAY TRAINS.**—Sir: The circumstances attending the late fire in the express train near Lancaster again make one deplore that, although we can telegraph almost all over the kingdom with ease and certainty, we are unable to communicate from one part of a railway train to another. Although several methods have been suggested, and in some instances tried, they have not become universal, chiefly, I apprehend, because of the extra trouble in forming the line of communication when "putting on" or "taking off" carriages during a journey. Any plan, therefore, which would seem to obviate this difficulty deserves consideration; and, as your widely circulating columns are ever open to a suggestion calculated to benefit the community, I beg to offer one which I think would go far to attain the desired object of easy communication in question. In the screen, or that part of the engine which usually contains the eye-glasses or windows which the driver uses in looking ahead, I would place a mirror or mirrors in such a position as to reflect the train. The driver could then almost see both ways at the same time, and any signal of distress from a carriage-window or the guard's van, fire, or a train in too close proximity behind, would, at any rate, not remain long unseen. If the guard's van were fitted with glasses in like manner, it would be all the better. The signals may be flags by day, and lights by night.—H. GREEN.

**LIVERPOOL CEMETERY COMPETITION.**—The Burial Board have received twenty-four sets of designs for the above competition, and it is their intention to exhibit them publicly the first week in December.

**A STONE CRUSHER.**—A machine is now being completed at the great ironworks of Creusot, in France, which will dispense with the painful necessity of employing human labour in the breaking of stones upon the roads. By this machine, invented by M. Demarchais, of Saint Gengoux, blocks of granite of the most enormous weight are reduced in a moment to stones, the size of which may be determined beforehand.

**MONUMENTAL.**—A large mural monument to those who perished of the 32nd regiment of light infantry at Lucknow and Cawnpore (including 15 officers, 448 non-commissioned officers and private soldiers, 4 ladies, and 96 soldiers' wives and children), is about to be placed in Exeter cathedral. It is executed by Mr. Richardson, sculptor. The subject is an enraged and wounded lion crushing a viper; the regimental colours and badges form a hack-ground.—A movement has been commenced on board H.M.S. *Cambridge*, in Hamoaee, Devonport, for the purpose of erecting a monument to the memory of the late Sir Charles Napier, as a mark of esteem and respect for his person, and of gratitude for the manner in which he has laboured for the bettering of the social condition of the seaman and marine.—It appears strange that the statue of Sir William Follett in Westminster Abbey should have no inscription to show whom it represents, the only intimation being that on a small board attached to it, with the words "Sir William Follett, 1845."

**COMPENSATION TO OWNERS IN PARIS.**—A jury has been fixing the indemnities to be paid to the owners and occupiers of thirty-two houses in the Faubourg St. Honoré, and the Rues de Poitou, des Bœufes d'Artois, de Balzac, and other streets, required to be demolished for the continuation of the Boulevard Beauffon. The principal case on which the jury had to decide was the amount of indemnity to be given to the Duke of Brunswick for part of his mansion and grounds, situate between the Rues de Balzac, de Beaujon, and de Bel Respiro. The daily papers say.—His Highness claimed not less than 1,326,895*l.*, of which 624,000*l.* were for the ground, 227,895*l.* for the portion of the house to be taken, 425,000*l.* for the depreciation which will take place in the value of the house by being reduced in size and deprived of the greater part of the gardens, and 50,000*l.* for the expenses which the expropriation will occasion. In support of his claim, the duke made an advocate give the jury a detailed account of the sums he had disbursed for laying out his grounds, constructing a handsome railing, building greenhouses, placing statues and fountains, ornamenting the house, &c. The municipality only offered 140,000*l.*, and the jury gave no more than 360,000*l.* Among the houses to be taken is one in the Rue de Chateaubriand, belonging to M. Arsène Houssaye, the well-known writer, but the jury were not called on to decide respecting it, he having come to an arrangement with the municipality of Paris to accept the sum of 575,000*l.* For part of a house in the Rue Beaujon, for which 580,000*l.* were demanded and 268,000*l.* offered, the jury gave 325,000*l.*; and for part of one in the Rue de Chateaubriand, for which 610,000*l.* were claimed and 84,000*l.* proposed, the jury granted 300,000*l.* For ground on which there are no buildings, the award of the jury was at the rate of from 150*l.* to 160*l.* the square metre. To seven owners of houses which are to be partly taken the municipality only offered 1*l.* each, on the ground that the new Boulevard will greatly increase the value of the remainder of the buildings; but the jury gave in each case from 10,000*l.* to 30,000*l.* The cases of the occupiers presented no great interest. Madame Odin, keeper of a ladies' boarding-school in the Rue de Chateaubriand, asked for 260,000*l.*: the municipality only offered 20,000*l.*, and the jury awarded 60,000*l.* The keeper of a furnished lodging-house at No. 19 in the same street claimed 140,000*l.*, was offered 30,000*l.*, and obtained 60,000*l.* The proprietress of another ladies' boarding-school at No. 21 in the same street demanded 55,800*l.*, was offered 8,000*l.* and allowed 12,000*l.*; and the occupier of 18, Rue Lord Byron, who asked for 80,000*l.* for the inconvenience to which he will be subjected by a partial demolition of the house, was offered only 1*l.* by the municipality, and obtained 10,000*l.* The whole of the demands of the owners and occupiers amounted to 8,267,087*l.*; the offers of the municipality to 2,775,258*l.*; and the awards of the jury to 3,926,105*l.*

**ELECTRO-TELEGRAPHIC.**—It is announced that a company is in course of formation to extend the telegraphic system "throughout the West of England and South Wales, so as to afford increased facilities for the transmission of messages to and from the metropolis, the North of England, and the Continent, at greatly reduced charges."

**NEW BRIDGE BETWEEN WESTMINSTER AND LAMBETH.**—Notice has been given by advertisement, of an intention to apply to Parliament in the ensuing session for power to form a bridge, to be called Lambeth-bridge, between Market-street, Westminster, and Church-street, Lambeth, and to take tolls, make approaches, &c.

**ROADS IN CHINA.**—The *Moniteur de Paris* says:—"Among the numerous details we have received from our correspondents in China, we find it mentioned that the road from Tien-tsu to Peking is entirely macadamised, and has the advantage over roads of the same kind in Europe, of not retaining water on the surface, so that it is quite dry in a few minutes after the rain ceases. The inhabitants declared to our correspondent that all the principal roads in China are made in the same manner, and have been for centuries." Abbé Huc says much the same thing; and, moreover, that there are comfortable public resting-places for travellers, at short intervals, on every road in the interior.

**THE STREET TRAMWAY MOVEMENT.**—Application is to be made to Parliament next session, for powers to be granted to a Street Rail Company (limited), to lay down iron rails and plates upon the streets of the metropolis, and other towns, and to keep the road between and beside such rails in proper repair. The intended Act will "reserve to all persons entitled to use such streets or roads the right to run over, upon, and along the said rails and plates, when laid down, with all ordinary road wheels and carriages, but will reserve to the company the exclusive use of flange-wheels, adapted to run on an edge rail, upon the edge rail as laid down."—Mr. Train's tramways, it appears, are not to have a monopoly of the streets in our towns, and Mr. S. C. Ridley, a Bostonian, is said to be about to lay down lines in the streets of Edinburgh and Glasgow. We observe, however, that, so far as regards Mr. Train, the subject at Edinburgh has been handed over by the Council to a committee, for consideration.

**PRIVATE ELECTRIC TELEGRAPHS.**—A correspondent of the *Jersey Times* says:—"Sir: A few weeks ago you inserted an interesting article from the *Builder*, entitled 'Progress,' and purporting to give an account of the latest discoveries and inventions in science and in art. Amongst other things was a notice of the electric telegraph; and that notice contained an account of an instrument for the transmission of local messages. It was described as cheap, portable, and easy to work. Now, sir, as we too, in this island, are in the road of progress, would it not be expedient that we should add to our local improvements that of a local electric telegraph, on the plan of that to which I have just alluded, which should have stations in every parish, and by which every locality, even the remotest, in the island, should enjoy instant communication with the town? Would not such a mode of communication between country and town greatly facilitate the dealings between both?"—The London District Telegraph Company, we observe, are now ready to erect special wires to unite branch establishments of private firms, &c.

**BALTIMORE: OPENING OF A CENTRAL PUBLIC PARK.**—There have been great rejoicings at Baltimore on the inauguration of a fine park of more than 500 acres of land, named Druid Hill from its fine old oaks, and comprising both extensive undulating open ground, ornamented naturally with clumps of choice trees of all kinds, and luxuriant and shady forest-land, ravines with natural springs and waterfalls, capable, together with the water for the great reservoir of the City Waterworks, of being easily and cheaply laid out into ornamental lakes, fountains, and ponds. The park may be said to have cost the citizens nothing, since not only has no rate been exacted on account of it, but a fifth part of the gross receipts of its street passenger railways, amounting to fifty to seventy-five thousand dollars per annum, exacted and secured to the city's interests, has been devoted to the realization and sustenance of this park. The site is central and of easy access to the majority of the citizens. The expenditure in completing this natural park will, it is said, be trifling, the ground being altogether of a very superior description to that at New York lately inaugurated. There will be little or no planting of ornamental trees, pruning rather than shading being all that is required.

IMPROVEMENT OF WORKING-CLASS DWELLINGS AT ST. PETERSBURG.—The company formed at St. Petersburg for building dwellings for the poorer classes have, during the three years since its first formation, constructed houses containing accommodation for 200 families.

BUILDING ACCIDENTS.—At Perth recently a scaffolding attached to a portion of a weaving factory, in North William-street, suddenly gave way, when three persons standing upon it were precipitated to the ground, and severely injured. — A foolish workman, perfectly conscious of the danger he was incurring, ventured to ascend an injured wire rope which is used for drawing materials from the Cathedral yard at Durham to the restorations on the central tower. He had gained an altitude of some thirty or forty yards when the rope broke, and he was precipitated to the bottom, sustaining injuries which, it is feared, will prove fatal.

ANOTHER NEW DYE COLOUR.—The recent discovery at Lyons of a new species of red dye more brilliant than any hitherto produced, and, above all, more solid than the best Chinese reds, has caused a sensation amongst the manufacturers. The colour is said to be particularly soft to the eye—something between scarlet and ponceau—the peculiar red beheld in the small garden-flower, the "blood of Adonis." It is already highly appreciated as a "rouge sullime" in the trade, and promises, it seems, to become very popular, both for furniture and dresses.

ROYAL ACADEMY OF ARTS.—The lectures for the season 1860-1 will be delivered in the following order:—Anatomy—Professor Partridge; 1. Monday, November 12; 2. Monday, November 19; 3. Monday, November 26; 4. Monday, December 3; 5. Wednesday, December 12; 6. Monday, December 17. Architecture—Professor S. Smirke, R.A.;—1. Thursday, January 24; 2. Thursday, January 31; 3. Thursday, February 7. Sculpture—Professor R. Westmacott, R.A.;—1. Monday, February 11; 2. Monday, February 18; 3. Monday, February 25; 4. Monday, March 4; 5. Monday, March 11; 6. Monday, March 18. Painting—Professor S. Hart, R.A.;—1. Thursday, February 14; 2. Thursday, February 21; 3. Thursday, February 28; 4. Thursday, March 7; 5. Thursday, March 14; 6. Thursday, March 21.

VICISSITUDES OF BUILDINGS.—Crossing this bridge (at Lyons) I came to the foot of a high hill, on the summit of which is the church of Notre Dame de Fonvrievres, i.e., Forum Vetus. Ascending this hill, I passed on my way Les Antiquaires, a former palace of the Cæsars, in which both Claudius and Caligula were born. It has now degenerated into a madhouse. Great buildings undergo strange vicissitudes. Malmaison and St. James's, both new palaces, were in their origin leper-houses. The Maladrerie at Caen, once the retreat of corporeal disease, is now a house of detention for moral offenders. Avignon and St. Germain, one the former palace of spiritual sovereigns, and the other of a monarch who lost his crown for adhering to those sovereigns, are both now barracks for the soldiery; and the Tuileries, now the chief palace of a great empire, was originally a tile-yard!—Mr. Wm. Beumont's Tour in France.

REPAIRING VANE OF ROMAN CATHOLIC CATHEDRAL, SALFORD.—At intervals, during several weeks past, attempts have been made to get ropes round the ball on the summit of the spire of the Roman Catholic Cathedral, Salford, for the purpose of removing or repairing the vane, which has been in a dangerous condition. Messrs. Hibbert & Co., of 52, Granby-row, have been entrusted with the work. The vane, and ornamental brass work with which it was connected, cut in succession every rope sent up by the aid of a kite. Ropes were at length flung around it, however, by the kite, and the vane was secured on several sides with the ground; then a rope was drawn around the base of the vane which rested on the ball of the steeple; a pulley was run up, and ropes strong enough to bear a man drawn through. A young man, named James Thomas, in the employ of Messrs. Hibbert & Co., then took his seat upon a piece of wood fastened to the rope connected with the pulley, and ascended from the leads outside the heltry. From this point, we were informed, the steeple measured upwards of 150 feet. He set to work on his arrival, and lashed ropes round the top in various ways. To do this he stood upon the board on which he had ascended, and knelt upon the ball of the steeple. A small scaffolding has since been suspended from the summit, to facilitate the removal or repair of the vane.

FLAT ROOFS, GIBRALTAR.—The cost of flat roofs, described at page 693, is about 8d., not 8s. per foot superficial, as accidentally stated.

GRAVESEND.—The new military establishment on the piece of land, in Milton, recently purchased by the Government, will shortly be in active progress, tenders for the erection of a new War Department. It is proposed at present to erect six blocks of soldiers' huts, one block of married men's huts, and one block of lecture-rooms. It is said that the Government authorities intend to erect sufficient buildings on this spot to accommodate upwards of 4,000 men.

THE NEW COURTS OF LAW.—A notice appears in the Gazette that her Majesty's Commissioners of Works and Public Buildings intend to apply to Parliament, in the session of 1861, for an Act to enable them to acquire, by compulsory purchase or otherwise, a site for the proposed new courts of law. The site will be bounded on the north and north-west by Carey-street, Lincoln's-inn-fields; on the south by Pickett-street, the Strand, and Fleet-street; on the east by Bell-yard, Temple-lar; and on the west and south-west by Yeates's-court, Clement's-inn, and the vestry-house of the parish of St. Clement Danes.

THE PRINCESS FREDERICK WILLIAM.—The Berlin Royal Academy of Arts elected the Princess Frederick William an honorary member at a full meeting a short time since. Her Royal Highness has accepted the election, and communicated her decision to the Academy in the following letter:—"I have received, with thanks and sincere joy, the intimation, from the Royal Academy of Arts of Berlin, that they have elected me an honorary member of their body. In this choice I see the acknowledgment of the warm and lively interest for the arts with which I am animated. In the wish to prove this sentiment, I willingly accept, after having obtained the approbation of his Royal Highness the Prince Regent, the election which has fallen upon me, since it brings me into closer connection with a corporation which possesses so important an influence over the cultivation and development of art in our fatherland.—VICTORIA, Princess Frederick William of Prussia, Princess Royal of Great Britain and Ireland.—Berlin, October 22, 1860."

PRIZE PLANS FOR LANDING-STAGES.—Prizes have been awarded by the Wallacey Commissioners, of 50l. for each of two plans for landing-stages at New Brighton and Egremont. The New Brighton plan is that of a raised platform or stage, supported by strong cast iron pillars at distances longitudinally apart 120 feet, with the spaces bridged by wrought-iron girders, and the roofing formed of planks laid upon transverse wrought girders. The stage thus constructed is proposed to be carried out on one level about 88d feet, and to terminate in a large rectangular space, supported by additional columns, and provided with stairs for landing and embarking at all heights of tide, with an ornamental lighthouse, &c. The whole cost guaranteed at 22,927l. The Egremont plan has a masonry slip, upwards of 60 feet wide, formed to a regular gradient of 1 in 22, and carried seaward so as to admit a steamer at low water. Upon the slips are laid three lines of rails. The movable stage consists chiefly of iron. It weighs 300 tons, and is 225 feet long, 48 feet wide, and divided into two parallel roadways, and mounted on strong wheels and axles, having a roof carried on columns. Two methods of moving the stage are laid down: two of these depend on hydraulic power, the third having its power in a counterbalancing weight fixed within a tower and well. The cost is estimated at 15,000l.

TENDERS

For new workshops at Colchester, Essex, for Messrs. Moses & Sons. Mr. N. S. Joseph, architect.— King ..... £225 0 0 Newman & Mann ..... 496 0 0 Furn ..... 479 10 0 Lee & Baker ..... 351 10 0 For the first portion of warehouses at Wapping-wall, for Messrs. Cooper & Aves. Mr. Wm. Reddall, architect.— Lawrence & Sons ..... £676 0 0 Asby & Sons ..... 629 0 0 Scott ..... 619 0 0 Blackburn ..... 596 0 0 Conder ..... 579 0 0 Holmes ..... 530 0 0 Case ..... 517 0 0 For a villa, to be built at Marden, Herefordshire: bricks, sand, and all building found by the proprietor. Mr. J. H. Ewins, architect, Hereford.— Edward Morgan ..... £212 0 0 Tew ..... 210 0 0 Mason & Crittenden (accepted) ..... 239 0 0

For the first portion of the Roman Catholic Church, Birkenhead. Mr. E. Welby Pugin, architect. Quantities supplied by Mr. Marples:— London Building Company ..... £1,623 0 0 Sherrin ..... 4,471 0 0 Farrell & Ledger ..... 4,129 0 0 Glalster ..... 3,451 0 0 Yates ..... 3,411 0 0 Waters ..... 3,333 0 0 Twist ..... 3,322 0 0

For the erection of a house at Huyton-park, near Liverpool. Mr. H. H. Vale, architect. Quantities supplied by Mr. John Longridge:— Barker ..... £2,378 0 0 Westmorland ..... 2,316 0 0 Campbell ..... 2,129 0 0 Lyon & Greenwood ..... 2,097 0 0

For building a house at Poplar-bank, Huyton. Mr. H. H. Vale, architect. Quantities supplied by Mr. J. Longridge:— Twist ..... £1,019 0 0 Barker ..... 987 0 0 Westmorland ..... 959 0 0 Campbell ..... 922 0 0 Lyon & Greenwood ..... 899 0 0

For sundry alterations and repairs at No. 31, Great Tower-street, City, for Mr. J. H. Machu. Mr. Robert Purris, architect and surveyor.— Turner ..... £2,498 0 0 Walker ..... 488 0 0 Rodkins ..... 467 0 0 Ashby ..... 461 0 0 George ..... 460 0 0 Porter ..... 442 0 0 Dale ..... 420 0 0 Prescott ..... 420 0 0 Ellis ..... 375 0 0

For Pinkley-park House, Lyndhurst, the seat of Mr. H. B. Powell. Mr. J. Baker, architect:— Hilary ..... £8,750 0 0 Lander ..... 8,726 0 0 Stevens ..... 8,630 0 0

For the erection of fifteen houses, to complete "The Company's terrace," Oxford-road, High Wycombe, Bucks, for the High Wycombe Land and Building Company, Limited. Mr. Charles Carter, architect, Great Marlborough-street. All Kils-Burnt Bricks.— Ward ..... £1,950 0 0 Goodchild ..... 1,725 0 0 Spicer ..... 1,725 0 0 If Stock and Place Bricks for Interior Walls. Siler.— Howard (accepted) ..... 1,612 17 6

For a new hall and other works in Cleveland-street and Howland-street, for Mr. Thos. Whitaker. Messrs. Shea & Jones, architects:— Knapp & Son ..... £1,782 10 0 Demison ..... 1,697 6 4 Perry ..... 1,676 0 0 Ashby ..... 1,610 0 0 Stevenson ..... 1,602 0 0 Kelly ..... 1,597 10 0 Duncannon ..... 1,547 0 0 Palmer ..... 1,543 10 0 Batter ..... 1,484 0 0 London Building Company ..... 1,428 0 0 Rudkin ..... 1,449 0 0 Walker ..... 1,398 0 0

TO CORRESPONDENTS.

Sir,—Will any of your readers kindly inform me what is the most durable process for fixing cast-iron dam-balls?—L. C. H.—I have no objection to your name being inserted in the notice (in private dispute).—R. O. (make the pit watertight; use the valve as described, and remove the result periodically for garden).—H. R.—E. S. P.—F. R.—J. W.—J. O.—J. C.—Mr. O.—Somerset.—J. P. E. (shall have attention).—W. H.—E. R. S. (in reply).—Peter (Hill).—J. H.—G. E.—H. & M.—E. C. R.—R. S. C.—E. J. W. (posted).—H. C.—L. B.—H. V.—J. F. P.—J. W.—3). R. P.—W. C.—Roadsiders.

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher." Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

ARTISTIC DESIGNS FOR WATCHES.—"A number of new and artistic designs for the embellishment of watches have been invented and exhibited by Mr. J. W. Benson, of 33 and 34, Ludgate-hill, who has exerted himself with commendable success to provide, in this particular branch of manufacture, the union of taste and usefulness so striking in the productions of the French artificers. The recent progress in the art of watch-making in England is owing to the enterprise and industry of several gentlemen, who are now reaping a just reward for their ingenuity. Amongst these Mr. Benson holds a prominent position, and his designs may therefore be recommended to the notice of the public."—Daily Telegraph. Benson's Illustrated Pamphlet, post free for two stamps, is descriptive of every construction of watch now made. Watches sent by post to all parts of the globe.—Advertisement.

# The Builder.

VOL. XVIII.—No. 930.

British Building Stones and Bricks.

VERY useful, and indeed, important volume has just been published by order of the Lords of the Treasury.\* It consists of nearly 400 octavo pages, almost all condensed into a tabular form, and chiefly devoted to an embodiment of useful particulars in regard to stones and quarries in all the different countries in the three kingdoms; together with similar tables as to bricks and clays, and other mineral products. Although confessedly far from being a complete record, the amount of information, of the greatest utility to architects, builders, and con-

tractors, which this volume contains, is immense. The tabular condensation of statistical and other details as to building stones, which extends to nearly 250 pages, comprises a host of particulars as to,—the names of quarries,—nearest railway stations, or shipping ports,—names of freeholders and of quarrymen,—local names of stone,—geological formations,—buildings in which used or purposes to which applied, and remarks,—prices of stone at quarries,—and average annual produce. Some idea of the scope of the work may thus be realized; but we may take a running glance through its pages, picking up a few particulars by the way, in order to show more distinctly of what sort of matter it is made up.

Beginning with Cornwall, the first county on the list, we observe, for example, under the head of the Cheesewring Quarry, that Looe is its nearest outlet,—that the freeholder is the Duke of Cornwall, and the Cheesewring Granite Company are the quarrymen;—that the name of the stone, both locally and geologically, is granite;—that as to the buildings in which used, &c., it has been used in New Westminster-bridge, and at Copenhagen, Birkenhead, Southampton, and other docks, mangrod-bouse at Devonport Barracks, and various public works;—that the price of the stone, at the quarry, is 1s. 4d. per cubic foot, scappled; 2s. 3d. delivered in the Thames;—and that the average annual produce is 146,566 feet. Such is the manner in which the information is given; but, in the few further items which we may extract, we shall not strictly follow the entries as they occur, but shall merely note a few of the more salient details.

The Dundry-hill oolite limestone of Somerset has its chief outlet at Bristol. It has been used in many old churches in the neighbourhood of Bristol, as in St. Mary's Redcliff, and St. Stephen's Temple.

The Hamhill freestone, of the same county, has its chief outlet at Bridgwater and Yeovil. Some of it is a conglomerate of the red sand-

stone formation; other quarries are in the inferior oolite; and the stone is of a brown colour, weighing 134½ lbs. per cubic foot.\* Three quarries of this kind yield an annual average produce of 7,000 tons.

The Dean Forest quarries, in Gloucestershire, belong to the coal measures: their chief outlets are at Lydney, Coleford, Bream, and Yorkley. The local name of the stone is merely Dean Forest stone. Much of it is suitable for dock and railway purposes, builders, statuary, paving, &c.; grindstones, troughs, &c. It was used in the construction of Newland Church and other old churches, in some of which the carving on the oldest graves and pinnacles is as sharp, clear, and defined as when first worked 400 years ago. This stone was used in the construction of Newport, Cardiff, Gloucester, and Swansea Docks; South Wales, Taff Vale, and Western Valleys Railways; Gloucester and Berkeley Canal; Gloucester Over-bridge; Folly-bridge, Oxford; Cardiff Castle, and National Provincial Bank; Marlborough and part of Llandaff Colleges; Assize Courts, interior of St. John's and Exeter Colleges, and Taylor and Randolph's Buildings, Oxford; Eastnor Castle and Whitley Court, Worcester; Langton House, Oxford (steps 18 feet long, and landings proportionate); and the towns paved with it are too numerous to mention. It is also manufactured into field and garden-rollers, pillars, &c. On Birch-hill an unlimited quantity can be obtained for ages to come. About 150,000 cubic feet were raised in one of the quarries by Messrs. Hemmingway & Pearson for Cardiff Docks, a great portion of which came from quarries now in possession of Messrs. Grindell & Co. Blocks of any size possible to be removed are easily obtained here, as also steps, landings, and grindstones. The Birch-hill and other kinds are sold in blocks, rough, at 7s. per ton; if pecked or scappled, at 7d. to 8d. per foot cube; common building stone, 1s. per ton; flagging, from 2d. to 2½d. per foot superficial; troughs and cisterns, 6d. per gallon of 231 cubic inches; gravestones, 6d. per foot superficial; grindstones at 2d. per inch diameter, up to 3 feet high; 7 feet about 5l.

The Bath stone of Boxhill, and other similar Wiltshire stones, are freestones of the great oolite formation, and have their chief outlets at Box, Hindon, and Corsham. There are numerous quarries, and the prices at one of these,—the Box and Corsham quarry,—is 9s. per ton, of which 30,000 tons 16 feet per ton is the annual average produce; at other quarries there are kinds of Bath stone sold at 3½d. to 5½d. per cubic foot, and 4s. 8d. to 7s. 2d. per ton, to the extent of 97,000 tons,—1,566,560 cubic feet average annual produce. The uses of Bath stone are well known. Mr. Hunt says, "Messrs. Randell & Saunders quarry at Box and Corsham not less than 26,000 tons (of 16 feet). Value, before delivery charges are incurred, about 9s. per ton. A cream-coloured stone; weight of cubic foot, 123 lbs. The Baynton stone is employed in Laycock Abbey, in the front of Wilton House and of Windsor Castle. The Box and Corsham quarry has supplied buildings in Bath, London, Plymouth, Liverpool, Manchester, Birmingham, Derby, Nottingham, Leicester, Oxford, Dover," &c.

After ranging through such counties as Cornwall, Devon, Dorset, Somerset, Gloucester, Wilt, Hampshire, Sussex, Surrey, and Kent, all more or less supplied with useful stones of some kind or other, we arrive at one sad item in the heart of the country, all that is said as to which we may here quote:—

"*Middlesex*.—There are no quarries in this county. Numerous gravel-pits are opened, and the flints found in them are used for building. In a few cases the indurated sands of the tertiary beds have been employed for building (see Brick Returns)."

This is all that can be said of the whole county under the head of building stones.

The Ketton freestone quarries of the county of Rutland have their main outlet at Stamford. They belong to the lias formation, and the

stone is locally known as Ketton stone. The Ketton quarries "produce a freestone of very superior quality: they are extensively worked, and sent to all parts of the kingdom for building. St. Dunstan's Church, Fleet-street, was built of Ketton stone; the modern parts of Peterborough and Ely cathedrals." It is a dark cream-coloured stone; weight of cubic foot, 128½ lbs.

The Rowley ragstone of Worcestershire has its chief outlet at Dudley. It is a basalt, and is used to an average annual extent of 60,000 tons for pitching and macadamizing roads, for which purpose it is sent to the metropolis and many large cities. Messrs. Chance have employed it in the manufacture of artificial basaltic stone, a description of the process of manufacturing which is given by Mr. Hunt in the volume under notice.

Of the red, white, and yellow sandstones of Cheshire, used in Birkenhead, Liverpool, &c., and the limestones, sandstones, &c., of Lancashire, also used in Liverpool and elsewhere, various useful particulars, in regard to prices and purposes, are given, but they are too much detached and particularized for quotation.

The York flags of Bradford belong to the coal measures, and are sold, to an extent of 5,000 tons annually, at 7d. to 8d. per cubic foot. The cubic foot of these flags weighs 142½ lbs.: they may be obtained in blocks of ten tons, and have been used in the London and other docks and bridges: the colour is light brown.

The North Anston limestone of Yorkshire, used in the new Houses of Parliament, is sold at the quarry at 1s. per cubic foot, to the extent of 124,464 cubic feet annually: its weight per cubic foot is 144 lbs. This stone belongs to the magnesian limestone formation, and is of a yellowish brown colour, as every one knows who has been at Westminster.

Of the Kendal Fell limestone of Westmoreland, which belongs to the carboniferous formation, we are told that any persons owning property in Kendal have a right to this stone free of charge. The town of Kendal is built of it. The cost for rubble walling at the quarry is 5d. to 6d. a cartload, and refuse for lime-burning about 3d. a cartload: ashlar stones cost 6d. per foot, however, at the quarries.

The Craigleith stone of which the new tower of Edinburgh, and the university in the old town of that city, were built, sells in cube stones at the quarry for 1s. 1d. to 3s. 7d. per cubic foot, according to size: ashlar and long stones are sold at from 6½d. to 2s. 1d. per linear foot, according to size. The harder portions of the (carboniferous) sandstone at Craigleith are locally called liver rock.

The Aberdeenshire granite of which Covent-garden Market, the river-wall of the new Houses of Parliament, the Duke of York's Column, &c. were formed, is sold at 2s. to 5s. the cubic foot, shipped at Peterhead.

Of the Irish marbles some interesting particulars are given in Mr. Hunt's tables. The black marble of Angham quarry, near Galway, described as "of very superior quality, and capable of receiving a very high polish," can be obtained in beds from ½ to 1½ foot in depth, and of breadths and lengths up to 10 by 20 feet. Limestone of dark blue colour, with shells overlying marble, can be got in blocks of ten tons. The price of it at the quarry is 5s. 6d. per cubic foot: it is worked up in Galway for chimneypieces, columns, and other ornamental work, and is also exported in the rough state. Another Galway marble is the light green serpentine of Barnanoran, which belongs to the metamorphic schists, and is sold at the quarry for 6s. per cubic foot. At the Merlin-park Quarry, near Galway, there is "black marble of the very finest description, and capable of receiving the highest polish: it is sold at 5s. 6d. per cubic foot, and is worked up in Galway, as well as exported in the rough. The Gieveham dark green serpentine marble of county Galway is described as being "very sound, and free from shakes of any kind."

The Quarry Returns in all comprise statistics and other particulars as to upwards of 3,000 quarries,—1,504 English, 158 Welsh, 678 Scottish, 667 Irish, and 8 Jersey.

\* "Memoirs of the Geological Survey of Great Britain and of the Museum of Practical Geology: Mining Records: Mineral Statistics; being Part II. for 1853. By Robert Hunt, F.R.S., Keeper of Mining Records." Longman & Co., 1859.

\* There is a separate and valuable table in the volume, containing particulars as to the weights of many kinds of stone.

General Summary of the Production of Building and other Stones in the United Kingdom of Great Britain and Ireland.

	Estimated Total in Tons returned.	Computed Total of entire Production.	Value of Computed Total.
	Tons.	Tons.	£
England....	3,935,939	7,500,000	4,705,408
Wales.....	1,229,863	3,500,000	898,133
Scotland...	853,888	4,750,000	1,211,393
Ireland....	—	—	800,000
Jersey.....	—	14,200	7,900
Total.....	—	15,764,200	4,622,824

The returns of bricks, tiles, pipes, &c., show an estimated quantity of all kinds, manufactured in England, Scotland, and Jersey, amounting to 2,503,004,000, and an estimated value of all kinds, at mean average market-price, of 2,911,950*l*. The whole returns are English, except 55,000,000, valued at 68,750*l*., from part of Scotland, and 5,529,600, valued at 6,925*l*., from Jersey. The Middlesex returns are 107,500,000, value 118,255*l*.; the Lancashire, 108,000,000, value 129,000*l*., which is the highest; and next in amount is the Yorkshire, 100,000,000, value 125,000*l*., which return is the same in number and value with a joint return from Staffordshire and Worcestershire. Durham and Northumberland also go together for 96,000,000, value 120,000*l*.; South Wales, 93,500,000, value 116,000*l*.; North Wales, 86,250,000, value 107,000*l*.; all the other returns are in value below 100,000*l*. each.

“Until 1833 an excise duty was charged both on bricks and tiles (the latter being then exempted from the duty), so that their manufacture was placed under surveillance. It was ordered by 17 George III., c. 42, that bricks made for sale should be 8½ inches long, 2¼ inches thick, and 4 inches wide, on pain of forfeiting, for bricks of less dimensions when burnt, 20*s*. for every 1,000, and proportionally for a greater or less number. It was also provided that the size of the sieves or screens for sifting or screening sea-coal ashes, to be mixed with brick earth in making bricks, should not exceed ½ of an inch between the meshes. The duty was entirely repealed in 1850.

In 1821 the number of bricks, &c., paying duty were	899,178,510
“ 1840 “ bricks only “	1,677,811,134
“ 1847 “ “ “	2,193,829,491
“ 1849 “ “ “	1,462,767,154

This being the year when the oppressive nature of the duty on bricks was strongly urged, and the repeal expected, many large buildings were delayed, and consequently, as we see, the make of bricks diminished. From 1849 until the present, no attempt has been made to determine the value of the manufacture.

WEIGHT OF BRICKS.

Worcester, solid .....	8½ lbs. Machine made.
Do. perforated 6 “	Do.
Staffordshire, solid ..	9½ “ Hand made.
London Stock, solid 5½ “	Do.

A cubic yard of bricks is estimated to contain 384 bricks, and on the average about 373 bricks go to the ton.”

From the extensive and valuable information received from all parts of the country, the following proximate computation of the value of all the earthy minerals of this country has been derived:—

Clay unmanufactured:—this includes only the superior kinds of clay, and it embraces China stone .....	£. 285,846
Bricks, tiles, &c., estimated at the cost of production .....	2,911,980
Building and other stones.....	4,622,924
Sands .....	10,250
Coprolites .....	65,500
Rotten stone .....	750
Ochre, amber, &c. ....	5,450
Barytes .....	15,500
Gypsum .....	17,750
Fuller's Earth.....	13,500
Flour spar .....	4,625

Total value of the earthy minerals of the United Kingdom..... 7,954,075

By reference to Part I., it will be seen that the total value of metals, metalliferous minerals, and coals, produced in 1853, was 31,266,932

Thus we see that our annual mineral produce has the enormous value of..... £39,221,007

And with this general summary, which, as Mr. Hunt takes care to point out, can afford, as yet, but an approximation to the truth, we must now conclude, with a strong recommendation to our professional brethren, to owners of quarries, and the members of the building trades generally, to lose no time in procuring copies of this volume, and to aid by affording information in rendering the next edition of it even more valuable.

THE GUILDHALL, AND ST. PAUL'S CATHEDRAL.  
NOTES IN THE CITY.

SEVERAL correspondents express their anxious desire that the year of office of the Right Hon. William Cubitt, the present first magistrate of the City of London, should be distinguished by some permanent memorial bearing on his own peculiar calling,—architectural construction,—and tending to the improvement of the district over which he now reigns. The public, also, would doubtless view this with satisfaction. One such work, Wren's statue, was suggested a few weeks ago. Another presents itself to our minds, which, if well executed, would reflect lasting credit on all parties concerned, and prove a satisfactory memento of the civic supremacy of one of the craft. A popular head over municipal institutions wonderfully smoothes the way towards the accomplishment of works of utility and beauty, which otherwise linger on from the generation that proposes, to a remote succeeding one that carries out the idea; and, in the interim, the originating benefactors are forgotten.

Let us, then, endeavour to induce all the parties concerned to assist in executing some good work so effectively and speedily, that it shall stand as a mark of this very time.

What we propose is briefly this,—that the inappropriate ceiling which now disfigures the otherwise noble Guildhall of London shall be swept away into the dusthole, and be replaced by a handsome timber roof, in accordance with the style and fine proportions of this municipal and national edifice.

Do not let us quarrel as to the age of the suggestion; but, if it be desirable, as we believe, let us strive to have it carried out. Of its necessity, an inspection of the Guildhall is sufficiently convincing. The ceiling has been a reproach to the corporation for years, and a disfigurement to an otherwise fine hall full of interesting associations. We have ourselves often urged this before. The look with which a foreign architect, who had been taken to the dinner on “the 9th,” regarded it when his eyes had travelled up, if photographed, would have made a forcible illustration for these remarks.

The City architect did, we believe, once make a design for new roofing the Guildhall; but he would doubtless now feel himself in a position to go farther than he did then. Knowledge of Gothic architecture has made such rapid strides during the last few years, that nothing but a thorough work would satisfy the exigencies of the times. The great and wealthy corporation of London, in whose hands the responsibility of carrying out the alteration rests, must have the work completely and beautifully done, as Mr. Bunning knows so well how to do it, and so as to leave a noble memorial to the admiration of future generations. If, further, the Hall were properly decorated, one result would be the saving of a large sum of money now annually spent on the temporary adornment of it. A comparison of the present incongruous ceiling in the Guildhall, with the roof of that of Westminster, will save a world of argument and controversy.

There is a second work in the City that needs doing, the removal of the ponderous iron railing around St. Paul's Churchyard; and although this rests, we suppose, with the Dean and Chapter, the corporation could of course greatly aid in bringing it about. When we first urged this, some years ago, in the interest of the public and of the fame of Wren, our contemporaries of the press repeated our views far and wide, and the desirability of the removal was loudly expressed. But nothing was done. We need not, however, be discouraged. Nothing was done when we first called for the removal of the railings which were around and disfigured our public statues; yet at this time the chief of them have been freed from the disfigurement. The gain that would result to the public in respect of traffic and power of circulation, if the railing around St. Paul's were removed, would be immense, and was the original ground of our

argument. Beyond this, however, if the area were levelled and paved to within a few feet of the cathedral, the beauty and grandeur that would be added to the edifices can scarcely be overstated. A light and appropriate railing, placed at a short distance from the building itself, would not interfere with the view of the architecture, and would preserve it from any accidental injury. If there be any one who doubts the charming effect that would be produced—not content with Continental illustrations—let him note the open area in front of the Royal Exchange. Moreover, let him take the trouble to get inside the inclosure of St. Paul's Churchyard, go to the farthest possible spot from the cathedral, place his back against the railing, and then look up at the grand pile; surely he would exclaim that he had never seen St. Paul's till then. From within and without this huge grille, the cathedral is an entirely different structure;—in the one case dwarfed, disfigured, distant, and defaced; in the other noble, grand, devotional, and elevating. No man of taste can entertain a doubt as to the propriety of removing this iron mask, if he have taken these means of forming his judgment; and we strongly urge all who have any power to aid in bringing about during the present mayoralty what would so greatly improve their city. Rightly treated, a nobler space, and a grander temple to God's honour piled, could not be found in the whole world.

Let our children be able to say these two great improvements were effected when Cubitt was mayor.

FRIENDLY SOCIETIES AND THE SOCIAL IMPROVEMENT OF WORKMEN.

It is gratifying to note the efforts which are being made to improve the condition of the industrial classes in this country. Their increase of knowledge, the establishment of workmen's institutes, the opening of marts for the sale of provisions and wares, at cost price, the attendance at libraries, the establishment in connection with large manufactories of independent means of providing medical attendance in the time of sickness, are all marks of social advancement.

Societies which, about forty years ago, were looked at with suspicion by the Government, and with considerable contempt by the general masses of the people, have grown in wealth, numbers, and respectability. In the establishment of societies of “Odd Fellows,” for the purpose of enabling men to meet together in lodges, which were presided over by some of the most intelligent of them, the rules were and still are framed with good intentions. Arrangements were made for the purpose of giving assistance in the times of death and sickness; persons of bad character were not elected; and by means of these societies men in search of employment would be sure of a kind reception and help in strange towns. The name of this large and prosperous association seems now not to be appropriate. It may, however, at the commencement, have been significant of the idea at that time so generally entertained, that it was an odd notion for the English workmen to combine for useful purposes. Since the establishment of the “Odd Fellows,” the “Forerunners” have formed in vast numbers, and both in town and country other associations have been founded with advantage.

Mr. Tidd Pratt, the registrar, remarks that we have an account of an establishment of this kind at Athens, 280 years before Christ; and the first in England is ascribed to Daniel De Foe, in 1696.

About 100 years ago, in most towns in the kingdom, friendly trade societies were extensively formed, for the purpose of giving mutual aid in times of ill-health, to pay certain amounts at the death of members, their wives and children, and to allow certain annuities after the subscribers had reached the age of fifty-five or sixty years. Most of these societies were started at taverns and public-houses. At the time of their commencement the members chiefly consisted of young men, or those who had not reached the prime of life. Unfortunately, however, the payments were not sufficient to meet the risks and subsequent expenses; and persons who had made regular payments for twenty, thirty, and even more years, found, in their old age, after the payment of a sum so large that with good management a certain provision should have been made,—that the societies, as years passed on and members were becoming old, were hopelessly bankrupt, and had not a shilling left to pay expenses.

In such conditions the younger men seceded, and formed fresh societies, which in due course came to the same end. At the time mentioned

the chances of life and health had not been fairly calculated; and the managers and those connected with the life societies did not seem to be aware of the circumstance that, supposing a society to be established, its members being under 35 years of age, it would be found that comparatively little sickness would occur during the first ten years, and consequently that which was called a surplus was, as Mr. Tidd Pratt truly observes, no surplus at all. But considering the accumulation of capital which would be sure to arise as so much profit, this was from time to time divided; and hence one of the causes of the ruin which took place. It appears that since 1793 there have been 23,000 friendly societies established in England, of which 7,000 have ceased to exist. These figures show that after a period of 67 years about one-fourth of those establishments which have been formed are not now in existence.

It has been the practice to charge the working classes of this country with improvidence; and unfortunately this is, to a certain extent, true,—particularly in the large towns. It is a fact—stated by Mr. Pratt—that the number of members of friendly societies is 2,500,000. If we cannot take the male adult population of Great Britain at more than five millions, the above figures show that one-half of our male population who have arrived at the age of maturity are subscribers to friendly societies. If we exclude the number in the army and royal navy by whom little or no provision can be made; persons who have been too old to avail themselves of this provision; and the very large number whose inclination or circumstances do not lead to the use of the friendly societies,—it seems plain that a very large majority of the industrious portion of our population must be members of those friendly institutions.

On November 20th, 1859, the number of depositors in the savings banks was 1,479,723, and the amount deposited was 36,152,140*l*. Although it may be found that the depositors of the savings banks are not of the working classes to such a large extent as might be desired, it is known that large sums have been invested by servants, and young people of both sexes, whose means are limited.

Of the depositors at the above date there were—

213,473 who had an average investment of.....	20	5	0	each
291,739 Ditto.....	2	10	6	"
191,133 Ditto.....	6	15	4	"

Of benefit building societies, there were about 2,000, with a paid-up capital of not less than 8,000,000*l*.

It is gratifying to find that the friendly societies are now established on more sure principles than in former days. Mr. Pratt suggests that the best average rates of payments are 1*s*. 1*d*. per month, for persons between twenty-four and thirty years of age, in order to receive up to sixty years of age (in case of protracted sickness or incapacity), 10*s*. per week; up to sixty-five, 1*s*. 2*d*.; to seventy, 1*s*. 3*d*. There are other safe means for the use of those who are disposed to be careful; and we believe that the changed habits of the young workmen who are now rising up, the advance of education, the facilities of meeting which are in course of progress for young men, and the other agencies which are at work, will, year after year, add, to an extent which it is difficult now to estimate, to the amount of the savings of the working part of our population,—a circumstance which will give them a right position in the State.

When we refer to the plays and novels of about the commencement of the last century, and compare the pictures which are given in them and elsewhere of the usanners of the English nobility, and refer to the amusements, peculiarities, and prejudices of the same class which are described in various works,—when we reflect on the rude hospitality, and somewhat coarse manners and impudence of a large portion of the British agriculturists,—of the complete isolation, even antagonism, which existed between the gentry and the industrious communities in our large towns, it is pleasant and promising to see the efforts which are now made, by persons of rank and cultivated intelligence, to mix with, and amuse, instruct, and benefit the multitude.\*

\* Mr. J. Harris gives the numbers of Odd Fellows and Foresters as under:—

	Odd Fellows.	Foresters.
England.....	267,394	159,838
Wales.....	23,011	2,561
Scotland.....	3,977	823
Ireland.....	1,613	161
Abroad.....	10,566	2,098
	305,561	166,570

It is not without benefit further to glance at the homes of our farmers,—to compare the present with the past,—to note the pictures, books, musical instruments, and other signs of advancing taste; and, in looking into the dairies, gardens, fields, and stackyards, we find that instead of the produce of the land having declined in quality or quantity, by the improvement in knowledge and manners, crops are raised which would have been considered impossible by our grandfathers. The working classes have a hopeful future if they will earnestly strive for the social and intellectual advancement of their order. This can be best done by co-operation of all classes. On this point Mr. Bright remarks, "The workmen are great in numbers, growing in intelligence, and their power of combination is without limit. They will contend for themselves, by themselves, if condemned to remain a separate and suspected order in our social system; and this contest has in it seeds of future and tremendous evil, to them and to the great industrial interest of the country. I wish to unite all, to have no separate interests, to bind all in a common sense of common rights, and thus to give peace and strength where now discord and weakness too much prevail." The way best to do this is the question that needs solving.

ACCESSIBLE ARRANGEMENT OF GAS AND WATER PIPES.

MR. CHARLES BAXIS has published a plan for the arranging of water and gas pipes and telegraph wires, so as to be accessible for any purpose without incurring the expense of excavating the roads and pavements.

This object is sought to be effected by placing the pipes and wires in chambers composed of lengths of tubing, which may be of any suitable or convenient size and form, and joined together so as to form a continuous chamber, in which openings are made at the top. It is proposed to construct the chambers of cast iron or bricks, or tile arches in cement, or other suitable material, with an opening extending along the upper side of the chamber, which will be hollow, and form the kerf. The sides or edges of this opening are provided with grooves, in which may be slidden plates or frames to close up the chamber.

The plates will be composed of cast iron frames, into which flag-stones may be inserted. Strong sheets of glass may also, if desired, be let into the cast iron plates or frames, at intervals, to admit light to the chambers beneath.

It is proposed that a chamber under the foot-pavement, and being the larger and more accessible of the two, shall be devoted to the reception of telegraph wires; while, in the other chamber, to extend under the roadway of the street, it is proposed to place the water and gas pipes. The chambers are so constructed as to allow the upper surface of the kerf plates and the other plates or frames being brought flush with the pavement; and it is proposed that this part of the structure shall form the kerf of the roadway, and will present a stone surface to the passengers' feet, for which purpose, and to strengthen and protect it from the carriage traffic, a strong fill or projecting piece is to be cast along the outer edge. The long continuous chamber may also be strengthened internally by means of webs or ribs.

If the gas and water pipes are placed in the chamber farthest from the houses, then short transverse ways or spaces must be reserved, and taken out of the other chamber, in order to enable the supply-pipes to be passed through the chambers.

It is proposed that the principal water and gas main pipes shall remain in the centre of the road of the leading thoroughfares, and that one supply-pipe, say four or six inches in diameter, should be carried into the chamber at the commencement of each street. The projector thinks that as there would be only one supply-pipe from the principal gas main in each street, and the supply-pipes to the houses being connected with the supply-pipe in the chamber, and perfectly accessible, the escape of gas would almost entirely be prevented, as there would be scarcely any necessity ever to interfere, or disturb the principal mains, whilst the joints to the supply-pipes in the chambers could be made as secure as the gas pipes that are carried through the rooms of dwelling and other houses; therefore that the saving to the gas companies by the use of the chambers would be great. In the several supply water pipes in the chambers there could be inserted, at given distances, large taps with washers and waste, so that a leather or other hose might be screwed on, taken through

an aperture by removing one or more of the before-mentioned movable plates or frames, and be of essential service in case of fire or for other purpose.

There are obvious objections to the general adoption of the plan, as compared with the formation of more comprehensive subways—the interference with vaults as at present formed beneath the footway, and the retention of the mains in the road, with the multiplication of pipes. Nevertheless, for some situations it would be worth consideration. The enormous size to which gas and water mains are now reaching threatens to increase the difficulty of introducing subways of any kind.

THE PUGIN MEMORIAL AND THE OBJECTORS.

SIR,—The opinion of Professor Donaldson carries with it so much just weight, that his expression of dissatisfaction at the conditions of the Pugin Memorial cannot fail to be injurious to its success. I make no excuse, therefore, as one both privately and officially interested in the undertaking, in briefly calling your and Professor Donaldson's attention to some obvious considerations which I am surprised to observe, have escaped his view; but which in my opinion ought to neutralize his unfavourable judgment.

If we had any intention of casting a slur on, or impeding, the study of Continental architecture, no language could be too strong to brand such bigoted folly. But where is the evidence to be found of such an *animus* in our prospectus? Architecture, if studied in a large spirit, must be studied in a cosmopolitan one. But I have yet to learn that a cosmopolitan spirit means a spirit which excludes our own country while it includes all others. If I am right, it follows that the perfect architect, while he is at home when abroad, must not be abroad when he is at home. It seems very little to ask of our young architects that while they "get up" their Paris and Cologne, their Florence, Venice, Rome, or Athens, they should at the same time have devoted some one summer of their "prentice years to a personal survey of York, Lincoln, Durham, Ely, Sarum, Oxford and Cambridge, Tintern, Kitevaux, Chesham, and Conway, not to mention the numerous country houses of the sixteenth and seventeenth centuries, which are still in existence up and down our rural counties.

The most ambitious promoter of the Pugin Memorial does not expect to be able to do more than to raise funds sufficient to enable one student to take this tour each year. No other public provision for such a tour at present exists; and, unless Professor Donaldson can prove that it is likely to be injurious to the young man who embarks in it, I fully believe that he will forget his letter to Mr. Clark; and, with his accustomed generosity and kindness, contribute his influence and help to the good cause of the Pugin Memorial.

A. J. B. BEFFROSS, HON.

\* \* \* It is not, as Mr. Ilope supposes, an objection of Continental and home architecture with those who, like Professor Donaldson, object. The prospectus sets forth that the interest of the fund shall be expended by the recipient "in travelling in the United Kingdom, and in examining and illustrating its *Medieval* Architecture, Sculpture, and Painting." It is this limitation that is objected to. If the committee for the fund are disposed to remove the word "*Medieval*," they may at once get rid of the objection; and, practically, precisely the same object will be attained; the *Medieval* works preponderating so greatly in this kingdom as they do. Mr. Ilope, when he includes the "country houses of the sixteenth and seventeenth centuries," goes probably nearly as far as the objectors would desire,—certainly beyond the limits marked by the prospectus, and will probably be willing to assist in obtaining the desired change.

We have since received a copy of the reply which has been returned to Professor Donaldson by the hon. secretaries:—

"We feel that your letter of the 26th instant demands an official reply, as it appears to presuppose a feeling on the part of the Committee and subscribers to the 'Pugin Memorial' which we are sure that the majority of them would disclaim."

We have united together with a single and a very simple object,—to commemorate in the most appropriate, and at the same time the most useful manner which we could devise, a very eminent architect, a man of very extraordinary ability, and who was not only the most zealous and successful of those who have brought about a revived taste for and appreciation of the true principles of Polished architecture, but who, in carrying out that object, indirectly elucidated principles of the highest importance to our art in all its varieties. It is commonly the case that the most zealous agents in

any great cause lay themselves open to the charge of exclusiveness. It may, perhaps, be an inherent imperfection in the human mind that in carrying out any great movement exclusively in some degree a coalition of great access. There may be minds so great as to override this, but we think you will find that the revivers of Classic Architecture, whether in Italy, France, or England, were amenable to the same charge which you bring against Pugin.

Be this, however, as it may, it is unfair to charge this upon those who wish now to commemorate the services of this highly gifted man. We may do more, as individuals, agree with him in such of his views as you object to: many of us may agree with him to the full in his feelings towards Gothic architecture, without adopting his censures upon other styles; but, whatever may be the varieties of our individual sentiments (and they are, no doubt, pretty numerous in their shades), we feel sure that all are agreed in this—that in commemorating and doing honour to Pugin, we have no wish either to press our particular tastes and preferences upon others, or to imply any shade of censure upon those who may happen to differ from Pugin or from ourselves.

Holding, however, these views, we nevertheless strongly feel that to commemorate Pugin otherwise than in connection with that style of architecture to which he devoted his life, and in which all his feelings and aspirations were centered, would show a degree of sickly liberalism which would justly incur the contempt of persons of all shades of opinion. Pugin was devoted to the study and revival of Gothic architecture, and his memorial, to be a memorial at all, must be connected with that study and that revival. To make it other than this would, as it appears to us (to borrow your own expression), be "stupid and cowardly."

To commemorate a man, however, in connection with the pursuit to which he devoted himself, by no means implies exclusiveness. We wish to connect his name with a studentship in the Institute of British Architects, founded for furthering the study of that branch of our art in which Pugin was eminent. Surely there is nothing exclusive, in an objectionable sense, in this. Why, if it is not a month since Mr. Tite founded, in connection with the same Institution, a prize for 'Proficiency in Italian Architecture,' even specifying the individual artists whose works illustrate the particular variety of the style he meant to encourage. Did any Gothic architect object to this? If this view become general, there can be no specific teaching at all. Our universities and schools possess prizes, studentships, &c., for particular branches of learning or science; but these do not imply any censure upon any other branches. Why, then, if, as you frankly admit, the two great styles of architecture now practised amongst us are equally worthy of study and encouragement, should a studentship in our great Architectural Institute aid the study of one of these by connecting certain prizes with the memory of one of its leading revivers, be awarded before the public as either a reward or a distinction and emphatically disclaim any such principle or intention on the part of the supporters of the Pugin Memorial.

JOSEPH CLARKE,  
"THE FABRIC DEPT."

#### SIZE OF PIPES FOR COMBINED BACK-DRAINAGE.

##### THE SWANSEA SEWERAGE.

An important question is in course of settlement at Swansea. The town-surveyor, Mr. Cousins, having planned the sewerage of the town, in which he laid down a system of back drainage for combined blocks of houses with 6-inch pipes generally, Mr. Rawlinson was consulted as to the whole plan, of which, it is stated, he approved, including the 6-inch pipes for combined drainage. The local Water and Sewers Committee, however, having considerable doubts that the pipes so authorised were not of sufficient size for subordinate sewers generally, the surveyor (who still retains his opinion in favour of 6-inch pipes) was instructed to go over the plans again with Mr. Rawlinson. This has been done, and the result appears to be that Mr. Rawlinson has reported that 9-inch pipes ought to be applied to all combined back drainage. A controversy has thus arisen in the local Board of Health; and, after a good deal of discussion, it has been resolved that the Water and Sewers Committee be authorised, by personal interviews of the chairman and surveyor with the Local Government Act Office in London, or by such other means as they may think best, to ascertain the proper dimensions of pipes to be used for subordinate drainage in this borough, and to report thereon as speedily as possible.

There are some points in Mr. Rawlinson's recent and special report on the Swansea drainage which we must select on account of their general importance, as well as with reference to their special application to Swansea:—

"The plan of combined back-drainage will be most economical for the owners of property, and very much better and safer in a sanitary point of view for the residents in the houses." Pipes of 9 inches internal diameter will be sufficient for any group of houses in Swansea, as shown on the plan of the town. Pipes of 6 inches internal diameter will be sufficient for drains from the largest house; and pipes of 4 inches diameter for sink, house, and soil-pool drains. In using earthenware pipes they must be sorted and matched, so as to have even joints. Pipes of equal diameter should not join, but the lesser should part into the greater, and the tops should be level, not the inverted bottoms. Pipes of equal diameter may come to a same manhole. The invert of the tributary should be higher than the main. All inlets to drains should be protected, so that solida passing through may traverse the pipe. The places as undernamed have been surveyed and drained with earthenware pipes: Alwick, Northumberland, town of 7,000 inhabitants, pipes from 18-inch to

4-inch. The outlet sewer is upwards of a mile in length, and has a fall of 1 in 400. Alwick Castle, the seat of His Grace the Duke of Northumberland, earthenware pipes from 12 to 4 inches in diameter. The dairy and dairy-grounds of Alwick Castle, pipes from 9 to 4 inches have been used: stables, cowsheds, and piggeries are drained. In Alwick there are about 1,000 sockets in use: the works have been in operation some six years without complaint or inconvenience. At Carlisle some 3,000 houses have been drained with 6 and 4-inch pipes. At Wigan some 5,000 houses have been drained with 6 and 4-inch pipes. At Bowdoin, the seat of the Marquis of Lansdowne, earthenware pipes are used from 12 to 4 inches in diameter. Howick, the seat of Earl Grey, in Northumberland, is drained with earthenware pipes of 9, 6, and 4 inches diameter. At Worthing and at Workshop earthenware pipes are used, and with perfect success. Many other places could be named in which I have raised small pipes, as also in which other persons have used them with success. In pipe sewerage and drainage, care and truth in workmanship and materials must be aimed at. Herein consists the secret of success. An earthenware pipe of 9 inches in diameter, laid with a fall of 1 in 60, will deliver about 1,500,000 gallons of water each day of twenty-four hours. A small pipe, truly pointed, and evenly laid, is preserved clean with much less water than any pipe or sewer of larger diameter. If pipes and sewers are so large as to allow of deposition of solids, choking becomes a work of time. In small pipes, the water must remove the solids. I recommend that, for combined back sewerage, and for blocks of houses, pipes of not less than 9 inches diameter may be used; that house drains may be of pipes 6 inches in diameter; that branches on house-drains may be 4 inches in diameter."

In a recent report the town surveyor, notwithstanding this, says:—

"A 6-inch pipe with a fall of 1 in 60 will pass through 200 gallons per minute, equal to 420,000 gallons per twenty-four hours. This is equal to a volume of water due from thirty-one of the largest houses in the town."

In practice it is found that the same volume of water will more easily remove a deposit through a small pipe than a larger one. If, therefore, a 6-inch pipe be used to carry away all the water that can possibly come into it, it is evident that it is preferable to one of larger dimensions.

I have recommended 4-inch pipes for branches for house-drains, so that every inlet is of smaller size than the subordinate sewers into which they will discharge, and therefore any improper substance likely to choke a drain must pass through a length of 6-inch pipe before it reaches the subordinate sewer; and the fact of its having passed through a length of 1-inch pipe is a sufficient reason to suppose that it will not readily stop up a 6-inch pipe.

The use of 6-inch pipes for back drainage of blocks of houses is no new scheme, but has been adopted and carried out with success in several towns that have been drained with the last ten or twelve years.

After fully reconsidering the matter, I see no reason why I should alter my opinion as to the sufficiency of 6-inch pipes for such purposes as I propose to apply them. The chief object to be aimed at is to have the pipes truly and evenly laid, and to have a plentiful supply of water to flush them."

In our own experience, we may here remark, we have found 6-inch pipes to fail in such a position, and would therefore recommend the change to 9-inch pipes.

#### THE GROWTH OF OLD ENGLAND.

If the commencement of the Roman rule in England was, say, fifty years before the birth of Christ (or 1910 years ago) and each generation lasted on the average thirty years—rather a high rate of vitality probably in the Early and Middle Ages—we find that about sixty-four generations have gone to dust since then; and how much farther back we must look for the commencement of the English history it is difficult to say. The archeological information obtained of late years shows that at the time of the Roman invasion there was a larger amount of civilization in Ancient Britain than has been generally supposed. There seems to be good evidence that in addition to the knowledge of the old inhabitants in agriculture, in the training and rearing of horses, cows, and other domestic animals, they were able to work in mines, had skill in the construction of war chariots and other carriages, and in the manufacture of metals; and there is evidence that cheese and other British manufactures and materials were exported to certain parts of the Continent, probably in British vessels. The peculiarities of the specimens of the ancient coinage of this period which remain are well worthy of attention. To what country may the style of art be traced? To what people do we owe the mysterious circle of Stonehenge? [Mr. Fergusson and others say to the Buddhists rather than to the Druids;] and those other remarkable stones which still remain as memorials of the past, exciting, in the minds of the thoughtful, indescribable feelings of wonder and curiosity?

When noting the various circumstances to be found in connection with the Ancient British period, it would seem that probably 2,000 years before the Roman times there had been in Great Britain a certain degree of civilization, which, from various causes declined in extent. If Stonehenge may be considered as of the same antiquity as similar remains in various parts of the East—which are considered by good authorities to be 4,000 years old,—we had in

this country a degree of civilization which was contemporary with the prosperous period of the Egyptian empire; and, in times more immediately preceding the Roman occupation, we know that Britain was the grand source of Druidical illumination (whatever relation that may have had to a true civilization) to the whole of Continental Europe.

That the Ancient Britons, even after they were conquered by the Romans, had still a strength considered dangerous, is shown by the fact that upwards of forty barbarian legions which were the wards of the Roman standards were settled chiefly upon the northern and eastern coasts; and it is supposed that a force of about 19,200 Roman foot and 1,700 horse was required to secure peace, and the carrying out of certain laws in the island. It is calculated by some writers that a revenue of not less than 2,000,000*l.* a year was raised by the conquerors of Britain from the land-tax, pasture-tax, and customs, besides legacy duties, and those levied on the sale of slaves, auctions of goods, &c.; and it may be remarked that these customs were levied by the Roman governors in lieu of direct tribute, to which, it seems, the spirit of the Britons would not submit.

In the Saxon reign of Edward the Confessor, notwithstanding the strife and bloodshed which had reigned for a long period, the land-tax alone (exclusive of houses in towns, which were also rated) amounted in our money to about 390,000*l.* sterling. Other revenues would produce much more.

In the Norman period (1213), the duty on dyo stuff alone, used for native manufacture, amounted to about 600*l.*

In the reign of Henry II., Fitz-Stephen says that no city in the world sent its wealth to so great an extent and to so great a distance as the city of London, so that then our metropolis had begun to occupy the distinguished position which it still holds among the nations; and he enumerates amongst its imports gold, spices, and frankincense, from Arabia; precious stones from Egypt, purple cloths from India, palm-oil from Bagdad, furs and ermines from Norway and Russia, arms from Scythia, and wines from France. From various parts lead and tin were sent abroad in large quantities, and probably hides, skins, and woollen cloths; and so great was the quantity of silver in the kingdom that it could afford to raise 70,000 marks—equal in weight to nearly 100,000*l.* of our silver money; and some idea of the great value at that time of this amount may be formed from the circumstance that about 1135 wheat averaged only 4*s.* the quarter; sheep, about 5*d.* each; hogs, 1*s.*; cows, about 4*s.* 6*d.*; and breeding mares less than 3*s.* in 1205 the expense of building two arches of London-bridge was 25*l.*

In the twelfth century the revenues of the English monasteries alone amounted to 730,000 marks a year. In the reign of Edward III., the crews of the ships employed by that king at the siege of Calais numbered 11,151 persons. In 1354 the duties paid on the exports of wool amounted to 81,846*l.*; and the total value of the exports to 212,338*l.* 5*s.* Taxation was then very high.

In 1391 the customs duty on such exportation alone amounted to 160,000*l.*; and so opulent became the merchants, that one individual was able to lend the king, Edward III., 18,500*l.*

From that date to the present time the growth of trade, commerce, and manufactures in England has been marvellous to contemplate; and great as this has been, the powers now at work promise a result even greater.

B. & D.

#### GLEANINGS AS TO OLD LONDON, FROM VARIOUS SOURCES.

*The Ancient Shopkeeper*.—Proteus Redivivus—re-published in 1854—presents the following sketch:—"Methinks I see him, standing at his shop door, in cold weather, either blowing his fingers, eagerly waiting (if he be a young man) for a kick at the foot-ball, and betting his sides with his own hand, and so makes every cold day a Good Friday to chastise him for the sins he hath committed. If any person pass by him, and but look into his shop, he fondly imagines him a customer, and entreats for his own necessities by asking others what they lack. If any chance to step in, he hath hocus tricks enough to delude them, and rarely shall they stir out (like sheep engorged in briars) but they shall leave some feece behind them. Some have dark shops with false lights, which wonderfully set off a commodity; others (for want of that) make use of their own

\* Of this we are not quite certain, by the way.

longues, arrogantly commending their own wares, and protesting whatever they exhibit to view is the best in the town, though the worst in his shop. His words are (like his wares) twenty of one sort, and he goes over them alike to all comers."

The same authority says that the traders of his time have broken through a custom of their ancestors, and made Monday a general day for the settlement of accounts instead of Saturday, which the author says "is the melancholiest part of the whole week, not so much by reason of the poppish and humorous planet which governs it, but by reason of too many unsufferable dens, who tread the streets in terror; and that is the reason some citizens can as well be banged as keep out of nine-pin houses in Moorfields on this day, to be out of sight of these ghastly apparitions that haunt their ghost at the end of the week."

*Hackney Coaches* were admitted into Hyde-park before the year 1694, but were expelled at that period, through the singular circumstance of some persons of distinction having been insulted by several women, in masks, riding there in that description of vehicle.

"*Proclamation against Swearing Workmen.*"—During the building of St. Paul's, the commissioners for erecting that structure with Sir Christopher Wren issued the following very proper order:—"Whereas, among labourers, &c., that ungodly custom of swearing is too frequently heard, to the dishonour of God and contempt of authority; and to the end, therefore, that such impiety may be utterly banished from these works intended for the service of God and the honour of religion, it is ordered, that customary swearing shall be sufficient crime to dismiss any labourer that comes to the call; and the clerk of the works, upon sufficient proof, shall dismiss them accordingly. And if any master, working by task, shall not, upon admonition, refrain this profanation among his apprentices, servants, and labourers, it shall be construed his fault, and he shall be liable to be censured by the commissioners. Dated 25th September, 1695."

*Schools.*—Aubrey (MS. in the Ashmolean Museum) says, in 1678, "There were very few free schools in England before the Reformation. Youth were generally taught Latin in the monasteries, and young women had their education, not at Hackney as now, but in the nunneries, where they learnt needlework, confectionary, surgery, physic (apothecaries and surgeons being their rare), writing, drawing, &c. Old Jack, now living, hath often seen from his house of St. Mary's, Kingston, in Wilts, coming forth with the nymphs with their racks and wheels to spin, sometimes to the number of seventy, and of whom were not mus, but young girls, sent there for education."

*Houses.*—The same authority says, "Anciently, before the Reformation, ordinary men's houses, copyholders, and the like, had no chimneys, but flues like louver holes: some of 'em were in being when I was a boy."

"In the halls and parlours of great houses were wrote texts of Scripture on the painted cloths."

"In days of yore lords and gentlemen lived in the country like petty kings, had *juva regalia* belonging to seignories; had castles and boroughs; had galleys in their liberties, where they could try, condemn, and execute; never went to London but in Parliament times, or once a year to do homage unto the king; they always ate in their Gothic halls at the high table or orsille (which is a little room at the upper end of the hall, where stands a table), with the folks at the side table. The meat was served up by watchwords. Jakes are of but late invention: the boys did turn the spits, and licked the dripping for their pains. The beds of the men-servants and retainers were in the hall."

The *hearth* was commonly in the middle, whence the saying, "Round about our coal fire." Before the Reformation there were no poor rates: the charitable doles given at the religious houses and the church ale in every parish did the business. In every parish there was a church-house, to which belonged spits, pots, &c., for dressing provisions. Here housekeepers met, and were merry, and gave their charity. The young people came there, too, and lud dancing, bowling, shooting at the butts, &c. Mr. A. Wood assures me there were few or no almshouses before the time of Henry VIII.; that Oxon, opposite Christ Church, was one of the most ancient in England. In every church was a poor-box, the like at great inns.

"Glass windows in churches and gentlemen's houses were rare before the time of Henry VIII.:

in my own remembrance, before the civil wars, copyholders and poor people had none. In Herefordshire, Monmouthshire, and Salop, it is so still. About ninety years ago, noblemen's and gentlemen's coats were of the fashion of the beards' and yomen of the guard (*i. e.*), gathered at the middle. The henchers in the inns of court yet retain that fashion in the make of their gowns."

*Quakers' Meeting-houses, &c.*—After the Restoration the Quakers were much persecuted in London and elsewhere: many were sent to Newgate, which place, an old writer says, instead of being a den of thieves, became a house of prayer. On the 11th September, 1664, the Lord Mayor, Alderman Brown, the sheriffs, and several officers and watchmen, came to the Bull and Mouth meeting (whence, it should be observed, the congregation had before been expelled, and actually held their meeting opposite the door in the street). The Lord Mayor at his entrance expressed himself thus:—"You have been warned many times not to meet here; but, if it please God, I will try whether your obstinacy or the law shall take place." Then he ordered his officers to bring the persons assembled severally before him, and committed eighty-three of them to Newgate for the first and second, and twenty-two for the third offence. Amongst them was Mary Boreman, who, being asked by Alderman Brown what was her name, answered, "You may, instead of my name, write thus,—Afflict not the widow and the fatherless; and then, when you look over your roll, you may see your duty."

*First Methodist Meeting-house.*—About 1740, Wesley preached to many thousands of persons in Moorfields, at Kennington-common, and Blackheath. The first metropolitan chapel of this celebrated preacher was at the "Foundry," in Moorfields.

*Theatres.*—Charles I., observing the continual opening of theatres and other places of amusement on Sundays, passed an Act in the first year of his reign forbidding all theatrical amusements, or any of the inferior pastimes of the people, on Sundays. It, however, appears that, in the latter end of the year 1659, some months before the restoration of King Charles II., the theatres, which had been altogether repressed during the Commonwealth, began to revive, and several plays were performed at the Red Bull, in St. John-street, in that and the following year before the return of the king.

Charles II. granted patents to two distinct companies, — one to Sir William Davenant, and the other managed by Henry Killigrew; the company of the latter received the title of "The King's Servants," and acted at the Drury-lane Theatre: Davenant, that of the duke's company, he appropriated to the theatre in Dorset-gardens. The King's Servants were considered part of the royal household, and about ten of them had cloth and lace allowed to them for liveries. The Lord Chamberlain styled these "Gentlemen of the Great Chamber." It will be remembered that before this reign females were never admitted upon the stage.

*Cock-pits.*—With the following note of a London cock-pit in 1725, we must for the present close these extracts:—"A cock-pit is the very model of an amphitheatre of the ancients. The cocks fight in the area as the beasts did formerly among the Romans; and round the circle above sit the spectators in their several rows. It is wonderful to see the courage of these little creatures, who always hold fighting until one of them drops, and dies on the spot." In a journey through England in the above year it is mentioned,—"I was at several of these matches, and never saw a cock run away; however, I must own it to be a remnant of the barbarous customs of these islands, and too cruel for my entertainment. There is always a continued noise amongst the spectators in laying wagers upon every blow which a cock gives; who, by the way, I must tell you, wear steel spurs, for their surer execution; and this noise seems fluctuating backwards and forwards during each battle, which is a great amusement. . . . If an Italian, a German, or a Frenchman should by chance come into these cock-pits, he would certainly conclude the assembly all mad by their repeated outcries of six to four! five to one! ten pounds to a crown!—which is always repeated here, and with great earnestness, each spectator taking part with his favourite cock, as if it were a party cause."

THE RECENT EXPLOSION, ST. MARY'S, OXFORD.—Mr. Rosser wishes us to say, that the statement, that the gas-pipe was broken "in laying the hot-water pipes, has no foundation in fact."

## ARCHITECTURAL EXAMINATIONS AND THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held on Friday evening, the 23rd ult., at the House in Conduit-street. The President (Mr. Roger Smith), occupied the chair.

The minutes of the last meeting having been read and confirmed, the following gentlemen were, on ballot, elected members of the Association:—Messrs. B. H. Jones, S. H. Vernon, Charles Harris, and — Henry.

The Curators (Messrs. Lewes and Harris) laid on the table a report respecting the property of the Association. The report contained a recommendation that an attempt should be made to establish a lending library of architectural works.

At the suggestion of the President, the report was received, and its consideration postponed until a future day.

### Architectural Examinations.

The President said that the next subject for their consideration that evening was that of architectural examinations. It had been discussed in the public papers, and in their Association; and, towards the close of the last session, the council of the Royal Institute of British Architects had brought it formally under the notice of their members. The council had also prepared the outline of a scheme of examination, upon which they wished to take the opinion of the Institute. A discussion on the subject took place on the 25th of June, which resulted in the passing of a resolution that it was desirable to afford an opportunity for a voluntary professional examination. Beyond this there was no expressed opinion of the Institute, and the consideration of details was postponed. During the recess the Institute prepared a circular, with the view of collecting the sense of the Provincial Associations, in which a request was made that they would consider the main question, and offer any suggestions which might occur to them, either upon the subject as a whole or upon the details. A copy of that circular had been sent to the Architectural Association, but it remained unanswered because it had been received when the Association was not sitting, and because it was considered undesirable to summon a special meeting at a period of the year when it would have been difficult to secure a large attendance of members. The present was, therefore, the first opportunity which arose for entering upon the subject. It might, he thought, be divided into two or three different branches, and it occurred to him that it might be desirable they should lay down a rule as to the specific manner in which they were to discuss it. With this view he would suggest that members who had any observations upon particular points to offer would reserve them until the subject to which they more immediately related should come on for discussion. This would save time, and enable them to arrive at a more satisfactory solution of the questions to be laid before them. He believed that some of their members would be prepared to move and second, in the first instance, a resolution to the effect that the Association agreed in the opinion expressed by the Institute, that it was desirable to afford an opportunity for a voluntary professional examination. This resolution would not pledge the meeting to details as to under what circumstances an examination should take place, and therefore he thought it might be desirable to pass it as an abstract proposition. If, however, any members were of opinion that an examination was altogether inadvisable, this would be the time to say so. But let them in the first instance consider whether it was desirable that there should be any examination at all. The next points would be in what subjects it would be desirable to have an examination, and who should be the persons examined. A second resolution would be proposed raising the question that it would be desirable that the examination should include such and such subjects; and a third resolution would have reference to the persons who should have the conduct of such examinations, for it was important that one of the resolutions should embody a suggestion as to the hands into which the matter should be left.

Mr. Arthur Smith said he was prepared to move the following resolution:—"That the establishment of an architectural examination, under competent authority, might be rendered advantageous to art, and improve the standing of the profession." There could not, he thought, be a second opinion as to the desirability of passing such a resolution; for, when they considered that auctioneers, valuers, and tradesmen, were endeavouring to obtain business which they were wholly incompetent to execute, it became necessary that some protection should be extended to gentlemen who had studied their profession

position of an all-wise Providence, the man and the knowledge were forthcoming to provide for the growing wants of society. On the introduction of railways, it was requisite that a vast amount of mental energy and of physical exertion should be employed, in order to render the development as rapid as possible. Mr. Locke possessed peculiar qualities of mind which secured for him the confidence of capitalists, by whom the construction of the Grand Junction Railway was entrusted to him.

At an early period of the railway epoch he became the engineer of the South-Western line, whence he almost naturally sought for and ultimately accomplished the extension of the system to France; where, in the construction of the Paris and Rouen and Havre lines, he introduced English capital, English workmen, and English contractors, and initiated the Continental railway system. He was thus the first who promoted the establishment of the present rapid communication between the great commercial capital of Great Britain and Paris, the fashionable metropolis of the Continent.

Returning to the field of his early labours, he undertook the extension of the lines from Preston to Carlisle, and thence to Glasgow, Edinburgh, and ultimately, to Aberdeen, thus becoming also the pioneer of the Scotch railway system.

Without entering minutely into the details of his professional life, which would be given in the official memoir, it would be admitted, from what has been stated, that Mr. Locke was entitled to be considered one of the great engineers of the period, and a distinguished pioneer in the introduction of the railway system.

There was a curious coincidence in the circumstances of the deceases of the three distinguished men who had been removed within little more than a year. Each one had departed on the eve of, or at, the completion of some great work. Mr. Brunel might be said to have died as the *Great Eastern* steamer commenced its trial voyage. Mr. Robert Stephenson was taken away on the eve of the completion of the great Victoria-bridge over the river St. Lawrence, Canada; and Mr. Locke's decease occurred on the completion of his long-cherished project—the extension of the narrow gauge line to Exeter, the capital of the west of England.

The President then remarked on the distinctive features which marked Mr. Locke's professional career, especially attention to financial results.

It was not, he continued, that Mr. Locke feared engineering difficulties; for, when they were inevitable he encountered and overcame them with skill; as, for instance, in the works of the Manchester and Sheffield Railway. But his great anxiety, and which secured for him the confidence of a large body of capitalists, was to attain his object by avoiding difficult and expensive works, from a desire that all the works on which he engaged should be commercially successful. The abnegation of professional renown, arising from the construction of monumental works, whilst establishing his reputation as an economical engineer, induced him to turn to the locomotive engine, and to tax its powers (in which he had, from the earliest period, the greatest confidence), for overcoming steeper gradients than had hitherto been deemed compatible with economy and safety. In this he was very successful; and, when viewed in conjunction with the previously-mentioned general features of his professional life, it must be conceded that the decease of Mr. Locke had caused a gap in the profession which would long be felt.

The discussion upon Mr. Scott's paper, "On Breakwaters, Part II.," which was commenced at the closing meeting of the last session but was not then concluded, was continued throughout the evening.

On the 20th ult., the paper read was "On the River Orwell and the Port of Ipswich," by Mr. George Hurwood, M. Inst. C.E.

#### CAMBRIDGE ARCHITECTURAL SOCIETY.

At the annual meeting, a report reviewing works in the county was read. The following notes occurred in it:—

"The Guildhall is fairly settled in its design, and a contract has been entered into to complete it by next October. However we may regret that a good Gothic design has not been carried out, we still rejoice that something is really being done to supply the town with better accommodation than the present rooms afford. We memorialised the committee on the question of style, but without any effect. Among architectural works in the county, of course, Ely Cathedral stands the first. Mr. Le Strange's work on

the roof of the nave has had another year added to it, but is still far from being completed. The planks of the scaffolding have lately been partially removed, so that some idea of the effect may be obtained from below. We do not like to criticise unfinished works, but this certainly promises to be one of the most successful of the kind during modern times. One effect of the work is to give the appearance of increased height to the nave. The tone of the colours is remarkably pleasing, which, together with the masterly conception and bold treatment of the whole, renders it particularly fine."

"The old gateway to the churchyard at Burwell, commonly called the Guildhall, no longer exists. We are sorry to add that such a work of demolition has been carried on in the most legal manner. The Inclosure Commissioners, the Charity Commissioners, the Trustees of the Burwell Charity Lands Charity, the Vicar and Churchwardens, are all implicated in this work of destruction. We much regret that no voice was raised to stop this demolition, because this gateway was the only example of the kind in the county, and as such ought to have been preserved."

"The Dean and Chapter of Ely have an interesting work in hand at Hauxton Church. This is one of the oldest churches in the neighbourhood, and has very many interesting points about it. On taking out the old wooden-framed east window, the fragments of a decorated window were found in the walls, and this has been re-worked in Ketton-stone. On further examination, the jambs of an E E triplet were discovered; and on examining the foundations, the chancel was found originally to have had a semi-circular apse."

"Before concluding this report, your committee wish to lay before you a scheme which has been set on foot for a memorial to the late Mr. A. W. Pugin. The plan proposed is, not to erect a monumental effigy to his honour, but to found Travelling Studentships, which, whilst it forms a valuable plan for increasing the opportunities for the study of architecture, is one founded on his own words. We think that this should meet with the support of all interested in architecture; and we hope that some will be found among the members of the University who have sufficient regard for Mr. Pugin and love of art to give liberally to so desirable an object."

#### COMPETITION: THE LEEDS MECHANICS' INSTITUTION.

ABOUT twenty sets of designs were sent in for the intended new building for the Leeds Mechanics' Institution and Literary Society, and School of Practical Art. The committee have decided in favour of the plans marked "M. I. B. A.," which have been prepared by Mr. C. Brodricke, the architect of the Town-hall. The committee selected Messrs. Perkins & Baskhouse's plans as the second best, and Mr. Shaw's as the third. We shall have more to say on the subject.

#### FOREIGN INTELLIGENCE.

At Plombières, recently, took place the inauguration of the asylum presented to the town by the Emperor. M. Malgras, Inspector of the Academy, presided at the fête, assisted by all the authorities, civil and clerical; the children, and the lady patronesses, &c. During the ceremony it was announced, amid cheers of "Vive l'Empereur," that the Emperor proposed adding a spire to the church out of his privy purse.

At Berlin, on the 5th of November, the statue of Thier was uncovered in the presence of several members of the royal family and most of the ministers. The model for this statue, 9½ feet high, was finished by Rauch. It bears the following inscription:—"To Albert Thier, born in 1752, died in 1825, founder of scientific agriculture, erected by his grateful country."

Explosions of steam cylinders and boilers occur abroad as well as in England. On the 26th October, says the *Echo du Loire*, a drying cylinder in a paper manufactory blew up with a terrific explosion. The accident happened in the establishment of MM. Tonnelier & Co., of La Combe, and caused much damage. The workmen had had a miraculous escape, if they had been but slightly bruised and scalded. The cylinder weighed nearly two tons, and such was the force of the explosion, that two months must elapse before the works can be carried on.

At Antwerp, a few days ago, a boiler explosion took place under singular circumstances. Three brothers, named Retsin, sons of a conductor of that name, proceeded to the *Tête de Flandre* to get up the steam in a small pleasure-boat belonging

to the family. The little steamer being aground on the shore, Louis Retsin landed again, leaving his two brothers to mind the fires till the tide came in. No sooner had he quitted the vessel than the boiler exploded, blowing the boat to atoms. The neighbours all rushed to see what had become of the two lads on board. One was found 10 metres off, mutilated and dead; the other was picked up closer by, severely, though not dangerously, injured. The absence of sufficient water in the boiler is stated to have been the cause.

#### PARLIAMENT BUILDINGS, OTTAWA CITY, C.W.

A CITIZEN of Ottawa writes.—You notice the laying of the corner stone of the Government buildings here, in your number, dated 29th September, 1860, but you are not quite correctly informed. H.R.H. the Prince of Wales laid the foundation stone of the *Parliament* buildings, of which Messrs. Fuller & Jones are the architects. These buildings form one of the longer sides of a quadrangle, the two shorter sides being occupied by the buildings for the Government offices, called locally the "Departmental Buildings," of which Messrs. Stent & Laver are the architects.

The exterior of the latter buildings has been made to harmonize with that of the *Parliament* buildings, which are by far the most important group, and equally ornamental, internally and externally, while the Departmental buildings are necessarily quite plain inside.

It is due to Messrs. Fuller & Jones, as architects to the building honours by the ceremony performed by H.R.H. the Prince of Wales, to make this statement.

I should add that Mr. Thomas McGrew is the contractor for the *Parliament* buildings; and Messrs. Jones, Haycock & Co. have the contract for the Departmental buildings.

#### SOCIETY OF ARTS.

##### INTERNATIONAL EXHIBITION OF 1862.

THE Society of Arts commenced its session on Wednesday, the 21st November, Sir Thomas Phillips, chairman of the council, in the chair.

Sir Thomas Phillips delivered an address, in the course of which he gave an account of the steps which the council had taken in order to the holding of a second Great International Exhibition of Works of Industry and Art, in 1862; and said, in conclusion of this part of his subject:—

"The council have seen no reason to relinquish the conclusion to which they came—that an International Exhibition of 1862 would elicit even more valuable results than were achieved in 1851—if managed with the same spirit and intelligence as its great predecessor. The great expansion of our commerce, as evidenced by the increase in our exports and imports; the former from 71,000,000 in 1850, to 130,000,000 in 1859, and 161,000,000 in the first nine months of 1860; the numerous inventions and improvements in our manufactures; the large increase in population and wealth; the extension of the means of locomotion by the multiplication of railways at home and abroad, and the desire for travel thus engendered; the more intimate knowledge of this country by foreigners; the spread of education; the growth of liberal commercial principles; an increased knowledge of and love for art, will each and all contribute to swell the numbers who will seek admission to the exhibition; whilst the manifestation of the marvellous progress of the last ten years in the staple productions of this and other countries will afford the most powerful stimulus to future improvement. The society may be congratulated on the eminent success which has attended the efforts of the council to provide an adequate guarantee fund. When their intention to promote the holding an International Exhibition in 1862 was first made known to the public, their resolution was regarded by many with apprehension and distrust, but the favourable opinion of the undertaking in various walks of active life afforded satisfactory proof that the council had interpreted aright the feelings of their countrymen. The same motives which animated manufacturers and inventors in 1851 will exist in full force in 1862. Men hitherto but little known will provoke rivalry and challenge competition, whilst men better known and established will not be left behind in the struggle for distinction.

The council therefore not only confidently expect to witness a successful exhibition in 1862, but by the success of that undertaking to ensure the establishment and Royal sanction of periodical International Exhibitions of Works of Art and Industry. The foundation of such exhibitions

DRINKING-FOUNTAIN, ST. GEORGE'S COLEGATE, NORWICH.—MESSRS. BENEST & NEWSON, ARCHITECTS.

as a permanent institution will form an appropriate distinction of the country in which an international exhibition was first conducted with entire success."

We now look for active steps on the part of the council.

#### DRINKING FOUNTAIN IN ST. GEORGE'S, COLEGATE, NORWICH.

This fountain is executed in Portland stone, except the basin, which is in veined marble, supported on an octagon pedestal, and lying in a cluster of water lilies. The octagonal canopy over the basin, with battlements and finial, has water lilies carved on its pendants, and the water issues from the centre of a lily. On each side of the octagon pedestal are arched troughs for dogs. Above the marble basin, and under the canopy, the following lines are engraven in old English characters on a marble slab:—

"Wayfaring man, for thee this fount was given,  
A channel to impart the boon of Heaven;  
Drink, and thank God! and in this water trace  
An earnest of His love, an emblem of His grace!"

Below are the initials of the donor and the date,—  
"J. C. B., 1860." The height of the fountain, to the top of the finial, is 9 feet; and the width, 5 feet. The canopy projects 1 foot 4 inches from the churchyard wall. The fountain was presented by Mr. J. C. Barnham; designed by Messrs. Benest & Newson, architects; and executed by Mr. Joseph Stanley, mason, of Norwich.

#### ALL SAINTS', BOYNE HILL, BERKS.

The church, parsonage-house, and schools at Boyne-hill, are the work of private founders. The original scheme was undertaken by two sisters, and the works were afterwards considerably enlarged by means of a benefaction given to the church.

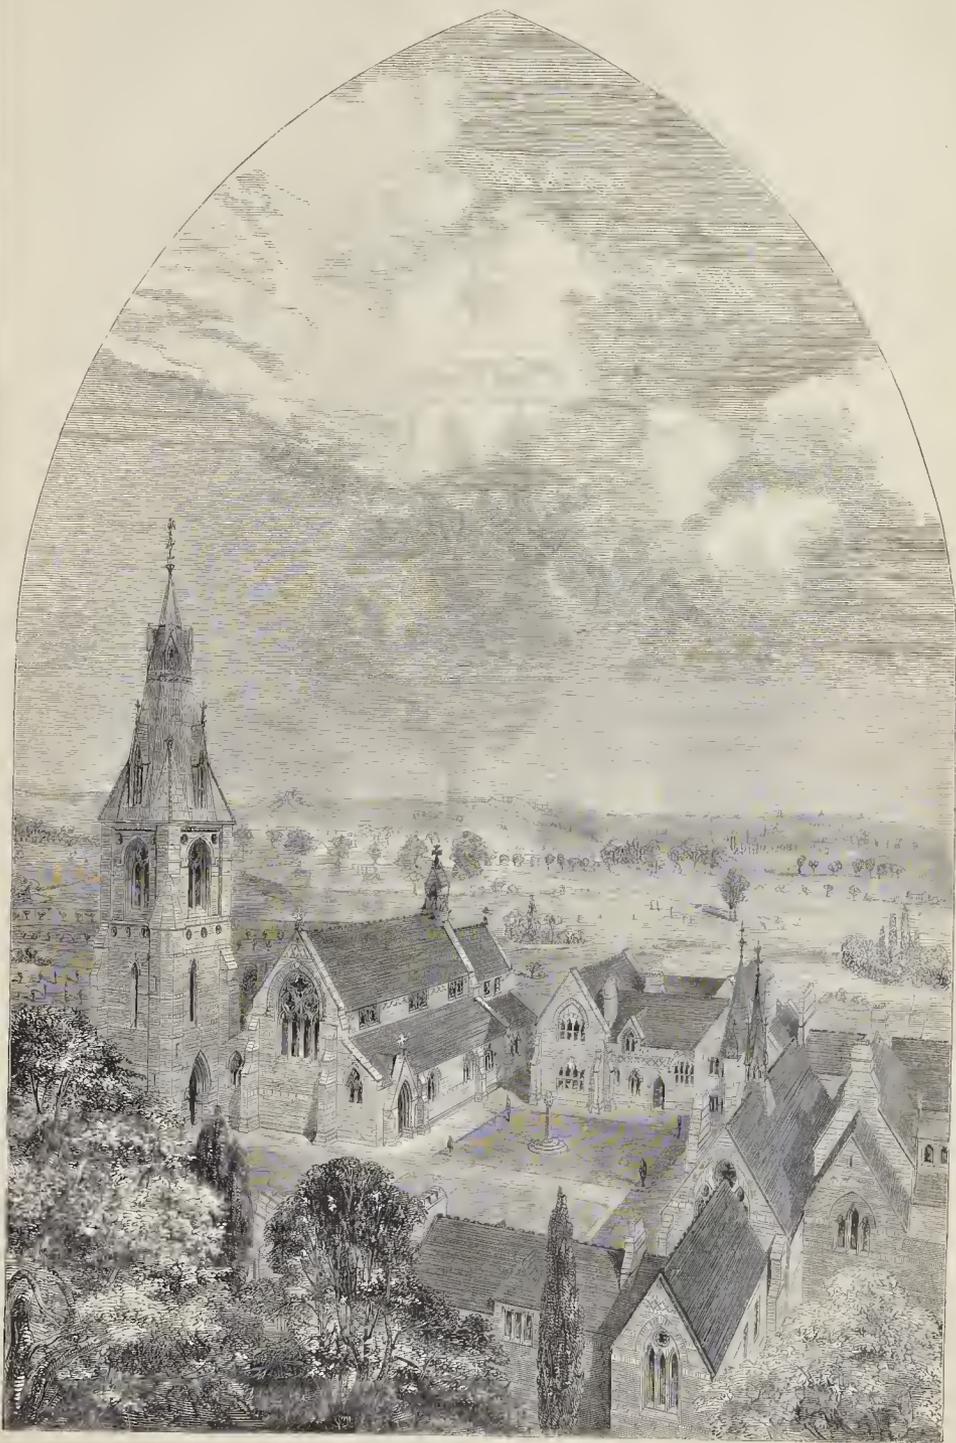

The buildings already completed form three sides of a quadrangle, and the tower and spire shown in our view will, it is hoped, in course of time, be erected. The north side of the quadrangle is occupied by the church. There is a

nave of four bays, with aisles, a chancel, and south chancel aisle. Most of the windows are of stained glass, those at the east and west ends being the work of Mr. Hardman. The interior of the church is finished in the same way as the exterior, with red brick and stone.

The chancel walls are further enriched with coloured tiles, and courses of polished alabaster. In the spandrils of the nave arcade are sculptured a series of "stations,"—subjects, from the Passion of our Lord; these, and the rest of the sculpture, were the work of Mr. Earp. The altar cloths, hangings in the sedilia, &c., are richly embroidered. The chancel screens are of stone and wrought iron.

The parsonage house is on the east side of the quadrangle, and is of considerable size. The south side of the quadrangle is occupied by schools for girls, boys, and infants, and a master's house.

The whole of the buildings, with the sculpture, glass, embroidery, &c., have been erected from the designs of Mr. Street. The church was consecrated by the Bishop of Oxford, in the autumn of 1857.

ALL SAINTS', BOYNE HILL, BERKS.—MR. G. E. STREET, ARCHITECT.

## INDUSTRIAL REFORM.

We are asked to state that the promoters of the Amended Combination of Workmen's Act (22 Vict., c. 34), the Equitable Councils of Conciliation Bill, and other measures, think it desirable a conference of delegates should be held in London, to consider the present state of the statute laws having reference to the settlement of disputes by arbitration, the payment of wages in all trades in the current coin of the realm, and not otherwise,—stoppages from wages under different pretexts,—the unsatisfactory state of the law relating to contracts, and such other statutes as press heavily and unjustly upon the freedom of action among the working classes: and those societies who agree to the foregoing propositions are requested to communicate with Mr. Thomas Winters, of 263, Strand, their secretary.

## IRISH BUILDING NEWS.

The Messrs. Martin have just completed their new shipping offices at the North Wall Quay, Dublin, from the designs of Mr. Charles Geoghegan.

The members of the Unitarian Church in Dublin propose to erect a new house of worship in Stephen's Green; and we understand that Messrs. Deane & Woodward, Lanyon & Lynn, and Raffles Brown, are amongst the architects who have been invited to furnish plans.

The total amount realized up to the present by the sale of the Bray "Commons" is 9,000l. The entire of the lower Commons has been purchased by Mr. O. Kelley Dease, for 1,800l., which amount is included in the above mentioned sum. The parts sold by auction for building lots have gone as high as 1,500l. per acre.

Rathgar, in the suburbs of Dublin, which but twenty years ago contained only a few houses scattered along the roadside, is at present assuming a considerable degree of importance. Four houses of worship are at present in course of erection there; streets are being added; and Kenilworth-square, which bids fair to rival any of the city squares in size and effect, is all but completed.

A new Roman Catholic church is in progress of erection at Rathgar. Plan is oblong, 132 feet by 45 feet in clear, with granite portico in front, and campanile over it. Mr. Byrne is the architect; Mr. Freeman, builder.

The foundation-stone of the new Turkish baths at Sligo was laid a few days ago, by Miss Jane Lyons, eldest daughter to the Mayor of that town.

The Clomel gas-works have been reconstructed by Mr. Anderson, of Leadenhall-street, London, who recently erected the Cork gas-works likewise. His patent system of heating retorts by tar alone is here carried out.

An "Athenaeum," with an exclusively Protestant directory, and "having for its object the moral, intellectual, and social improvement of young men, without religious distinction," has been opened at Dublin.

Mr. Hawkshaw, the commissioner appointed to inquire into the water supply of Dublin, has recommended that the river Vartry should be the source adopted for the improved supply.

Sir John Arnott, M.P., has undertaken, at his own expense and unolicitedly, to erect the necessary works for the supply of water to the town of Kinsale.

A harbour lighthouse is to be erected at the south entrance to the North Wall Quay, Dublin. Mr. Halpin, C.E. (to Ballast Corporation).

Shop-buildings in Dublin is rather brisk just now: old fronts are being demolished, and new ones (some of very incongruous design) erected instead. House-rents throughout the city, north and south, are increasing in value: the streets are being better paved and sewered, and altogether the general aspect is of an improving character.

Tramways are to be laid down by Mr. Train at Cork, from the Passage Railway Terminus on Albert Quay, through the South Mall, the Grand Parade, Patrick-street, and the Lower Glanin-road, to the Great Southern and Western, and Cork and Youghal termini, subject to removal at any period when required.

It is proposed to commence the works of the Derry and Letterkenny Railway forthwith.

The Liffey branch line for goods traffic, from the Midland Great Western Terminus at Broadstone to the North Wall Quay, is announced for contractors to tender for. This line will connect the shipping at Dublin by rail with Galway Harbour.

The Bagenalstown and Wexford Railway Company are about building a station-house and goods store at Ballywilliam, county Wexford.

A station is about being established at Foxrock by the Dublin and Wicklow Railway Company, and the requisite buildings will be commenced immediately, on plans by Mr. Wilkinson, architect.

In the same neighbourhood, at Kill, it is proposed to build a new church. This district is rapidly springing up; green fields are becoming towns, and streams of people have been moving to and fro during the summer months.

The new church at Toghdoo, county Kildare, is being built after designs by Mr. McCarthy, and has nave, 58 feet 6 inches by 21 feet; chancel 18 feet by 15 feet; tower and spire 75 feet high; upper part of timber, slated, at north-west angle, &c. At the east end is a triple lancet window, a two-light ditto at west end, and single lancets at sides. Roof timbers, open and stained. Mr. Beardwood is the builder.

A new Presbyterian church is to be built at Wicklow, after plans by Messrs. Hay, of Liverpool, architects.

## PUBLIC BUILDINGS IN THE PROVINCES.

*Bury St. Edmunds.*—In reference to the proposed new Corn Exchange, "a merchant," says the *Bury Post*, "whose name, if it were given, would command the attention of our municipal body, expressing his pleasure at the proposed erection of a larger market, observes that the consideration next in importance to space is that of light, as to which so many mistakes have been made, that great care should be taken lest it should be deficient. The best Corn Exchange in this part of the country, he says, is that of Lynn, the cost of which was 2,600l. There the entire roof is of glass, which gives all the light required, and that of the best kind. Side windows are objectionable, the light from them being partial. Unfortunately, he remarks, these buildings have often been spoiled for use by over-attention to architectural principles; but the Lynn, Hull, and other markets have proved that all that is wanted is, on the sides, walls of sufficient height; an entire glass roof; and let the architect do as he likes with the ends."

*Aldershot.*—A town-hall, board-room, cloak-rooms, &c., are about being erected in the market over the shops fronting the High-street (to which it has a frontage of 60 feet). This will supply a long-felt requirement of the town. An additional portion of the open area will at the same time be covered in with a roof, partly of glass, to meet the increased demand for stalls and standings. Mr. T. Goodchild, of Guildford, is the architect.

*Croydon.*—At a recent meeting of the Local Board of Health, Mr. Robins, the architect of the Cemetery Chapels, submitted to the Board plans for improving the Assize Courts at the Townhall, together with a plan of the courts as at present arranged. In reply to the Chairman, Mr. Robins said he roughly estimated that the first plan suggested, with the least alteration, could be carried out at a cost of 1,000l.; and his second suggestion, which, in his opinion, was the better of the two, would be about 250l. more. Mr. T. L. Robinson said he had had a good deal of conversation with Sir John Jervis, Baron Alderson, and the Lord Chief Baron, respecting the Assize Courts at Croydon. The late Baron Alderson was said to have the best idea of what an Assize Court should be of any judge of his time. He (Mr. Robinson) had told him that the inhabitants of Croydon were anxious to make their courts available for holding in them an annual assize. His lordship pointed out the various improvements that might be made; and, having communicated with Mr. Robins, that gentleman waited upon him, and he (Mr. Robinson) pointed out to him the various improvements upon which the plans now before the Board were founded. After some discussion the further consideration of the question was adjourned.

*Gravesend.*—The estimates for the harrack buildings to be erected in the field adjoining Lovelace have been sent in to the War Office, and it is understood that one of them has been decided on. The buildings will be situated at the upper part of the field adjoining Christ Church, and will cover a site having a frontage east and west of 383 feet, by a depth, towards the Parrock-road, of 540 feet. The principal entrance will be from Waterloo-street, opposite the Brewers' Arms. The guard-house will be close to the entrance, and the commandant's house about 50 feet eastward of the guard-house. The first contract for the works about to be commenced shortly will be for the accommodation of 300 men, and includes six blocks of buildings for single men and one for married men, besides a lecture-room. A gate at the end of Farrington-street is also marked on the plan.

*Marlow.*—A public hall is about to be erected in St. Peter's-street, Marlow, from a design by Mr. Charles Carter, architect.

*Birkenhead.*—A liberal offer has been made to the township of Birkenhead. Mr. Wm. Jackson, M.P., Mr. Brassey, Mr. John Laird, and other owners of property in Hamilton-square, are willing to give as a site for a town-hall the present gardens in the centre of the square, comprising about four acres or 20,000 square yards of land. The land, taken at its minimum value, is said to be worth not less than 25,000l. or 30,000l. In order that no time should be lost, Mr. Laird has taken upon himself the responsibility of giving the requisite parliamentary notices, in the *Gazette*, of the intention of the commissioners to apply in the next session for an Act conferring upon them powers to erect a town-hall, to purchase land in Hamilton-square, to levy rates and borrow money, and to amend the present acts. A new county court-house and offices are about to be erected at the corner of Pilgrim-street and Chester-street, and the foundation-stone has just been laid. Mr. Charles Reeve, of London, is the architect; and Mr. H. Fisher, of Birkenhead, the builder.

## SCHOOL-BUILDING NEWS.

*Grimsbury (Banbury).*—The foundation-stone has been laid of new schools in Grimsbury. The buildings will be erected nearly opposite to South-place. They are to be of the Pointed style of architecture. The contract for the building has been taken by Messrs. Davis, of this place. The amount of the contract is 1,260l.

*Long Ashton.*—The foundation-stone of new national schools has been laid at Long Ashton. The structure, the cost of which is estimated at nearly 2,000l., will be in the Early English style of architecture, and built of the Pennant stone of the neighbourhood, with freestone dressings and slated roof. It will be upwards of 90 feet in extent, and will comprise a boys' school, 53 feet by 23 feet, capable of accommodating 100 boys; also a girls' school, 46 feet by 18 feet, receiving the same number of girls; with a class-room for each department, and play-grounds, in addition to a dwelling-house for the master and mistress. Mr. J. Wilson, of Bath, is the architect, and the contract for the building has been taken by Mr. Tucker, of Ashton.

*Birmingham.*—New schools, of which the architect is Mr. Yeoville Thomason, of Birmingham, are about to be erected in connection with and adjoining the Congregational Chapel, Francis-street, Edgbaston. The foundation-stone has been laid. The new buildings will be in harmony with the architecture of the chapel, and will comprise a Sunday school (adaptable as a lecture-room), infants' school, and the usual rooms and offices. The larger school-room will accommodate 300, the smaller about half that number. The cost, exclusive of internal fittings, will be about 750l.

*Huyton (near Liverpool).*—A new school, with class-rooms and offices, to serve also as a lecture-room, to seat 300 persons, is about to be built in connection with the Congregational Church, Huyton, and at the sole expense of Mr. A. B. Walker, of Huyton-park. The buildings will cost about 800l., and are to be erected according to plans prepared by and under the superintendence of Mr. H. H. Vale, architect, Liverpool, selected in a limited competition (the unsuccessful competitors also being remunerated). Mr. R. Barker, of West Derby, is the contractor. A new organ, we may here add, is to be placed in the church, and the committee also contemplate the erection of a tower and spire, from designs by the same architect.

*Great Horton.*—The inauguration of the new National Schools at Great Horton has just taken place. These schools have been built from the designs of Mr. Samuel Jackson, architect. The style is Decorated Gothic. The building comprises three schools, namely, one for boys, another for girls, and a third for infants. Each school-room measures 60 feet by 20 feet, and each has a class-room, 17 feet by 14 feet, and a separate entrance. The schools are in the  $\perp$  form, the horizontal stroke being the front; and by movable partitions the three rooms can be thrown into one. They are heated by means of hot water. The roof of the schools is open, the wood being stained. At each end of the schools is a house, with three rooms on the ground floor, as residences for the master and mistress. There are two play-grounds.—The Primitive Methodist body at Great Horton have begun a new Sunday-school on a piece of vacant land, in the rear of their chapel, at Town End, Great Horton. The building is being erected from the designs of Mr. T. C.

Hope, architect. The building will be divided into a school-room, 40 feet by 27 feet, with gallery at the end, arranged to be used as a platform for public meetings, or for the infants; two classrooms, 11 feet by 10 feet 6 inches; and an infant class-room, 17 feet by 15 feet, with gallery at the end. The large school-room will be 16 feet high from the floor to the highest part of the ceiling, which will be in the form of a flat segment. The ceiling will be plastered, and divided into panels by curved moulded ribs. A ventilator will be fixed in the centre of each panel, communicating with the false roof, from which the foul air is carried away by means of two ventilators in the ridge of the roof, and one in the side gable. Fresh air will be admitted from the windows, the upper halves of which will be made to slide. The school will be heated with hot water, and the class-room by fires. The elevation will be in the Tudor style of architecture, having circular-headed windows and ornamental gables. The principal entrance will be in the centre of the end gable, having moulded architrave and raised quoins alternately. The following are the several contractors:—For the excavators and masons' work, Mr. John Priestley; joiners' work, Mr. Thomas Taylor; plumbers' work, Mr. John Schofield; plasterers' work, Messrs. J. and M. Bolton; painter, Mr. Hird; heating apparatus, Messrs. Jennings & Stott. The total cost of the building will be 450*l*.

**Hilgay (Norfolk).**—A new school was opened at Ten-mile Bank, Hilgay, on the 5th inst., through the liberality of the rector, Rev. W. J. Parkes, who has borne the expenses. It is of white brick, with stone and red brick dressings, and stone coping to gables, and will accommodate about ninety scholars. A louvred spirelet is constructed in the centre of the roof, in which the bell hangs: the roof is open and stained. The style is Italian Gothic, of a plain character. Mr. W. Lawrie, of Downham Market, was the architect; and Mr. Jno. Smith, Littleport, the contractor.

#### STAINED GLASS.

**St. Giles's, Cripplegate.**—The old church of St. Giles's, Cripplegate, has recently had put in two painted glass windows by Messrs. Rees & Baker, of London. The subjects are St. James, and the Evangelist St. John. They are enameled with decorated backgrounds, and are the gifts of the churchwardens.

**Felmersham Abbey Church.**—Five painted glass windows have been erected at the west end of Felmersham Abbey Church, near Bedford, by Mrs. Pain, as a memorial. The windows were executed by Messrs. Rees & Baker, of London. The chief subject is the Resurrection of our Lord, which forms the centre. Two side openings have Christ at Emmaus, and the Incredulity of St. Thomas. The two extreme side openings contain figures of the evangelists; the whole inserted in geometrical forms, with emblems. The backgrounds are filled in with clustered foliage, carried out after the same manner as the colouring to the large south transept window of St. Saviour, Havestock-hill, executed by the same artists, three years since.

**Aylsham Church.**—A stained-glass window, the gift of Mr. R. W. Parmeter, one of the churchwardens, has been placed in the east end of the north aisle. The subject is the Ascension. This makes the thirteenth coloured window placed in this church within the last twenty years.

**Louth Parish Church.**—In the design for the new east window of this church, by Messrs. Clayton & Bell, of London, the lower seven lights represent the principal events commemorated in Passion week, and are intended to show our Lord's Humiliation. The central light is filled with the Crucifixion: the figures immediately on the right of it exhibit our Lord before the High Priest; the next one the Denial of St. Peter; the side one our Lord before Pilate. The compartment on the left of the central one is filled with the Betrayal; the next one the Agony in the Garden; and the side one our Lord washing his Disciples' Feet. The upper seven lights represent our Lord's Glorification; and the central figure exhibits the Descention. The next two lights on the right show our Lord's Charge to St. Peter; and the western one, the Transfiguration. The two lights on the left of the central one are occupied with the Confession of St. Thomas, and the eastern one represents St. Mary Magdalene washing our Lord's Feet. The tracery in the upper part of the window is occupied by angels bearing shields with emblems. Through private subscription, the tracery, the two central, and the four side lights will be executed at once, and it is

anticipated that before many months are over sufficient funds will be raised to warrant the completion of the design by filling in the remaining eight lights. The entire work will, it is estimated, cost about 900*l*.

**Hereford Cathedral.**—Subscriptions were lately solicited by Archdeacon Freese to enable him to erect some suitable memorial to the late organist of the cathedral; and sufficient sums have been promised to defray the cost of the coloured glass now erected in the small window in the north aisle of the choir. It consists of eight medallions, containing representations of some early musical celebrities, the intervening space being filled with a simple pattern of a cross intersecting a circle in red and blue. It was executed by Messrs. Clayton & Bell, of London.

**Bedale Church.**—A memorial window has been erected at the west end of the north aisle of this church, by the Rev. J. J. T. Monson, M.A., the rector, in remembrance of his mother, the Hon. Ann Shepley Monson. It is in two compartments. The subjects are:—"Cast thy bread upon the waters, for thou shalt find it after many days;" "Her children arise up and call her blessed, her husband also and he praiseth her;" and at the top of the window, "The righteous shall go away into life eternal." Mr. Wailles, of Newcastle, was the artist.

#### ROMAN CATHOLIC CHURCH BUILDING NEWS.

**Farm-street, London.**—A chapel in honour of the Blessed Sacrament has just been erected from the designs of Mr. Henry Clutton. It stands upon the site of the chapel which was burnt down last Easter twelvemonth. The roof is groined, with ribs running parallel to each other, which rest upon a carved cornice, breaking around the marble columns, which are placed below the principal ribs. The work is executed in Caen stone. The east end is occupied by some French tracery, the design of which appears to be somewhat marred by the narrowness of the chapel. At present spaces are vacant, but we presume they are to be filled with frescoes or paintings. The walls are lined with polished alabaster, broken up by inlaid work. The chapel opens into the sanctuary through a colonnade of marble shafts, which forms a kind of sedilia, the caps of which are carved with considerable power and taste. The altar is composed of marble. The whole of the building has been carried out by Mr. Earp, of Lambeth. A heavy expense has already been incurred, and the work is still far from being complete.

**Chelsea.**—Contemporary with the above, another chapel for a similar purpose has been erected at the Roman Catholic Church, Chelsea, and will, we believe, be opened on the same day. It is from the designs of Mr. Welly Pugin. The chapel is divided into three bays, with groined intersecting ribs, having carved bosses at each intersection; the principal ones representing the Sacrifice of the Mass, the Resurrection, and the Virgin seated on a throne surrounded by angels. The ribs are supported on elaborately-carved caps, which terminate eight Galway green columns, rising from a polished alabaster base. The walls are formed of Sicilian and Devonshire marbles. The chapel is lighted from four hexagonal tracery windows, which break into the upper portion of the groin. The altar is a highly-finished work, in the centre of which, and standing immediately above the altar, is the tabernacle of polished alabaster, inlaid with spars and other coloured marbles. The cresting round the arch is formed of passion-flowers, interwoven with conventional foliage. Above this is a throne for the reception of the monstrance, round which, and forming a canopy too, is a vesica of angels, adoring and holding instruments of the passion. In the centre of the panel will be an I. H. S. in embossed metal-work, with rays and stars. The cresting is formed of angels interwoven with leafage. The upper portion of the reredos is supported by marble and porphyry columns, between which are carved clusters of foliage. The side panels are also adorned with angels. The principal portion is worked in alabaster. The altar frontal is wrought in Caen stone, the chief subject being the Adoration of the Lamb. The metal-work, we are told, is being executed by Messrs. Hardman. The chapel is connected with the present church by means of an areading supported by marble columns. The work is executed by Mr. Farmer, of Mead-place.

**Donegal.**—The New Roman Catholic Church of St. Johnston, county Donegal, of which we gave a view in a previous volume, is to be dedicated on the 9th instant. The entire length of the church

is 109 feet 5 inches, and its greatest breadth 56 feet 5 inches, and from the ground-floor to the apex of the roof the height is 50 feet. Its principal light is obtained from tracery windows in the four gables or extremities of the cross. In the interior the chancel arch forms an important feature, the central part of which rises from pillared corbels of marble, with sculptured heads of the apostles St. Peter and St. Paul. The arches leading to the side chapels, which are placed in the north and south transepts, have plain soffits, relieved with polychrome. From the chancel-arch five steps of polished stone lead up to the high altar, which has sedilia, piscina, credence-shelf, ambray, and reredos. The altar is built of Caen stone, and rests against a reredos of the same material, from the atelier of Messrs. Barff & Co., Dublin. The panels of the altar and reredos are enriched with mosaic and enamel work, containing suitable monograms and ecclesiastical emblems. The reredos is divided into seven compartments, the central one rising higher than the others, and forming a canopy over the tabernacle, terminating in a cross. All the windows are filled in with tinted cathedral and stained glass, in lead sashes. The stained glass has been all supplied by Messrs. Barff & Co. There is some carving on the spandrels and corbels of the west window, executed by Mr. Doherty, of Derry, a native artist. The entire masonry and tiling of this church was executed by a builder from the parish, Mr. Samuel McIlwee, of Carrigans. This church has been erected after a design by Mr. E. W. Godwin, architect.

#### THINGS WHICH OUGHT TO BE SET ABOUT AT ONCE.

A NEW street from the open space in Fetterlane eastward, down Stonecutter-street to the intended railway station on the Fleet prison site, over Farringdon-street by a viaduct. This, in connection with the proposed new street from Covent-garden to Carey-street, would take most of the West-end traffic to the new Kentish railway. A further improvement might also be effected by a short street from Newgate corner to the station.

The canal bridges over the canal in the Regent's-park and the Harrow-road have become a nuisance from their narrowness; and if the company cannot be compelled to rebuild them to meet the wants of the public, the parishes might, at a very moderate expense, take down the parapet walls, and carry a footway over the sides on iron brackets (notwithstanding a gentleman with an eminent name has pronounced against this plan at London-bridge). This question, in St. Pancras, seems to have died away. If the Canal Company are bound by their Act to keep the bridges in repair, I think that by law or equity they are bound to build new ones when the old become insufficient for the traffic over them.

The removal of the iron gates and railing in Harwood-place, Oxford-street, which would relieve the blockade of carriages at the Circus, and improve the property in the square.

Also the throwing back of the railing in front of the church in Langham-place to the first step, the ugly bosses of the hinges having been planned apparently to meet the eyes and nose of the passengers over the narrow footway.

Queer,—as to the new subway scheme, which has been begun in King-street, Covent-garden,—where is the money to come from? Q.

#### THE USE OF DRAWING TO WORKMEN.

A LECTURE on "The Use of Drawing to Workmen in the Building and other Trades" was delivered last week in the hall of the Mechanics' Institution, Otley, by Mr. Walter Smith, Master of the Leeds School of Art. After bringing before the notice of the audience some cases where drawing would be of especial use to workmen, and quoting from the *Builder* of November 3rd cases where the absence of the power acted prejudicially on the skilled workman's prospects, Mr. Smith concluded by saying that,—

"There was a grand old lesson taught us, in words which we often hear, and generally interpret in a very narrowed significance. They are these:—'Fight the good fight of faith.' I regard this as a sublime precept, because all really good work must be done in faith; and it is oftentimes a hard fight and a long one before we can see the result of our faith; but still it is pre-eminently a good fight. We will apply this precept to the conduct of a workman. The public, through the medium of the master, will pay an ordinary workman for his work, which he can do well or ill in the proportion of his faith. Every workman in this room at present knows that he could do his work in such a manner as would satisfy his master; and yet, if he choose to do so, he might scamp it and sliver over bits that are out of sight, and no one be the wiser. He

will be paid for his work as well as if he took infinite pains over it; and this is the galling part of the matter, and the point where the honest workman must fight the good fight of faith. His good work may be hidden in the middle of a stone wall, if he is a builder, or hidden away in the foundation of a house; but still his faith in good work must compel him to put the best work he can possibly execute in the hidden places as well as those open to the eye. It is the duty of the workman to do rather better work than he is paid for than worse, and it is his interest to do more than is expected from him than less. But this is a hard battle, for very many workmen do less than is expected of them, and not of the best quality, which men also get as well paid for, and are apparently thought as highly of, as the good workmen who do rather more than they are paid for. Here, however, let me urge you to fight the good fight of faith. Have perfect faith that, sooner or later, you will be the better for your conscientious work; or, to use an old saying, your corn will be measured to you in your own bushel. You will be casting your bread upon the waters, but it will return to you after many days.

A belief in this principle of action will lead you to employ all the means in your power for making yourselves good workmen; and, amongst other means, this one of drawing in cases where, as I have shown you, it would be useful. If it makes you, as I have tried to convince you, better workmen,—if it gives you a higher interest in your work than you previously had, and infuses into your labours a nicer taste, a greater discrimination between good and bad work, and encourages you to strive after improvement and perfection, it will do you a kindness, and amply reward the pleasant task of becoming proficient in the art."

SCHOOLS OF ART.

*The Southampton School.*—The annual prizes have been distributed to this school at the usual public meeting held for the purpose. The mayor presided. The master's report stated that "the school continues to extend its sphere of usefulness in this town, and in the towns of Romsey and Ringwood, where branches have been established." Of this, however, we have already spoken. The report also stated that, in the examinations, "hitherto those reaching 'good' have been rewarded with prizes; but, in pursuance of a notice issued by the Department of Art a year ago, the standard is now much higher, and 'excellent' must be reached in order to obtain a prize. 'Good,' however, is registered towards a prize studentship, and a certificate is given to the candidate. In the first, or lower grade, the exercise is of a similar kind, but much easier; and those who pass in this grade receive certain useful articles, such as a small drawing-board and T square, &c." The mayor distributed the prizes.

*The Wolverhampton School.*—It has been announced that this school will not be closed, as was expected, but will be carried on as usual.

*The Bath School.*—The distribution of prizes in this school has also recently taken place. The attendance was not large, and among those absent were several of the successful competitors. The mayor presided. The financial position of the school, he stated, was not so favourable as on the former occasion when they met; and it might become necessary that an appeal should be made to the public for support. No great amount would be required, for he believed that 40l. or 50l. would be sufficient to place the school on a firm footing. The Rev. E. D. Tinsling said that the school was hardly sufficiently appreciated. He saw by a paper on the table that there were seventy-seven students in the school at the present time. The ladies' class consisted of twenty-four; the mechanics', forty-five; and another class, held in the afternoon, eight. In addition to these there were nearly 800 children of the poorer classes taught in the different schools, including the Blue Coat, the Bathfurn, the Widcombe, and other schools in the city. He remarked that out of the 100 national medallions that were distributed through the kingdom, Miss Margaret Elmer had been successful in gaining one; and also mentioned that at the last examination as many medals were taken by students in Bath as in Liverpool, and more than in Bristol and some other places. The rev. gentleman distributed the prizes.

*The York School.*—A *conversazione* has been held in connection with the distribution of prizes to this school; Colonel Smyth, M.P., in the chair. There was an exhibition of drawings from the Shepherds' collection, at Kensington Museum, lent by the Art Department. The committee's report congratulated the meeting on the steady progress of the school. The average monthly attendance this year has been 147 instead of 134, was last year. At the last examination, 63 were decreed prizes, eight local medals, and one a national medallion. The payments by pupils amounted to 134l., being an increase of 18l. on the fees of the preceding year. The public school fees amounted only to 10l.; and, although this was a slight increase on last year, it must not be forgotten that other towns of smaller population obtain much greater sums from the same

source; Darlington, with a population of 12,000, receiving 32l. a-year, and Stourbridge, whose population is less than 8,000, as much as 65l. The subscriptions were 89l., being a decrease of 3l.; these have rarely been so low as at present, the average for many years being about 95l. The total income amounted to a balance of 12l., while the expenditure has been 251l., leaving a deficit of 9l. due to the treasurer. The committee earnestly appeal to the gentry, and the manufacturers of York and the neighbourhood, to strengthen their hands by giving them increased funds, so as to make the school thoroughly efficient for the object for which it was established.

DESTITUTE INCURABLES.

ALLOW me to introduce to your notice the following paper, which was read at the late Glasgow meeting for the Promotion of Social Science, on the subject of the Destitute Incurables in Workhouses. The scheme therein proposed was devised by a lady of much experience in workhouse visiting, and is no mere piece of speculative philanthropy, but a simple and practical expedient for mitigating the sufferings which none but hard hearts would refuse to alleviate, if they could only see how to do it. If you, who always hold out a helping hand to all practical schemes of usefulness, can do anything to promote this, it will greatly oblige those who have the matter at heart.

SIGMA.

"\*\* We have not room for the paper, which has already appeared in several quarters, but would gladly advance its objects. Rightly the estimable author of this paper says:—

"There needs no laboured appeal to convince us that the horrors of a death of dropsy or cancer need not the evils of poverty and destitution to aggravate them. The question is, what provision have we made to meet all this wretchedness? The answer is sad enough.

For curable patients we support 279 hospitals and infirmaries (besides dispensaries) open to every known malady, in every town in the kingdom.

For the incurables—for those whose diseases are the most agonising which human nature can endure, and who have not even the consolation of hope to support them—we have provided one hospital. For some 20,000 or 30,000 sufferers there are precisely 112 beds.

Of course the result of this state of things is, that the actual asylums for the destitute incurables in England are the workhouses."

The plan suggested is this—

1. That paupers suffering from acute and distressing diseases—such as dropsy, consumption, and cancer—should be placed, in each workhouse, in wards especially allotted to them, to be called the Wards for the Male and Female Incurables.

2. That in these particular wards private charity be permitted to introduce whatever may alleviate the sufferings of the inmates.

The granting of these two articles alone would secure a blessed change in the circumstances of these sufferers. Beyond physical comforts, the plan urged would obtain for the patients what they need even more perhaps than any such things, the consolation of the occasional presence of compassionate fellow-citizens.

BUILDERS' BENEVOLENT INSTITUTION.

YESTERDAY (Thursday, Nov. 29), this valuable Institution held its sixteenth election of pensioners at the London Tavern, Bishopsgate-street, Mr. George Plucknett in the chair.

The Chairman, in opening the proceedings, said, he found the list contained the names of eighteen candidates who were desirous of receiving the benefits of their excellent Institution. He was, however, sorry to say that from the want of funds, out of so large a number of applicants, they would only be able to elect two. All the cases were urgent and equally deserving, and called forth their warmest sympathy. He, therefore, regretted that they were enabled only to elect so few; but the position of the Institution was now most encouraging, and he hoped that the time was not far distant when most of the applicants who were before them that day would be entered as recipients of their funds. He believed from the progress they were making that that was not too much to anticipate. He found that they had elected since the establishment of the Institution, twenty-eight males and thirteen females, and he trusted that their funds would soon be in such a position as to meet the necessities of all the applicants.

The election was then proceeded with, and at the close of the poll Robert Clements, a builder and contractor for thirty years, was announced as the successful male candidate; and Sarah Cain, widow of a builder, the successful female candidate.

Mr. Joseph Bird, in the absence of the Chairman, said he regretted exceedingly that he had

not the pleasure of announcing more successful candidates than the two now elected; but he hoped that, by May next, by the careful doing out of the funds, with the well-known economy of the directors and officers, many more would be added to the list.

Mr. George Bird (treasurer), expressed his dissatisfaction at two only being elected out of eighteen of their poor and distressed brethren, leaving the remaining sixteen to go away despondent. He had laboured hard in the cause of the Institution for thirteen years, and found it all up-hill work. They had received no legacies, and none of their affluent or richer brethren had ever come forward with 100l. He therefore, in June next, intended to retire from his official duty, in favour of some gentleman who had more time on his hands, and probably greater favour.

Mr. T. Cosens, the founder of the Institution, spoke in a very cheering manner of their progress, which before the close of the year would be plainly seen.

The usual vote of thanks then closed the proceedings.

THE STAGE.

*The Lyceum Theatre.*—Madame Celeste has not been quite so fortunate in obtaining good pieces as she deserves to be. This remark, however, does not apply to "Adrienne, or the Secret of a Life," in which this admirable actress has an opportunity to display her peculiar ability to much advantage. Mrs. Keeley, too, always fresh, genial, and forcible, Mr. George Vining, and Mr. Neville, have also good parts. The duel in the mist, and the last scene, amongst the mountains, are very effectively arranged and painted. A delineator of Irish character new to London, Mr. John Drew, appears to be very successful in "Handy Andy."

*Gallery of Illustration, Regent-street.*—This Gallery is now occupied by Signor Poletti, a conjuror, or "illusionist," as the term now is, who performs a number of feats very neatly. Some of his tricks are quite as incomprehensible as the doings of the spirit-rappers, who, to the disgrace of our age, are still turning the heads of men and women who ought to know better. All that we hear of the proceedings is had and worthless; but the results in some cases have been so serious, and the evil is so widely spread, that authoritative steps should be taken to sift the matter to the bottom.

LECTURE ON "CO-OPERATION," BY MR. W. CHAMBERS, THE JOURNALIST.

An interesting and important lecture on this subject has been delivered by Mr. William Chambers, in Edinburgh, at the request of a large body of operative printers and book-binders there. The *Scotsman* of 20th November, gives a report of it, from which we quote.

Of all the systems hitherto fallen upon for improving the condition of the operative body, Mr. Chambers remarked, none was open to fewer objections, nor so likely to be attended with such marked success. He then referred to the failure of fanciful schemes, such as Communism and Socialism, and observed that the arrangements he proposed to describe had no such lofty aspirations, and had nothing to do with politics, neither did they at all interfere with religious belief. They took from no man his individual character, but, on the contrary, added to his personal responsibility, and made him feel that there could be no improvement in his condition without a certain measure of self-sacrifice. After quoting the opinion of Lord Brougham in favour of co-operation, the lecturer proceeded to describe its simple form, which aims only at the setting up of a store, such as formed the basis of the gigantic associations of Rochdale; and he remarked that, should the workmen of Edinburgh even go no further than that rudimentary condition, and take full advantage of it, a very great benefit to each and all of them would be the consequence. In his narrative of the progress of the Rochdale Society, he showed that it began in 1814 with only 25 members, and it had now 3,360 members. As illustrating its enormous progress, he gave the following comparison of its position in 1845, when its first balance was struck, with its position in 1859:—

Number of members .....	1845.	1859.
Amount of Funds .....	74	2,793
Business done .....	2,151	27,656
Profit made .....	710	10,412
	32	10,739

Nearly 11,000l. had thus been saved in one year by a body of working men, simply by buying things at a co-operative store instead of at shop

According to information he had just received, there were twenty-four members who held 100% of stock, while a considerable number had from 50% to 90%. Co-operative societies of one kind or another had now spread in all directions, but more particularly in Lancashire and Yorkshire. There were several in Scotland, and probably altogether about 200 in the United Kingdom. With respect to the moral and social consequences in Rochdale, he had been informed by one of the clergymen of that town that the co-operative societies had been of the greatest possible benefit in promoting self-respect, provident foresight, habits of temperance, and domestic comfort. It would seem that the whole factory population of South Lancashire and the West Riding of Yorkshire were becoming sensibly alive to the benefits of co-operation. A list had been published of thirty-one co-operative manufacturing companies either wholly at work or in progress of organization. Co-operation might therefore be called a truly gigantic movement, of which no man could as yet see the end. There was much less to surprise us in the wish to form these great co-operative concerns than in the capacity to organize and manage them with sound discretion. The Rev. Dr. Begg moved a vote of thanks to Mr. Chambers, which was cordially responded to. The lecture is to be printed.

#### SURVEYORS.

SIR,—If a surveyor wishes to connect himself with his profession, what institution or society is there that he can join?

An architect becomes a member of the R.I.B.A., a civil engineer of the Inst. C.E. Now I am neither an architect, nor do I pretend to call myself a civil engineer, although perhaps qualified to do so. There is a large class of men holding positions as surveyors to corporations and local boards of health, and others engaged in private practice; and it would be most desirable if they had some recognised head.

X. Z.

#### THE ARCHITECTURAL EXAMINATION QUESTION.

SIR,—It appears that at a late meeting of the Liverpool Architectural Society, of which I first saw a report in your columns, a letter which I had written to the president was commented upon as involving an inconsistency, in my regretting the absence, in the proposed architectural examination, of a test which I yet, according to the interpretation of the critic, held to be impracticable.

It would have been more to the point to have disproved my assertion that the Fine Art of Architecture is its essential element; as, until this, which I unhesitatingly reiterate, be negated, there can be nothing inconsistent in doubting the efficacy of an examination in architecture which will not embrace this its real essence.

The letter in question, in passages not included in your quotations, gave, I think, a sufficient explanation of my meaning; as I there stated that the course for architectural students in the Royal Academy seemed to me better fitted than that proposed by the Institute to test their powers of design; and that I thought the diploma work required from members of the Academy came nearer to a suitable ordeal for the matured artist than what is proposed as "the higher examination."

I question in no degree the value of the knowledge of which the proposed elementary course would afford some test; but it seems to me that it might be creditably passed by those who could never afterwards by any skill in design establish a true claim to be considered architects, and that others might fail on most points of such an examination, while possessing powers sufficient to gain them rank among true artists in this walk.

Unless the practice of architecture without a diploma be made penal by statute, a surely impossible contingency, I cannot think that the scheme proposed will accomplish its professed aim. John Martin was never even an associate of the Academy of Arts of his country, but his works contribute to that country's fame; nor do I believe that the lack of a diploma from the central body of British Architects could prevent the frequent recognition and employment of obscure architectural talent by those who can appreciate it, and, in so far, the defeat of the object of such diploma; and, on the other hand, there is the certain danger under such a system that the prestige of licensed mediocrity may raise an additional barrier to the engagement of unobtrusive genius for the direction of works of the kind and importance which place the selec-

tion of their architect beyond the range of individual judgment.

These considerations lead me to the opinion that the adoption of the course proposed would be "an attempt to systematize too far," and that a middle course, somewhat such as sketched at the close of my letter, and quoted by you, would prove more efficient and more advisable.

II. P. HORNER.

In response to the invitation in a late number of the *Builder*, I venture to offer some suggestions on the above subject; for, if the wise propositions of the Institute are not generally acceptable, as yet they are but propositions, and therefore susceptible of modification.

The first modification submitted by the council is, I think, unsatisfactory; and I would suggest the substitution of the following, as more in consonance with the previous announcement, viz. ;—

"That it is desirable to establish a compulsory professional examination in January, 1866, for all who shall present themselves for election after that date as members of the Royal Institute of British Architects."

"That an elementary examination be established for students (adopted so far as drawing is concerned at the Academy), a higher examination for associates, and a complete examination for fellows of the Institute."

Supplementary to this proposition I would suggest the immediate establishment of the proposed board of examiners, who should be empowered to grant certificates of competency to any member of the Institute desiring to receive that distinction, in the interim, by submitting himself to a voluntary examination.

As a consequence of the adoption of the proposed compulsory examination, the extension of the second proposition, to include the provision of special classes for the students, and other educational advantages, seems inevitable; and further, while it is desirable that the leading men in the profession should take the lead in the contribution of papers to be read at the ordinary meetings, the junior members should be encouraged to do the same. The premiums and medals of merit presented by the Institution of Civil Engineers are chiefly presented to the authors of the various papers read thereat, which has the effect of stimulating emulation to excel in the production of papers worthy of that distinction, and thereby lending additional interest to the ordinary meetings of the Institution.

E. C. R.

#### DESIGNERS FOR STAINED GLASS.

In your impression of the 10th ult., a correspondent addresses you on the subject of competition for stained-glass windows: his suggestion is a good one thus far, that persons wishing to have a good and artistic design should throw the same open to public competition; because it is just the want of the competition of design (for which, in the few instances where competition is resorted to, has been substituted the competition of price), that is the cause of the miserable trash, in the shape of painted windows, which we see daily created, to the disfigurement rather than the adornment of our sacred edifices.

A good stained glass window is, without doubt, a work of very high art; but in how very few modern windows do we see even a trace of art.

A designer for stained glass must be a man who is more than simply an artist, as witness the failures of Sir Joshua Reynolds, West, &c. He must have a perfect knowledge of architecture, and be thoroughly acquainted with the style and character of drawing in the works of art of the various periods from the twelfth to the sixteenth century. A searching and conscientious study of the master works of these centuries is of the first importance, because the bad copies of had specimens of these periods, which are in general circulation, give no idea of the real merits and beauties of the really artistic works of the time. He must also be well acquainted with the mechanical parts of the cutting, painting, and leading together of the glass, in order that the execution of his design may be practicable.

There are many men in this country who are thus qualified, and whose abilities competition for tend in a great measure to put a stop to the degrading system of copying German prints on glass at so much per foot; or rather, at so little, that the mechanics' wages, nor allow, even then, more than a limited time for making designs.

One of the worst consequences, however, of the present system is, that the art of glass-painting having degenerated into a trade, a person of vulgar taste who wishes to present a window to a church, not content with choosing his subject, will very

often dictate the whole arrangement, or change, to his own ignorant fancy, the drawing or coloring of the design. Imagine a retired butcher endowing a church, and insisting on his own bullock's-head ideas being carried out in the erection of the building. Would the architect submit? No! nor would the artist in stained glass. But the manufacturer of stained glass windows is obliged, because if he do not another will.

Under these circumstances how is it possible that the majority of windows placed in our churches and cathedrals should be other than a disgrace to the artistic taste of the English people?

I, therefore, approve your correspondent's idea, as I said in commencement, to a certain extent; but his notion that two or three artists, whose designs might be chosen for different good qualities, should combine together, one putting his idea, another his drawing, and a third his colouring, appears to me a very singular suggestion; as, in the first place, I doubt if you would find any artist to agree to it; and, in the second place, if you did, you would certainly make a miserable jumble, of which none of the parts would harmonize.

In conclusion, I would observe that with reference to any remarks I have made as to the present system of designing and executing painted windows, I do not of course apply them generally; on the contrary, there are several well-known establishments which produce good and artistic works, but these works are the exceptions, not the rule.

PETER.

#### THE VENTILATION OF HOUSES.

I DESIRE, with your permission, to offer one or two remarks on this important subject.

My experience has certainly been unfavourable to the Arnott valve, under circumstances perhaps different from those under which your correspondent "W." made use of it. In a comparatively small room lighted with gas I have found it necessary to remove an Arnott valve, because, whenever the gas was alight without a fire, and sometimes even when the fire was burning, the action of the valve was liable to become reversed, and sooty particles or smoke were drawn into the room. I have since tried a Sheringham valve in the same room with decided advantage. This valve is, as your readers are probably aware, one to be fixed in an external wall to admit the outer air, which it directs upwards against the ceiling. The Sheringham is less likely than the Arnott to become clogged, and consequently one can almost always depend upon its closing when a current commences to act the wrong way. I believe, therefore, that a Sheringham valve and an Arnott valve combined in the same room would form a very complete, safe, and simple system of ventilation, especially if the Arnott be cleaned occasionally, as your correspondent "W." suggests.

Years ago the Society of Arts offered a premium for the best system of ventilation applicable to dwelling-houses already built. The premium was awarded to a well-known member of that Society, Mr. Vanley, for an invention at once simple and workable, which provides, like the combination of valves I have above suggested, an inlet for external air and an outlet for vitiated air, and a ready means of distributing the one and collecting the other. It would be very desirable to procure from the inventor a description of this contrivance, which is a very inexpensive one.

In a Blue-book—"The Report on Barrack Accommodation for the Army,"—there is an account and an engraved illustration of a system of ventilation, adapted for use in rooms having two external walls, which has been introduced with the greatest success into barrack dormitories under the directions of Colonel Jebb. The plan is to establish a ventilating trunk, perforated throughout and running from wall to wall, with a division across it in the centre, and a metal valve at each end communicating with the external air: one half of the tube always acts as an inlet, and the other half as an outlet. I have been given to understand that the best ventilated of the wards at St. George's Hospital are fitted with an analogous apparatus.

There is a very old plan of withdrawing vitiated air from a room, which I have seen at work with the utmost possible success, namely, that of employing an inverted syphon, the short leg to communicate with the room, the longer one to run up the chimney flue. The syphon will act more powerfully, and will be more free from the possibility of a down current passing through it, than will the straight tube suggested by your correspondent, "M. G.," and it possesses this additional advantage,—that if the bend of the syphon be at

all accessible, so that the action could be set up in it by means of a gasket, or even a lighted piece of paper, it will then continue to act as long as the room is at all warm, whether there be a fire in the grate or not, though of course the fire will stimulate the action. This invention forms the subject of a long since expired patent. I have been informed that it has recently (and of course illegally) been again patented. The original patent was granted to Nathaniel Merriam in 1803, and has been printed and published by the Commissioners of Patents, and can be had for 6d.

In conclusion, as some of those interested in the subject may be unaware that a Parliamentary Report exists upon it, I may mention that there is a voluminous and, on the whole, valuable document published in 1857, and being the "Report to the General Board of Health by the Commissioners appointed to inquire into the Warming and Ventilation of Dwellings." The Report is signed by Messrs. William Fairbairn, James Glaisher, and Charles Wheatstone: a large portion of it is taken up with the question of warming, and much of what it says with regard to ventilation is more applicable to new buildings than to existing ones; but it will well repay a perusal. T. R. S.

**THE LINSEED OIL ADULTERATION.**

AFTER the correspondence which took place last year in your columns concerning "Adulterated Linseed Oil," I had hoped by this time we might have had a better article, but such is not the case: on the contrary, the oil has not improved in quality; for, directly the paint is used, the work seems in good order;—unnaturally so, for the paint is hard at the commencement, in distinction to that of former times, which, although soft at first, gradually hardened. But, with the present paint, though the work seems in good order for a few weeks, soon the whole begins to stick, and never properly hardens again; and when the ladies' wad dresses, or anything else, touch, the spot becomes quite black, and dust adheres to the paint every where: in fact, the work is spoilt. Formerly, in making paint for inside work, half oil and half turpentine were mixed: now, it matters not what quantity of either be used, the same unpleasant results follow.

In what was published last year, it was said some good oil could be procured at the higher class of manufacturers, who vend it genuine; "but I have tried to get some good, but in vain;" all the samples I have had have the same inconvenient quality, that of sticking. No reliance is to be placed on the sellers of linseed oil, as they run no risk, and are not responsible for the work spoilt by their rubbish, but the employers themselves.

The oil question is a matter of interest to the working man, and to all in general, as the damage done effects both low and high; because, with the present oil no honest man can recommend house painting, except in cases of extreme want; and when houses have been painted, and owners come to see the effects of the bad oil, they will have nothing further to do with it; and, what is worse, discourage their friends likewise from using it. Now, if by this article something could be done towards so important a subject, indeed it would be a boon to all. Are not searches made into different objects? Then why not examine the oil, and thus solve the mystery connected with it? We want to know the real facts of the question.

**A FRIEND TO THE UNEMPLOYED.**

**THE BOILER EXPLOSION AT KING'S CROSS.**

Sir,—The public have now before them the result of the adjoined investigation respecting the fatal explosion which took place on the Metropolitan Railway at King's Cross about four weeks ago.\* In the first stage of the inquiry, immediately after the occurrence, the coroner very properly declared, that it would be more satisfactory to himself and the jury, if, before recording their verdict, they were to hear the opinions entertained by practical engineers, who, after examining the remains of the

\* \* \* The jury sworn to inquire as to the cause of the deaths of George Wiggins and Charles Tamm, on the 1st November, 1859, find that their deaths were caused by the explosion of the fire-box of the engine Albion (the property of Mr. John Jay, contractor to the Metropolitan Railway), on which they were at the time employed, and that there is no evidence to show that any person is criminally responsible in regard to such accident. The jury cannot separate without expressing their great obligation to Mr. Anon, of the firm of Messrs. Easton & Anon, and to Mr. George England, for the scientific evidence they have furnished, and also to Captain Tyler, R.E., of the Railway Department of the Board of Trade, for his most elaborate report on the subject, and they respectively request that the coroner will be pleased to communicate that report to the Government, in the hope that Captain Tyler's valuable suggestions, as the means of guarding the public against similar accidents, may receive proper attention and obtain the publicity they deserve."

engine, would be better qualified by their previous experience to throw light on the *quæsitæ* as to the cause of the accident, than they, the jury, by their proceeding with the inquiry, with the insufficient means at their disposal, would probably be enabled to do. The justice of this determination was too evident to be controverted. Yet, whether a verdict might not have been delivered on the first occasion, if the report of Captain Tyler, the Government may be considered as anything but a waste paper, is by no means clear. By what process of reasoning the jury reconcile with their verdict the evidence given by Captain Tyler is best known to themselves. A locomotive engine, notoriously old, and individually defective in construction, explodes, killing on the spot two men, and seriously injuring another. The Government engineer, among others, is requested to report on the cause or causes of the accident, and states as follows:—"Looking at all the circumstances I can come to no other conclusion than that the boiler gave way in consequence of the weakness of its construction, at a pressure not very much exceeding that at which it was ordinarily employed, and at a pressure under which it ought to have been perfectly safe."

In the face of such powerful testimony as to the utter weakness and dangerous state of the boiler, how a verdict virtually exonerating from blame all persons connected with the unhappy affair could be recorded, it would be difficult to understand, were it not that, in one important particular, it did respect to the probable amount of pressure at the time of the explosion. Mr. England, a practical engineer, entertained an opinion decidedly antagonistic to that of the Government inspector. When the facts discussed shall be decided. To say, perhaps, can scarcely be censured, under such circumstances, for refusing the grave responsibility which would otherwise attach to them by registering a verdict in accordance with the views explained by Captain Tyler, but it is well thought that they ought to have expressed themselves a little more strongly against the carelessness, to speak mildly, that has undoubtedly been exercised by making use of an engine such as the locomotive in question, without first ascertaining and adopting suitable means to rectify the faults in construction which, in so leud a manner, were pointed out by Captain Tyler, whose valuable suggestions, which ought not to have been omitted, relative to the careful testing of steam-boilers, cannot be too strongly commended to the notice of the proper authorities. AN ENGINEER.

**COMPENSATION TO YEARLY TENANTS.**

Before William Griffiths, Esq., J.P., and Valentine Knight, Esq., J.P., at the St. Marylebone Court-house. *Bigrove v. The Metropolitan Railway Company.*—This inquiry was held on Friday, 10th November. Mr. Edward Roberts conducted the case for the claimants, and Mr. R. A. Withall for the company.

It appeared, from the opening statement and the evidence, that the claimant has occupied No. 1, London-street, opposite the Great Western Hotel, for fourteen years as a yearly tenant, from Michaelmas quarter, and carried on the trade of a coffee-house. She gave 260l. for the goodwill, and 200l. for the stock in trade. In 1856 she took a lease adjoining for additional sleeping rooms, and during her occupation had increased her business threefold. One feature of the case was, that the landlord raised the rent in 1856 from 90l. to 104l., thereby giving force to the argument, it was maintained, that a yearly occupation is continuous so long as the tenant performs the covenants, the only condition to be adjusted from time to time between the tenant and landlord being the amount of rent to be paid.

The profit of the trade, including beds, is now about 500l. a year. Mr. Daniels, one of the witnesses, stated that this lease would in the trade be worth three years' purchase, and that, knowing Mrs. Bigrove had been fourteen years a yearly tenant, he would give 500l. for the goodwill, at the risk of being disturbed by the landlord.

Mr. Withall said that the "Landlord and Tenant Compensation Act," that the justices were precluded from doing more than to allow for the value of the tenancy from the 1st February, when the company required possession, until Michaelmas next, when it would expire, and that no allowance should be made for any prospect of continuing the tenancy. He called the landlord to show that he intended to give notice to quit, and to build an hotel on the site.

Mr. Henry Barker, district surveyor, gave evidence to the effect that the claimant was not entitled to the expense or loss on removing her fixtures and trade furniture, as she would be compelled to do so at Michaelmas next by effluxion of time. He estimated the entire compensation at two-thirds of a year's purchase of 150l., which sum he considered to be the net profits, instead of the 500l. claimed.

Mr. Withall in summing up, said that the Legislature had intended that the Justices should have summary jurisdiction only in small cases, and referred to the clause giving jurisdiction to Justices in cases under 50l.

Mr. Knight held that the 121st section of the Act directed the Justices to give compensation for any damage and injury whatever sustained by the claimant, and if such damage were shown in this case, they would be bound to give full compensation.

Mr. Roberts replied upon the evidence for the defence; and the Justices awarded 300l., including costs. The claimant to take away all fixtures, &c. The case occupied upwards of five hours.

**Books Received.**

*Geological Treatise on the District of Cleveland, in North Yorkshire; its Ferruginous Deposits, &c.; with Observations on Ironstone Mining.* By JOS. BEWICK. London: Wreale, High Holborn, 1861.

ALTHOUGH Cleveland has only very recently become celebrated as an iron-producing district, its iron has been known in modern times for a good many years, and in ancient times it was evidently well known to the Romans, from the remains of their workings which have been discovered. It was only after the opening of ironworks in 1850, however, that the richness of the deposits became generally known, although a few energetic men,

such as Mr. Bewick, sen., appear to have been long preparing the way as pioneers to the ultimate renown of the district. In 1850 a seam of the enormous thickness of 16 feet was discovered, and one company alone turned out from their open quarries and mines the extraordinary quantity of from 1,000 to 2,000 tons of ironstone daily. The sensation and excitement in the public mind, in the north especially, which these operations occasioned at the time, are still fresh in recollection, and the richness of the seam, still fresh in the quarter was henceforth a popularly known fact. An immense increase of mining adventure in this district has taken place since then, and there is still every probability of its further and rapid extension. It is to the development of this district, and to the black band discoveries of Scotland, in no inconsiderable degree, that we are indebted for the cheapness of iron of late years. There is great and pressing need of improvement in the chief port of shipment for the Cleveland iron at Whitby, but the extension of railways, and the growth of the iron trade of the district, will probably soon force on what is requisite in this respect. In the same quarter, we understand, there is hope of finding coal.

The work under notice enters fully into the geological and mineralogical features of the Cleveland district, and is an important one to all interested in the iron trade.

**VARIORUM.**

UNDER the title of "Pre-Raphaelitism Tested by the Principles of Christianity,"—an Introduction to Christian Idealism," Mr. W. Cave Thomas has printed a pamphlet "for private circulation."\* The main purpose of the thoughtful writer appears to be to show—

"That the terms, 'earnest and conscientious endeavour,' are misapplied to that very prevalent, abject imitation of nature as it is, such imitation being mere slavish acquiescence in things as they are, a total abnegation of the faculty of judgment, of moral discrimination, of selection, which, instead of elevating human and other nature by cultivation, by those regenerative and reformative powers which science should command, tends to debase the former by a false aim, which enervates the judicial faculty, and the latter, by denying it the aid of human intervention and art."

Mr. Thomas combats the present meaning attached to the words *nature* and *truth*, and urges, ally, the importance of separating the transient from the permanent, the accidental from the essential, the special from the general, and so to realize IDEAL EXCELLENCE.—The first number of the new magazine, "Temple Bar," gives a considerable variety of agreeable writing for a trifling sum. Part of it is "smaller" than we expected, but time will enable the editor to strengthen his staff.

Mr. Hepworth Dixon gets a hearty piece of applause for his "Lord Bacon;" and the editor begins his travels in Middlesex. The Rev. J. C. Bellon contributes a paper entitled "Over the Labyrinth to Baalbek," which is unfortunately more about the journey than the goal. He gives a plan of the ruins from his "own measurements, and drawings on the spot," and notices two inscriptions on "the centre stones in the crowns of the arches" of the vaulted gallery under the great temple, one *Disio Vascii*, the other *Disio Charii*, the meaning of which he is unable to discover.

**Miscellaneous.**

SCULPTURES AND BOOKS.—Some of our readers may find it worth while to examine the works in terra-cotta, books, &c., collected by Mr. Casentini, which are to be sold in Hercules-buildings, Launceston, next week.

ARCHITECTURAL UNION COMPANY.—The ordinary general meeting of this company is fixed for Wednesday, 5th December, at three o'clock. The directors propose to pay a dividend of 10s. per share (5 per cent.), which will leave a respectable balance in hand.

"RICHARD THE FIRST"—This statue has, I think with you, been over-praised. The grand fault in it to me is this,—that the king appears to be sitting on his horse *quilty*, just as a groom does when without a saddle; whereas, as the attitude is supposed to be a *momentary* one, the figure should, with uplifted arm, have been raised in the stirrups. This would have given life to the figure, and would have connected it, as it were better with the horse. No man on a prancing charger would be lifting up his sword in a supposed dignified position with his feet dangling carelessly in the stirrups. The pedestal is shocking. G. T.

\* 23, Holles-street, Cavendish-square.

**GEORGE STEPHENSON AT OXFORD.**—A statue of the late George Stephenson, is about to be erected in the Oxford Museum. Mr. Woolner, the sculptor of the statue of Bacon, already there (the gift of the Queen), is to be the sculptor.

**PNEUMATIC DESPATCH.**—The Pneumatic Despatch Company are said to have satisfactorily completed their preliminary experiments at the Soho, Works, Birmingham, and will now proceed with the construction of the permanent tube intended to be laid between the General Post-office and Bloomsbury, a distance of a mile and a furlong. The tube will be 2½ feet in diameter.

**REVIVAL OF CITY GUILD.—THE PAINTERS' COMPANY.**—Mr. John Sewell, ex-master of the Painters' Company, has addressed a communication to each member of the Court of Assistants of that Guild, calling attention to the desirability of considering as to the initiatory steps to be taken towards the realization of another exhibition of decorative works of art. The matter is to be taken into consideration at the next Court.

**REMINGTON'S SPRING HINGES FOR SWING DOORS.**—Many springs used to keep swing doors in their place have the fault of being least powerful when the door is shut, and thus allowing it to be moved by the wind. Messrs. Remington & Son, of Skipton, Yorkshire, have produced a spring which is most powerful (if we may judge from the specimen submitted to us) when the door is closed. It works easily, opens both ways, and seems well adapted for any kind of doors, double or single. It merits attention.

**IMPROVEMENTS IN COVENT GARDEN.**—On the 22nd ult., the first festival was held at the new building recently erected in Hart-street, Covent-garden (for the benefit of the poor of this locality), at the sole cost of the Duke of Bedford. The sum expended was 2,000*l.* *The Athenaeum* says—340 children are being educated; women are brought together to receive help and instruction in respect to home duties; a lecture has been established; together with a Penny Bank,—the whole being under the immediate superintendence of the Rev. Henry Hutton, M.A., the rector. The savings collected amount to 400*l.* per annum. The necessity for these measures will be felt when it is stated that within a short distance of the new building there are 274 rooms, each of which is occupied by a single family.

**MANCHESTER ACADEMY OF FINE ARTS.**—The members of this academy have held their first annual meeting at the Royal Institution. Mr. J. A. Hammersley, F.S.A., the president, occupied the chair; and there was a pretty fair attendance of members, associates, and students. The Chairman called attention to the reasons why such an academy had been started. Its main object was, that the artists who were isolated and had no very enlarged or systematic opportunity of meeting together, might meet in social convalescence. This idea had been productive of much good, for artists had strengthened their intimacy by close and frequent inter-communication. Another object was, that there should be classes established for the study of details, both in the antique and from life. They had been numerously attended, and of a productive of good. The third object was that of seeking to have more control over the annual exhibition of pictures at the Royal Institution; and the exhibition this year would testify to the advantage of this arrangement. The hon. secretary (Mr. L. Brodie) read the report of the council.

**TIMBER SALE CUSTOMS.—CHALONER versus WRIGHT.**—From a case which recently came before the Liverpool County Court, it appeared that defendant had attended a timber sale at which plaintiff acted as broker. A log was offered for sale, described in the catalogue as "defective heart," being what is called "plugged," as then supposed, at one end only. Defendant purchased the log, and finding afterwards that it was "plugged" at both ends, refused to accept it. A re-measurement was then made by the plaintiff, who awarded what he considered was a fair allowance for the defect in question, but which was repudiated by the defendant. Afterwards plaintiff resold the timber at a loss upon the original sale, and charged the difference in price to defendant. Plaintiff was cross-examined as to the custom adopted in such disputes, and he stated that in all cases it was delegated to him to make a re-measurement, and adjudicate upon them without reference to any other person in the trade. The judge thought, that under the whole of the circumstances, defendant was bound to pay the difference, as claimed by plaintiff, on the resale of the timber. The question, as had been stated, was not one of pounds, shillings, and pence, but of principle; and it was no doubt desirable to have the opinion of the court upon it.

**DESTRUCTION OF THE KILBURN NEW TIMBER CHURCH BY FIRE.**—The new edifice situated in the Capton-road, Maida-hill, Kilburn, formed of timber with an iron roof, and over 100 feet long and 70 feet wide, has been entirely destroyed by fire. The origin of the disaster is unknown. The Rev. J. Irving, the rector, it is understood, was insured in the Sun Fire-office.

**THE STRIKE IN BRISTOL.**—At the adjourned meeting of the Master Builders' Association, on Monday, the following resolution was unanimously adopted:—"This meeting sees no reason to depart from the resolutions passed at former meetings respecting the present strike of the operative masons, and that this meeting, at its rising, stands adjourned until Monday, the 3rd of December next." Thus the vexed question at issue remains *in statu quo*.

**ACCIDENT WITH A GIRDER.**—A large girder fell recently from the scaffolding in front of the fifth floor of a tea warehouse in Worwood-street, London, owing to the breakage of the hoisting machinery at the moment the beam was about being landed on the summit of the building, where it was to be used in additional stories now erecting. The weight carried all beneath it to the pavement, but left about 100 feet of scaffolding standing. Fortunately the footway was hoarded off, which prevented the loss of life that must otherwise have occurred.

**A NEW CENTRAL METROPOLITAN HOTEL.**—Notice has been given of an intention to apply to Parliament in the ensuing session for an Act to incorporate a company for the purpose of erecting a hotel and other buildings, to occupy the space between the Strand on the south, and Wyck-street on the north, the west end of St. Clement's Church-yard on the east, and the east end of the church-yard of St. Mary, Wyck-street and the south end of Newcastle-street on the west, all in the parish of St. Clement Danes; the Act to empower the company to purchase and pull down the buildings at present occupying the required site.

**A DIRTY TRICK.—TENNY.**—A council meeting was held on the 13th ult., for the purpose of receiving the estimates for the furnishing of plaques, &c., required for the draining of the town: several estimates were sent in, the one from Mr. Burns, of Ely, being more in detail than the others, but rather more in the amount of money required for his services. It was resolved to profit by the labour of his brain—and the exercise of his genius—by sending a copy of his conditions to several of the competitors, to know for how much less they would perform the same amount of intellectual labour, an act of great encouragement to those who expect a committee to decide for the one that displays the largest amount of ability.—*Haverfordwest Telegraph*.

**MORE DEATHS FROM BAD DRAINAGE.**—An inquest has been held as to the deaths of twins, named Emma and James Read, aged fourteen months, who died from the poisonous effluvia arising through an overflowing cesspool, at No. 12, Boston-street, Shoreditch. There were two more children very ill, and in a dangerous state of health. The mother stated that she had lost two children about two years since in the adjoining house, and she attributed their deaths to the filthy and unwholesome condition of the house, for the room in which they lived was frequently overflowing with night soil. Mr. John Gay, the senior surgeon of the Great Northern Hospital, believed that the children had been poisoned from the foulness of the house, which was in a frightful state of filth. The jury returned the following special verdict:—"That the deceased died from poison, arising from effluvia, through bad drainage in the house where they resided; and the jurors further say, that the conduct of the landlord of the said house was highly censurable. The parish authorities were to blame for allowing the premises to be in such a dangerous condition to health."

**STATE OF NEWGATE-STREET.**—Sir: I wish to call attention to the present state of Newgate-street. At the further end, as you go towards Cheapside, some houses have been partly pulled down, and have remained in that disgraceful state for some considerable time, doing a great amount of injury to the trade and prosperity of the neighbourhood, not to mention the miserable aspect it gives to every thing around.

A PASSER-BY TWICE A DAY.

**TENDERS**

For the erection of a foreman's house, at the Gillingham Gas Works, for the Rochester and Chatham Gas Company. Messrs. J. H. Andrews & Son, architects.—  
Pankhurst ..... 239 0 0  
Gurrell ..... 387 10 0  
Stump ..... 378 0 0  
Clothier (accepted) ..... 313 0 0

For Victoria Hotel, Sheffield. For the whole of the work, except foundations, which are done, and bridge and approach to the Midland Railway. Mr. M. E. Hadfield (late Hadfield and Gollie), architect.—

Barter ..... 216,500 0 0  
Carr ..... 15,172 0 0  
Wade ..... 14,601 0 0  
J. & A. Craven ..... 14,515 0 0  
Fowler ..... 14,250 0 0  
Chadwick ..... 13,155 0 0  
N.B. The lowest tender, omitting the cast wing for the present, was accepted.

For Model Lodging-houses in Bethnal-green, for Mr. Charles S. Butler, M.P. Mr. William Reddall, architect.—

Stevenson ..... 21,420 9 0  
Levere ..... 14,114 12 0  
Noone ..... 14,000 0 0

**NOTICE.**—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher."

Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

# The Builder.

VOL. XVIII.—No. 931.

Mr. Falkener's "Dædalus."\*

THE story of Dædalus, the Athenian, who, charged with the murder of his nephew, and imprisoned in the labyrinth he had built at Crete, in the time before history was, escaped, together with his son Icarus, by means of wings, made by him, and fastened to the body with wax, is known by all.

remember that Icarus flew so high that the sun melted the wax, and he fell into the sea and was drowned, while the more diffident and careful father, flying lower, reached Sicily in safety. Let it be, as some say, that the fable meant to show Dædalus had escaped by means of sails, of which he was the supposed inventor; as others, that it conveyed a series of lessons which should be borne in mind by those who would attain success,—that Dædalus did not build a temple to Apollo at Capua,—that his works in sculpture and architecture were not, though Plato calls them so, works of great value,—even that there never was a Dædalus; nevertheless statues were called after him, *δαίδαλα*, sculptors bore his name till the time of Socrates, and the city Dædala, according to the legend told by Alexander, was built where Dædalus, being killed by the bite of a water-snake, was buried. Mr. Falkener did very well, therefore, when he took Dædalus for his title, though few, we suppose, will agree with him that "a work on sculpture can bear no other name." Mr. Falkener is an enthusiast touching classic art, and very desirable it is that we should have a few enthusiasts in this respect rubbing to an extreme, and so helping to keep a just balance, or the rising generation of architects under the present teaching might be led to believe that the world was not made until the twelfth century, or thereabouts. We dissent from many of his inferences, but we have read the book with pleasure and advantage. It is scholarly and elegant. He has brought together a large number of quotations, more or less valuable,—so many, indeed, that he feels it necessary to remind the reader, as an apology, that the only way in which he could exhibit the genius of ancient art was by giving the opinions of the ancients upon the subject. These opinions he has endeavoured to classify and methodize, so that conclusions may be more easily be deduced from them. He believes, and we agree with him, that every tradition is pregnant with a meaning,—though, as he might have added, it is sometimes not a very weighty one.

An introduction of twenty-five pages and the frontispiece are devoted to re-setting forth, with reference to the Parthenon, the opinion of Quatremère de Quincy in respect of the temple of Jupiter Olympian at Elis, that the ceiling was of circular form. This introduction we printed in full some time ago,† together with a section of the Parthenon, showing the vault-formed ceiling. No positive proof can

be given that it had not such a ceiling, but we cannot find that Mr. Falkener has afforded any evidence that it had. M. de Quincy supports his theory by imagining that the arch

which is shown on many coins bearing Grecian buildings represents the vault of the temple, that the artist endeavoured to show in one view, the front portico, and the interior of the temple, with its statue and vault over. But then all these coins are Roman. Moreover, the author of "Architectura Numismatica" supposes that these conventional types of temples are mere baldachinos, instead of temples. Mr. Falkener's own argument may be thus stated. He considered that the interior had two colonnades, one above the other (as was doubtless the case). He made the size of the upper column arbitrarily about half the size of the lower. When this was done there was still considerable space to fill up, while on the other hand the utmost altitude was required in order to admit the statue. This space being just sufficient for a semi-circular arch, and the arch being the form which filled up the angular lines of walls and rafters with least sacrifice of room, "I did not hesitate to adopt it," he says, "particularly as I considered that this was the only form capable of admitting the colossal image, and that it was the only form in which the hypæthral opening could partake of a graceful character."

This reasoning, however, depends too much on supposition to be readily received. Consider the upper story sufficiently lofty, and a roof of three spans may be made to meet all the circumstances. That the arch had been used at this time there would seem to be no doubt; Egyptian and Assyrian monuments supply evidence of it; but in proof of the theory that vaulted ceilings were used in Greek temples we have not yet discovered any evidence. Mr. Fergusson's ingenious theory of an elevated clerestory with span-roof on each side, though not free from objections, seems more in accordance with the spirit of Greek architecture.

As an appendix, Mr. Falkener prints the opinions of several eminent persons who have given attention to the subject. Mr. Cockerell, Colonel Leake, and Mr. Bonomi, accept the vaulted ceiling; the latter saying,—“When I read your essay, and consulted the lexicon for such terms as *αψίδα*, *προρμη*, and *ψαλίς*, used by writers of the time when the roof of the Parthenon and other Greek temples were standing, it seemed to me impossible to withhold consent.”

On the other hand, M. Hittorff, Professor Gerhard, of Berlin, and Professor Donaldson, refuse to do so. The latter, apparently overlooking that the claim is for an arched wooden ceiling, says:—

“No concentric stones have been found in the ruins of the Parthenon. Could they all have escaped? Thirty years ago I entered upon the question in the supplementary volume to Stuart's 'Athens'; but I could make nothing of it, the Greek terms were of such doubtful interpretation, and so few monuments in Greek art, except the subterranean chambers, to reason upon. However, ventilating the question can produce no harm. Facts, they say, are stubborn things; but preconceived notions are stubborn, so you will have a hard fight to go through to overcome the established conviction of pure Greek architecture having been entirely treabated.”

M. Hittorff, in his letter, speaks of the publication of the completion of his first volume on the Ancient Architecture of Sicily, and concludes with words which may be English, “I ask from the Supreme Architect the favour to be permitted to complete my works upon the ancient remains of that beautiful and wonderful country, and I beseech Him, also, to

sustain you in your glorious endeavours to assist in the spread of a love for and more intimate knowledge of ancient art, which, whatever may be said and done, will always be the purest source whence modern art may draw.”

We must pass on to another part of Mr. Falkener's hook. When he comes to inquire into the causes of the high degree of excellence attained to by the ancient Greeks, he dwells on the fact that each man laboured for distinction, each man was content with glory. If the artist's design met with approbation, it became his object so to improve and perfect it, that the finished work should rank with the masterpieces of his age, and be treasured up by posterity as a sacred heir-loom. That it would be so treasured, if excellent, he knew full well. Cicero, in his oration against Verres, the Sicilian pretor, for his spoliation of that province, thus sums up his declamation by enumerating several of the most celebrated works of antiquity:—“What remuneration,” he says, “do you imagine, could compensate the Rhegians, now Roman citizens, for the loss of their marble Venus? What the Tarentines, if they were to lose their Europa on a Bull, their Satyr, and other works deposited in their temple of Vesta? What the Thespians for their statue of Cupid, for which alone strangers crowd to Thespis? What the Cnidians for their marble Venus? What the Coans for their image of that goddess? What the Ephesians for the loss of their Alexander? What the inhabitants of Cyzicus for their Ajax or Medea? What the Rhodians for their Ialysus? What the Athenians for their marble Bacchus, their picture of Paralus, or their bronze heifer by Myron? It would be tedious and superfluous,” he concludes, “to dwell upon all the rarities which attract strangers throughout Asia and Greece.” While the house of Socrates, including his furniture, was valued at 18*l.*, and the price of an ordinary house in Athens, was about half an attic talent, say 100*l.*, sixty talents (say 12,000*l.*) were offered for a painting by Nicias, the Athenian, which he refused, preferring to give it to his country.

“By the general interest thus excited, the artist felt that every eye was upon him, each man was able to appreciate or criticise his labours: his work was no offspring of private caprice, but looked forward to anxiously by the public eye. Nor was this all: he himself felt that he was as much a citizen as any other, that he was working for himself, and that he would be as much grieved as any one did the monument not answer to the expectations raised of it.”

It was, our author maintains, the excellency of their teaching, their seeing around them men distinguished by all that was great and glorious, and their beholding on every side the masterpieces of their art, at once serving for instruction and incentive, which enabled the Grecian artist to succeed in imparting a charm to everything he touched.

Each town desired to have the most perfect images of the several divinities, but especially of its protecting god. It was thus that each city became filled with works of art. The number of statues contained in Corinth surpasses belief. In Athens, after being so often plundered, Pausanias describes three hundred statues as worthy of particular notice. Altogether, Pliny supposes that there must have been three thousand in this city, and as many at Olympia. From Delphi, after having been ten times pillaged, and five hundred bronze statues had been carried away by Nero from the temple of Apollo only, there remained some hundreds more to be described by Pausanias. In short, such was the wealth of Greece in works of art that after three centuries of Roman conquest, Pausanias was able to describe two thousand eight hundred and twenty-seven statues, thirty-three of which were colossal.

When we come to consider in what the excellence of Greek art consisted, the first principle which we meet with is, that it sought always the beautiful.

“Nothing common or vulgar,” says Mr. Falkener, “was to be allowed: every object was to be exhibited in the most beautiful aspect of which it was capable. The ancients, says Aristotle, pronounced the beautiful to be

\* “Dædalus; or, the Causes and Principles of the Excellence of Greek Sculpture.” By Edward Falkener, Member of the Academy of Bologna, and of the Archæological Institutes of Rome and Berlin. London: Longman, Green, Longman, & Roberts. 1860.

† See p. 213, *ante*.

the good. And so Socrates,—Nothing is beautiful which is not good."

Which do you think, asked Socrates of Parthiasus, do men behold with the greatest pleasure and satisfaction—the representations by which good, beautiful, and lovely manners are expressed, or those which exhibit the base, deformed, corrupt, and hateful? The most beautiful of all spectacles, says Plato, for whoever wishes to contemplate it, is it not that of the beauty of the soul, and beauty of the body, united, and in perfect harmony with each other? The Greeks ever believed beauty, more especially of the female form and countenance, to be indicative of goodness.

"Every spirit, as it is most pure,  
And hath in it the more of heavenly light,  
So if the fairer body doth procure  
To habit in."—Spencer.

The sculptor sought to convey to the marble the hidden attributes of the soul, to awaken by bodily forms the secret operations of the mind; and this was not an occasional exercise, but a constant duty.

It is asserted by an ancient author, and we agree with him, that he who erects a monument unworthy of his country, has inflicted a wrong which will cease only with the destruction of the monument.

In the chapter on Ironic Polychromy, our author brings together much interesting information bearing on the fact, which must be considered settled, that many of the Greek statues were coloured. He considers that while colour was used most sparingly for the flesh, positive colour was probably used in the accessories; otherwise the marble might look dirty, and that it is, perhaps, through a neglect of this consideration, that modern attempts, by Pradier on the Continent, and Gibson in this country, to restore iconic-polychromy, have not been more successful. The coloured casts of the Elgin marbles, exhibited in the Crystal Palace, he considers can only be regarded "as a cannony upon Greek taste, as a gross libel upon ancient art." The much debated word *circumlitio* is of course discussed: he considers it to refer to the act of polishing. As to Polychromic architecture, he says,—

"It is sufficient for us to know that every monument of Grecian art, of puro style, whether of Greece, Sicily, Metapontum, Xanthus, or Itali-carassus, was adorned with colour; and if we judge by the evidences of colour on the monuments themselves, instead of by the unfounded 'restorations' by modern architects, we must, if capable of appreciating art, confess its heauty:—*"Il s'y avoit pas, dans toute la Grèce, un seul temple construit avec soin et avec quelque luxe, qui ne fût plus ou moins coloré."* Such is the remark of the diligent inquirer, the Chev. Bröndsted.

The same chapter treats also of chryselephantine sculpture, and is learned, interesting, and admirable.

In his review of modern sculpture, for which, nevertheless, he has few good words himself to say, he cautions others against injustice to the modern artist, and calls upon the ignorant critic to pause,—

"Before he proceeds to condemn a work which has entailed labour, thinking, and expense, united with a long study of the antique, and a constant analysis of modern wants, let him reflect that he is seeking to gain a transient reputation for his pen, at the permanent loss of reputation to the artist; that possibly his criticism may be false, and therefore, as the artist has no opportunity of being heard in defence, he is taking upon himself the part of a calumpniator rather than that of a critic."

So say we; and further, let not the artist be overlooked. Let him rather feel that it is a distinction and an honour to be an artist, and that such honour and distinction are recognized by the public. Quite true is the proverb, "Difficult are the beautiful." Mr. Falkener in this is fully with us.

There is an interesting and valuable chapter on Perspective, in the course of which our author's prejudice against Medieval work is curiously shown; for while he points to the figures in the west front of Wells Cathedral (which look well in their place, but are found to be disproportioned when brought down to the eye), as an illustration of the necessity of

representing proportions, not as they are, but as it is desired they should appear, he refuses to adopt the conclusion natural to be drawn from the premises here given; as otherwise he says, he would "have to attribute to these sculptures an amount of skill and refinement quite incompatible with the state of the arts in the Middle Ages."

Here, however, we must end. We have left ourselves only sufficient space to say, that the book is illustrated with a number of photographs and chromo-lithographs of classical sculpture, including the Minerva Borgheese, the Laocoon, Diana Agotera, the Apollo Belvedere, the Venus de Medici, and a beautiful mosaic of a female figure, in the museum of the Archbishop of Tarento. The work is, moreover, admirably printed and bound; and is altogether such a book as the man of taste and refinement, and the directors of libraries, should feel it a duty to purchase.

#### THE SEWAGE FOR THE SOIL. CROYDON.

The great question how best to bring town sewage and agricultural soil together, to the mutual advantage of both town and country, has now been pretty long agitated, and it is full time the question were settled. This is not to be done by opinion alone, but by practical experiment combined with rational theory; and, indeed, such experiment is in course of progress; and wherever there is any prospect of its extension, it is a pity to check it too severely by adverse and warning opinions and statements, unless there be some thing obviously and incontestably absurd or wrong in the particular experimental scheme to put a stop to which the attempt is made. Should the financial or economical, or even the sanitary, expectation be unsound, the error will, ere long, correct itself; and, in the mean time, in a question of vital and national importance, the public will be gleaming invaluable experience from almost all the practical schemes which may be devised or carried out.

These preliminary ideas have been suggested by the scheme which we lately announced for making use of the Croydon sewage in irrigating the land in the vicinity of the town, and by an interesting correspondence to which that scheme has led. In this case, for example, no disinfectant is contemplated. Now it is easy to get up a *diletante* outcry against any practical endeavour to solve the great problem without the use of (but too generally expensive and, in this case, impracticable) disinfectants—or deodorizers rather,—agencies which are so important and invaluable in town use; but it still remains to be fully proved whether, as we have long and repeatedly suggested, the earth itself may not be an adequate deodorizer of diluted materials such as town sewage, simply "irrigating, not drowning," the land itself. Wherever a feasible attempt is being made to try this great question, we say,—Give it fair play—do not forestall the conclusion by exciting the now wide-enough-awake public opinion as to want of "disinfection." The earth is a very potent deodorizer and disinfectant: there can be no doubt about it; and quite recently, if we mistake not, Mr. Spencer, of Liverpool, has incidentally been shedding some new light on this subject in what he has said of the magnetic oxide of iron and ozone\* in connection with the filtration of water through soils or strata, and the purification of the water thereby. The experiments of the Rev. Mr. Bowditch, of Wakefield, on the power of clay to fix sulphuretted carbon and other abominations of foul gas, also seem to bear indirectly on the same important subject. Let the power of the soil itself, then, in deodorizing the sewage of towns, why all means be fairly and fully tried, as it is about to be at Croydon, which,—once so notorious for ill-health, and now likely to become, from sanitary

\* Although we are here urging a fair trial for the soil itself as a great natural deodorizer, we are quite alive to the possibility,—nay, we had almost said the probability,—of some artificial deodorizer being after all found absolutely necessary in the disposal of town sewage, whether over the land or not. But either way it will be right to keep in view that another great natural deodorizer besides the soil is ozone, whether in the air or the earth, and whether naturally or artificially applied. If its artificial application be found requisite, there can be no doubt, we believe, that Schönbein, the discoverer of ozone, was right in pointing to permanence of power as a perfect or complete ozonizer, and hence deodorizer. It is this same agency that is known as "Condy's fluid," and with which some successful experiments we recollect were made some time since made at the metropolitan sewage. This, too, is the air test used at Manchester, and so much recommended by Miss Nightingale and others; and it is a test for purity in water as well as air.

experiment, no less celebrated for good health,—seems to have somehow assumed the peculiar distinction of being the "vile body" for more than one salutary "crucial experiment" of great as well as decisive importance to the public and the country at large.

An interesting correspondence, as we have said, has recently been going on (in the *Times*) on the subject of this Croydon sewage scheme, of which Mr. Shepherd, C.E., is the engineer.

Mr. Rawlinson cautions the public or the Croydon Sewage Company against this scheme, or rather against extravagant outlays on liquid manure irrigation-works (though decidedly in favour of *liquid* sewage) and other points of importance, implicitly applying them to this scheme; and he addresses the Carlisle experiment as the example which ought to be followed, or the criterion of what should be done. "At Carlisle," he remarks, "where there is a population over 90,000, the entire volume of sewage is pumped and applied to some fifty acres of land by means of surface irrigation. The capital sunk for such irrigation is under 1,000. I have not heard of any extravagant income from this speculation; but, on the contrary, I have heard of some difficulty in disposing of the grass when grown and cut." The capital of the Croydon Sewage Company is 30,000, and they propose to use the same quantity of sewage in the irrigation of a much larger surface of land.

Mr. Shepherd in his reply to Mr. Rawlinson, says:—

"The attempt of putting the sewage of Carlisle, with a population of 90,000 inhabitants, on fifty acres of land, and to expect that those fifty acres of land will pay all expenses of steam-engine, pipes, labour, &c., are results of sheer insanity; nor do I wonder at the proprietors not being able to dispose of the grass. For Mr. Rawlinson to say that all the sewage of Carlisle has been pumped on these fifty acres of land I think is mere 'figure of speech' on the part of that gentleman. For the information of Mr. Rawlinson, I beg to state the corporation of the town of Croydon (also 30,000 inhabitants) has taken not fifty but ninety acres of land; and, after irrigating nearly all these ninety acres of land with most astounding success, in the shape of abundant and healthy crops, only a small quantity of the sewage could be used, the vast bulk of it running to waste in the river Wandie."

Mr. Rawlinson had remarked that the crops on sewage-irrigated soil must be consumed quickly: this Mr. Shepherd denies, and states that at Croydon hay is made of the grass, rye-grass, and clover, and stacked, as are the oats; and that they are not, and do not require to be, consumed quickly. Mr. Rawlinson speaks of the cost of underground irrigation: Mr. Shepherd states that his plan is for surface irrigation. He thanks Mr. Rawlinson for suggesting a reduction of the Croydon Company's capital to 3,000; but fears that by doing this he should be only repeating what Mr. Rawlinson states is a failure at Carlisle.

Mr. M'Dougall, the engineer of the Carlisle works, and the manufacturer of now pretty well known disinfectants, next writes, stating that it is "unwise in any corporation or local authority to permit the application of sewage to land in the vicinity of towns without well-considered means for rendering the sewage permanently inoffensive." This of course bears directly upon the question of disinfectants, but, as we have already observed, it remains to be seen whether the soil itself be not sufficient for all purposes. The application of deodorizers in tanks or reservoirs where sewage is to be stored, or the covering up of these, is a separate question, however, well worthy of consideration. But it must be here noted that disinfection may be very requisite with much sewage on little land, while it is not so with the same sewage diffused and spread, and exposed to the disinfectant power *both of earth and air* on much land. The latter, too, looks much more like a natural and satisfactory solution of the problem on a great and national scale.

The next correspondent is Mr. J. F. Bateman, C.E., who corroborates Mr. M'Dougall's views as to disinfection, and gives his testimony to the success of Mr. M'Dougall's process at Carlisle. In the close of his letter Mr. Bateman says,—

"Very careful experiments, continued for a considerable period, and on a tolerably large scale, on the sewage of Glasgow and Edinburgh, which were conducted in conjunction with Dr. Thomas Anderson, led us both to the conclusion that no process of precipitation would be likely to succeed as a commercial speculation while a solvent or non-precipitating agent, like that of Mr. M'Dougall's, would most probably effect all that could be desired.

In conclusion, I will only add that the result of my investigations leads me to concur in the opinion of Mr. Rawlinson, that if the sewage, in its ordinary state, must be applied quickly and cheaply to be beneficial to the farmer. I do not think it will bear the cost of expensive works or distant transport, and it ought on no account to be used in the immediate vicinity of towns without being previously rendered innocuous to health."

Here let us repeat, lest we ourselves,—one of

which looks as if it could be executed for the money, and you would have your money's worth. The towers and spires of all three chapels are specially good. The mortuary is remarkable for a post-mortem chamber, and for an unusual treatment of roof, quite original, though not in harmony with the other chapels. The author must have been thinking of Norway churches or Chinese pagodas. The lodges on each side of the gates are simple and good. The piers are very poor and show evidence of haste; the gates and railings are not drawn in. The superintendent's house has a heavy tower with a Norway church roof. It seems unfortunate that the board should have required this clock-tower for the superintendent's house, as, independently of its superfluity when there are three towers for the chapels, it puzzles the architect's brain how to tack it on to the house. In almost every design exhibited, these unfavourable conditions and results are exhibited.

No. 6, "I labour with Hope,"—consists of eight funeral-looking drawings, drawn with care and labour, but this is all that can be said in favour. The Episcopalian and Nonconformists are to have a nave, with apsidal east end, transepts with apsidal ends, a place for coffin stands (far too crowded), with apsidal form of end, and urinals and water-closets opposite, also with an apsidal end; the tower of entrance in the centre of the side. The Roman Catholics' chapel is a long nave, with octagon altar end; south transepts for coffins, north transept for urinals; meeting-room and vestry in transepts at the west end. This is not a bad-looking plan, but all the seats in the long nave are fixed longitudinally. Externally the favourite style of the author is mixed Georgian and Batty Langley, with a dash of Milan Cathedral. The extravagant shape of the gabled apsidal chapels, precisely the same forms over chancel, transepts, space for the bodies and urinals, is notable. The entrance-gates resemble an enormous sarcophagus, supported by arched ways and piers. The mortuary is a small octagon room, roofed pyramidally with gables from each of the eight sides.

No. 7, "Hiram," nine drawings, occupies the post of honour in the room. The Episcopal chapel is to have nave and transepts, with the spaces for forty bodies where the chancel would be; a tower and spire at the south-west corner, and a carriage-way and waiting-room at the north-west side. The Nonconformists'—nave and transepts, with apsidal chancel, to be used for the space for the bodies: a carriage-porch, and porch under the tower on the north side, entering into the north transept. Here are no less than four doors entering this chapel, at all points of the compass—rather a draughty arrangement, we think, if the forty bodies and the mourners were being simultaneously conveyed into the chapel. Externally, the style is Flamboyant Decorated. The three towers and spires are good combinations of the Northamptonshire and Lincolnshire steeples; but too imposing and vast for the money to be expended. The Episcopal and Roman Catholics have a profusion of crosses and metal terminations, and the Dissenters a profusion of metal termination only. The general impression that is produced from examining the three elaborate perspective views in one frame, is that it would be impossible for any contractor to execute them faithfully for the money. The mortuary resembles a handsome school and offices; the superintendent's house, a handsome mansion: the lodge has a bell gable, and the entrance gateways a spire-like turret in the centre of them.

No. 8, a Triangle with Three Circles, eighteen drawings, is conspicuous for a polychromatic treatment by red and white bricks and stonework. The plan of the Nonconformists' and Roman Catholic chapels is peculiar. There is a space for the bodies at one end of a nave, and a corridor with an isolated tower at the other extreme end. The isolated positions of the towers and spires in all the chapels is unpleasant and unusual. We do not see the use, nor how it can be afforded, to have so many bell and other turrets, on the roofs and elsewhere, in addition to the bellies on the towers and spires. The style is consistently adopted throughout,—Early Decorated. The mortuary is square, and treated somewhat after the style of the abbot's kitchen at Glastonbury. The entrance-gates are remarkable for very tall lamp-post piers, and very lofty, inelegant gates.

No. 9, "Fidelitas" has twenty-nine sheets, and one with six views, framed, very carefully drawn, and elaborately designed. The chapels have Lincolnshire spires, hipped and gabled, costly form of roof (with superfluous bell-turret in the centre of the pyramidal roof, over the covered porch), the

general detail being of Lombardic character, with a free use of coloured bricks in bands. The mortuary, in plan, is provided with a post-mortem room and lavatory. We cannot comprehend this feature in two or three of the designs. Does the Board purpose establishing dissecting-rooms in connection with the mortuary? Externally, the character is that of a miniature cemetery chapel, with roof hipped and gabled back into the hips, in the same costly way as the chapel. The superintendent's house is similarly treated as to the roof, and would otherwise be good in design (the campanile with clock-faces excepted). There is an alternative Italian design for the superintendent's house, and an alternative Greek design for the entrance in this author's elaborate collection of drawings.

No. 10, "Faith," has a remarkably curious clerestory for the chapels, of about a hundred narrow lights.

No. 11, "Nec Timere, Nec Timide," is conspicuous for devoting two towers and spires to each of the Nonconformist and Roman Catholic chapels, and one spire only to the Episcopalian.

"Alpha," in several drawings bound up into a volume, has for the chapels an apsidal chapel for the bodies, with a corridor round it for monuments, the style adopted,—mixture of all the known styles of Gothic, with a little Swiss mixed up.

"Delta," in a series of dirty drawings, shows that the author had spasmodic attacks of "brilliant ideas," which were immediately jotted down, with no reference to any particular plot or plan.

"Look Again."—Another set unworthy of the importance of the subject, and shows evident signs of a careless or a pretence hand.

#### ON CHURCH AND CONVENTUAL ARRANGEMENT.\*

"C'est à la religion à relever la tête pour l'homme vers Dieu, c'est à Paris à le soutenir. Les architectes sont, après les prêtres, les co-opérateurs les plus efficaces de la grâce du Seigneur."—Pillé de Lisieux, in M. Trebutien's "Caen."

THE Upper Chamber of Jerusalem was an ordinary dwelling-room, built like many of the Norman houses, over store chambers. The first mention of a church occurs in St. Paul's Epistles; the next is of the early part of the third century. The word *εκκλησια*, or church, occurs first in the writings of the succeeding century.† The form adopted was that of an oblong, allegorical of a ship, a symbolism preserved in the name of nave (navis), as the spiritual church was described as "The Ark of Christ;" and the triple arrangement of the lower arcade, triforium, and clerestory, bear an analogy to the first, second, and third stories of the Ark. In the "Anecdotal Constitutions" of the fourth century, the direction is given—"Let the church be oblong, turned towards the east, with lateral chambers (*παροισακια*) on both sides, toward the east, as it is to resemble a ship; let the bishop's throne be in the midst, with the presbytery sitting on either side, and the deacons standing by."‡ The church of SS. Vincenzo and Anastasio, at Rome, built by Honorius I., c. 630, has its wall curved like the ribs of a ship. However, in the poem of St. Gregory Nazianzen, "The Dream of Anastasia," Carm. ix., Op., tom. ii., p. 79, mention is made of "a Christian temple of four parts, with aisles in the form of a cross."§ At Djemilah, in Egypt, Lenoir states that the foundations of a church, anterior to the time of Constantine, were discovered; it contained a square cella, inclosed by walls; a nave of five bays, with arcades opening on three colonnades, without a porch, but having a door on one side.

At Thebes,§ Baalbe, Philæ, Sebota, and Maharraka, mentioned by Belzoni, the Christians effected a new internal arrangement of the Pagan temples; a plan not uncommon, as we find in Eusebius, c. 380,|| and in Sozomen.¶ The atrium was roofed in and subdivided, as a nave, into aisles.

Eusebius,\*\* describing a church, or basilica, at Tyre, built c. 313—322, by Paulinus, mentions

in it a semicircular apse, having sacred inclosures, and forming a Holy of Holies. Stalls for the bishop and clergy ranged behind and around a central altar, with a wooden trellised screen parting it off from the nave, which was a square divided into three aisles; seats for the congregation; a lectern in the centre of the nave, flanked by singers and communicants; side porches, and a large vestibule; upper galleries for women; and lastly, a square court, surrounded with a trellised colonnade, and having a fountain in the centre. It is not difficult to recognize here the antitype of the Jewish temple, which contained a triple division, the inner sanctuary, preceded by an enormous porch, and subdivided into (1) the worldly sanctuary, (2) the holy of holies, and (3) the outer court of worshippers. From the fourth century a corresponding and uniform division of the Christian churches was made, and the two former appellations frequently were re-applied. A church at Edessa\* was thus modelled, c. 202. In the Church of the Apostles, built at Byzantium by Constantine, the rooms of the priests were built along the sides of the colonnade, as in the Temple of Zion, as the baptisteries were also circular, in imitation of Solomon's sea of brass.

A relic of this intentional correspondence may be traced in the entrance on the east in the old churches of Rome, St. John Lateran, St. Cecilia, Quattro Coronati, St. Peter, St. Clemente, and originally in those of St. Paul and St. Lorenzo, an arrangement that re-appears in the decline of Gothic art at Seville, although another assignable cause is the original ground-plan of the basilica having an entrance on the east.

The Parthenon and Temple of Theseus were exceptions to the rule of orientation observed by the Greeks, and according to Hyginus and Plutarch, by the Romans. Paulinus of Nola, ep. xxxii., ad Severum, mentions that the church there was a similar exception. Sidonius Apollinaris, speaking of the church of Lyons built by Bishop Pothin, faced the east; so also did St. Mary's, Antioch; and that of Tyre, both built by Constantine. Walafrid Strabo says that the principle of orientation was introduced only after a considerable lapse of time. Tertullian (Adv. Valent., c. 2), c. 200, speaks of the church facing the east.

The Byzantine arrangement was of three kinds. 1. The circular, as at Jerusalem, imitated in the round churches of the west. 2. The basilican, with apsidal termination to the transepts, as at Bethlehem, imitated at Noyon, Soissons, and Bonn. 3. The so-called Greek cross, as at St. Sophia, Constantinople, imitated in Provence, owing to commercial relations with Greece and Constantinople; in the west of Aquitaine through the intermediate seat of St. Mark's, Venice, owing to Venetian settlers; and on the borders of the Rhine owing to the support given by Charlemagne to Oriental art.

The circular form of the Holy Sepulchre built by the Empress Helena at Jerusalem, rebuilt by Charlemagne in 813, was caused by its erection round a tomb: octagonal churches, such as those of Antioch and Nazianzum, like baptisteries, were built on symbolical designs. The church erected on the Mount of Ascension powerfully affected the Eastern mind, and became a model for similar buildings; the domes of which were inscribed with the grand words of the angelic salutation to the Apostles.‡ The dome was a necessary constructional development as the fittest covering for a round building. Constantine built the first round churches in the west, those of St. Constance, and SS. Peter and Marcellinus at Rome. In the interior of the latter and of St. George, Salomica, built by him, with its seven trigonal chapels; in those of the Holy Sepulchre; and in the eight little apses of the Church of the Apostles, at Athens; and of S. Vitalis, at Ravenna, built by Justinian; we observe a singular resemblance to the chevet with its radiating chapels.

An octagonal church, internally circular, occurs at Hierapolis, of an early date. Circular and polygonal churches are also frequent in Armenia. That of Etchmisdzin is a square, with a central dome and apses to each arm of the internally marked cross.

In the Church of the Apostles at Constantinople, Constantine adopted the form of the Latin cross, as in the church of S. John Studius, and a central dome above the sanctuary;§ the nave had a timber roof. However, the necessary construction of four pillars to carry the dome, and of vaults to

\* Read by the Rev. Mackenzie E. C. Wallcut, M.A., Membre de la Société Française d'Archéologie, as elsewhere mentioned.

the nave and transepts, led to the abandonment of the flat ceilings and roofs of the Latins.

The circle or polygon was thus combined with the Latin cross; and the Gammad, or Greek cross, arose from the combination of four gannas, the numeral designating the Holy Trinity. Arculphus describes a church of this form at Siehem, in the seventh century. The cupola in time was extravagantly developed, and the aisles reduced to narrow passages in the time of Justinian. S. Sophia, consecrated A.D. 537, of which the Emperor Justinian said, with a burst of emotion, "I have equalled thee, O Solomon!" forms a square with an eastern apse and a central cupola, and the form of the cross is formed internally by two square halls on either side of the dome; a portico ranges along the entire front of the building, as at S. Vitalis, Ravenna. Sometimes doors only mark the form of the cross. Cupolas erected over each of the four arms served the same destination. After the reign of Justinian, the Eastern churches received a better arrangement, a central dome, a nave with aisles (there are five in the Panagia Nicodemi, at Athens), an inner porch, and three apses to the choir, as at Mistra. In the Benedictine Church of Daphnis, near Eleusis, probably built by the Venetians, the ground-plan is a Greek cross, with central and eastern cupolas, an apsidal choir, aisles, and square lateral chambers. The dome at first flattened, as the builders grew bolder was afterwards elevated, after it had received the addition of a supporting arcade, pierced with windows. The latter were round-headed, and sometimes arranged in triplets; and were closed with trellises of stonework. Belfries were of late introduction in the East, by the Maronites, in the thirteenth century,\* as the wooden clappers were long retained, and did not appear until the Franks began to exercise ostensible influence. There is one of the pointed period at Mistra, and a central tower occurs in Tenos. Chisels seldom occur until the fifteenth or sixteenth centuries. After the Turkish invasion, domes fell into desuetude, and the Latin cross was adopted. The central apse formed the sanctuary, with the altar in the chancel; that to the north the prothesis, or place of the eucense; the southern was the sacristy or diaconicum; the choir was arranged under the dome, and separated from the altar by the iconostasis, a solid screen with a central door, hung with curtains; in the men set below, the women occupied galleries. The chancel screen, *καθλίς*, is first mentioned by Theodoret.† Sometimes the men were on the south, and the women on the north side. The choir sat on either side of the *αμβών*,<sup>‡</sup> or pulpit, which had a little desk attached to it for the use of the reader. A long, narrow wand-like colonnade (the narthex) before the west front, imitated in the porches of S. Mark's, Venice, of a later period, had three doors,—the central for the clergy, the north for women, and the south for men. It was at once a baptistery, chapter-house, vestry-room, and lych-gate; and was occupied by the catechumens and penitents. It contained a *stoup*\*\* for washing. It was sometimes provided with an inner narthex. St. Chrysostom and St. Augustine used to preach from the altars.

The cross was not set up in churches until the middle of the fourth century; and towards its close, pictures of saints and martyrs were introduced. The earliest sculpture is that of the Good Shepherd, carved upon a chalice, as mentioned by Tertullian.

I may mention in passing, that the first notice of a formal consecration of a church occurs in the fourth century: that Venantius Fortunatus, makes the earliest mention of the use of glazing, when speaking of the cathedral of Paris, and the custom of burials within the church, may be referred to the interval between the seventh and tenth centuries, and was of gradual introduction.†† S. Gregory, of Tours, says it was a Frank custom to hang tapestry round the altars of martyrs.

The Byzantine style, which has been called a combination of the Latin basilica and the round chapel of martyrdom, the latter being derived from that of the catacomb; or, more probably, the round church of Jerusalem, exercised a widely-extended

influence, seen not only in the flat cupolas of the Saracen, the apse of the Armenians, and the bulbous domes of Russia. The Catholic Cathedral at Athens, probably the oldest Greek church remaining, and perhaps anterior to the time of Justinian, is nearly identical in ground-plan with that of St. Basil, Kieff, of the close of the tenth century. The cathedral of S. Sophia, in that town, of the eleventh century, consists of seven apsidal aisles, with broad lateral and also apsidal additions. The Russian type was a square ground-plan, a central dome surrounded by four cupolas, three apses, and a narthex, according to Mr. Fergusson, and found in the fifteenth century in the church of the Assumption, Moscow, built by a Bolognese; but the lateral eastern apses are parted off by screens into chapels. It is also perceptible in the West, in the Byzantine cupolas, introduced primarily owing to the influence of Venetian commerce and colonists; at S. Front de Perigueux, built 984—1047, on the plan of St. Mark's, and presenting a narthex; in the cupolas of Cahors and Angoulême, at the beginning of the twelfth century; at Souillac, Saligues, St. Hilaire de Poitiers, and Fontevrault; in the chapter-house of S. Sauveur, Nevers; in the three eastern apses and the porch of Autun, c. 1150; at S. Medard de Soissons, built 1158, in imitation of Santa Sophia; all buildings of the eleventh and twelfth centuries; and up to the twelfth century in the churches of Normandy, Aquitaine, Poitou, and Anjou; while the Basilican and Byzantine forms are united. It is seen in the round churches of S. Constance, built by Constantine at Rome; St. Stephen, of the fifth century, on the Cælian Mount; St. Martin's, at Tours; St. Benignus, at Dijon, of the seventh or eighth century; at Aix, built by Charlemagne; a church, initiated in the twelfth century, at Ottmarsheim; at S. Germain Auxerrois; at Perugia, Bergamo, and Bologna, in the tenth and eleventh centuries; at Charroux, in the twelfth century; at Segovia, Montmorillon, Leon, Metz; in England, in the temple churches (that in London was consecrated by Heraclius, Patriarch of Jerusalem); in the foliated octagon of Justinian in S. Vitalis, Ravenna, bearing a marked affinity to S. Sophia, and the earliest Byzantine church in Italy; in the apsidal terminations to the transepts of S. Martin's, Cologne, c. 1035, S. Maria del Capitulo, in the same city, of the eighth or thirteenth century; at St. Germainy des Pres, built 807, as at Bethlechem, and at Noyon, of the twelfth century; in the ground plan of St. Tibertius, at Rome, of the time of Constantine; of St. Cyria, Ancona, of the close of the tenth century; St. Cesar, at Arles; SS. Vincent and Anastasius, Paris; at Torcello; and lastly, in the superb cathedral of S. Mark, completed in the eleventh and twelfth centuries, which contains the pulpit and iconostasis of Santa Sophia, as well as a rood-screen.\*

In the East, the clergy-house (*παιδοφορία*, Sept. transl. Ezek. xl. 17), libraries, a guest-house, and decanica or prisons adjoined the church.†

These outer buildings were known as Exedrai, and the garth, which succeeded to the Pantheon temenos, as the perihotos, tetrastion and peristation †

The Pagan temples in the West were, from their small size and peculiar arrangements, not readily convertible into churches; the earliest so transformed was, probably, the Pantheon, consecrated as All Saints', in 610; the next, perhaps, St. Urbano Alla Caffarelli, in the suburbs of Rome. The Parthenon of Athens was transformed into St. Mary's.

When the Christians obtained the right of toleration and open celebration of public worship, they took as their model, or rather actually occupied, the basilica, tribunal, exchange, and hall, which, by their form and dimensions, were admirably adapted for the purpose; they retained the name of basilica, understanding it in the sense of the "palace of the great king." The name may be traced back to the Stoa Basilicæ of the Archon Basilus; the Basilica, the first built at Rome, was erected 210 B.C. by Porcius Cato. The judgment-hall of Pilate was a basilica, and its gabbatha or pavement the raised tribune. St. Paul, apparently, was a prisoner in the crypt of Herod's basilica. The atrium remains perfect in St. Clemente, which, though rebuilt in the ninth century, is a complete specimen of a basilica of the fourth or fifth century; also at St. Laurence Without, St. Agnes, St. Praxedes, and St. Cecilia. In St. Ambrogio, Milan, rebuilt in the twelfth century, is an apsidal

basilica, fronted with a large atrium. The apse, with one of the western towers, dates from the tenth century. At Segovia, St. Mellan has lateral exterior galleries, a feature common to this part of Spain and Germany, being the peristyle turned inward, in a transitional state to the cloister. Constantine converted the Vatican and Lateran basilicas into churches, and these formed a type for subsequent structures. The plan was the following. In front of the church was a court, atrium, or paradisus, like the court of Gentiles in the Temple; and the prototype of the future cloister, surrounded by a colonnade; entered by a vestibule (*prothrum*), and having a fountain (*cantuarus*) in the centre, covered by a cupola, at which the faithful washed their hands before entering the church. This court served as a cemetery, and station of penitents, catechumens, and neophytes. Where the court was wanting, they assembled in the narthex, a porch in front of the church, into which the doors opened; on the left side of it was the font.

The basilica itself was a parallelogram, forming with its pronos and alæ a nave, divided into three, or sometimes five, alleys. The central body had sometimes an upper gallery or triforium for women auditors. The aisles on the right hand were allotted to men, those on the left side to women, the tribunes and galleries on the left being given up to widows, and on the right to young women who had undertaken a religious life. In Trajan's five-aisled basilica, 360 feet by 180 feet, and 125 feet high, there was a gallery of this description. In the centre of the platform of the apse the prator or questor had sat, and on either side, upon a hemicycle of steps (which on the ground plan is subdivided like the radiating chapels of a Gothic minster), had been ranged his assessors. In the chancel of the apse had been the altar of libations. In the three-aisled basilica of Maxentius, built three centuries later, we find a lateral apse, resembling that of Germigny de Prés. The chalcidice, the transverso aisle, occupied by the advocates, became the transept, as at St. Paul's, c. 386; and St. Maria Maggiore, c. 432; and the five-aisled basilica of St. Peter, c. 330, where in the latter case it extends beyond the line of nave, to connect it with two circular tombs on the north side, which, possibly, covered the apostle's place of martyrdom, and may have suggested the round tomb-houses of a later period. At St. Apollinare, Ravenna, c. 493—525, the transept is wholly wanting, but a rectilinear compartment, inserted in front of the great apse, offers the first approach to a modern chancel. At Pisa, towards the close of the eleventh century, we find the transept thus developed, with an apse extended into a choir. The triforium gallery under the aisle roofs is found at St. Lorenzo, c. 580, and St. Agnese, c. 625; and IV. Santi Incoronati, c. 625. But the system never came into general use, owing to the preference for a long entablature covered with pictures or mosaics. At Conques and Fontfroide galleries were constructed in the nave aisles. In the early German churches near Bonn, a manner-chor—a gallery for young men—is found in the triforium.—(Whevell, Germ. Arch., p. 91.) At Parenzo, c. 512, and at Autun, c. 1150, there are three, and at Torcello, five, of the beginning of the eleventh century, eastern apses; at St. Miniatto, begun 1013, there is but one. At Romain Mortier, c. 753, the plan included a stunted transept, three apses, a narthex of the tenth century, and a west porch like a small galilee of the eleventh or twelfth century. Ara Culi, at Rome, had a cruciform shape.

The dais of the apse was raised off by amcelli for a presbytery or hem, where the bishop occupied the questor's chair (cathedra), remaining at Parenzo, San Clemente (of the ninth century), San Agnes, SS. Nereus and Achilles, Rome; and the priests the seats of his assessors (*exedra*).<sup>‡</sup> A choir was added constructionally, which reached into the nave, from which it was separated by a marble balustrade (*septum*) for the chorists, acolytes, &c. Ambones, or pulpits, were erected on either side of the chancel arch or door; one (*amalgion*), for reading the Epistle; the other (*ambo*), for reciting the Gospel, serving also as a pulpit, with the paschal candlestick placed on a stand beside it, reproduced in French cathedrals, as at Paris and St. Denis, at the top of the sanctuary stair. A triumphal arch (*porta sancta*, or *regin*) formed the entrance to the sanctuary, which contained the altar covered by a *ciborium*,—a *cibo sacro*, from the reservation of the Host, or from the shape of its cupola resembling the Egyptian bean,—a pavilion raised on columns, and standing above the crypt or confession. The theory

was that every church (as St. Agnes, St. Lorenzo, St. Martino, and St. Praxedes) was crected over an actual catacomb; where this was impracticable a crypt was made, and the ciborium or tabernacle was an imitation of the sepulchral recess of the catacomb. There were two tables of proposition, one for the elements, and one for the vessels used in the office: one remains at San Clemente; two at SS. Nereus and Achilles, Rome, c. 800. Where there were secondary or eastern aisle-apses (*postoforia*), that on the left (*diaconicum minus*) served as the sacristy, library, and monument-room; that on the right (*prothesis*) as the vestry and credence-chamber.

St. Peter's at Rome had two aisles on each side of the nave; a transept on a level with the nave; and an apse on the west side, with a floor raised to a height of 5 feet, forming the platform of the presbytery, which extended about 9 feet into the transept. The entrance was at the east end. At the extreme west point was the pontifical chair, raised on a platform above the level of the presbytery; on the right and left of the chair the walls of the apse were lined with the seats of the cardinals. At the edge of the platform stood the high altar, under a ciborium or canopy: it was raised by steps above the level of the presbytery. On each side a flight of five steps led down into the transept. Beneath this platform was a semi-circular crypt, close to the walls of the apse, used as a burial-place of the popes. The entrances were at the junction of the choir and transept. In front of the high altar was the entrance to the confessional, the subterranean chapel of St. Peter, containing an altar. In front of the steps were twelve columns of marble, in two rows, said to have been brought from Greece or Solomon's Temple; and, being enclosed with marble walls breast high, and lattices of metalwork, formed the vestibule of the confessional. At the beginning of the thirteenth century the stairs to the confessional were removed and the entrance blocked up. The nave was divided from the transept by the triumphal arch, under which a beam was fixed, and in the space between, a cross—an arrangement corresponding with the roof-beam on the south side; and nearly under the arch was the ambo, from which the Gospel was read. The choir of the canons was a wooden structure in the nave. (Willis, Cantabr. Cath.)

In the churches of Bethelchem, St. John Studios, Constantinople, in Asia Minor, and Syria, we find the basilican form.

At Athens there is a very ancient church in ruins, apsidal, and with three lateral distinct naves (those on the sides being designed, probably, for women), an area, and central fountain.

In Asia Minor the Byzantine style exhibits one class of domed buildings resembling S. Sophia, and a second like a modification of a basilica, as at Pitzounds (probably built by Justinian), St. Clement Ancyra (slightly later), and Hierapolis. In the former the circular buildings, found detached at Pergamus and Trabala, are incorporated, forming eastern lateral apses.

Pergamus church, c. fourth century, was an aisleless basilica, with galleries, eastern apse, transept, and two round buildings, one on each side of the transept, serving for a tomb-house, a sacristy, or a baptistery. The same principle may have induced the construction of apsidal ends to the transepts.

The Roman basilica of St. Peter, built by Bishop Agrippinus in 328, forms the central part of the cathedral of Treves; it is the only remaining example on this side of the Alps. Schmidt has shown that it was a square, divided into three aisles, and with a central apse on the east. It probably had a portico with five doors on the west.

The gradual development appears to have been the following:—First, to remove the inner narthex and the women's gallery, seating the congregation on one plane; and to build apses to the aisles, as at St. Saba, Rome; St. Cecilia, St. John and St. Paul, St. Peter's-ad-Vincula, and at Torello. Secondly, to build in front of the sanctuary (as at St. Paul's, Rome), a wall parallel to the principal front, which was the origin of the transept. Thirdly, to develop the apse by prefixing to it a parallelogram, as at St. Apollinaris, Ravenna. Fourthly, the construction of a triforium, like the upper colonnade of the earlier basilicas, with an external wall passage or arcade forming a communication between the transepts and choir, as at St. Sophia at Padua. The font, in Italy, was transferred to the nave in the eleventh or twelfth century from the baptistery, but at an earlier date in Rome.

The sepulchral cell of the catacomb formed the model of the memoria, or funeral chapel; the

tomb of the dead was the first altar, the catacomb the earliest church at Rome.\*

"I was accustomed," says St. Jerome, "to visit the sepulchres of the apostles and martyrs, and often to go down into the crypt dug into the heart of the earth, where the walls on either side are lined with the dead." These catacombs were quarries for furnishing the volcanic sand which forms the subsoil of Rome, and was well adapted to form long galleries; and, it is of interest to remember that a common punishment of the Christian was to work as a sand-digger. One of our Homilies (Peril of Idolatry, p. iii), says,— "Vaults are yet builded under great churches to put us in remembrance of the old state of the primitive church before Constantine."

Wherever a space intervened in the passages closed by a blank wall, lateral recesses were hollowed out for the reception of sarcophagi; the roof was curved like a dome, and the upper part of the tomb was the altar, as in the early church of San Sebastian. The crypt was known as the martyrdom or confession. It had three arrangements:—First, when a church was built over a catacomb, the old entrance was preserved, as in San Lorenzo and San Sebastian, with steps to descend into it. Secondly, if the tomb was on the ground, then a crypt was built round it, and steps were made, while the sarcophagus was replaced by an altar tomb. Thirdly, when a martyr was translated, then the crypt was made to harmonize with the church. In the church of Santa Sabina, the large stair is in front of the altar, at St. Paul's behind it; at St. Saba's, the stairs are in the nave aisles, and the crypt, forming a narrow passage, is reached by corridors, reminding us of the crypt at Ripon. At the Quatuor Coronati, a round stair leads down into it from the benches of the presbytery, as at Torello, where there is a double wall in the apse. St. Mark's and St. Praxedes, Rome, have narrow galleries like the passages of the catacombs leading to it: there is a subterranean church at St. Martin des Monts and St. Mary, in Cosmedin, c. 790. At Inkermann there is a rock-cut church, apsidal, with square-ended aisles.

Rock hermitages occur at St. Aubin (near St. Germainy de la Rivière), St. Antoine de Calumies (E. Pyrenees), St. Baume (Bouches du Rhône), Monserrat, Warkworth, and the Roche Rocks, Cornwall; and in the grotto of Fontgamhand, near Blanc.

In some instances a martyrdom was built like a little crypt, under the altar, with a shrine fenced off by a screen, or perforated marble, as at St. George's, Velahro, and SS. Nereus and Achilles. Sometimes a small hole (jugulum) permitted the head of the devotee to be inserted, or the passing of a cloth to touch the relics. Crypts remain under the eastern apses of Spire, Mayence, Besançon, and Strasburg.

The round church was, probably, peculiar to towns either unimportant or of a limited population.† The baptistery of Florence, built by the Lombardic queen Theodelinda, was the old cathedral, and, until the eighth century, was the church of St. Lorenzo, of the time of Justinian, was the cathedral of Milan. An octagonal building, to the east of it was, possibly, a chancel. A baptistery stood on the south. The baptistery of St. Agnes, and the tomb of St. Helena, St. Stephano Rotunda, Bologna, of the fifth or sixth century, and the tomb of Theodor, now St. Maria Rotunda, were circular. Again, we have also octagonal buildings, such as the Lateran baptistery, and mention is made by Eusebins of an octagonal church at Antioch, built by Constantine. The tomb, however, of Galla Placidia, at Ravenna, built before 460, is cruciform. The circular form had been adopted for the mausolea of Augustus, Cecilia Metella, and Adrian, and the temples of Vesta and the Sun. Almost all the German churches of the time of Charlemagne, as at Aix-la-Chapelle, Nimeguen, and Magdeburg, were circular. In England, and frequently in Germany, as in Spain and Italy, a choir was added to the round church. At Bonn, an oblong nave, as in France, was built in conjunction with the circular building.

In the eleventh or twelfth century circular churches began to disappear. In England and Germany the nave was of this form; but in France, the choir, as at St. Benigne's, Dijon, of the seventh or eighth century, and partially reconstructed in the beginning of the eleventh century, St. Martin's, Tours, of the fifteenth century, and Charroux. At Perugia, Bergamo, and Bologna, of the tenth or eleventh century, the nave was round, and the choir oblong and apsidal. The

round nave of the Templars' Church, at St. Segovia, c. 1204, has a choir and aisles terminating in apses.

Round churches are found in the island of Bornholm. At Wisby a two-storied church has an octagonal nave and rectilinear choir.

The public baths of the Romans, in some cases, became converted into baptisteries: the piscina was the ordinary cold bath of a Roman villa. After the conversion of Constantine, distinct buildings of an octagonal shape were built in front of churches, as at Rome, Nocera, Piacenza, Torello, Novara, and Ravenna, a plan perpetuated to the thirteenth century by the Lombard architects; but almost universally, with this exception, were no longer built after the eleventh century, when parish churches were permitted to have a font. The western baptistery became, after a while, merged in the western apse in Germany. In Italy it served still as a baptistery or a tomb-house.

The basilica was a parallelogram, with an internal transept, and apsidal termination at one end, and a porch at the other extremity. The Byzantine church subordinated nave, choir, and transept, as the supports of a central dome; which was the development of the vault, as the vault was of the arch: the ground-plan at first was a round or octagon, became a square, rendered cruciform by the four limbs rising above the angles round the cupola; three semicircular, latterly polygonal, apses formed the east end.‡ The Lombardic, which lasted from the seventh to the thirteenth centuries, comprised both these types.† It had a long nave, triforium, a central octagon, and cupola, set on a square base, making an internal dome; an east end terminating in three apses; sometimes an octagon and an oblong were arranged to form a church.

The eastern aspect of the sanctuary and the cupola are its Byzantine features: the Latin cross, the lengthened nave, the apsis and crypt, the latter becoming spacious and lofty, are Roman characteristics. Triforia, or galleries, for women, are built along the aisles of the nave and transept; pillars are grouped; and the roof is of stone, vaulted; but the narthex disappears, to be resumed in the eleventh century as a porch. The baptistery and campanile are nearly invariable, but detached adjuncts. The earliest Lombardic church existing is that of St. Michael, at Padua, built 661. Conventual buildings became prominent and numerous, such as the cloisters of Verona, St. John Lateran, Rome, and Subiaco, of the twelfth and thirteenth centuries. At Colhenz, in 836, and at Cologne, the Lombardic style established a home, reaching France in the beginning of the eleventh century, and England in the latter part of the reign of Edward the Confessor.

The addition of towers, which were rare until the eleventh century, exercised a very marked influence upon the ground-plan of churches.‡ They possibly were suggested by the pillars of the Romans, and originally were designed as landmarks to point out the position of the church, and as an ensign of power, rather than as helms, as the bells were for several centuries but small, and St. Bernard forbade their construction, as they were not for use, but for pomp.

The first tower attached to a church was built by Pope Adrian I., elected 772, in front of St. Peter's at Rome.§ One of the time of Justinian, a circular building, was attached to St. Apollinaris at Classe, at Verona; two ancient round towers are found at Verona, one dating from 1017; another, of the same date, remains at Bury, near Beauvais; a third, of a later period, at St. Desert, near Chalons-sur-Saône; while square towers are found in Italy in the eighth and ninth centuries, as at St. Paul's and St. John's, Rome; and one at Porto, near Rome, built 830.

Towers originally built in the close, as at Verona and Toscella; and before the church doors, as at St. Maria Toscanella and St. Lorenzo, in Italy, however, never forming integral parts of the design, were at length attached to the west front of the church, singly as at Lyons, St. Martin at Tours, Poissy, St. Benoit-sur-Loire, Puy, Limoges, St. Savin, and St. German des Prés, and at Paris in the thirteenth century. In the south of France, until the middle of the thirteenth century, in Italy and Spain, they remained generally isolated.

Two sometimes flanked the west front, as at Jumièges, and St. George, Bocherville, with a porch in the centre. In German churches they were frequently connected by a gallery. At Germerode

and Worms two round towers flank the western apse.\* Rouen has six towers. At Clugny there were seven, each bearing the name of ecclesia, in imitation of the seven churches. Laon, like Chartres, was designed to have as many. Rheims had six, and a central fane. Five towers occur at Tournai (Schayes, iii. 11). Round towers are found in East Anglia; and in Ireland, erected between the fifth and thirteenth centuries, tapering upwards, a form employed owing to the peculiar material of each district. There are also round towers at Brechin and Abernethy, and at Tchernigov, near Kiev, c. 1024. The French round towers appear to have come from the north of Italy, as they are found at St. Mary's and Vitalis, Ravenna; and reappear in the ninth century at Centula, Charroux, Bury, and Notre Dame, Poitiers. Towers were sometimes used as record chambers, or as courts of justice.†

At Germigny, built 806, there is a central tower; and at St. Alban's it was added c. 1077-1093. In the province of Toulouse, the earlier churches had a single west tower as Limoges, in the eleventh century and Alby, built in the fourteenth century, had. The larger monastic towers appear to have been built partly for purposes of defence, partly out of emulation, with the castles, the abbays being equally with the nobles great feudal lords. The belfry story and the spire, however, formed the characteristics of the church tower. The cathedral towers of the eleventh century served also as municipal belltowers. M. Viollet le Duc has traced two schools of towers, one of the West and the other of the East, at Perigord; the one introduced probably by the Venetians, the other derived from the banks of the Rhine, which gave place to a national school in the middle of the twelfth century. In the west of France conical spires appear in the eleventh and twelfth centuries, some being supported on an octagonal belfry, rising from a square tower. Normandy was distinguished by its central square towers.

One of the earliest instances of the Pointed style is St. Andrea, Vercelli, built by an Englishman in the thirteenth century. It has a square east end and two polygonal chapels attached to each transept, like the ordinary type of Cistercian abbey. The west end is flanked with towers, and there is a central octagonal dome. At Sienna, begun 1243, we have the triple-gabled front, circular window, and three portals of the characteristic Italian type; a square east end, with the central apse having a niche-like apse in the wall, three aisles throughout the church, with eastern square chapels to the transept, and to the south wing a belfry attached, and a central dome. Florence, begun at the extreme close of the thirteenth century, is triapsal, like the early churches of Cologne, and a central dome. Milan, commenced 1385, has a five-aisled nave, a shallow transept with aisles, and a triapsal apse. The cathedral of Bari, a three-aisled basilica of the twelfth century, has a circular apse flanked by sacristies. A western transept is found, in conjunction with an octagonal tower, in the centre of it, at St. Antonio, Piacenza, c. 1014; and two western towers, like a quasi transept, appear with a western cloister, at St. Ambrogio, Milan, rebuilt in the twelfth century.

In the double church of Assisi, finished in 1230, the upper is a Latin cross without chapels; the lower with a nave lined with chantries, and the shrine of St. Francis in the centre of the transept, standing above a crypt. It was the work of a German architect; and a double church occurs at Rheindorf, consecrated in 1151. The design was to accommodate two congregations, as in the two-storied chapels of the castles of the period; and the double church of Pakefield, two aisles under one roof,—which was used by two distinct parishes, Wisby is a double-storied church. The Duomo of Milan, and the church of St. Giovanni, at Naples, were built by German architects in the Gothic style, but there to remain, with a few others, as isolated specimens among the structures of the new school of Pisano. The development of Lombardic into Gothic architecture is marked by rapid changes, the crypt and Latin cross remain; but a spire rises over the central lantern, lateral towers flank the west front, the baptistery shrinks into the font, a lofty screen rises before the choir, which is lengthened out, and porches over the entrance doors.

The formation of the western apse, the construction of an eastern aisle, the development of the choir, the formation of the ante-choir, and the double gate at its entrance with the altar of the Saviour, were probably innovations of the northern

architects. The next great change was the erection of a central tower upon four pillars, like the Byzantine dome.

Charlemagne constructed the central dome of his churches on eight pillars, introducing a still more important change—isolation, a passage on every side, a method of central junction by means of arches, and an advance to a loftier method of construction. Four central pillars, a development of this primary idea, are found at St. Martin d'Angers, built by the Empress Hermengarde, not long after Germigny, and in all English churches of the period; also at Hitterdaal, a timber building, in Norway; and at St. Savin, Aquitaine, begun 1023. At Germigny the choir occupies this central space, and at Vignory, a square in a similar position, before the tenth century, marked out by pillars. In the church of St. Savin, Aquitaine, begun 1023, we find four central piers, a transept with an eastern apsidal chapel in each wing, and five semicircular chapels ranged round the choir, which is an arrangement never found in the south. To the necessity for strengthening the central supports, we may refer the construction of engaged shafts, as in the church of St. Miniato, at Florence. At Vignory, before the tenth century, there was a square of six pillars, inclosing the choir with a processional path opening upon six chapels.\*

BRITISH ARCHÆOLOGICAL ASSOCIATION. PAINTINGS IN SOUTHWOLD CHURCH.

The opening meeting was held on Wednesday, the 28th ult., Mr. T. J. Pettigrew, F.R.S., in the chair, when twenty-five new associates were elected, making sixty during the year.

The Rev. Mr. Ridgway communicated notes by Mr. Christopher, architect, on the Lübeck brass, which we may print on another occasion.

Afterwards, Mr. Blackburne exhibited representations of the paintings in Southwold Church, and the following remarks by that gentleman were read:—

The accompanying figures are from the panels of the chancel and north aisle screens at Southwold, in Suffolk. Those representing the apostles are from the former. The latter has representations of the nine orders of angels, two among the number of which are shown in the framed drawing, with two angels bearing respectively the emblems of the blessed sacrament and the Holy Trinity. These occupy the end panels, north and south of the aisle screen, and have a very appropriate reference to the dedication of the chapel which the screen encloses, viz., to the Holy Trinity. There is a similar screen at the east end of the south aisle, dedicated in honour of the Blessed Virgin. The panels here had originally the greater and lesser prophets painted on the panels. A very few of these only are now discernible to any extent. The figures of Moses and David are the most perfect, though the names of the others are still traceable. The chancel screen has the twelve apostles, of which the drawings give the most perfect, though all the others remain more or less so. The order in which they appear is as follows, St. Peter and St. Paul occupying their accustomed positions right and left of the doorway:—

St. Philip.	St. Matthias.	St. James Minor.	St. Thomas.	St. Andrew.	St. Peter.
St. Paul.	St. John.	St. James Major.	St. Bartholomew.	St. Jude.	St. Simon.

Taking the three screens, there are, altogether, thirty-six figures, the whole very richly painted in gold and colour. Those of the centre or chancel screen are particularly so, and the execution is far superior, artistically considered, to the majority of existing examples. The grounds upon which the figures of the apostles are painted, or rather which finish the portions of the panel not occupied by them, are diapered in relief in a kind of mosaic and gilt, and in places picked in in colour, to lighten the same. The diaper of the dresses is simply painted in gold and colour. These, and the ornamentation of the nimbi are very interesting.

The mosaic enrichment is continued all over the chancel screen. There is hardly a moulding of it that is not so ornamented. The buttress faces are almost entirely covered with it, the design of the enrichment including in it small figures under canopied niches, some of which have been protected by glass, looking like so many small framed pictures. The tracery of the leads of the six main compartments of which the screen is composed is remarkably beautiful. It is double tracery of exceeding lightness, composed of a small gilt bead and cusped, placed between a parti-coloured ogee, and a hollow alternately green and red, studded with relieved flowers at intervals. The screen is altogether one of the richest and best preserved examples to be met with.

The side screens are less rich in the decorations, but still very beautiful and interesting. Mosaic relief is here also adopted in the hollows and on parts of the buttress faces. The tracery of the beads is of the same description as that of the chancel screen. The grounds of the panels are here in colour, powdered with stars and flowers,

and the tracery leads of the panels have alternately red and white hollows and gold fillets, the former ornamented with flowers.

The date of the screens is circa 1460. In connection with the chancel screen, or rather with the roof figures which anciently stood above it, there is a very richly-painted ceiling, representing in its panels angels holding scrolls and the implements of the Passion. It appears to have been a common practice to more highly ornament the bay of the church roof which was immediately over the rood. There are several instances of it in Suffolk.

THE ARCHITECTURAL MUSEUM COMPETITION.

THE prizes annually offered to artist-workmen through the council of the Architectural Museum have this year been responded to by twenty-five specimens, viz., eleven for the prizes for modelling in clay, given by the council of the museum and Mr. S. C. Hall; three for the wood-carving prizes, supplied from the same source; seven for the prize given by the council of the Museum for a cartoon for painted glass; and five for the prizes for coloured decoration offered by the committee of the Ecclesiological Society of Loudon and Mr. Beresford Hope. The specimens, many of which are very creditable to the competitors, are now exhibited in the gallery of the Architectural Museum. It is proposed to distribute the prizes in March next, in connection with a course of lectures to which we have already alluded.

STAMFORD TERRA-COTTA WORKS.

A LARGE statue of Diana has been recently manufactured in terra-cotta by Mr. J. M. Blashfield, of Stamford. The height of the statue is 10 feet 6 inches, and of the pedestal 5 feet 6 inches. It has been copied from the antique statue, the Diana Borghese. Among the works just finished is a new and original statue of Erin. The figure is life-size and semi-nuda. This piece of sculpture has been designed at the works, and executed to order for R. N. Newcomb, esq., proprietor of the Stamford Mercury; it has been wrought by Mr. Hale. Among other works recently removed from the kilns, are two vases made to order for the Hon. G. W. Fitzwilliam: one is a copy of the celebrated Warwick vase, modelled from the original at Warwick Castle; and the other is a copy of the Alliano vase, from the Louvre, at Paris. A fountain has just been executed for Earl Ducie, composed of a large fish-pond basin, 16 feet in diameter: the rim is divided into four parts by plain block pedestals for statues. In the centre of this large basin there is a tazza from an antique form at Rome 12 feet in circumference, adorned with masks of river gods.

WATER FOR ST. HELLER.

It was announced some months back in the Builder that Mr. James Easton, C.E., had made surveys and plans for the supply of water to the town of St. Heller, Jersey. A company is now formed to carry out that object.

To the numerous vessels daily sailing from the harbour, to the extensive garrisons and fine public institutions, as well as to the large houses of business and widely-spread mansions, this project will prove not only a great accommodation, but a stride in advance towards economy and sanitary improvement.

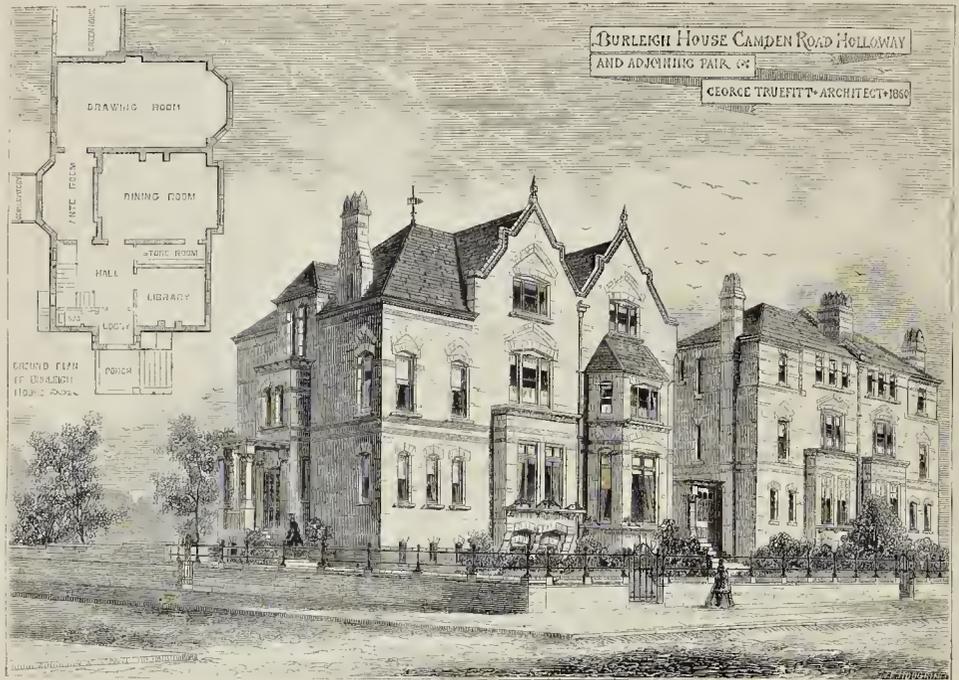

In all populous and business towns the presence of fire-mains is of the first importance. The service by gravitation to the upper stories—the softer and purer quality of the water, which insures immense aggregate savings—the supply of fountains and markets—the avoidance of cost incurred for cartage of water (first pumped by hand), to considerable distances—all these advantages are attained by the modern system of pipe water service. And at the same time, the irregularities and expenses of sinking and repairing pumps are avoided, the perfect system being also the cheaper.

The formation of joint stock companies of limited liability, hitherto not sanctioned by the legislature, is now under consideration of the States of Jersey, and the essence of the Act 19 & 20 Viet. is likely to be adopted.

ROTHERMITH, SURREY.—At a meeting of the board of guardians of this parish, on the 29th ult., in the new board-room, Mr. George Legg and Mr. John Davis Paine were appointed to prepare the intended new Surrey map and valuation. Rothermith comprises about 2½ miles of wharf and river frontage, the Grand Surrey and Commercial Docks, railways, gasworks, and upwards of 4,000 miscellaneous properties. The former survey was made in 1812, by the late Mr. George Allen and Mr. Porter, of Bermondsey.

\* To be continued.

#### HOUSES IN CAMDEN ROAD, HOLLOWAY.

The accompanying engraving represents some houses lately erected in Camden-road, Holloway, from the designs of Mr. George Truefitt. The corner one, built for Mr. R. P. Harding, has been well finished. The drawing-room has been decorated by Mr. Sang, from the architect's sketches: the gas-chandeliers, brackets, &c., were executed by Johnston, Brothers. We find here hot and cold water throughout the house; Hobbs's locks; no lath-and-plaster partitions, all internal divisions being 9-inch or 4½-inch brick in cement. The same also in the adjoining houses. The porch is glazed with large squares of plate glass, as are the windows of principal rooms. The basement is out of the ground, *i.e.*, level with it. At the front is a green bank; another at the back, with a double flight of steps leading down to the garden. The basement windows have all bars;—no shutters anywhere in the house, except revolving ones to the door from ante-room to conservatory. The hall is paved with Poole Pottery tiles, as are also the fire-places and hearths, on which stand dog grates, with fire-bricks backs in all the sitting and bed rooms.

#### THE FIRST STEP OUT OF DOORS IN AID OF THE EXHIBITION OF 1862.

We have reason to believe that the council of the Institute of Architects propose immediately to take into consideration what course shall be adopted that architecture may be completely illustrated, and construction fully represented, in the Great Exhibition proposed to be held in 1862.

#### THE PUGIN TESTIMONIAL.

The following rejoinder has been addressed to the Honorary Secretary:—"I am favoured with your and our friend Talbot Bury's official remarks on this matter, which fairly state your feelings on the subject. I have also read Mr. Beresford Hope's candid letter in the *Builder*, and am ready to accept his interpretation of the term 'Medieval,' as to the period to which he so frankly extends it.

It is a striking fact, that in the passage quoted from the 'Apology for the Revival of Christian Architecture in England,' in your appeal, Welby Pugin does not use the word 'Medieval,' and he names certain of our Gothic edifices, (without, however, restricting the study to those only,) as volumes of ancient art open for all inquirers.

Let the committee, therefore, omit the word, 'Medieval,' which is not used by Welby Pugin, and adopt the period named by Mr. Beresford Hope. Let the terms run thus:—"In examining and illustrating the antiquities in Architecture, painting, and sculpture of the United Kingdom to the end of the sixteenth century inclusive," or "to the beginning of the seventeenth century exclusive." The objection of a numerous body of the profession would, I conceive, be removed; the sectarian 'Shibboleth,' or party cry avoided, and the testimonial would become a general, instead of a partial, tribute to the merits of a very distinguished man in our art.

THOS. L. DONALDSON."

#### ARCHITECTURAL COMPETITION, AMSTERDAM.

The *Société d'Architecture* of Amsterdam offer a premium for the best design for a group of buildings necessary for the University of a large town, to include accommodation for the five faculties—theology, jurisprudence, philosophy, the natural sciences, and medicine. The number of students to be 600. The whole is to be Monumental in style, with ornaments of painting and sculpture in harmony with the destination of the edifice. The competition is open to foreign architects, and a premium of 500 florins "*de Hollande*," with a certificate of honour, will be given to the author of the selected design.

The conditions, which are published, state that the designs must be sent to the secretary of the Society (Herr A. N. Godfroy), Oude Thuismarkt, B. 56, Amsterdam, before the 1st of November, 1861.

#### LONDON STREET ARCHITECTURE.

WAREHOUSES FOR MESSRS. SAMUEL COURTAULD & CO., ALDERMANBURY.

The buildings represented in our engraving occupy a site opposite the church of St. Mary, Aldermanbury, on land the property of the parish, with a frontage of about 65 feet by an average depth of about 104 feet, giving a superficial area of 6,760 square feet. The floor area of the whole of the stories amounts nearly to 30,000 square feet, and the cubic contents of the whole of the buildings are about 360,000 feet. There are two distinct warehouses. No. 18 occupying the whole of that portion of the buildings fronting Aldermanbury (with the exception of a part on the

ground-floor story) is in the occupation of Messrs. John Wroford & Co. No. 19, comprising the remaining part of the Aldermanbury front on the ground-floor, and the whole of the back portion of the premises, are occupied by Messrs. Samuel Courtauld & Co., for whom the whole of the premises were built. The entrance to this warehouse is by the central doorway in Aldermanbury, and a corridor of ornamental character, with the counting-houses on the left, conducts to the spacious ground-floor area of the warehouse, with wide galleries above; the whole lighted by a skylight of great size, receiving only the pure northern light, so necessary for the purposes of the business carried on here. Light is transmitted to the basement story from the same source without the employment of an open well-hole: none of the valuable ground-floor space is thus sacrificed.

The upper stories of Messrs. Courtauld & Co.'s occupation comprise dining and bed rooms, kitchen and other household accommodation for those employed upon the premises. This part is mainly supported across the area of the warehouse on a wrought-iron box girder of great strength. This material has also been largely used in other parts of the structure, especially in the formation of the fire-proof floors which separate Messrs. Courtauld & Co.'s counting-houses from the other part of the premises. The elevation next Aldermanbury is ornate, but business-like, in character; the ground-floor, with its moulded piers and arches, carved frieze, &c., being executed in Portland stone, the remainder in white brick, with Portland cement dressings.

One of the buildings formerly standing upon the site of the new warehouses was once the mansion of the celebrated Judge Jeffries. Medieval coins, a dagger, and other relics, were discovered in excavating for the foundations, as also a stratum of charred remains, probably deposited after the Great Fire.

Mr. Edmund Woodthorpe, of Basinghall-street, is the architect; and Mr. Wm. Brass, of Silver-street the contractor for the works.

THE ROYAL ACADEMY.—It may have been seen in our advertising columns last week that, at a meeting of the Royal Academicians, held on Wednesday evening, the 28th November, Mr. George Gilbert Scott was elected an Academician in the room of Sir Charles Barry. We desire, however, to record the satisfactory event in this portion of the paper.

WAREHOUSES, IN ALDERMANBURY, LONDON.—MR. EDMUND WOODTHORPE, ARCHITECT.

THE "HASLAM."  
THE ANGLESEY STATUE.

ALL persons who read the account of the ingenious manner in which the colossal statue of the Marquis of Anglesey has been raised on to the gigantic column, erected by public subscription in 1816, close to the Menai Bridge, must have been extremely interested with the narrative, and must greatly regret that the clever young engineer who planned the efficient and inexpensive substitute for the usual cumbersome paraphernalia of scaffolding should have been so early snatched away from a profession he was so well qualified to adorn.

The statue is by Nohle, and is 12 feet 4 inches high. It is of bronze, weighing 25 tons. The arrangement is thus described:—

Two balks of timber, about 70 feet long, were placed vertically at the foot of the column, and formed a sort of double mast, on which were placed what sailors term cap and cross-trees, to admit of a topmast, which was hoisted up and secured between the two lower masts, the whole attaining a height of 120 feet, giving a clear 20 feet above the column itself. On the capital of the column a shorter mast was erected, and between these two masts a large pair of traverse beams was laid across, on which a small travelling truck was placed: the whole were firmly bolted together and secured with several pairs of shrouds. The structure looked of so slender a nature, that when the great mass, weighing 25 tons, which was about to be lifted into mid-air to an elevation of 120 feet, was seen, every one felt considerable misgivings. The hoisting apparatus consisted of a large hawser carefully attached to the statue, and leading through rollers on the travelling truck along the traverse beams, and down on the opposite side of the column, and attached to a heavy three-fold tackle, forming the principal purchase. Besides this, two other tackles, likewise attached to the traveller on the summit, and thence to the statue, were used as supports to the main hoisting apparatus.

I will not occupy space by describing the operation: suffice it to say, that, when the statue had reached the summit, it was slid by means of the main purchase, checked by two tackles at the opposite end of the truck, until it was poised over the column: the preventer tackles were then un-racked, and it was lowered into its place amid the cheers of the bystanders.

So far the event, this brief account of which the *Builder*,—ever ready to bestow the laurel wreath where due,—will not decline to print.

I cannot say I advocate the St. Simeon Stylites fashion of perching our heroes on columns, midway between earth and heaven: it removes them too much from our daily acquaintance, and from our affections; although it certainly has the good effect of making them more notable as landmarks to society, examples to be followed. But the merits or demerits of the custom we have not now to discuss. The work had to be done, and the only question was, how to accomplish it in the most successful and inexpensive manner. It was a hazardous undertaking, and the late Mr. J. Haslam most signally conquered the difficulty; while, in addition to the present success, he has bequeathed a new arrangement to those who come after; thus enriching his profession and his country with a servicable idea.

On this ground, I would respectfully submit, to the members of the Institution of Civil Engineers, that, if they would ordain that the skeleton scaffold used in this engineering exploit be named "The Haslam," in memory of its youthful inventor, they would greatly gratify a large circle of appreciative lookers-on, and would be paying only a just tribute to him who was called away ere he could witness the triumph of his bold and ingenious conception. \* \* \*

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The ordinary meeting of members was held on Monday evening last, at the house in Conduit-street.

Mr. Godwin, V.P., occupied the chair.

The minutes having been confirmed,—

Mr. T. Hayter Lewis (hon. secretary) announced several donations to the library.

Mr. Penrose (hon. secretary for foreign correspondence) said that he had to acknowledge on behalf of the Institute two presents from M. César Daly, of Paris, to whom they were already indebted for many valuable contributions. The first was the "Revue Générale d'Architecture et des Travaux Publics," which, he might observe in passing, contained drawings of a certain class of building with which we were unfortunately too cognizant in England, namely, a poor-house, intended to be built in France. With regard to the other present, he had received a letter from M. Daly, in which that gentleman requested that the Institute would do him the honour of accepting the first portion of a new work, entitled, "L'Architecture Privée au Dix-neuvième Siècle

sous Napoléon III.: Nouvelles Maisons de Paris et des Environs." The work, when complete, would contain 200 plates, comprising the best specimens of the private or domestic architecture of Paris and its neighbourhood; showing the ingenious contrivances for which the French appeared to have such an aptitude; and also great beauty of design and elevation. He had also to announce with deep regret the death of one of their most distinguished foreign members, the Chevalier Bunsen. He was educated at the University of Göttingen, under Heine, and subsequently repaired to Rome, where he obtained an appointment on the staff of the Prussian minister. In the year 1835 he succeeded that minister, and represented the court of Berlin at Rome until 1839, when he was recalled in consequence of the vigorous part which he took in defending the King of Prussia against the Papacy in the matter of the Archbishop of Cologne. While at Rome he studied architecture with Canina, and he succeeded in solving what had long been a vexed question, namely, the direction which the Forum took, which he pronounced to be towards the Arch of Titus. Subsequent excavations proved that he was perfectly correct in his diagnosis. After he became Prussian minister at the court of St. James's he published his celebrated work on Egypt, and in 1848 his other important work, entitled, "The Church of the Future." He died at Bonn, in the seventieth year of his age; and his death would be not only deplored by his friends, but he felt as a heavy loss in most literary and artistic circles, of which he formed a prominent ornament. Personally, he (Mr. Penrose) had to thank the chevalier for many kind introductions in Rome and elsewhere.

Mr. H. B. Newton observed that, with regard to "L'Architecture Privée," by M. César Daly, it was originally the intention of that gentleman to publish drawings of all the private villas, &c., which had lately been erected in Paris and its immediate neighbourhood. This project he had, however, for obvious reasons, abandoned, and the work would now contain selections of the best designs. With regard to the re-distribution of sites the work would be found to contain a great deal of information, and also many valuable hints of great interest to the architect generally. The work would be published in fortnightly parts.

The Chairman said he was glad that attention had been called to the subject and to M. Daly's merits, and he hoped it would lead to the purchase of the work in England. His "Revue" deserved to be better known than it was. No one could be more competent to conduct such a work than M. Daly, as he had not only travelled in England, Scotland, and Ireland, but had visited the most remarkable places on the Continent; and had ultimately carried his investigations across the Atlantic, where he had explored the hurried cities of America. He (the Chairman) then added that he wished to avail himself of the present opportunity to state that the Council of the Institute felt it desirable again to postpone the consideration of the question of architectural examinations. The ground upon which the council had arrived at this conclusion was that, as other architectural bodies were still discussing the matter, they thought it undesirable that it should be brought under the notice of the Institute until they were in possession of the resolutions agreed to by the other bodies.

Mr. Kerr inquired how many architectural societies were still discussing the subject.

The Chairman said that the council were mainly waiting to hear from the Architectural Association and the Scottish Society.

Mr. Kerr apprehended that the Architectural Association might devote a long time to the discussion of the subject, and expressed his opinion that the Institute ought not to wait an indefinite time for any other society in the country.

Mr. Newton inquired whether the council had postponed the subject indefinitely.

The Chairman replied that the council at their meeting that evening had not fixed any particular day for bringing the subject before the body generally, because they were of opinion that it would be premature to do so until they were in possession of the resolutions agreed to by other societies. He had, however, no doubt that the council would fix the earliest possible period for the discussion.

Mr. Kerr submitted that the council had no power to postpone the subject *sine die*. On the former occasion when an evening had been fixed for the discussion a resolution was moved to postpone it to another day then named (the 10th of December), and he thought that the proper course would be to move a similar resolution appointing some given day for the consideration of the question.

The Chairman said that if Mr. Kerr thought that his proposition would be more consonant with the feeling of the meeting than the simple intimation on the part of the council, he would take a resolution from him to that effect.

Mr. Brandon observed that, in his opinion, the matter was not of such pressing consequence that it could not be postponed for a month, or perhaps two. It was necessary to bear in mind that other societies were quite as much interested in the subject as they were, and that full deliberation was absolutely necessary. He hoped that, when the question came on for discussion, it would receive the calm and deliberate consideration of the Institute; and, to secure that object, he would move that the subject be adjourned until such time as the council might appoint.

Mr. Hausard, in seconding the motion, reminded the meeting that, when the council first mooted the subject, they had expressed their anxious desire to receive from all the information which the other societies could give them. The question was in very good hands when left to the discretion of the council, and he for one did not participate in the apprehension which Mr. Kerr appeared to entertain, that it would be shelved by them.

Mr. Kerr said, the Architectural Association was, in point of fact, the only body for whose decision they were waiting, but that the Association did not expect to be able to dictate to the Institute. The Association was composed of young men; they were only expressing imperfect views; and they knew them to be imperfect. Under these circumstances, he thought it would be unadvisable for the council to postpone the consideration of the subject *sine die*. He would move, as an amendment, that the subject be postponed for a fortnight; and he put it to the good sense of the meeting whether his proposition was not reasonable.

The Chairman said, that as the present proposition for an architectural examination as a test of professional fitness had originated with the council of the Institute, it was extremely improbable that it would allow it to drop, at the same time, as the Institute had invited the opinions of the other architectural bodies, they were bound to wait a reasonable time for them. The amendment now being seconded, he would put the original motion proposed by Mr. Brandon.

This was carried unanimously.

Thanks having been voted to the donors of contributions to the library,

The Rev. Mackenzie Walcott read a paper "On Church and Conventual Arrangements," which we shall print in full. Part of it is given in our present number.

At the conclusion,

Mr. Fergusson, in proposing a vote of thanks to the reverend gentleman for his interesting and erudite paper, said that the author had so thoroughly exhausted the subject, that very little remained to be said. One point, however, struck him (Mr. Fergusson), and that was that Mr. Walcott did not appear to have sufficiently observed the original use of the basilica and the round church. In his (Mr. Fergusson's) opinion, the basilica was a place of assembly, or a parliament, in which the bishops were in the habit of ruling the Church, and that the ceremonial church was the round church. They subsequently became amalgamated, but in the early times of the church they were separate, the one being secular, and the other wholly ceremonial. This was the only point which it occurred to him to notice; for really Mr. Walcott's lecture was so full and complete, that little further could be said upon the subject. He had, therefore, only to express his gratitude to the author for the information which he had afforded; and, when the paper was printed, they would be able to give it that attentive study and consideration which its great merit unquestionably demanded at their hands.

Mr. Penrose seconded the vote of thanks, and expressed a hope that when the paper appeared it would become a book of general reference. With this view he wished to call Mr. Walcott's attention to the necessity of providing an index of names and subjects, to accompany it.

Mr. Ferrey wished to add his voice in praise of the zeal, research, and learning which Mr. Walcott had brought to bear on his task. The subject was, in fact, so comprehensive, that it would be impossible to follow it off hand in all its vastness. A point, however, had occurred to him, with which Mr. Walcott did not appear to be so familiar,—he alluded to those churches of the Rhine where a church was found above a church. There were, he believed, also several specimens of this peculiar style in Russia, but they did not

appear to have entered into Mr. Walcott's classification. In his remarks upon gallees porches, also, he had omitted mentioning that at Snettisham, in Norfolk, which was the only porch of the kind in England belonging to a parish church. Neither had he made any allusion to the orientation of churches. As it was desirable that nothing should be wanting in so admirable a paper, he took the liberty of suggesting that Mr. Walcott should add a few notes in reference to these subjects.

Mr. Kerr remarked that Mr. Walcott had referred to "Tombland," in Norwich, as if the name had been derived from Mediaeval times. He (Mr. Kerr) thought it not improbable that the name originated from the circumstance that, at the time of the plague, the bodies of persons dying of that disease were buried there. Such, at least, was the tradition in the locality; "Tombland" being a place or square outside the precincts of the Cathedral. Then with regard to the western towers, did Mr. Walcott mean to infer that they were raised as defences by ecclesiastics against the worshippers when in a state of *émeute*? for if so, it was a new reading of their origin. Again, with regard to the cellarer's apartment, he was not aware of a reason for assigning a separate apartment in cathedrals for the use of that functionary. He (Mr. Kerr) merely asked these questions for information; for he agreed with former speakers that Mr. Walcott's paper exhibited learning, research, and application.

Mr. Papworth said the western towers were intended not to protect the ecclesiastics from an *émeute* among the worshippers, but to protect the property of the parishioners from attacks; and there were not wanting instances in history (especially among the Pyrenean churches), where they proved useful in that way. With regard to the paper itself, he wished to point out the use which might be made of it. It required to be indexed; and this being done, he would recommend it, not only to younger students in architecture, but to all the members of the profession, as a common-place book to be interlarded and carefully noted. If there was one suggestion he might be allowed to make, it was that Mr. Walcott would append authorities for some of his statements (which certainly appeared striking), as it was desirable in such cases to have chapter and verse.

Mr. Seales and others having spoken,

The Rev. Mr. Walcott, in reply, said that the only answer he could make was that of Sebastian in "Twelfth Night,"—"Thanks, thanks, ever thanks." With regard to the galleried porch in Snettisham Church, he would hear in mind the suggestion of Mr. Ferrey, reminding that gentleman, however, that he had confined himself to monastic churches. With respect to the round churches, as distinguished from the basilica, what he had stated was, that the former had been used as the baptistery; but the observations of Mr. Fergusson on the subject were so striking and full of interest, that he would endeavour to throw some light on the distinction which he had drawn. With regard to double churches, the subject had not escaped his attention, but he was necessarily obliged to leave out many points, and content himself with throwing them into notes and illustrations. He hoped, however, that Mr. Ferrey, having started the point, would himself carry it out. With respect to the western towers, he could not call to mind any instance in which they had been used by the clergy as places of protection against an *émeute* among their parishioners. He did not believe they were built with any such view, but that they were intended as defences against foreign invasion; such, for instance, as the invasions of the Danes, the Saxons, and the Normans, which were not infrequent. He could not, however, lay claim to this solution as original, as he had adopted the views of others, which appeared to him to be based on probability. The only manner in which he could account for the cellarer having a separate room was that the ecclesiastics probably fancied that, if the cellarer had a dormitory under the same roof with them, he would be at hand to draw them any wine or beer which they might require after a hard day's work. The name of "Tombland" at Norwich he imagined to have arisen from the fact that a chapel and convent were built at the entrance of the place, and that it had been used as a place of sepulture. In this conclusion he was fortified by the circumstance that, when Mr. Ferrey was restoring Christ Church and others, he found a crypt full of human bones similar to that discovered at Hereford, which proved that in these times, instead of carting off bones in cart-loads, as we do now, they deposited them decently and reverently in a crypt. With reference to the calcifactory, he had mentioned it not only as a place in

which the fire was kindled for the incense used at the altar, but as a sort of sitting-room or parlour, in which the monks could sit in cold weather. Mr. Papworth had suggested the desirability of appending notes in certain cases where opinions were advanced of an unusual character. He had not, however, overlooked the propriety of this course, and he had carefully appended notes in all cases in which his own authority might be brought into question. With regard to orientation, he could only say that he had devoted six or seven weeks to the examination of the churches in Caen, and that he had not been able to find any attention had been paid to it. He had stated that in the generality of cases the earlier churches faced the east, but neither at Caen nor at Rome had he found it to be the case as a rule. He begged, however, to remind the meeting that he had endeavoured carefully to keep within bounds as an archaeologist, and that he had not attempted to obtrude upon their notice as an architect, having no claim whatever to that definition. He felt gratified by the comments which his paper had elicited from so many eminent members of the profession, and all he could say in conclusion was, that he felt at that moment very small indeed, for he feared that he had given but brass and had received gold instead.

The Chairman, in putting the vote of thanks, observed that there were several cases in history in which churches had been attacked. The old tower of Bow Church, for instance, had sustained a siege, when Longbeard, Lord of London, took refuge in it. The received theory appeared to be, that the round towers of Ireland were built as a means of protection. There was only one observation with which he would trouble them before putting the question, and that was a practical one. It had been made quite evident that, whether the builders of the old churches were Benedictines, Cluniacs, or Cistercians, they placed their buildings where they were the most convenient, and they arranged their churches to suit their wants and rubric. If we in our turn adopted the same principle, rather than copying exactly what they did, we might sooner arrive at a nineteenth century architecture than some people seem to imagine. The vote of thanks having been unanimously accorded to Mr. Walcott.

The Chairman announced, that at the next ordinary meeting, on Monday, the 17th inst., a paper would be read, "On Acoustics," by Mr. T. Roger Smith.

The following gentlemen were balloted for, and declared duly elected Fellows of the Institute.—Mr. Robert Howard Shout, of 1, Deane-street, Portland-place; Mr. Sidney Godwin, of 24, Alexander-square, Brompton; and Mr. Charles Edmund Giles, of 24, Westbourne-park-road.

Mr. Henry Marley Burton, of 6, Spring-gardens, was elected an Associate.

#### THE ARCHITECTURAL UNION COMPANY.

The third ordinary general meeting of shareholders was held on Wednesday last at their premises in Conduit-street.

In the absence of Mr. Tite, M.P., the chair was taken by Mr. Charles Mayhew.

The secretary (Mr. Moody) read the report of the directors, of which the following is a copy:—

"The directors have much pleasure, in submitting their third annual report to the shareholders, to be enabled to congratulate them on the continued success of the undertaking; all the tenants named in the last report still occupy their holdings,—and since then the 'Society for the Encouragement of the Fine Arts,' the 'Architectural Photographic Association,' and other kindred societies, have become their tenants.

The capital account approximates to a close, the only business in hand not completed being the granting of a new lease by the Corporation of the City of London, which it has undertaken to do, of that portion of the property at present held by the Company by virtue of several leases granted to Lord Macclesfield, which leases comprehend other property not purchased by the Company, and which the directors have agreed to exchange for one lease comprising the whole direct from the Corporation. This sum of 212*l.* 8*s.* 3*d.* to meet the same and the costs of their solicitor, and have placed the amount as a deposit at the Company's bankers, bearing interest.

The directors have taken a sufficient number of additional shares to close the capital account, as at present stated, and there are now 1,637 shares in the register, on which 1*s.* 8*d.* have been paid.

The Board deeply lament the death of Sir Charles Barry, their chairman, and have to report that they have elected William Tite, esq., M.P., F.R.S., F.R.I.B.A., &c., &c., their late deputy-chairman, to succeed him; and Charles Mayhew, esq., F.R.I.B.A., to be their deputy-chairman.

The following directors retire by ballot:—Sancton Wood, Robert Hesketh, H. B. Garling, Sydney Smirke, W. G. Habershon, J. M. Lockyer, and John Whiteford, esquires,—and are eligible for re-election.

James Lockyer and Frederick P. Cockerell, esquires, retire from the office of auditors; but, being eligible, offer themselves for re-election.

The revenue account is made up to the 26th day of September last, and the directors propose forthwith to pay a dividend of 1*s.* per share, which will amount to 21*s.* 10*s.*, leaving a balance in hand of 19*s.* 8*s.* 7*d.*"

The balance-sheet showed that the total receipts for the financial year ended the 26th September last, amounted to 1,084*l.* 10*s.* 3*d.*; and the expenditure, including interest on mortgage of 4,000*l.* and all incidental charges, amounted to 406*l.* 11*s.* 8*d.*; leaving a balance at the bankers' of 677*l.* 18*s.* 7*d.*

The Chairman moved, and Mr. Jennings seconded, the adoption of the report and accounts.

In reply to questions from a shareholder named Williams,

The Chairman explained that the capital account was now considered closed, and that, in order to effect that desideratum, the directors had themselves taken the necessary number of shares. The actual cost of the building, conveyance, &c., amounted to 14,960*l.* 2*s.* 7*d.*; and the only liability undischarged was on account of law expenses; but to meet these the company had reserved 212*l.* 8*s.* 3*d.*, which they hoped and believed would be sufficient.

Mr. Mair complained of the enormous law expenses, and stated that the company had paid, or would have to pay, 500*l.* legal charges.

Mr. Edmeston (honorary secretary) said that the company had paid 57*l.* that day to the City Solicitor for expenses in connection with the conveyance of the property, and that all that now remained to be paid were the charges of Lord Macclesfield's solicitor and those of their own.

Mr. Nash inquired whether the 4,000*l.* raised upon mortgage was to be considered as a permanent debt, or whether it was intended to liquidate it by the creation of a reserve fund?

The Chairman said that the directors hoped to be able to reduce the interest upon the debt from five to four per cent., and that in such case it would be better to allow the debt to become a permanent charge.

Mr. Jennings expressed his opinion that it might be more prudent to limit the dividends to 4 per cent., until the mortgage debt was paid off; at the same time he was quite willing to leave the matter in the hands of the directors.

Mr. Haywood inquired whether the 212*l.* 8*s.* 3*d.* reserved to meet law expenses was the actual amount which the company would have to pay, or merely an approximate estimate.

Mr. Edmeston replied, that it was an approximate estimate, but that he believed it was quite sufficient to meet any demand that was likely to be made upon the company, in respect of law charges.

The motion for the adoption of the report and accounts was then agreed to.

On the motion of Mr. Haywood, seconded by Mr. Edmeston, the retiring directors were re-elected. Messrs. James Lockyer and F. P. Cockerell were re-elected auditors, and votes of thanks were passed to them, as also to the directors and honorary secretary for their services.

A vote of thanks was also passed to the Chairman, and the meeting separated.

It was stated that in all probability the dividend warrants would be issued before Christmas.

#### LIVERPOOL ARCHITECTURAL SOCIETY.

At the fifth meeting of the session, held on the 29th ult.,—Mr. Stubbs, vice-president, in the chair,—

Mr. Boulton announced that works intended for the forthcoming architectural exhibition in London could be sent to him, and he would be glad to forward them.

Mr. G. A. Audsley delivered an address to the student members; at the close of which he said, to give proof of the interest he felt in the progress of the student in architecture and its sister arts, and with the concurrence of his brother, he begged to present to the society a copy of their illuminated work, "The Sermon on the Mount," value six guineas, which would be published next year, to be given to the successful competitor in a contest thrown open to all the student members of the society still in their pupillage.

Mr. Andsley then read a paper on "The Rise and Progress of the Art of Illuminating during the Middle Ages, and its useful Application in the Nineteenth Century to Architecture and Art Manufactures." He traced its rise in the schools of Greece and Rome, in Egypt and the Eastern nations, and showed that it had become known in Ireland at a very early period. Certain it was that whilst the Continent of Europe was bathed in profound social darkness, a steady light of civilization was burning in that little island of the West,

and there the art of decorative illumination was known and practised, as many wonderful memorials remained to testify. He held it necessary for him who would be a true architect to be conversant with all the arts in connection with architecture and their æsthetical principles of design. Who could depreciate the value of the union of architecture and painting? yet how very little it was encouraged amongst us! Where did they see it shunned as it apparently was in matter-of-fact England? And it was a fact beyond dispute that this country as a nation was far behind in the appreciation and application of colour in architectural works as well as in manufactured articles of all kinds. He was puzzled to tell how a reformation could be accomplished; but it was satisfactory to know that many eminent men were doing their best for the advancement of architectural art. The correct decoration of buildings would form an educational medium whereby public taste would be advanced. Ecclesiastical or Gothic buildings admit of the most complete system of decoration, and the leading features of illuminated works may be exactly reproduced on them. Referring to the art of glass-staining, he described it as being at the very lowest ebb; although, as a decorative art, it should take its stand in the foremost rank.

#### THE OXFORD ARCHITECTURAL AND HISTORICAL SOCIETY.

The third meeting of this Society was held on November 28; the Rev. the Master of University College in the chair.

The officers for the ensuing year were elected. The Rev. J. W. Burgon then delivered a lecture upon a series of rubbings which he had made of inscriptions on the marble and stone slabs which covered the graves of the early Christians in the catacombs. He considered the date of the greater number of them to be about the time of Constantine. He began with the simple inscriptions of the three bishops, Eutychius, Anteros, and Fabian, but suggested that in some cases the inscription was probably added some years after the decease of the person it commemorated. He then proceeded to some of the more curious Jewish inscriptions, on which the commonest symbol was the seven-branched candlestick. To one of these, in which the inscription was both in Greek and Latin, a few Hebrew words were added, one of which he showed was the precise equivalent of the "In pace;" and no doubt the origin of this most common termination of an inscription was Jewish. The D. M., *i. e.*, the Dis Manibus, he remarked, was very common on even Christian tombs, but meant nothing more than now is meant by reference in poetry to urns and shades. On one of the tombs the word *kuppela* occurred, signifying clearly a grave, and he would venture to suggest the connection between this word and the chapel, because where there were graves there was probably a place of worship.

#### CHURCH-BUILDING NEWS.

**Gainsborough (Lincolnshire).**—A commencement has been made to improve the internal appearance of the parish church here. A portion of the old high square box-pews has been removed, and substituted by carved oak benches: other improvements are to follow. The architect is Mr. Alfred Allen, of Newark; and the builder, Mr. Jabez Taylor, of Gainsborough.

**Stowmarket.**—In consequence of the old and dilapidated condition of the present Congregational chapel, and want of accommodation for the Sunday school, it was decided some time since to erect a new chapel, with class and school rooms. A building committee was appointed, and Mr. Barnes, of Ipswich, was chosen architect. Tenders were advertised for, and given in, and Mr. H. B. Smith, of Ipswich, was selected as the builder. The tenders appeared in last week's *Builder*. The new chapel is to be built of Kentish rag stone, with Caen dressings. Its site will be that of the present one, the burying-ground being arched over. Three old houses, which hide the present chapel from view, are to be pulled down, and Ipswich-street will be improved in appearance.

**Ipswich.**—St. Mary Elms Church has been in the hands of the builder, and the whole of the old square high paving has been removed and new open benches substituted. The altar-piece, altar-railing, and pulpit, all of a bastard classical design, have likewise been swept away, and a new railing, and a pulpit of ecclesiastical character and carved, provided in lieu of them. The east wall, where the altar-piece stood, has been lung from the floor to the under side of the window, and also

round the north and south walls, as far as the altar railing incloses, with green cloth, on which is a diaper of amber-coloured *fleur-de-lis*, the whole having an edging of moulded polished wood. The whole of the henching, &c., is executed in pine, slightly stained and varnished. The floor of the chancel is laid with encaustic red and black tiles, and the nave and north aisle with *terro metallica* ware of the like colours. The tower, which has been for some years blocked up and made a receptacle for rubbish, is now thrown open. Iron pipes, beated with hot water, are laid below the level of all the passages, and covered with open gratings. The additional accommodation secured by the benching amounts to upwards 100 sittings, including the children's seats. The architect, Mr. Phipson, proposes (funds permitting) to case the outside of the church with red and grey brick-work similar to the western tower. The work has been executed by Mr. Seager, of Ipswich, and the expenditure up to the present time amounts to about 320*l.* The church has been re-opened.

**Hadleigh (Suffolk).**—The works of restoration have been confined at this church. The fine old roof and other portions of the chancel were restored last year. A *recedo*, carved by Mr. Farmer, has also been erected from the design of Mr. G. E. Pritchett, architect, it being chosen by the committee in a select competition. The additional works have been carried out by the same architect.

**Canterbury.**—A movement has been set on foot to repair St. Mildred's Church, in this city, and the estimated expense is 1,000*l.* Towards this sum subscriptions, among others, have been received from the Archbishop of Canterbury, 10*l.*; the curate of the parish, 105*l.*; Archdeacon Harrison, 100*l.*; the Dean of Canterbury, 25*l.* We trust the public generally will co-operate in this praiseworthy undertaking, as the parish is a poor one, and that the contemplated repairs will not be delayed for want of liberal and generous support. The parishioners are doing their utmost. Subscriptions may be paid into Messrs. Hammond & Co.'s bank, in this city, and to the curate of St. Mildred's, Canterbury.

**Southampton.**—St. Luke's Church has been re-opened, after being enlarged. By the erection of a new aisle, which has completed the architectural design, 330 additional sittings have been provided, and, by continuing the north gallery across both aisles, 160 more, thus making a total of 820 free seats, besides 520 for renting. The work has been executed by Mr. G. Brinton, builder, the architect being Mr. G. Elliott.

#### DEATHS FROM BAD DRAINAGE.

Under the title of "The Death Drains at Brighton," a letter, as many of our readers are probably aware, recently appeared in the *Morning Post* and *Lancet*, from Mr. W. Acton, M.R.C.S., a resident of "one of those fine eastern terraces facing the sea at Kemp-town." In reference to the taking of this house he remarked,—"The abundant rain which had fallen probably prevented me from detecting any disagreeable smell at the time, and the agent, in reply to my inquiries, told me that the drainage was excellent. In the course of a fortnight, however, I began to be annoyed by foul effluvia from the drains, and soon afterwards the cook was prostrated with fever, and confined to her bed during a space of ten days. My children and servants sickened in succession, and were attacked with headache, sickness, and febrile derangements, clearly attributable to poisonous atmospheric agency. Examination showed that the drainage of the house was wretchedly imperfect. My youngest child did not, unhappily, escape so lightly as the rest of my household, and I have just brought her back to London, suffering from a most severe form of diphtheria, which I need not tell your readers arises almost invariably from bad drainage."

I sought an interview with the late mayor, who is a fellow-practitioner, and asked his assistance. He told me there was no officer of public health at Brighton. He admitted the objectionable state of the drainage of the town, and told me he had been for years urging the subject on the attention of the town council, but in vain. . . . All agree that as long as Brighton fills, and the profession recommend it as an autumn residence, the rate-payers will not incur the expense of making sewers in place of cesspools, nor will individual landlords even trap the old ones. I regret to see in the obituary of the *Times* the death of a distinguished officer from diphtheria at a house in Brighton, only a short distance from my late residence." Alarm has been felt, by those inter-

ested in the prosperity of Brighton, in consequence of such renewed complaints; and it has been urged that the evils alleged are not general; but the admission of the mayor himself is not to be easily set aside: it is strongly corroborative of our own repeated warnings as to the state of the Brighton drainage. It is so far satisfactory, however, that the Health of Towns Act has at length been adopted by the town council,—whether for the sincere purpose of amendment, or for a mere blind, we do not know. The borough surveyor, Mr. P. C. Lockwood, C.E., in coming to the rescue of the council and their constituents, the lodging-house keepers and house-agents, has only aided in proving how essential it is that thorough drainage should be carried out. A correspondent of a local paper announces a "Brighton Inland Sewage Company," with "an air-tight vehicle, with pumps and hose," to carry out a system of cesspool cleansing, which may be all very well as a temporary measure, but cannot for a moment be put side by side, as is done, with systems of drainage as a substitute for any or all of them. In the *Times*, Mr. Acton, in a long letter reurging and defending what he had previously stated, alludes to Mr. Hawksley's examination of the Brighton sewerage; but it is to be hoped, as we have before said, that a system which proposes to discharge the Brighton sewage into the sea, straight in the face of the town and in the midst of the bathing ground, will not be carried out. The proposal of Mr. Rawlinson to carry it off obliquely to some distance, whether for utilization in the country or for final disposal in the sea, seems a preferable one in these respects.

At Tottenham-court-road, a coroner's jury, sitting on the body of a child, nine months old, who died in 23, Draper's-place, Burton-crescent, have returned the following special verdict:—"That on the 21th of November, John Sparrow did die from the mortal effects of congestion of blood on his brain and disease on his lungs and air passages, and that the said diseases and the death of the said John Sparrow were accelerated by the unwholesome condition of the locality in which the said John Sparrow had lived." A surgeon, who visited the place, stated that the stench from the bad drainage was most abominable, and one woman told him she had to keep her slop-pail three or four days till she could find a place to empty it. The house was situate in a paved court at the back of Burton-crescent, and at the rear of the house in question a man was in the habit of drying lacon cloths, which emitted a frightful stench. The house itself was in a most dilapidated condition, the stairs being almost unsafe to ascend.

#### STAINING WOOD.

In reply to "An Architect," who wishes a little information on staining woodwork, allow me to inform him that in using stain on any description of wood, the stain should always be allowed to get quite dry before sizing, as that gives it a fair chance of striking into the wood. Glue-size is the best for stained wood, made so thin that there is no fear of putting it on in patches. After the size is quite dry also, varnish; and if the first coat does not stand out quite sufficiently to please the eye, give it a second. Some people use stain and varnish together, doing away with size altogether; but this is a very poor method, for should the wood get scratched or damaged in any way, the varnish and stain come off together, leaving a white place, if it be white wood that is stained. Now, in using it as I have informed him, it will stand any weather; no matter how hot, cold, or wet.

#### IMPROVEMENT OF IPSWICH.

DOUBTLESS you have a knowledge of the flourishing town of Ipswich, and many readers of your publication, who by a vast number are not all architects or builders, know that it is not only renowned for its bricks and, in common with the rest of its county, for (as the poet Bloomfield styles it) Suffolk hang, but also for its crooked streets. This may be accounted for by its being a very ancient town, and most of its business streets not more than two centuries ago were country lanes. There are in the heart of the town two good streets, viz., Northgate and Brook street, both having the same width, and these would, if a small piece of property about 5 yards by 60 yards were removed, be in one continued straight line, which would then be the largest, straightest, and finest street in the town. I think that now is the best time for the Corporation of the town to buy it,

because the land is cheaper than it will be in a few years' time, and the property is in a bad condition. Pray urge it upon them.

A RESIDENT.

#### THE BROMPTON v. BRITISH MUSEUM.

In taking up a visitor's guide to the metropolis, I was greatly struck at the contrast between the hours of admission to both of these highly valuable institutions; South Kensington accessible on all days (Sunday excepted), and at most hours; the British Museum, by far the most central, numbers its hours "eighteen per week;" Thursdays being exclusively given up, I may say (and I speak as an old student), to about a dozen youths. An important educational establishment like the British Museum, in these days of progress, remaining closed as of old, when Charlies, oil lamps, and hackney coaches, for and far between prevailed. Should this be? Can it continue? The sums voted for the Museum are enormous, considering the admission value the public receive in return. Day and night should such an Institution be accessible; even if on students' days a small charge of admission were made available for payment to the officers for additional services. Thousands now are entirely excluded from its advantages, and tens of thousands would be benefited by its enlarged hours, and extended usefulness.—E. R.

#### A REGISTRATION OFFICE.

Sir,—Allow me to bring very strongly under the notice of your new creations, in the offices of architects, engineers, and builders, the great want of a Registration office. Such an office, if properly carried on, would prove a great boon not only to draughtsmen, but also their employers, and would gradually become an institute worthy of notice, besides facilitating the re-employment of those who sought appointments.

I cannot pretend to enlarge here on the advantages to be derived from such an office; but this I can say,—provided fifty others will subscribe a sovereign a-piece, I will put mine in too. It only wants some energetic man to take it in hand, and he will receive a vote of thanks from more than a hundred ere twelve months elapse.

T. SQUARE.

\* The want is partly met by the Architectural Association, Conduit-street, who keep a register, which might easily be extended.

#### HOUSE VENTILATION.

With reference to your correspondent "Salus," and those who have followed him, let me mention to them Dr. Chowne's air-siphon ventilator.\* I have for several years made use of the system both in old and new buildings with signal success. The cost in the former is necessarily greater than in the latter, but in any case the first cost rarely exceeds thirty shillings for each ventilator, and is subject to no further expense, being self-acting.

With Arnott's Ventilators, the common complaint is that the smoke, more or less, is emitted into the rooms; but with Chowne's, where it is inserted in the smoke-flue, this is not the case.

The idea, however, that ventilation means simply providing an exit for foul air, is so prevalent, notwithstanding your continual exertions to subvert it, that I will venture to repeat, that unless the means of admitting fresh air be provided, as well as the means of discharging foul air, it is vain to expect any benefit from either the one or the other. It is not generally known that fresh air admitted vertically will ascend several feet without spreading materially. If, therefore, it be allowed to enter our rooms from inside the window sills, or from behind wall linings, or from pedestals, brackets, or any decorative features above the heads of the persons seated, it will diffuse itself regularly, and without any appreciable current or draught. This is the mode adopted in some of the French military hospitals; and I can personally answer for its success here, in my own works, both in bed-rooms and reception-rooms. This inexpensive arrangement, not subject to patent charges, in combination with Chowne's siphon, I for one pronounce to be, without exception, the cheapest and most effectual self-acting system in operation in this country.

EDWARD ROBERTS.

#### THE STAGE.

Royal St. James's Theatre.—Some years ago, when Mr. Wigan undertook the management of the Olympic, we expressed our gratification on the part of the public, on the ground that, besides being an actor of eminent merit, he was a gentleman, with scholarly taste and feelings. We were not misled in our estimate. After a time ill-health forced him to resign his position there, to the loss of the public, for since his retirement, notwithstanding the ability, as an actor, of the present manager, then one of Mr. Wigan's staff, the Olympic has not been what it was. Once more Mr. Wigan, strengthened by repose, undertakes the duties of management, this time at the St. James's Theatre, and once more with added warmth we offer him our good wishes, and call on those who regard the theatre as a teacher to whom the multitude will listen,—a teacher whom they will love,—and who should therefore be of the right character,—to support him in his under-

\* Messrs. Holland and Messrs. P. Anson are, I believe, licensees of the patent.

taking. More especially it is health we should wish him, and success would he found his best preservative doctor.

Recently he has introduced to the London public a young actress and dancer, said to be from Servia, of very remarkable ability and attractiveness, Madlle. Albina di Rhona, who, while thoroughly mistress of the poetry of motion, is at the same time competent to the expression of poetry of another kind.

In the clever little ballet-vanderwie in which she acts, "A Smack for a Smack," she is very well supported by Mr. Belmore, a low comedian new to this end of the metropolis, and promising good things.

#### Books Received.

*Paradise and the Peri, from the "Lalla Rookh" of Thomas Moore; illuminated by Owen Jones and Henry Warren.* On stone, by ALBERT WARREN, Day & Son, Gate-street, Lincoln's-inn-fields.

THIS is a remarkable specimen of ornamental design, and chromo-lithography. The text is printed on a golden panel on one page; and, on the opposite, a similar panel contains figures "illuminating" the text. Both are surrounded by continuous borders, sparkling with colour and gold; and these are the great feature of the book. For the figures themselves we have not much to say: the best are those illuminating the lines,—

"She saw a wearied man dismount

From his hot steed, and on the brink

Of a small inn's rustic fount

Impatient fling him down to drink,"—

and those beginning,—

"Best tears of soul-felt penitence!"

but in the borders the designer and compiler displays, not alone his great facility in the production of such forms, but his skill in the harmonious arrangement of colours. It is difficult, without circumscription, to point out particular pages; but amongst the most beautiful are certainly those in which black, green, and gold are made to concur. A graceful "Finis" in foliage of blue, red, and gold, and very elegant binding, involving the foliage which Mr. Owen Jones may call his own, extort admiration at the opening and the shutting of the book.

*Specimens of Encaustic Tile Pavements, Manufactured by Maw & Co., of Bentham Works, Broseley, Shropshire.* London, 1860.

MESSRS. MAW'S new book contains some very good designs, and shows the continuance of endeavours on their part, of which, before now, we have offered commendation.

The patterns are all of ecclesiastical character, most of them adaptations from ancient Mediaeval pavements, occurring in this country and on the Continent.

Lord Alwyne Compton designed No. 206 for them, and the remainder are mostly by Mr. Goldie, Mr. D. Wyatt, and Mr. Gurling. The volume contains, further, a price-list, made as intelligible as may be.

#### VARIORUM.

IN the second edition of a pamphlet issued by Mr. Weale, of High Holborn, titled "On the Construction of Horse-railways for Branch Lines, and for Street Traffic," Mr. Charles Burn, C.E., reurges the construction of horse-railways in England and the Colonies, and shows the advantages of this system for the intercourse of agricultural and mineral districts; also for branch lines to small towns and large villages; so as to place them in communication with the existing network of railways; and for the streets of towns, with a description of the various models of construction, illustrated by diagrams. After the country had been pretty well intersected by trunk and branch railways, we frequently took occasion to remark, that without milder and more ramified feeders, our railway system resembled a tree without leaves, or with little else but bare trunk and branches, and that it was impossible for the system to flourish as it would do were such a ramification once effected. The using up of the old deserted roads, and the advisability of economy in the construction of the more slender and numerous feeders to the great trunk and branch system, were also urged. It is not "lately" therefore, only, that "many articles have been devoted by the *Builder* to a consideration of the subject," as Mr. Burn seems to infer. The fact is that our journal is so per-

petual a pioneer, and often so far ahead in most improvements, that its suggestions and its efforts are lost sight of in the distance; and, when reverted to for a moment, as time flies, they are apt to be undervalued or discredited. Many of our readers must well remember the time, however, when scarcely a single issue of the *Builder* ever appeared without a lengthened article on the progress of our railway system, in which all sorts of suggestions for its improvement and advancement were constantly being made. The issue of a second and enlarged edition of Mr. Burn's pamphlet denotes a growing interest throughout the country in the question of horse-railways, whether as branch feeders, or for town streets; and it is satisfactory to observe so many Parliamentary notices as to the formation of minor branches and junctions connected with the railways already formed; because, as we have often said, it will only be when the tree sends forth its twigs and leaves throughout the land that its vital circulation and its prosperity will be fully established.—A very full report (the fourth) of the Chelsea Parish Vestry, under the Metropolitan Local Management Act, 1855, has been issued, in which Mr. Lahee, the Vestry Clerk, remarks that,—

"In order that the incipient borough may take its proper place in the municipal scale, and that its sanitary and social regulations may vie with those of the enlightened boroughs and towns throughout the country, the vestry have given their attention, amongst other things, to the improvement of the parson's fire engines, and the introduction of fire escapes; to the establishment of bath and wash-houses; to the provision in their new vestry-hall (just opened, by the way) of rooms for reading and music; to the prevention of dangerous buildings, and the occupation of underground rooms in the dwellings of the poor; to the amendment of the law relative to vaccination, as a check to the dire scourge, small-pox; to the enforcement of the law with regard to dangerous buildings, and obstructions and offences upon the highways; to the erection of trials, and the removal of brothels; to the naming of the streets, and the numbering of the houses; and, lastly, though not least in importance, to facilitating the success of a cheap local press, by permitting the publication of the reports of their proceedings."

On sanitary subjects, it is stated, that "the large expenditure of the board, at the outset of their career, in the sanitary improvement of private dwellings, nearly all of which has been repaid either voluntarily or by compulsion, has had the effect of making this a very small item this year." In reference to the delay in erecting the drinking-fountain in Sloane-square, it is stated that "Mrs. Gurney having given the sum of 100*l.* to the Association, to be expended as they pleased, they had determined to erect at that spot a more expensive fountain than that previously selected." It is to be hoped taste as well as mere expense will be looked to.—"Our Winds and Storms; with an Essay on Weather and its Varieties." By Thomas Hopkins, M.B.M.S. (Longman & Co.) is a well-argued and ingenious theory, in which the influence of the sun in the evaporation of moisture, and the reverse process of the recondensation of that moisture, are shown to have much to do with the production of winds, through the liberation of heat occasioned by the condensation, and the absorption of heat (or liberation) of cold, as we may conversely call it) occasioned by the evaporation. We suspect the author labours too much, however, to disprove the present views as to the direct action of the tropical sun, and of the polar colds, upon the atmosphere itself, in disturbing its equilibrium, and causing a flow of rarified air above from tropic to pole, and of cooled air below from pole to tropic. The true theory probably involves the action of both air and moisture in the production of winds. It is, nevertheless, always pleasing and suggestive to find some more prevalent doctrines assailed with ability, whatever may be the upshot: it prevents that stagnation in the scientific air which frequently renders it at length supercilious and offensive towards all attempts at progress, when allowed to go on too long without an occasional breeze to keep it in a wholesome state.

#### Miscellaneous.

IMPURE WATER SUPPLIED AT INVERNESS. — Complaints have been frequently made of the water of the Ness, as it runs through Inverness, as unfit for culinary purposes. Between the old and new bridges all the fill of the town—from water-closets, ash-pits, and public sewers, &c.—is poured into the river. The local public have moved the authorities for a large pipe to run along either side of the river, for the purpose of carrying off these abominations, in order to insure wholesome water for the town, and to improve the air in the locality.

**THE CHAPEL IN FARM-STREET, LONDON.**—Mr. G. P. White, of Vauxhall-bridge-road, informs us that the first portion of the work here, including lining the walls with alabaster, was executed by him. Some of the figure sculpture was done by Mr. Phylers.

**INSTITUTION OF CIVIL ENGINEERS.**—On the 27th of November, Mr. Hawshaw, V.P., in the chair, the paper read was "On the Maintenance and Durability of Submarine Cables in Shallow Waters," by Mr. W. H. Prece. The following Tuesday evening was occupied in the discussion of it.

**NEW ASPHALT PAVEMENT.**—A new species of pavement, which attracts much attention, is now being tried in the Rue Neuve des Petits Champs, one of the most crowded thoroughfares in Paris. The system consists in a new application of pure asphalt. In place of melting it with a mixture of bituminous matter, the asphalt stone is pulverised and then heated in an oven, so as to render it adhesive. When it is sufficiently heated it is spread over the road to the thickness of 3 inches. The road is previously prepared with stone and mortar. When spread over the road the asphalt is rammed down with hot iron rammers. When this preparatory work is concluded a large heavy roller, heated by steam, is drawn over the road by two men.

**STEEL IN NEW ZEALAND.**—We are told of the existence in New Zealand of a large extent of sand, which when smelted yields 66 per cent. of pure steel, and that half a dozen persons in London have subscribed the requisite capital to work a grant of the district which has been obtained. Some experiments have been tried with samples, and it is stated that a ponton made from the produce was driven through two penny-pieces, one over the other, without any injury to the edge. One fear to be entertained in such cases is lest the mass should not be found the same as the transported samples, but as in this case the public are not being appealed to for the formation of a company, our caution is unnecessary.

**FIREPLACES IN CHURCH TOWERS.**—In reply to inquiries on this subject, a writer in *Notes and Queries* says.—Till the reign of Elizabeth, baptism was always given in this country by immersion, no matter however cold and chill might be the weather. The use then of a fire, before which to dry the wet child and dress it, became a positive want in a climate like ours; and the very best place wherein to supply it, was the western tower. The spot upon which to set the baptismal font is, for symbolic reasons, at the entrance of the church, near the south-west door, hard by which in most places stands a bell-tower; from the font to this tower is but a step or two, and, once within this tower's thick walls, and its door shut, the child's cries—and most children cry loudly when baptized—were thus hindered from breaking in upon the public services, were any going on, or wounding the ears of the people at their devotions. By the fire in the western tower the baby, that sometimes had to be carried home a long way, might be leisurely dried, dressed, and, if need were, suckled too; and the godfolds could becomingly wash their hands, as by the rubric they were told to, before they left the church.

**IMPROVED PERMANENT WAY FOR RAILROADS.**—At Wormwood Scrubs, on the Great Western line, is laid Seaton's patent safety saddle rail, which has been under trial for upwards of two years and a half. The alleged superiority of the patent safety rail and the sleepers consists in the fact that the latter is cut diagonally instead of rectangularly from a square balk of wood. The two triangular sleepers which are thus produced from the balk are laid longitudinally with the base downwards, the apex being crowned by a saddle rail, of which the flanges cover a portion of the sides of the triangle. Chairs, fish plates, and turnals are all done away with by the new system. The first cost per double mile on the London and North-Western Railway, exclusive of wages, is 4,146*l.*, while under Seaton's patent the prime cost, it is said, would not be more than 3,300*l.* The cost per annum for maintenance on the North-Western Railway is stated to be 317*l.* per mile, whilst the maintenance under the new system is computed at 188*l.* A scientific inspection of the patent way on the Great Western took place recently, when the new line was found, it is said, to present a perfect even and level surface; the rails undisturbed, although from 50 to 60 trains pass over them, and the fastenings both longitudinally and to the "ties" perfectly tight and undisturbed, the line being in exactly the same state as when laid down upwards of two years and a half since.

**MONUMENTAL.**—Mr. Bacon is now engaged on a bronze statue of the late Sir John Franklin, proposed to be erected at Spilsby, Lincolnshire, his birth-place.—Mr. Muoro has been commissioned to execute a monument in honour of the late Mr. Ingram, of the *Illustrated News*, which that gentleman's admirers at Boston, Manchester, and elsewhere, propose to erect.

**A MOSQUE AND CARAVANSERAI, IN PARIS.**—It is proposed to construct in Paris a magnificent Turkish mosque, and a Turkish hotel or caravanserai. The object of these constructions is to attract to Paris as many Mussulman travellers as possible. It is further proposed to erect a school close to the mosque for the education of children of the various followers of Mahomet.

**ASSOCIATION OF ASSISTANT ENGINEERS AT GLASGOW.**—A numerously attended meeting of gentlemen connected with the engineering profession has been held at Glasgow, with a view to the formation of an Association of Assistant Engineers there. Mr. J. M. de Conceicao was in the chair. It was resolved that such a Society be formed, and a constitution was agreed upon. A committee was also appointed to carry out the necessary arrangements. Upwards of forty members were enrolled.

**THE SWANSEA SEWERAGE.**—After a consultation with Mr. Austin, C.E., of the Local Government Act Office, it has been finally decided that, although the smaller pipes for combined back-house drainage be used wherever they can possibly be so with safety, the larger ones, where circumstances render them necessary, should be substituted. A list of subordinate sewers to be altered from 6-inch to 9-inch has also been specified, and the whole difference of cost beyond that contemplated by the surveyor's plan will, it is said, be only about 80*l.*

**RAILWAY MATTERS.**—The North London Railway Company have given Parliamentary notices for a Bill to authorize the construction of a branch from Kingsland station to Liverpool-street, Old Broad-street, City. The estimate, including three lines of rails, is stated not to exceed 1,000,000*l.* The history of the North London Railway, says the *City Press*, is a curious one. Originally constructed solely with a view to goods traffic, it has, by a system of quarter-hour trains and cheap fares, become one of the most frequented passenger lines in the world, the number of tickets issued in the year 1859 having been, it is stated, between 6,000,000 and 7,000,000. With such a traffic, the saving of time and distance which would be effected by the new project must be regarded as of the utmost public importance. The annual number of passengers at the London-bridge station is, however, not less than 11,000,000 to 12,000,000, and the number of trains daily during the busy season, exclusive of empties, is 365. The traffic returns of railways in the United Kingdom for the week ending November 17 amounted to 499,740*l.*, and for the corresponding week of last year to 474,245*l.*, showing an increase of 25,495*l.* The gross receipts of the eight railways having their termini in the metropolis amounted to 204,553*l.*, and for the corresponding week of 1859 to 209,814*l.*, showing an increase of 739*l.*

**BUILDING ACCIDENTS.**—A mill that was in the course of erection in a field near Burley-brow, Oldham, has been blown down. The mill was three stories and an attic high, ten windows long, and three broad. The roof was on, and all the windows were put in except those of the lower room; and that portion of the mill faced the wind, which was blowing with great violence. In consequence of the roughness of the weather, all the men employed about the building had left except two, who had a narrow escape, one being injured. The mill was being built by Mr. George Purday, of Hollingwood. It was supposed by some parties connected with the building trade, who went to the place immediately after the accident, that the foundation had given way on one side; but the men who had worked there considered the mill had been blown down in consequence of the wind obtaining admission by the lower windows.—At Shipston-on-Stour, a few days since, the floor of a newly-erected granary gave way under the pressure of fifty bags of corn. This building has recently been erected under Government contract.—A scaffold accident has occurred at buildings in erection by Mr. Meader, at St. John's park, Ryde. It appears that several men arrived on the scaffolding together, and simultaneously discharged hods of stone, the weight of which had the effect of causing a piece of timber placed across two projecting portions of the building to give way. In the fall consequently sustained one of the men was severely injured, and all the others were more or less hurt.

**CITY OF LONDON GAS COMPANY.**—A difficult erection of gasometer column and framing has been completed at this company's works, Dorset-street, Salisbury-square, by Messrs. Westwood & Wright, of Dudley. The machinery was planned and arranged by Mr. T. Wright, one of the firm, and his foreman, Mr. Wm. Werry. The spot is surrounded with houses and buildings. The Gas Company provided the men with a supper at the Rose and Crown, Dorset-street, presided over by the company's secretary.

**A NEW GENERAL POST-OFFICE FOR THE WESTERN DISTRICT OF LONDON.**—A new General Post-office for the western district of the metropolis is being opened in Vere-street, Oxford-street. The Oriental Hotel having become vacant, those premises, which occupy a very large area of ground, extending from Vere-street to Chapel-place, in the rear, have been fitted up for the purpose, and will replace the office in Cavendish-street, Cavendish-square.

**CESSPOOLS AT BATH.**—Some residents in the parish of Walcot, Bath, have complained to the Home Secretary as to certain cesspools which have been sunk at a higher level than that of their residences, in connection with two large colleges or schools and a number of villas recently built in the adjoining parish of Charlcombe. The memorialists apprehend the occurrence of evil from the pollution of their wells and of the air in their vicinity, and pray for inquiry and relief. The Home Secretary has forwarded the memorial to the Privy Council as the authority, under the Public Health Act of 1858, having power to direct sanitary inquiries.

**THE SHEFFIELD "SURVEYORSHIP."**—Mr. Jackson, the local chief constable of police, has been appointed to act as surveyor to the Sheffield Improvement Commissioners, in the place of the late Mr. Raynor, at a salary of 105*l.* per annum; Mr. Jackson still holding his position and salary as chief constable. The duties of the new surveyor being described as "attending to the sweeping and cleaning of the streets, and to see that the town is properly lighted, and the accounts kept;" he appears, in fact, properly speaking, to be the "inspector of nuisances," and the title of surveyor is therefore a misnomer, unless this title, like the also highly respectable one of "professor," be now destined to go astray altogether from its proper meaning, in order to denote any one who professes to "survey" any thing, from broadcloth to turpentine roads.

**THE DROWNED WALLSEND AND OTHER COLLIERIES OF NORTH TYNE-SIDE.**—Three years or so ago, we directed attention to the condition of some of the most valuable coal-mines in this district; and mentioned that the once far-famed Wallsend and other pits were rendered inaccessible, in consequence of the flood of water which had collected in the various workings. We are glad now to learn that arrangements have been made, so that, by the joint expense and exertions of those concerned, powerful steam-pumping engines will be erected, which it is hoped will be the means of causing this valuable description of coal to be brought again into the market. It may be worth while here to mention that the Wallsend colliery which rendered the "Tyne-side" coals so famous is situated close to the eastern extremity of the Roman wall,—hence the name Wallsend coal. There is no real Wallsend coal now in the market, although we have "Hetton Wallsend,"—from Hetton, a place perhaps ten or eleven miles distant; and from other parts of the county of Durham, and even from Yorkshire, we receive "Wallsend" coals for the metropolitan market. We are glad to hear that the "real original" Wallsend is again likely to be brought into use.

**NEW CHURCH AND SCHOOLS IN ST. JAMES'S, CLERKENWELL.**—A public meeting has been held for the purpose of promoting the erection of a district church and schools in the parish of St. James's, Clerkenwell. Some time since a temporary church was erected, and a congregation gathered. It is now proposed to erect a new church capable of holding 1,200 persons. Of the sittings, 500 are to be free. Schools in connection with the church, to educate 400 children, are also to be erected. A site has been obtained in Allen-street, Clerkenwell, at the cost of 1,200*l.*, which is half the market value of the ground. The sum of 1,000*l.* has been promised by the Diocesan Church Building Society, and it is expected that a special grant for the schools will be obtained from the Privy Council. The church is to be called St. Paul's, and it is to obtain an allocation of 3,000 of the population. The sum obtained or promised at the meeting, including the 1,000*l.* from the Diocesan Church Building Society, was about 1,900*l.*

BUILDING SOCIETIES.—It seems from a statement made by Mr. Tidd Pratt that there are now about 2,000 of them in existence, and that their paid-up capital is not less than 8,000,000.

A FREE LIBRARY FOR SUNDERLAND.—The Town Council have resolved to levy a rate for the establishment of a free public library. A presentation has been made to the town, by Mr. Candlish, of 4,000 volumes which lately belonged to the local Literary and Philosophical Society; and it is for the maintenance of this collection for the benefit of the inhabitants that the rate has been levied.

CAMPESE ASHE, SUFFOLK.—The Elizabethan house, the seat of J. G. Sheppard, esq., is now undergoing extensive additions and restorations under the directions of Mr. Salvin; and on the 23rd ult. Mr. Sheppard gave the whole of the workmen employed an entertainment at the Talbot Hotel. Fifty-six sat down to dinner, the chair being taken by Mr. W. Oldrieve, the clerk of the works.

CHELSEA NEW VESTRY HALL.—We learn from the daily papers that the new Vestry Hall for Chelsea is finished, and has been inaugurated with a dinner. Our readers will remember that designs were submitted in competition, and that their merits were discussed at some length. The cost of the building which has been erected is stated at 7,000l. The architect was Mr. Peacock, and the builders were Messrs. Piper & Son, of Bishopsgate-street.

SCULPTURE, BATH MINERAL-WATER HOSPITAL.—The front of this new building has just been cleared of the scaffolding. Messrs. Manners & Gill are the architects, and Mr. G. C. Mann is the builder. Some sculpture in the pediment, "The Good Samaritan," designed, modelled, and sculptured by Mr. H. Ezzard, jun., of this city, is well spoken of in the local papers. The figures are considerably larger than life. The caps were carved by the same artist.

MICHELANGELO IN LILLE.—A correspondent writes from Lille.—We have seen what was said at the Institute about the drawings ascribed to Michelangelo in the Wear Collection, but those who are concerned do not feel inclined to discuss the question. In the collection they found Michelangelo's original sketch for the staircase at the Vatican, and other proofs, that convince them they are perfectly correct in ascribing the other drawings to him. However, they don't seem disposed here to open the subject.—M. G.

THE STRIKE IN HALIFAX.—The strike of masons for nine hours a day, which took place on the 7th of August, may now be considered at an end, and we are told, for this season at least. The two great works which were at a stand—namely, the New Town Hall and Mr. Riley's new warehouse in Horton-street—have been resumed. The strike has not been formally terminated by the society men, but sufficient men have started to carry the works on at the old rates.

BUILDING BY CO-OPERATION.—Another great stride has been made in local co-operation by the initiation of a Co-operative Building Society, whose objects are to build, buy, and sell houses, mills, and workshops; to purchase, lease, and rent land for building purposes; and to transact other business connected with building. A rather wide range, truly; but, as the main intention is to build cottages on a new and improved principle, and such new and improved principle in building is a local desideratum, we wish the company success. The shares are to be £l each; the number held by one person is to be limited to a hundred, and the buildings purchased and erected are to be the property of the company.—*Zochdale Post.*

ELECTRO-TELEGRAPHIC PROGRESS.—The works of the United Kingdom Electric Telegraph Company, which proposes to reduce telegraphing to a uniform shilling rate, have been commenced by the planting of three poles in the Uxbridge-road, London. At a dinner in celebration of the inauguration of the works, it was stated that the system proposed to be adopted here had been successfully tried in Switzerland and Belgium. The lines of electric wire are to be carried along the various canals which intersect the country.—Mr. Reuter proposes, in connection with the private telegraph company, to telegraph information from his office to the offices of the newspapers, instead of, as at present, employing messengers. The company offer to connect these offices with Reuter's establishment in the Royal Exchange, and to let the wires to the newspaper proprietors at a small rental. By Professor Wheatstone's new invention, a person can be taught in half an hour the language of the telegraph, and thus the newspapers would have the news a few seconds after Mr. Reuter received it.

ALMSHOUSES AT JERUSALEM.—A private letter from Jerusalem states that an American Jew, at New Orleans, has bequeathed 10,000l. for the building and endowment of almshouses there for the infirm and destitute Jews.

THE SESSIONS HOUSE, CLERKENWELL.—A report, presented from the committee on the alteration and improvement of the Sessions House, shows that the cost had been 13,700l. We gave a view of the hall as altered, some little time ago. Gas.—The Swindon Gas and Coke Company have reduced the price of their gas to 6s. 6d. per 1,000 feet.—The small town of Pewsey is to be lighted with gas: a company is being formed for carrying out the undertaking.

A HORSE RAILWAY IN PERSIA.—There is some talk, according to the Russian journals, of a horse traction railway in Persia, from Teheran to Tauris, to facilitate the means of transport for passengers and merchandise towards the Black Sea, with extension to Trebizond, or by Erivan and Tiflis to Poli. BATHS AND WASHHOUSES FOR THE CITY OF LONDON.—I would ask you to persevere in your endeavour to obtain some public baths and wash-houses within the City boundaries, as it really is too bad that the capital of the town should be so long without such extremely useful institutions, nearly every parish in the metropolis and country towns having long since adopted them.—G. S.

FALLING IN OF A RAILWAY TUNNEL.—An accident has occurred on the Severn Valley Railway, on a new line in course of construction from Shrewsbury to Stourport. Close to Bridgmont an extensive tunnel is in course of excavation, which will partially run under the town. Above the entrance, and for some distance into the tunnel, there was a thickness of some 30 or 40 feet of soil, in which large trees were rooted. The usual props and supports had been used to keep up this mass while the brickwork was being executed. Sixteen men were employed in the tunnel, and these had only left work about an hour when the superincumbent mass fell in, choking up the tunnel with earth, rock, and trees, for a distance of 50 feet.

ESCAPE FROM FIRES.—In reference to the fearful calamity in Kildare-street, Dublin, Mr. Charles Gough, of that city, architect, has written to the Irish papers directing attention to the necessity of each house having a fixed step-ladder and glass-dormer door to the roof as a means of escape. In the Kildare-street case, there was a dormer ladder, but it was tied up. Mr. Gough says.—"I have in some houses constructed a narrow staircase from the head of the principal stairs direct on to the roof, for security or inspection, with most satisfactory results; and have always found the most perfect means of ventilation, in warm weather, by simply leaving the glass dormer open. When the escape from danger may be rendered so easy, neglect must be regarded as criminal, and were such provisions made compulsory by the statute, we should seldom have to deplore such a fearful tragedy as that which has recently so shocked every feeling of humanity."

INSTITUTION OF ENGINEERS IN SCOTLAND.—The report of the proceedings of the first meeting of the session 1860-61, held at Glasgow on 31st October, has been printed. The president delivered an introductory address, in which various subjects of interest, such as the use of iron in naval architecture, and the advisability of having street horse-railways in our towns were dwelt on. The president afterwards drew attention to a small American air-engine, on Captain Ericsson's principle, which was exhibited at work, and of which illustrations are given in the printed report. It appears that for limited purposes these engines are here and there coming into use: a member had seen one a fortnight before at Berlin, driving a thrashing-machine, and another had seen one (going very slowly) in Hamburg.—At a recent meeting of the Institution, papers were read "On the Use of Transversals in Ranging and Measuring Straight and Curved Lines in the Field," by Professor W. J. Macquorn Rankine; and "On Setting out Railway Curves," by Mr. William Froude, communicated by Professor Rankine; and a short discussion followed, which, however, was adjourned.

NORWICH.—The project of erecting a Masonic Hall for this city and province has been mooted among the Freemasons, and support promised from various quarters. A committee has been appointed, and a sub-committee, to make inquiries respecting a site. It is contemplated to provide such a room as could be used for balls, concerts, and entertainments—smaller than St. Andrew's Hall, and more spacious and convenient than the Assembly-rooms. It is also proposed that the building be used as a Masonic club-house.

TENDERS

For house and shop in the Whitechapel-road, for Mr. Thomas Paddon. Mr. A. Wilson, architect:—  
Blachburn ..... £1,810 0 0  
Hill ..... 1,663 0 0  
Ennor ..... 1,895 0 0  
Palmer ..... 1,590 0 0  
Tarrant ..... 1,573 0 0  
Wilson ..... 1,855 0 0

For two shops, Ha'ifax, for the Co-operative Industrial Society. Mr. Richard Horsfall, architect:—

Masons.  
Cockroft & Sons ..... £1,125 0 0  
Pratt ..... 1,100 0 0  
Foster & Co. .... 1,075 0 0  
Hanson & Drake ..... 1,030 0 0  
Charneck & Booth ..... 957 0 0  
Nicholl and Carey ..... 854 0 0

Joiners.  
Pulman ..... £625 0 0  
Mitton ..... 599 0 0  
Dyson & Son ..... 581 0 0  
Scott ..... 555 0 0  
Tuley ..... 537 0 0  
Noble ..... 508 0 0  
Hall ..... 490 0 0

Slaters and Plasterers.  
Wardsworth ..... £102 0 0  
Taylor ..... 98 0 0  
Whitehead & Nicholl ..... 84 10 0  
Lister & Pickard ..... 82 0 0  
Ambler & Taylor ..... 73 10 0  
Bancroft & Son ..... 69 12 6

Plumbers and Glaziers.  
Dyson ..... £191 10 0  
Holdsworth ..... 174 0 0  
Lees ..... 155 0 0  
Horsfall ..... 143 0 0  
Walsh\* ..... 134 0 0

Tenders for the whole of the Works.  
Pratt ..... £1,839 0 0  
Dyson & Son ..... 1,805 10 4  
Charneck & Booth ..... 1,800 0 0

For chimney-shaft, &c., for Messrs. Friebech & Mogge, Denmark-street, E. Mr. Andrew Wilson, architect:—  
Moreland ..... £610 0 0  
Langtrec (accepted) ..... 471 0 0

For alterations and additions to Messrs. Read & Co's premises, Commercial-road, E. Mr. A. Wilson, architect:—

Ennor ..... £1,116 0 0  
Hill ..... 1,089 0 0  
Wilson (accepted) ..... 1,665 0 0

For new shop-front to No. 10, King's place, Commercial-road, E., for Mr. Evans. Mr. A. Wilson, architect:—  
Hearle ..... £137 10 0  
Warkitt ..... 186 0 0  
Hicks (accepted) ..... 170 0 0

For house at Dulwich-wood, Surrey, for Mr. Henry Baily. Mr. Charles Baily, architect. Quantities supplied by Mr. Charles Baily and Mr. James Marsland:—  
Corder ..... £1,414 0 0  
Cannon ..... 1,398 0 0  
Patrick & Co. .... 1,392 0 0  
Ashby & Horner ..... 1,390 0 0  
Thompson ..... 1,388 0 0  
Marsland ..... 1,339 0 0  
Heath ..... 1,389 0 0

The above tenders do not include the founder's, plumber's, painter's, glazier's, nor ironmonger's works.

Tenders received for congregational chapel, Mile-end New Town. Mr. R. Moffat Smith, architect, Manchester. Quantities supplied by Mr. Thomas M. Rickman:—  
Piper & Son ..... £2,484 0 0  
J. & C. W. Todd ..... 2,396 0 0  
Cogswell & Day ..... 2,263 15 0  
Smith ..... 2,175 0 0  
Adamson & Sons ..... 2,073 0 0  
Tolley ..... 2,057 0 0  
Maers (accepted) ..... 2,037 0 0

For building eight houses and shops on Lloyd's Brompton estate. Mr. G. A. Burn, architect. Quantities supplied by Mr. G. H. Julian:—  
Lawrence & Sons ..... £15,260 0 0  
Piper & Sons ..... 13,670 0 0  
Cowland ..... 12,425 0 0  
Dove (Brothers) ..... 12,200 0 0  
Myers ..... 12,040 0 0  
Downs ..... 11,912 0 0  
Stimpson ..... 11,600 0 0  
J. & C. W. Todd ..... 11,311 0 0  
McLennan & Bird ..... 11,275 0 0  
Batterbury (accepted) ..... 10,950 0 0

For sewer-drains, cellars, and road, in laying out Lloyd's Brompton estate. Mr. G. A. Burn, architect. Quantities supplied by Mr. G. H. Julian:—  
Myers ..... £2,405 0 0  
Stimpson ..... 3,918 0 0  
Batterbury (accepted) ..... 3,862 0 0

MR. BENSON'S WATCHES.—"We have seen several watches from this well-known firm, and can speak with confidence of their exquisite workmanship and artistic finish. They keep time with very great precision, and have been declared by competent judges to be well worth the money. Parties wishing them can be supplied through the post-office."—*Glasgow Examiner*, May 19, 1860.

Benson's Illustrated Pamphlet, post free for two stamps, is descriptive of every construction of watch now made. Watches safe by post to all parts of the globe.—*Advertisement.*  
J. W. BENSON, 33 and 34, Ludgate-hill.

# The Builder.

VOL. XVIII.—No. 932.

## Wages and Condition of the Hindoo Artizans.

IN these days of social economy the smallest item of information respecting the "condition of the working classes" is possessed of a certain value. The following brief notes, which have reached us from Bombay, concerning the native artizans, are therefore worthy of attention. It is sometimes useful to turn our eye on a lower phasis of civilization; and it is curious to observe the differences which occur in the social development. For the facts here given we are indebted to a native carpenter, who fills the office of a subordinate clerk to the Peninsular and Oriental Steam Navigation Company at Mazagon, near Bombay. In itself his communication is a curiosity; but, as our present object is rather to impart instruction than to create amusement, we shall do our best to exhibit the sense of it.

Few of our readers are unacquainted with the singular division of the Hindoos into castes, and with the pernicious effects which flow from this fatal and superstitious policy. It is probably not so well known that the same exclusive principle is carried out to even a still more absurd extent, if possible, by the native artizans. These people, although sprung from what is considered the lowest and most contemptible order—in the theoretic idea of society—are as devoted to their religion as the Brahmins themselves, and as eager to perpetuate its ancient dogmas. The working classes of India, accordingly, are divided into as many sects as there are castes in their religion. For example, a native carpenter will neither eat nor sleep with a stonemason, nor a brass-founder with a copper-smith. When it is considered how nearly those branches of trade are allied to each other, the absurdity of the principle becomes more apparent. But this is not all. It sometimes happens, in some of the large works in the neighbourhood of Bombay, that the workmen consist of a mixture of Hindoos, Mahomedans, Parsees, and perhaps a sprinkling of Portuguese, all of whom profess different creeds, and hate each other with that perfect hatred which only theological differences can inspire. The old idea of Shylock pervades the whole community: "I will buy with you, sell with you, talk with you, work with you, and so following; but I will not eat with you, drink with you, nor pray with you!"

Another singular feature in the social condition of the Hindoo artizans is this, that every trade is held to be hereditary. If a blacksmith have a son he must make him a blacksmith. The weaver's family, in like manner, must be taught, while they are still infants, to tie the ends of the wool, and, finally, to drive the shuttle after the manner of their forefathers. One generation succeeds another with almost the blind and undeviating instinct of the lower animals. It is impossible for a man to strike out an original path for himself, for as soon as he is able to lift a hammer or any other implement he must go in with his father and there he must remain.

They serve no formal apprenticeship. In the building trades, for example, a Hindoo boy commences work, we shall say, at the age of ten or twelve years; but until he gets accustomed to the use of tools he gets no wages; and even

then he receives next to nothing—perhaps a rupee or two a month—which is increased by degrees, more according to the skill he exhibits than to any stated time or fixed rate. Properly speaking, he is paid by the quantity of work he can execute. It is not at all uncommon to see two lads of the same age working together in a carpenter's or a blacksmith's shop, one getting eight rupees per month and the other getting only six; and it is enrious to observe that no symptom of discontent is shown by the weaker of the two.

The standard wages of all mechanics in Bombay, we are informed, is about twenty-six rupees, or 2*l.* 12*s.* per month. In the carpenter's trade, for example, there are three separate branches—ship carpenters, joiners, and carvers,—all of whom are nearly equal in point of wages and regularity of employment; and in this case we may divide the journeymen into three classes, the lowest of whom gets ten, the second twenty, and the third from forty to fifty rupees.\* Some men of peculiar genius and skill, who rise to the position of freemen, often earn 100 rupees and upwards per month. The stone-cutters are scarcely so well off in their circumstances, from the reason that there is less demand for their services. They are not settled in shops, like the regular carpenters, but pursue a desultory life under sheds and out-houses, and not infrequently cutting their stone at the quarry,—or mine, as it is called in India. The highest rate of their wages is about twenty rupees per month. The blacksmiths and copper-smiths, who are highly ingenious mechanics, have shops of their own, where they prepare the articles of hardware, which are exposed in the ironmongers' shops. They are also largely employed in public works and private establishments. In other respects they are on the same footing with carpenters. The plasterers or bricklayers,—these branches are conjoined,—are a numerous tribe, as migratory in their habits as the stone-cutters, and also closely resembling them in their circumstances. The highest wages, in this instance, do not exceed twenty-five rupees per month. The potters are considered about the lowest of handicraftsmen. Their wages in most cases do not amount to more than ten or twelve rupees. Generally speaking they carry on their trade in their own miserable bungalows, separately and independently, and thus become in a manner the bondsmen of the shopkeepers, who have large establishments, and derive large profits from their work. The jewellers, on the other hand, who pursue the same system of isolated labour, scarcely belong to the category of workmen. They have shops of their own, where they sell jewels, as they make them up, to the public, who have a keener scent for cheap jewellery than for expensive pottery. They often realise very handsome profits. The precious-stone cutters are of course similarly placed, with this exception, that there is more irregularity in their employment. Sometimes they engage themselves by the day, in which case they charge a rupee or two, according to the value of the stone, and the quality of the labour.

Under such a condition of things, it is obvious enough that no trades-union could exist. Accordingly, our Hindoo manuscript gravely relates that, "there are no meetings of the working men to settle the rate of wages." "Those rates," it goes on to state, "are fixed by the option of the employers, and the public demand for labour." It is, however, customary sometimes for working men of the better orders, such as coach builders and carvers, to carry on their business in partnership, but whether on the co-operative principle, or that of limited liability, our informant is silent.

With regard to the education of these Hindoo artizans we are informed that it is generally neglected; as, indeed, we might reasonably infer from the circumstance of their being put to work at so early an age, and possessing so little after opportunities of acquiring knowledge. Nevertheless, it is proper to state that numerous instances occur in the trades of which we speak where the men are what even a European tradesman

would regard as good scholars. They are far inferior in point of skill to English mechanics; and this is particularly observable when they come in contact at the same work. It must be stated, however, that, in point of ingenuity and power of patient monotonous labour, the Hindoos are unsurpassed.

Some of the ornamental metal-work in their temples is equal to the most elaborate specimens of which we know. The talcoos of Coromandel are in many essential respects superior to those of Manchester. The silks of Moulton, the brocades and ornamental gauzes of Benares, the green muslins of Mysore, not to mention the fabrics of Cashmere, are noble specimens of what a barbarous ingenuity with natural endowments may accomplish. And, we must always remember that the poor Hindoo workman has no advantage from the division of labour, or the use of machinery. His capital for the most part is miserably small; yet, by virtue of sheer personal handicraft and natural taste, his productions are prized over the length and breadth of the civilized world.

It is, however, impossible not to see that under such a system of castes it must be long before the artizans will take their right position in our Indian empire. This wretched principle of hereditary succession must destroy all noble emulation and pride on the part of the workman, and prevent the assertion of individual character. Let us hope that in the progress of things those foolish impediments of which we have spoken may be swept away, leaving free and uninterrupted course to the development of the national resources. The great problem of Indian government is now a financial one, and the solution of it must depend to a large extent on elevating the condition of the native artizans.

## ON CHURCH AND CONVENTUAL ARRANGEMENT.\*

In Germany (Lenoir, ii. 209), at the end of the tenth or beginning of the eleventh century, a modified basilican form appears, at Gerrode, c. 960; Hildesheim, 1001; Limburg, 1035; Mayence, Worms, and Spire.

The type adopted was a double-apsidal cruciform ground-plan, as in the east of France, at Besançon, Verdun, and originally at Strasburg; west and east transepts, a long nave, a short choir, both of three aisles; small round octagonal towers were multiplied, flanking the apses, or attached to both the west and east fronts in churches not cruciform. Polygonal domes or octagonal lanterns were employed at the west end, and at the intersection of the nave and choir, and galleries were constructed under the eaves of the roofs for the accommodation of women.

At Hildesheim we find a short apsidal choir, with an aisle on three sides, not communicating with the nave; a western transept flanked, like the transept, with octagonal towers, and a west door wanting.

St. Geroon, at Cologne, of the thirteenth century, has a circular nave, and is one of the last examples of a domical building. Cologne has a chevet, with seven chapels, c. 1322, five aisles throughout the church, and a partially developed transept. Freiburg has a western steeple, found also at Ulm; a low, ill-developed transept, and octagonal towers flanking the junction of the nave and choir, round which are twelve chapels. Strasburg was intended to have two western towers, and the whole east part is a basilica of the eleventh or twelfth century; the transept is ill-defined. Ratisbon, 1275 to the fifteenth century, has three east apses, and a "subdued transept." St. Stephen's, Vienna, as Prague was designed to have, has two transept towers. At Bamberg there are two apses, west and east, flanked by towers. Naumburg is of similar design. Xanten has two western towers, without an entrance on this side, with a polygonal apse, and four flanking chapels opening in the choir and aisles. At St. Severus, Erfurt, three spires rise in place of a transept over the apse.

St. Cunibert's, Cologne, consecrated 836, was the first instance of the Lombardic style in the Rhenish provinces.†

German architecture resolves itself into three periods.

\* A rupee is 2*s.*

The pure Romanesque churches have a semi-circular domical apse, lower than the choir (as in several churches at Cologne, Mentz, Spire, Worms, Laach, Eberbach); and frequently the aisles have similar terminations; some churches (as St. Mary Capoline, the Apostles, and St. Martin), have apses to the ends of the transepts, instead of the usual triple eastern apse; and (at Jobanisherg, St. Peter's/Gelhausen, and Laach), the east sides of the transept received semi-circular apses. The towers are generally near the east end. There is an apsidal outer gallery round the choir at Laach, Eberbach, Worms, Spire, St. Gercon's, St. Martin's, and St. Mary Capoline, at Cologne. There are usually two pairs of towers and two cupolas or octagonal pyramids. St. Martin's and St. Castor's, at Cologne, are of this period. A portal cloister, as at Laach and St. Mary Capoline, Cologne, is another distinctive feature. The sides of the towers terminate in pediments, and in these gables Mr. Ferguson has ingeniously discovered the germ of spire-growth.

In the Transitional or Early German style the apse became polygonal, and of equal height to the choir, and the east chapels of the transept have seldom a simple semi-circular form, but have sometimes an additional recess (as at Gelhausen and Sinzig); or another form (as at Limburg), or wholly disappear with the transept (as at Audernach, Boppard, and Bamberg). At Mentz, Worms, St. Sebald's, Nuremberg, and at Bamberg, the eastern apse is round, and the west apse polygonal; at Bonn the ends of the transepts are polygonal, and the choir apse semi-circular. The churches are of three aisles, and often have a polygonal, as at Bonn and Marburg, or semi-circular end to the transept. Generally, where there are double apses, there are west and east transepts, as at Mentz, St. Cunibert's, the Apostles, St. Andrew's, St. Pantaleon's, Cologne; St. Paul's, Worms; and Nuremberg. Two pairs of towers on the east and west occur at Bamberg, Andrauch, Bonn, Arnstein, and Limburg. There is a central octagonal tower at Limburg, Gelhausen, Seligenstadt, Sinzig, Worms, Hermersheim, and Bonn; sometimes there is a central spire between a pair of towers; sometimes two eastern towers (as at Gelhausen and St. Cunibert's, Cologne); sometimes west towers, as at Limburg, Bonn, Seligenstadt, Sinzig, Hermersheim, and Boppard. A similar group is often found like a transept at the west end, and sometimes a single west tower in the central compartment of this front. The gables of the towers become more acute, and the cornices lighter. Buttresses were used, and porches were added at the west end.—(Whewell, p. 80, 105, 110.) Chapter-houses are rare in Germany and France, and seldom circular. A baptistry is attached to Meissen. At Worms, also, of the beginning of the twelfth century, there is a west octagonal lantern flanked with round turrets, a central octagon and east end flanked with round turrets. Spire, of the eleventh century, has an octagonal lantern at the intersection, and west square towers to the transepts. Mayence has a western apse composed of three trigonal apses, an octagonal steeple and west turrets, and an east lantern and a round turret. At Laach, c. 1093-1156, we find the ancient parvis before the church with a west cloister, as at San Ambrogio's, Milan; a western apse, used as a tomb-house; a square west tower, with a transept, flanked by lofty circular towers; an eastern transept, a central octagonal lantern, flanked by two square turrets; an apsidal choir, and transepts with eastern apses. Lateral porches supplied the place of a western door. The Apostles, at Cologne, has a tall west tower and transept, a central octagon, and two flanking turrets. St. Castor, Coblenz, Andrauch, and Arnstein have two groups of towers, but no central lantern. The third period is the complete or Decorated German, which occurs at Altenberg, Cologne, Freilburg, Ratisbon.—(Whewell, p. 113.) At Zurich the choir, of the eleventh or twelfth century, is square, while the aisles terminate in apses, and two west towers were contemplated. A thirteenth century church at Kaschau, Hungary, attributed to Villars de Honecourt, has a French arrangement of eastern chapels. Buda, of the same period, has three eastern apses and two west towers. Rooskilde, in Denmark, of the twelfth and thirteenth centuries, is a three-aisled apsidal basilica, with a western tower. Trondhjem, Norway, with square east chapels to the transepts, and an octagonal tomb-house at the east end, an aisleless nave and central lantern. Hitterdal, a wooden church, is surrounded by external galleries. The cathedral of Lubeck has a three-aisled nave with lateral recesses, an unimportant transept, and a

chevet, with seven polygonal chapels and cloister. St. Mary's is three-aisled, has two western towers with no entrance on this side, a low transept, consisting of chapels; and a chevet, with five polygonal chapels. Danzig is cruciform, with a west tower.

*Belgium.*—In Belgium the earlier churches had a square east end, and central and western towers; in later times we find, as in Germany, the French chevets; and the arrangement appears also in several Pomeranian churches. The oldest church in Belgium, that of St. Vincent of Soignies, of the tenth century, resembles Zurich: it has a square east end, and had a central and western tower. St. Gertrude, of Nivelles, has also a square east end, a central tower, and west tower flanked with two circular towers, and a double transept. Tournay has a transept, with apsidal ends of the eleventh century; a chevet with five chapels, consecrated 1223; and a central tower, round which four out of the original six lesser towers are grouped. Antwerp has an ill-developed shallow transept, a chevet with five chapels, a seven-aisled nave, and one of the two western towers which formed part of the design. St. Jacques, at Liege, has a circle of chapels round the choir apse.

Belgian Gothic architecture exhibits—1. Primary Pointed and Transitional, tenth to thirteenth century. The ground-plan is a Latin cross; the principal west door is isolated, and in the Transitional; lateral entrances are made to the nave and choir, but were removed under a single porch, deeply recessed, at the end of the transept in the thirteenth century. Porches at the west end are rare; towers were square: one stood at the west end, or two, as at St. Lambert's, Liege, and St. Sulpice's, Leu; or two flanked the junction of the cross and transept, as at St. Bavon's, Ghent. The principal door was on the west, under a porch, at St. Lambert's, Liege, and St. Mary, Dinant; but on the sides of the nave at St. Vincent's, Soignies, and St. Gervais, Maestricht. The west front, where was no door, had a large window, as at St. Vincent's, Soignies; Notre Dame, Louvaine; and where there are no west towers there are round turrets, as at St. Nicholas and St. Jacques, Ghent; St. Quentin's, Tournay; and in this case there is a central tower or octagon, as at St. Jacques, Ghent. In Transitional the choir was small, lower than the nave—as at St. Vincent's, Soignies,—square ended, or with a circular or octagonal apse. In the twelfth and thirteenth centuries it was enlarged. Sometimes it is aisleless, sometimes has a chevet and aisles, sometimes has not continuous aisles, throughout its circuit. The naves have no side chapels: the large triforium is painted in Primary and round-headed in Transitional. 2. Secondary—Pointed or Rayonnant, fourteenth to latter part of fifteenth century, is marked by the huge size of the windows above the entrances. The naves have side chapels; Lady-chapels are rare. There are sometimes as many as four doors at the west end, as at St. Gudule's. Recessed porches occur in the fourteenth and fifteenth centuries. Single or double towers flank the west end—square, as at St. Gudule's, or square below and octagonal above, as at Notre Dame, Antwerp, and St. Bavon's, Ghent, but were designed to carry a spire. At the end of the fourteenth and beginning of the fifteenth century they were intricately carved, as at Notre Dame, Antwerp; St. Gertrude's, Louvaine; and Mechlin; this was the period of wooden spires, as at St. Gertrude's, Nivelles, and St. Bavon's, Ghent. 3. Third Pointed or Flamboyant, latter part of fifteenth to latter part of sixteenth centuries. Notre Dame, Antwerp, has a fine octagonal cupola, a solitary instance. Spires became generally spherical or angular domes.—(Weale's "Quarterly Papers;" Schayes, "Hist. de l'Arch. en Belgique.")

*Spain.*—The Italian apse is a direct copy from the Roman basilica; the Spanish cathedrals present either the French chevet with a circle of chapels, or an apsidal aisle surrounding the altar, and opening on chapels with an eastern chevet, which, if the east end is square, is the Lady-chapel,—if circular or octagonal, as at Burgos and Batalha, a tomb-house. The transepts are ill defined. The interior arrangement is mainly that of the old basilica. The stalls of the clergy are ranged along the west end of the choir (which is shut off from the nave by a wall), and ranged westward of the transept, the whole space under the lantern—the cimborio—being railed in and unoccupied. The sanctuary (capilla mayor) contains only the high altar. It is curious to observe in passing that the canons' choir was in the centre of the nave at the Lateran, S. Maria Maggiore, S. Lorenzo fuori le Mura, and St. Clemente; and that

the circular font was placed in the north transept at St. Peter's, as the late Baptistery of Canterbury appears to have been built in accordance with that arrangement.

Leon, commenced 1199, terminates in a chevet with five chapels. Burgos, of the thirteenth century, has lateral chapels attached to the nave,\* two western towers, a central octagonal lantern, and octagonal eastern chapel, like that of Murcin. Toledo, commenced at the same period, is of five aisles, like Troyes, with an eastern chapel. Seville is a parallelogram, with five aisles and lateral recesses and an eastern chapel.

*Portugal.*—Batalha (Lenoir, ii, 229), of the fourteenth century, is a three-aisled nave, with a transept, having four eastern apses: to the eastward of the apsidal choir is an octagonal tomb-house, with radiating recesses, and an octagonal tomb-house inscribed in a square.

*France.*—M. de Camont divides French Mediaeval architecture into (1), Roman; (2), Ogival Primitif (thirteenth century); (3), Ogival Secondaire (fourteenth century); (4), Ogival Tertiaire, first epoch, 1400-1452; second epoch 1450-1550. In France,† as St. Gregory describes Tours, and Apollinaris Sidenius Lyons, the early churches in the north, Poitou, Auvergne, and Burgundy, as in the sixth century, preserved a basilican form, an apsidal oblong, with an atrium surrounded on the three sides by a colonnade. In one part of Aquitaine, and on the banks of the Rhine, they were aisleless; in Provence and Toulouse the basilica of Constantine, at Rome, seems to have been taken as a model. Fontevrault, of the twelfth century, has the plan of a basilica without aisles. From Auvergne to Nevers and Toulouse, the aisles and upper gallery of the basilica were preserved in the eleventh century. The double apse was found in the east of France, and on the borders of the Rhine; at Tours, Besançon, and Verdun; and, probably, Strasburg. Poitiers has also shallow niche-like apses to the transepts, and three choir alleys. The baptistries were circular. The naves were at length subdivided by pillars, as at St. Vincent's and Paris, by St. Germain, and at Clermont, by Namatius, the eighth bishop, in the fifth century; in the latter church an apse was added, and at St. Vincent's, which was called in consequence St. Cross, a transept. Namatius built Auvergne Cathedral in the form of the cross. In France, in place of the wall of the niche-like Roman apse, the architects constructed a screen of columns, with an external also opening into radiating chapels—a chevet. The chevet was deduced, probably, from the junction of the circular tomb-house so frequently found behind the altar with the basilica, by the removal of the intermediate walls. At St. Martin's, at Tours, the plan was initiated in the twelfth century by omitting half the eastern circle built by Perpetuus, and building the nave from the tangents, and was fully developed at Conques and Toulouse. Leon, like Dol, has a square end, but in the twelfth or beginning of the thirteenth century, we find semi-circular apses to the transepts of Nevers and Soissons, at Tournay, Belgium; and St. Martin's, Cologne. Till the middle of the thirteenth century the churches of the south of France, generally, had neither eastern aisles nor radiating chapels. In Provence, apses were usually polygonal; in the north, circular. M. Viollet le Duc gives some curious instances of a double east apse. The ground-plan is singularly deficient in a due expansion of transepts, which are often wanting, or frequently only indicated internally. Chartres, Beauvais; St. Maurice's, Angers; Autun, Poitiers, Carcassonne, and Rouen (the latter strikingly resembling the ground plans of Gloucester and Norwich), are the chief, not to say, almost the only exceptions. Bourges and Bazas are not cruciform, and, like many cathedrals, appear to have been constructed thus in distinction to the alleys, in order to show that a cathedral was a national monument built by the people. Portals, as at Laon, Chartres, Amiens, Rheims, Sens, Soez, Paris, Contances, Bourges, and Autun, are very distinctive of French arrangement, and were probably suggested by the large Clugniac porches. Another prominent feature in the thirteenth century is the prevalence of lateral chapel recesses to the aisles, and even when the aisles are double, another distinctive characteristic of the style, built between the buttresses, as at Rheims, Notre Dame, Paris; Troyes and Bourges; and at St. Martin's, at Tours, on the south side of the nave, and at the choir only, as at St. Omer's, Rouen. St. Front's,

\* Ferguson, Handbook of Arch.  
† Viollet le Duc, Dict. de l'Arch. s. v. Arch. Rel. Cathedrales; Abside, Chevet, Chapelle; Lenoir, i, 221; ii, 91.

Perigueux; Angoulême, Alby, Fontevault, and St. Maurice; Angers, are aisleless. Eastern apsidal chapels occurred in the choir of St. Front's, Perigueux; Nevers, Angoulême, St. Savin's, Fontevault; St. Hilaire's, Poitiers; Clermont-Ferrand, and Issoire. At Clugny, where there was also a choir-transept, there were double eastern apses to the main transept. At St. Benigne's, Dijon, and Langres, c. 1160, there were mere niches in lieu of transeptal eastern apses. St. André's, Vienna, has an eastern apse; so has St. Maurice's, Angers; Angoulême has four apsidal chapels attached; Clugny had an eastern apse with five chapels; Ronen has an apse with three chapels. A chevet with five chapels occurs at Rheims, Noyon, Tours, Clermont, Narbonne, Limoges, St. Ouen's, Bazas, Troyes, Clugny (now destroyed), Chartres, and St. Martin's, at Tours (Chartres has, however, an additional chapel on the east, connected by a staircase); with three at Fontevault and Conques, with seven at Beauvais, Bayeux, Amiens, Mans, Coutances, and St. Stephen's, Caen; and with four at Issoire, a fifth of square shape being inserted to the east. Chalons-sur-Maine, Carcassonne, and Angers, have an aisleless apsidal choir; Alby is apsidal, with lateral chapels round its entire circuit. St. Front's, Perigueux, as Clugny had, has an ante-church and porch. St. Hilaire's, Poitiers, and Laon, have square east ends, but in the former instance there are three shallow, niche-like apses. At St. Pierre Toscanella's, and at Spire, similar quasi-apses are attached to the transept. At St. Front's, Perigueux, an oblong building, with an apsidal termination, was carried out beyond the choir, like a lady-chapel. At St. Stephen's, Caen, a north-west chapel is attached to the nave.—(Lenoir, i. 275, 355; ii. 24, 95, 121, etc.; Viollet le Duc, i. 4, 232; ii. 423; iii. 226.)

**Chapels.**—The word chapel has been derived from St. Martin's cappa,\* which the kings of France carried out to their wars and deposited in certain tents, called, from the circumstance, "capella." In a chapel of Westminster, Carton set up his printing-press, a name from this circumstance attached to printers' workshops. The development of chapels requires particular notice. The first churches had but one altar; but in the sixth century, St. Germain built, at St. Vincent's, Alby, four, one in each wing of the cross, besides two additional chapels at the west end. Two centuries later, in the abbey of St. Gall, we find seven, four in each of the aisles, and an apsidal chapel of St. Peter at the west end of the church, in place of the mediana, or principal gate of the basilica. Chapels were first built for the sepulchre of saints. At St. Germain des Prés was an oratory of St. Symphorian, on the south-west of the front, in which St. Germain desired to be buried. On the north-west was the chapel of St. Peter. The cubicle mentioned by St. Paulinus of Nola, was devoted to prayers, reading of holy books, and commemoration of the dead. St. Praxedes, Rome, has two chapels near the entrance of St. Denecris Salonica, and another at St. Cecilia Transverberino; one on the south of the choir at Trieste, dedicated to St. Justus and St. Severinus, like the main church, composed of three apsidal aisles. Sens and Langres have a single eastern chapel; Cahors has three, and Angoulême four apsidal eastern chapels. Towards the end of the eleventh century, radiating chapels and an eastern aisle appear in Auvergne and Poitou, and the centre of France, extending in the twelfth century to St. Hilaire's, Poitiers, Notre Dame, Clermont, Nevers, and Toulouse; but in Normandy not until the beginning of the thirteenth century; but ordinarily the choirs in that province and the Ile de France were simply surmounted with aisles, as at Mantec, Poissy, and Paris. Laon and Chartres were almost destitute of chapels. At Bourges (c. 1230) and Chartres (c. 1220) the radiating chapels are mere apsidal niches; but in the twelfth century became important, as at St. Denis, and St. Martin des Champs. In the twelfth and at the beginning of the thirteenth century, chapels, according to an arrangement peculiar to abbeys, and afterwards imitated in the cathedrals, were enlarged, as at St. Remy, Rheims, and Vezelay, and communicated with each other by a subordinate narrow aisle. There are three radiating eastern chapels at Nevers, four at Clermont-Ferrand, five at St. Savin's, and only one on the east at Langres, c. 1160.

The difficulty of ranging chapels round the apse, as at St. Germain des Prés, led to the alternation or admixture of polygonal or square chapels with those of circular shape, as at Fontenello; and

in the thirteenth and two following centuries to the adoption of polygonal chapels only, as at St. Nicaise's, Rheims. Owing to this grouping of subsidiary apsidal chapels about it, the apse lost its significant name of chevet (capitulum). (Ducange, s. v. Capitulum, ii. 146; Lenoir, ii. 96.) The cemetery of great persons, as at St. Genevieve's at Paris, was on the east side of the apse, and a lamp was often set in a niche, so as to light both this garb and the crypt.

About the eleventh century the altars began to be removed out of the nave into eastern chapels, and the aisles were rendered continuous and enlarged, to afford a free passage round the choir.

In the thirteenth century the lady-chapel, like the radiating chapels of the apse, received a marked development, as at Rheims, Mans, Amiens, and Beauvais, built 1230-70, and at Coutances. The transepts also at Rheims, St. Hilaire le Grand, Clugny, and St. Savin's, as the choir had previously, in order that the altars might be soon entering the church. To multiply these chapels a second transept was added, as at Salisbury, &c. At Clugny it received north and south apsidal ends, as at Tournay and Noyon, a new arrangement of the eleventh and twelfth centuries. There are double aisles at Clugny and St. Hilaire's.

We are able to collect from the "Rationale" of Durandus, Bishop of Meude, who was born in 1220, and died in 1296, a clear description of a church of that period. It was cruciform, lying east and west, sometimes apsidal, and consisted of nave, chancel, and sanctuary, an apse, a crypt; the roof was tiled; the windows were glazed; the chancel was lower than the nave; there were altar-rails; a screen, and occasionally a rood-loft; a sacristy; a water-drain; there were carvings on the walls of carved images, the zodiacal signs, and Scriptural subjects; there was a veil separating the sanctuary from the choir, to be raised on certain occasions; and in churches "are suspended two eggs of ostriches and other things which cause admiration and which are rarely seen, that by their means the people may be drawn to church and have their minds the more affected." Among the conventual buildings and accessories he mentions a square cloister, chapter-house, refectory, cellar, dormitory, oratory, herb-garden, and well.

In France the naves did not receive their outer chapels (Viollet le Duc, i. 207; ii. 354)—constructed, as at King's College, Cambridge, between the buttresses—until after 1240, and the first instance occurs in Paris, where, in the choir, in 1260, the operation was continued. Limoges, Narbonne, and Troyes were designed without them; Laon, Coutances, Ronen, and Sens were modified for their arrangement, 1300-50. They were added at Amiens about the same period; but in the fourteenth century they disappear at St. Ouen's, while the chevet retains five radiating chapels, the easternmost being most prominent. The outer chapels were probably introduced owing to the enclosure of the choir.

The architecture of Ireland includes—1. Oratories, as in the south-west district of Munster; and bee-hive houses in Connemara, built of masses of rock, and vaulted with stone of a later period. 2. Celtic, small aisleless rectangular buildings, without an apse, usually in groups of seven, like the churches in Asin Minor and on Mount Athos, with a central west door, and occasionally provided with a chancel, as in the Patrick Temple, Galway, and in the early churches at Glendalough. In the fifth century they are of a type anterior to the Roman basilica; and some were built of timber. 3. Romanesque, ninth to twelfth century, with a basilican arrangement; the throne, or a bench-table, being at the east end, and the altar detached, as at St. Saviour's, Glendalough; the roofs are of high pitch, and the chambers are frequently constructed under them, or along the walls, for the clergy. The round towers, at once bell-towers, treasuries, and places of retreat, are both of this and the earlier period. That of Glendalough is said to be of the seventh century. Cormac's Chapel, Cashel, has transept-towers of the early part of the twelfth century. 4. Anglo-Irish, from the close of the twelfth century. The original plan of a simple oblong, or a nave and chancel, were preserved to the latest period. Bell-turrets were not common till the thirteenth century. St. Douglough's Church, of that date, is oblong, with a low square central tower, and adjoins an octagonal baptistry. Christchurch and St. Patrick's, Dublin; Gray, Kilmallock, and Cashel, are pointed; Jerpont and Dunbrody, Transitional. Newtown has Romanesque features. Transepts were added in (5), the Later-Pointed. In the fourteenth and fifteenth centuries the narrow

central towers were added. Cashel, Kilkenny, Waterford, Limerick, St. Patrick's, and Christchurch are, and Kildare was, cruciform. Their towers were central, with the exception of St. Patrick's and Limerick, which were on the west. There is no instance of two western towers in Ireland. The cloister of Kilkenny resembles cloisters in Spain and Sicily.—(Gen. Mag., N.S. vii. 433; Wakeman, Arch. Hibernica, 1818.)

The architecture of Scotland embraced—1. churches of wicker-work, which in the fifth century, gave way to stone churches, like that built by French workmen at Whithere for St. Ninian, and another constructed in the eighth century by monks from Jarrow. 2. Scotch-Irish, from the middle of the sixth to the middle of the eleventh century; it exhibited round towers, hee-hive houses, dome-roofed cells, small churches, often in groups, and, at Iona, priests' chambers over the aisle. 3. Romanesque Anglo-Scottish, 1124—1165, as at Dunfermline, Kelso, and Leuchars. 4. Lacet, 1165—1286; Kelso and Paisley had naves shorter than the choirs; Dunkeld, Dunblane, Paisley, Sweetheart, and Whithere had aisleless choirs; Brechin, Dunblane, and Whittemore, St. Andrew's, Aberbrothock, Dryburgh, and Melrose had only an east aisle to the transept. 5. Decorated, 1286—1370. 6. Flamboyant, 1371—1567. The saddle-back tower and polygonal apse are continental features; porches form a characteristic, as at Aberdeen, Paisley, and Dunfermline. Holyrood, Aberdeen, and Dunfermline offer the only instances of two western towers. Dunkeld has, as Glasgow had, a north-western tower. The spires are poor. The imperial crown of Edinburgh is almost unique. The transepts are seldom well developed. Edinburgh has double nave-aisles.—(Arch. Journal, xiii. 226.)

**English Architecture.**—The earliest English architecture of which we have any record, historical or material, was neither borrowed from France nor communicated from Germany. The Saxon churches (Poole's Churches, c. iii. p. 22; Lenoir, ii. 180) were divided into four classes (Canute's Laws, A.D. 1017, c. 3). The word "monastery" occurs in Iud's Laws, A.D. 693, § 6. St. Jerome mentions pilgrimages of the early British to Jerusalem. Wearmouth was built by French masons (Monasticon, i. 501). Stone churches are mentioned by Reginald of Darham (Surtus Publ. pp. 282, 281). Florence of Worcester speaks of the magnificence of Alfred's buildings, and Alcuin of York Cathedral: it was, in 627, a square basilica of stone (Ib. Fabric Rolls, p. vii.). Peterborough was built of immense stones, c. 655 (Hugo Can., ap. Lehaut, i. p. 3). Lasingham was of stone, c. 660 (Bede, Eccl. Hist., iii. c. 23). William of Malmesbury says that stone buildings were rare before the time of Benedict Biscop (Ib. i. c. 3). Polished stone is mentioned as employed, c. 674, at Ripon and Hexham. The word "basilica" is used by Eddius, Vit. Wilfridi, c. 17; Matt. Westm. Anno 750; Oronceus Vitalis, ii. p. 25; Will. Malm., fo. 43; Monast., iii. 135. In France it denoted a minister (Ducange, i. 611): in England, a church before consecration (Otho, Const. 1297, c. 1). At Abingdon, the church, like Clermont (Viollet le Duc, i. 209), had a double apse, with twelve chapels and twelve cells for the monks, in the seventh century (Monasticon, i. 512). The dome shown in Anglo-Saxon illuminations (Arch. Jour., vi. 359; i. 24; Jour. Arch. Ass., i. 29; vii. 270; x. 142) links the style with Byzantine. In the instance of Bishop Wearmouth, c. 675, we are informed that the church there was built after the Roman manner. We shall not pause to consider the stud buildings, like that of Glastonbury, but merely allude in passing to the timber church still existing at Greenstead (Jour. Arch. Ass., v. 1; vi. 191); Bury St. Edmund's, till 1092, was mainly of wood (Monasticon, iii. 101). There was a stud lady-chapel at Tykford (Ib. v. 206). Bede mentions St. Alban's memorial chapel at Verulam, c. 300, as being "of admirable workmanship," and the erection of a stone church at Galloway in 448 gave the name of Whithere, or Stonehouse, to the place. William of Malmesbury says that St. Aldhelm's "broad church survived whole to that day." St. Piran's Church, in Cornwall, of the fifth century, resembled the Patrick Temple of Galway. The nave door on the south was round-headed, with a chevron moulding, a keystone carved into a tiger's head, and two human heads upon the capitals. The font was octagonal. A single north-east side window, near the priest's door, lighted the east wall of the square-ended chancel; to the south-east was the altar, inscribed with a cross and the name of St. Piran. The stone chancel screen had an opening on the north side. A bench table,

\* Johnson, Canons, ii. 68; Durandus, ii. 10, 8; Gemma Animæ, i. 129; Ducange, ii. 103.

commencing on the south side of his screen, was continued round the nave to the east wall. At St. Gwythian's the nave had a south door, a chancel with a stone screen and altar, and a bench table against the north and south walls returned along the screen. St. Madderno's is a simple parallelogram, with a stone bench and division between the nave and chancel, a stone altar, and in the south-west angle a holy well (Arch. Jour., ii. 225; Jour. Ass. Soc., ii. 68). A similar well was found at Kirk Newton, in Durham.

King Edwin built a stone church at York (Comp. to Gloss. iii. 11). St. Augustine introduced the basilican form into England, but without the atrium or narthex. Norwich (Jour. Arch. Ass., xiv.) still retains evidences of a Roman type, where the steps of the bishop's throne appear in the wall behind the altar; at Canterbury the throne once occupied the site of the present altar, while the altar formerly stood on the lower platform; at Exeter the eagle,\* until recently, stood in front of the altar steps, being a vestige of the old custom of reading or preaching from that place.

In a history of Ramsey Abbey (Comp. to Gloss. iii. 18) of the time of Henry I., a church contemporaneous with those of St. Dunstan and St. Oswald, is described as having "two towers, one at the west end, the other central, according to the custom of the period." St. Bennet, Hulme, Belvoir, Wymondham, Durham, and Malmesbury, had two similar towers.—(Monasticon, i. 256; iii. 31, 288; Comp. to Gloss. iii. 21.) The western tower was eminently fitted for the defence of the most exposed portions of the church when it was in danger of assault during unsettled times.—(Lenoir, ii. 379; Viollet le Duc, iii. 340.)

Pope Sixtinians directed the employment of bells in 601. Baronus refers their use to the time of Constantine. Bells came from Italy: the large were called *campane*, the small *nabes*—(Wal. Strabo, c. 4, 5; Am. For., c. 1; Fleury, xviii. 42; Viollet le Duc, iii. 280.) In Scotland, at Aberdeen and Glasgow, the bells were hung upon trees. Bells are mentioned in England by Bede, c. 680 (Hist. Eccles. iv. 23). Turketil, who died 975, gave a bell named Guthlae to Crowland Abbey, and Ingulphus mentions a peal of seven bells there. By the laws of Athelstan the existence of a bell-tower gave the owner the right of a seat in the town gate, a place on the grand jury. Belfries are distinctly mentioned by a monk of St. Gall in the eighth century. One of the earliest bells remaining is that of Moissac, dated 1273. At Chartres (Dr. Billou, F.S.A., sur les Cloches, 1858) some of the bells bore the name of Les Commandes, as they gave notice for ringing the great bells. The same usage was adopted at Bayeux, where similar bells were called *Moneaux*—warners. At Clugny the bells were named after their destination—Prayers, Angels, Retreat, Toesin, &c. That at Strasbourg, used for the assembly of the Council, was called *Magistrat*; and one at Angers, *Evigilias Stultum*.

William of Malmesbury describes a church built by Alfred the Great, evidently showing the Rhenish type, as erected in a new way of building; four piers supported the whole structure, which had four round chancels in its circumference. Eddius (Comp. to Gloss. iii. 8, 9), Precentor of Northumbria, describes Hexham, built by St. Wilfrid, as "a structure of many parts, long and high, supported on various columns, and above many subterranean chapels;" and Prior Richard, in 1180, speaks of "its nave surrounded with lateral chapels, its walls divided into three stories, its columns leading to them, and oratories, with passages leading to them, and the covered vault of its sanctuary." He also mentions "porticoes (or apses) at Ripon." Alain describes Egbert's cathedral at York as "having many apses and curved roofs." At Winchester, St. Wolstan's Church had north and south aisles, an eastern apse over a crypt used as the burial place of bishops, several chapels, and a cloister to the west; and Miphelge, in the tenth century, added a west tower. We therefore gather from these facts that the larger Saxon churches were of stone, with a central tower, aisles, triforia, clerestory, apse, and crypts, although inferior in size and ornament to the Norman period. Bede (H. E. ii. 4) mentions a stone altar set up by St. Paulinus in 627, and similar altars are mentioned in the Council of Epaunne, 517, c. 26; Prudentius Apollinaris of France, in the fifth century; and the Excerpts of Egbert, in 750.—(Hierur.

Angl. 40; Camb. Camd. Soc. 1845; Canons, 714, c. 41; 816, c. 2.)

The church of St. Martin, at Dover, like St. Genoux, terminated in three equal eastern apses. While we recognise the historical fact that the cruciform shape of churches was one of gradual development, we must at least confess it would be difficult to assign any other reason than symbolical consideration as that which influenced our forefathers in laying out the ground-plan of their churches; and he would not be envid who should attempt to impugn their attempt to embody holy doctrines in external objects, and make the material fabric suggestive of Christian verities. As M. Martin (Hist. de France, iv. 337) observes, "Cet art n'est tout entier qu'une immense aspiration vers Dieu, vers l'infini aspiration ardente et douloureuse du cœur." In the tabernacle and temple the form of the edifice, the arrangement of its parts, and the order of its altars and furniture were made by Divine appointment according to a pattern. This model (Milman's Latin Christ. x. 29) in its main features was adopted and adhered to, as far as the different characters of the two dispensations would allow, in the adaptation of heathen buildings and in the positive construction of Christian churches. The doctrine of symbolism, however, must not be pressed too far. The principle of derivation of orientation is very questionable (Proc. Bedf. Arch. Ass. 1856), as far as it turns on the opinion that our Saviour died with his face to the south, or on the direction of the choir to that part of the sky in which the sun rose on the day of Dedication of the Church. The old English Homily on Wake-days (Poole's Churches, iv. 31; Orientator. Synh. of Churches, lxxviii, lxi.; Churton Eng. Ch. vi. 128), Isidore (Orig. xv. 8), the Gemma Animæ (i. 129), Durandus (v. ii. 27; i. 8), and Walafrid Strabo, mention simply the reason that Christians always prayed towards the east. Viollet le Duc (iii. 235) shows that the declination depended on mere constructional causes. St. Michael's, Coventry, Tynemouth, Boham, Liebfeld, and York bent to the south, and St. Mary's, York, and St. Ouen's, to the north.

At Canterbury the Saxon cathedral was arranged in a great degree in imitation of St. Peter's Church, at Rome. In the very ancient church of St. Gall, c. 820 (Lenoir, i. 32; Viollet le Duc, i. 243; Arch. Jour., v. 85), attributed by Mabillon to Eginhard, the architect of Charlemagne, the ground-plan embraced a long nave with screened chapels in the aisles, a transept with an altar in each wing, a short constructional chancel ending in an apse. A screen ran across the first bay westward by the cross, with lateral doors and in front of the ambo. (At Clairvaux the second or outer choir was used by the sick monks.) The ritual choir occupied the space of the lantern, and was furnished with seats for the singers; a western screen ran in front, and had a central entrance flanked by the analogia, one on each side,—an arrangement which reappears centuries later in the double screen to which I shall presently allude, and in the altars attached to the choir screen in Gothic churches. The high altar stood at the top of a flight of steps, on each side of which were smaller altars, and a lesser altar was placed in the apse. In the centre of the nave was the altar of the Holy cross (Lenoir, ii. 17; Monasticon, iii. 80); probably the first instalment of the future rood-screen. The confession, or cell of the saint, lay under the high altar. In each of the western towers was a chapel. The processional path lay between the arcade of the nave and its lateral chapels in the aisles. The doors in the north aisle, led to the porter's room; in the south aisle, to the poor man's hospice; in the south transept, to the cloister, crypt, sacristy, and dormitory; in the north wing, to the crypt, library, scriptorium, abbot's lodge, and guest-house. Canterbury (Willis Cant. Cath., ch. ii.) was a long parallelogram, divided by two arcades into three alleys. At the west end was an apse with the bishop's throne, fronting the lady-chapel altar. Many altars were dedicated to St. Peter and St. Paul; the eastern apse was allotted to the altar of the latter in reference to the scene of his labours, and the western to the former, in allusion to the pontifical throne (Lenoir, ii. 7). On each side of the nave was a tower, forming a quasi-transept: that on the north was occupied as the Novices' School, that on the south was entered by a porch, and contained an altar. The choir of the canons was inclosed by a screen breast high; at the upper end was an altar with lateral doors in the screen, which closed it on the north and south. In front of the apse, in the chord of which was the altar of the daily mass, were flights of steps on the north,

south, and west, ascending the altar platform, below which was a crypt containing an altar, and extending under the presbytery. Against the east wall of the apse stood the high altar. A passage from the south aisle led into the octagonal baptistry, or church of St. John Baptist.

Edward the Confessor (G. G. Scott, Proc. R.I.B.A., 1860), after "a new kind of building," changed the ordinary Saxon parallelogram into a Latin cross with a lantern at the intersection; the great area of the church had a lofty vaulting; the end had double arches on either side; the choir stood in the cross below the tower; and above and below were little chapels furnished with altars. St. Mary's in the Castle, Dover, built in the early part of the same reign, the latest date assignable, is cruciform and aisleless, with a central tower. St. Edmund's, Bury, completed 1095, had, besides a central tower, two octagonal west towers; the east end was apsidal, the transept had eastern apses, there was a crypt under the choir (Monasticon, iii. 1095).

*Ground Plan.*—In the Norman and Transitional Norman church, the grand characteristics were the great length of the nave, at St. Alban's, Winchester, Norwich, Ely, Peterborough, Jorvaulx, and Byland: a triapsal arrangement, the choir, shorter than at a later period, ending in an apse,\* and the transept having an eastern apse to each wing; the latter feature appearing at Norwich, Gloucester, Ramsey, Thetford, Castle-Acre, and Christ Church, Hants. Oxford, St. Cross, and Ramsey, had a square east end. The ritual choir occupied the space under the central lantern, and included the first two or three eastern bays of the nave. The apsidal east end, as at Gloucester, Canterbury, Waltham, Leominster, (Arch. Jour., x. 111), and Norwich, often terminated in an aisle opening into one eastern and two lateral chapels. In 1250 aisles were added to the transept of York; and in 1370 a choir transept. Reading had three eastern apses, and two eastern apses in each wing of the transept. (Archæologia, vi. 61.) Battle had three eastern polygonal apses (Horsfield's Sussex, i. 539). Wells and Lichfield have polygonal ends to the Lady-chapel. Eastward of the choir was the presbytery, with the altar standing in the chord of the apse, and the bishop's throne elevated on a platform behind it; the circular aisle behind forming a processional path. Apses are rare in the north, probably owing to the influence of Iona. Of a later period we have the "French Chevet," a circle of pillars, comprising aisle and a crescent of radiating chapels, as at Tewkesbury, Pershore, and Westminster. At St. Alban's the nave was filled with altars arranged against the piers. The central tower was at length commonly regarded as forming the natural division between the nave and choir; and this recognition, coupled with the introduction of eastern shrines and of a solid rood-screen, necessitated a complete reconstruction or prolongation to the eastward. Under the east tower arch the rood-screen was placed, and a recedes divided the new constructional and ritual choir from the retro-choir. (Viollet le Duc, s. v. Clôture.) Lateral stalls enclosed the choir, and open screens the presbytery; both partitions being inserted in the lower arcades. Access was thus permitted to the entire circuit of the church, without interruption to the choir services; the double aisles of the French churches served the same purpose more efficiently. The obstruction to the progress of a procession offered by the lateral chapels led to the erection of chapels external to the nave-aisles at Chichester, Manchester, Melrose, and Elgin. At Winchester, the recedes, with a more easterly screen, enclose the capitular chapel. At Westminster, St. Alban's, and Dury St. Edmund's, the retro-choir was occupied by the chapel and shrine of the patron saint. Crowland terminated in an apse without lateral chapels.—(Stukely, Iter. Curios., i. 33.)

*Crypt.*—The original ground-plans of the eastern portions of churches many sometimes be traced in the early crypts: an apsidal oblong martyrdom at Winchester has its aisles, and a smaller apsidal crypt for the altar to the east.

Crypts were employed as chapels and oratories, charnels (where no distinct charnels were built), mortuary chapels, and chambers to secrete the church jewels in time of danger. They are two kinds, one a square hall, the other a subterranean church, with apses and aisles. They occur at Repton (Jour. Arch. Ass., vii. 263, 275), York (three-aisled), at Gloucester (three-aisled), Christchurch (an apsidal oblong), St. Peter's,

\* Durandus, iv. c. xxv. The eagle of St. John was often carried on the pulpit (Lenoir, ii. 136).

\* *ἄψις*, a how. Passow, Lex. Gr.; Lenoir, i. 148, 201, 276; ii. 91; Ducange, i. 31.

Oxford, Bosham, Hytch, and of small size at Hereford (three-aisled), and Exeter, Ripon, and Hexham (Arch. Jour., ii. 239); in the latter two instances shaped like cells. Rochester has a crypt of seven aisles, full of chapels, but not apsidal, begun in the thirteenth century (Jour. Arch. Ass., ix. 279, 281).

At Westminster there was a crypt, as at Wells, with an altar under the chapter-house. Wells are found in them at York and Winchester; at York there is a lavatory. The crypt of Glasgow, of the thirteenth century, extends under and beyond the choir. A similar large crypt at Worcester wants the eastern lesser crypt, but is provided with an additional southern chapel (Britton's Cath., Proc. Arch. Ass. Worcester, p. 105); and the perfect subterranean church at Canterbury, vividly described by Erasmus, with its iron grille round the tomb, is a three-aisled apsidal oblong, with a transept, having two apses in each wing, and apsidal chapels at the east, while beyond is a second apsidal oblong with aisles, and a round crypt at the extreme east end. The latest English crypt is that of St. Stephen's, Westminster. The apse of a church is generally its most ancient portion, as the choir was always the first part built, and was always rebuilt with reluctance, being devoted to the most sacred offices of religion, and invariably of the strongest construction.

The crypt of Chartres had a martyrdom of St. Denis, with an ambulatory and large chapels (Ducange, ii. 682; Lenoir, i. 209; i. 157; Viollet le Duc, s. v. Crypte, iv. 117). St. Benigne de Dijon, of the eleventh century, is circular, with an eastern oblong chapel of St. John, and western auto-crypt, with four apses. St. Saurin, Bordeaux, of the eleventh century, is a nave of three aisles. St. Eutrope de Saintes, is apsidal, of three aisles, with three radiating chapels. At Auxerre, there is an apsidal crypt of the ninth or tenth century, of three aisles, with an aisle all round, opening into a small east apsidal chapel. The reliquary and altar of the saint occupied the east end.

At St. Servais, Belgium, there was a thirteenth-century crypt of three aisles, retaining its altar within the apse till 1806; the second, or *caréon funéraire*, as M. Schayes calls it, remains. A subterranean church of the same period, c. 1078-1092, an oblong of five aisles, with a pentagonal apse, is to be seen at Anderlecht. That of St. Bavon was a square of three aisles (ib. iii. 24). The crypt of St. Avit (De Caumont, Rapp. Verb. s. E.A., 1859), of the tenth century, and St. Aignan, a century later, at Orleans, are of three aisles, with a martyrdom or confession under the sanctuaries, and an apsidal church beyond the wall which bisects the entire building.

Glasgow and Llandaff (Freeman's Llandaff) are oblong churches; Canterbury, Lincoln, Salisbury, Worcester, Rochester, Southwell, and Beverley have, like Clugny had, a choir transept; rudiments of a similar arrangement appear at Wells, York, Hereford, and Exeter. Martin (Hist. de France, iv. 338) mentions a similar but exceptional instance at St. Quentin's, but observes that the choir transept is ordinarily found only in abbeys of a period previous to the Ogival style. The stalls of the clergy, probably reached from the choir transept into the nave (Viollet le Duc, i. 200), the choir transept being allotted exclusively to the clergy, and the western transept to the accommodation of guests. Durham and Fountains have an eastern screen; Peterborough, Lincoln, and Ely have a western screen; Exeter has one in a smaller degree. The choirs of Rochester, Kilkenny, and Christchurch are isolated from their aisles. Dunblane choir is aisleless.

I have been informed that the ground-plans of Minsters\* are invariably submitted to the Pope, and that many remain in MS. in the Vatican. We possess, however, the ground-plans of St. Gall, Clugny, Clairvaux, Cîteaux, and Clermont, which afford sufficient information for our purpose. The Benedictine (Viollet le Duc, i. 256) arrangement was uniform, a cruciform building with towers and chapels, marked by great magnificence. The Benedictine abbeys generally have a parish church immediately adjoining them.

Austin Canons.—Austin Canons, an order of regular clergy holding a middle position between monks and secular canons, adopted naves of great length, as at Jedburgh, Christchurch, &c., for the

purpose of accommodating large congregations (Johnson's Canons, ii. 233; Peckh. Const., 1281, c. 16), as they were a community of parish priests living under rule; and the prior's lodge is almost invariably attached to the south-west angle of the nave. The east ends are ordinarily square, and the choir—never very large—is sometimes, as at Lanthony (Arch. Camb., i. 201; i. 82, 3rd ser.), and Christchurch, shut off from its aisles. The towers are very seldom of any importance, and are generally additions of a late period at the west end, as at Christchurch (Curry's Christchurch), Dorchester (Addington's Dorchester; Arch. Jour., ix. 158), Bolton, and Waltham.\*

TOWN SEWERAGE, AND SEWAGE APPLICATION TO LAND FOR PURPOSES OF AGRICULTURE.

The questions of town sewerage, and works for the application of sewage to land, for purposes of agriculture, are not simple and easy. Town sewerage is a complex affair. Some of the items involved are—Site, area, and relative elevation; climate, rain-fall, surface gradients, and character of subsoil; population, water-supply, house-drainage, the use of cesspools, and the relative use of water-closets and soil-pans. Each of these items may be divided, and even sub-divided, fully to treat the question.

A town site may be inland, and the sewage may be taken by gravity over an area sufficient to use up the fluid as a manure; or the whole of the sewage may necessarily be delivered at so low a level as to require to be pumped before any use can be made of it. Then, agricultural land, available for the purpose of sewage irrigation, may be near, or it may be distant; and intervening works may require to be simple, or they may necessarily be expensive.

Steam power must also be estimated from the cost of coals and labour in a district, and I need not tell practical engineers that these elements vary widely in different parts of England. Coals are 5s. per ton in a coal district, and 20s. per ton in many places, where steam-power is required. The cost of lifting water or sewage in any place will be as the head overcome; that is, the vertical height, plus friction. It is of no practical use giving the cost per ton for Croydon, without giving such items also.

Sewage in any town is a varying volume, depending on many causes, but principally on the state of the weather, on the number and strength of subsoil springs, and surface streams. Sewage works—if these involve brick tanks, steam-engines, and underground pipes of cast-iron, for conveyance and distribution of sewage,—must be rigid. If such works are only just sufficient to manage the ordinary flow of sewage, they will be found in practice to be far below the requirements of constantly recurring excesses; and at such times sewage must be lost; and if persons are annoyed or damaged by the escape of sewage past the works of a company, such company may be actionable for this form of nuisance.

Sewage is "rich" or "poor" in proportion to the numbers of soil-pans in use by any population, the numbers using such apparatus, the wealth or poverty of the inhabitants, and to the extent of dilution with subsoil water and with other matter; the power of sewage to fertilize being in proportion to its richness up to a certain point. The richest sewage may have a manuring value (as tested in the laboratory) of 1ld. per ton of fluid; or the value may only be a fraction of a farthing per ton of fluid. Chemists of eminence state the annual value of sewage at 6s. per head per annum, and experience proves that all the nitrogen cannot be used by the plants, even under favourable circumstances.

I have devised and executed plans for the main sewers of some thirty towns, varying in population from 7,000 up to 50,000 each town; and in each town sewers are so designed and constructed as to render the use of sewage easy, when any parties will undertake the application of it to the adjoining land. At Carlisle sewage is pumped from man-holes, previously arranged for this purpose. At Chorley the sewage may be passed over the land below the outlet by gravity; but no one takes up the work. The time is ripe for active work in sewage utilizing: the field is large; and, if no more costly blunders are committed, the work will go on. In the towns sewered by myself I find that in the driest seasons, and at the driest periods of such seasons, subsoil water (spring-water) is always in excess of the water used by the inhabitants, which latter alone can be termed

"sewage,"—that is, the refuse-water containing house-washings and soil from water-closets. The spring-water in some towns removed by the sewers is up to twenty times in excess of the volume of water used by the inhabitants. In chalk districts, such as Croydon, excesses of this sort are found.

In England seasons vary in the amount of rain-fall about as one to two; and, in extreme excesses, (blunder storms), as one to several hundreds. The minimum fall of rain in a town may, for one year, be 20 inches; this will be a dry season. The maximum fall of rain may be 40 inches: this will be a wet season. There may frequently be three months without any available rainfall to cleanse the sewers, with occasionally much longer periods of dry weather; and, as in this year of 1860, rain may fall in excess week by week for several months. These are all items in the questions of tanking, pumping, and also for the distributing sewage by the intervention of steam power and cast-iron mains.

Mr. Shepherd brings forward instances of increased value to land, as at "Mansfield, from 3s. to 12l. per acre, per annum; in Scotland, to 16l., and 35l., per acre, per annum;" and also states, "from long and careful inquiry, I am clearly of opinion, that, when the sewage is applied to its legitimate use, each person residing in our towns will furnish sufficient sewage annually to irrigate an acre of land in the country." This latter statement is so beyond the mark, that, in my opinion, it is sufficient to invalidate anything Mr. Shepherd can say upon the subject of utilizing town sewage. At Mansfield, and in Scotland, the sewage of many persons is applied to one acre of ground, and is necessary to produce the results set forth in Mr. Shepherd's own letter to the *Times* of the 24th ult.

Water is of value in irrigation, but it will not give a profitable return on the cost of large brick tanks, steam-engines to pump it, and miles of underground cast-iron mains to convey it to the land and to distribute it. I can state, from my own knowledge, that in Croydon (which stands on the chalk formation), spring-water is many times its volume in excess of that which is true sewage. The farmers will soon find it out should they ever be induced to use the fluid on their land.

All experience in sanitary science proves that excess of disease in town populations is intimately connected with foul cesspools, foul sewers, and a foul subsoil. As cesspools have been and are abolished in any town, and as the liquid and soil refuse is speedily removed in water, by sewers, beyond the area of any town; so has the death rate of such town been reduced. The metropolis is a notable example: Wortling, Ely, Croydon, Carlisle, Lancaster, Rugby, and many other places, give favourable results, as vouched by the Registrar-general. Rivers and streams may have been fouled in excess, as the Thames, for instance, in the summer of 1859; but, even with such fouling of our rivers and streams, the gain, in human comfort, and in a diminished death-rate, has been considerable. Take the foul water of our towns to the land, and filter it through the soil in the cheapest possible manner, and then both town and country will be gainers. If sewage, with all its complications of dilution and intervention of machinery, occasional disinfection, &c., is not of sufficient value to farmers to induce them to find the capital, and run the risks indicated, then let the towns pay a sewage disposal-rate, in aid of the cost of works and management. At Rugby the sewage is paid for, but the proprietor has found out, by experience, that the town ought to be payers and not receivers.

At Rugby it has also been discovered that half the expenditure, to apply the sewage to half the area of land, would have been wiser and more profitable. The population is about 7,000: the area over which the power of irrigation has been extended is some 400 statute acres. The proprietor, by years of experience, finds that 200 acres would be sufficient. Mr. Shepherd would irrigate 7,000 acres,—at one person to each acre;—or, take adults, and say 2,000 acres,—that is, ten times the area experience warrants.

A company may intervene betwixt a town and any agricultural community, and, with economical works and honest intelligent management, be of service to all parties.

Closest and laboratory calculations must be taken with great deductions for practice. Town sewage is generated continuously, and, if used in agriculture, must flow unceasingly on to, over, and through the soil dressed with it. Plants can only take up and assimilate (in certain proportions) any manure, not the whole, but only a part (and most frequently a small fractional part): the

\* The term *Monsasticum*, as seen in our woodcut, applied to large conventual churches, is first used by Eusebius.—(Hist. Eccles., l. ii. c. 17.)

\* To be continued.

bulk must therefore be lost, partly by evaporation, partly by surface washing in time of rain; and at all times more or less by subsoil infiltration. Sewage must, therefore, be given to the land in excess, to produce the best and most economical results. Experience has proved this, both in Scotland and in England.

In conclusion I may state that I do not object to the formation of a town sewage company: I only object to wild statements as to the value of sewage, to the collection of a large capital to be expended in works and on salaries; knowing that, if the capital is so expended, there cannot be any profitable return. Railways are useful, but British shareholders, as a body, have reason to think that a more careful expenditure in the first instance would have given more satisfactory dividends. Lead and other mines may either make or ruin the proprietors. It has been said that all the ores raised in Cornwall and Devonshire, if fairly valued, have cost the speculators some 25s. for each 1*l.* sterling of value realised. Town sewage companies may easily expend more capital than they can earn dividend for. The sewage and spring water of Croydon cannot in my opinion pay working expenses and dividend on a capital of 30,000*l.*

With respect to Mr. Walker's letter in the *Times* of the 24th ult., I am not so ignorant as to even wish to imply that the sewage of 30,000 persons can be continuously placed on fifty acres of land: I, however, stated a fact as regarded a sewage utilization experiment at Carlisle.

The area of the land to which any sewage can successfully be applied will depend on the manuring richness of the sewage, and also on the character of soil, subsoil, and mode of cultivation. Sand and gravel are "hungry soils," and will filter and convert, area for area, larger volumes of sewage than heavy clay lands, giving more abundant crops of grass. Deep and close drainage will modify clay lands, and enable them to convert, usefully, larger volumes of sewage. I do not repudiate a judicious use of cast-iron pipes for sewage distribution: they may be used, but not extravagantly. I most sincerely hope no one will persist in saying that I wish to prevent a settlement of this most important question. But, having necessarily been brought into contact with the subject, and having seen existing works and having investigated the cause of some failures, I have found that extravagant expectations on the one hand as to results to be obtained from town sewage, and costly works on the other hand, have landed sewage speculators in failure. It is not advisable that the solidifying process failure at Leicester should be parodied in the liquid form at Croydon. Let the liquid sewage of Croydon go to the land by all means and at once, but in so economical a form that the speculation shall pay.

ROBERT RAWLINSON, C.E.

#### COLLIERY EXPLOSIONS.

No less than from 135 to 140 out of 200 persons have been killed by the fire-damp explosion in the Black Vein Pit at Risca, near Newport, South Wales, and many of the remainder have been severely injured. In regard both to ventilation and to safety-lamps much still requires to be done on behalf of our poor colliers, whose work is, at the best, one of the most repulsive and slavish kind, and would require every possible improvement to render it even tolerable to any but those who have been habituated to it from childhood. We lately noticed a new safety-lamp invention, in which any attempt to open the enmeshment of the light inevitably puts it out in the act. Some such invention promises well; for it is often from working with or otherwise using naked lights that such explosions as the dreadful one under notice occur. Where the liability is to "choke damp," as it is called, such an invention would be of course of no avail; but as against the combustible and explosive fire-damp it would be an important aid; although, without adequate ventilation, nothing can suffice to prevent deadly accidents in collieries.

Scarcely a month passes but we have dismal accounts of such accidents. Sometimes, as if by the interposition of Providence, only two or three lives are lost: at others the deaths amount to ten, and again to fifty, or one hundred, or even more, as in this sad case. Men and boys, in the prime of health and strength, are suddenly swept away, and widows and orphans created. The *Bristol Post* states that this black-vein pit at Risca, which is 150 yards deep, and the workings of which extend about three miles, has been prolific of accidents during the past fifteen years; that, within that period, first nearly forty were killed; then, eight

years ago, eleven were killed; and, five years ago, four or five more deaths took place.

While we sit at home by the side of our pleasant coal-fires, in the dull and cold season, we do not sufficiently reflect on the dangers and inconvenience which are experienced by the hard-worked miners. Apart from deaths and injuries by explosions and by choke-damp, the injury to health and the number of deaths which arise from the ill-ventilated condition of some of these mines are enormous; but we hear less of these than as regards the violent accidents to which that want of ventilation also leads.

When thinking of this, and of the numerous benefits for which we are indebted to the pitmen, who dig, at the constant risk of life, from the deep bowels of the earth, those supplies on which the comfort of our homes so much depends, and without which our steam machinery could not be made, or, when completed, would be motionless and useless,—who dig the black diamonds which are the means of lighting our streets and buildings, and which, to such an important extent, add to the national strength and prosperity,—thoughtful and well-disposed persons ought persistently to inquire if proper care be taken of these miners; or if, in this age, with all our scientific knowledge and mechanical appliances, such loss of life and destruction of health cannot be prevented.

Some of the best and most practical authorities now living are of opinion that, to a very great extent, they can be prevented, by the introduction of more certain methods of ventilation, greater care in the working of the seams of coal mines, and by the appointment of a greater number of persons in the management of collieries who, by education and other good qualities, are fitted for such an important trust.

This is, however, a matter of expense which, in too many instances, far more likely to be taken into consideration than the mere risk of human life. Such reckless disregard ought not to be allowed; and the matter is well worthy of the inquiry and interference of the Legislature; for there is certainly required a larger amount of intelligent and careful, as well as more general and more constant, inspection of mines, by gentlemen of high attainments, who, by being connected with the Government, may be supposed to be quite independent of the coal owners, and who will act vigorously for the safety of the workmen. Nor should miners be left, with impunity, to pursue the reckless course which they too frequently take at present. By the lighting of a single pipe, it may be, one person will cause the destruction of many. By the opening of his lamp for the purpose of enabling him to get better on with his work,—to enable him see more clearly that he does not mix any slaty matter with the coal, for which he will be subjected to loss in the price of his labour, &c.,—he may also cause an explosion. Admitting this carelessness of the men to be too common, it is clear that, if the ventilation of the pits were thoroughly managed, it would only be instances that one of those terrible accidents could take place at all. Nevertheless, with improved general arrangements of the mines, measures should also be taken, in connection with the miners, which might be likely to remedy the carelessness complained of. It is probably true, as is stated, that a number of the men who suffered from the recent explosion were found with tobacco-pipes, although this was forbidden; but how could these have been used if a vigilant and proper amount of inspection had been exercised? Perhaps the overlookers themselves were indulging in the same enticing but dangerous practice.

On this point it is worth while to inquire if the "Davy," or "Geordie" lamps are, in all pits, carefully examined, each time they are required for use, by a person of sufficient trust; if the locks which fasten the tops when required for use, in dangerous parts, be sufficiently tested, and of the best design and construction. It is also worth while to ask if it is not possible to improve on the present lamp, by such inventions as that we have alluded to, of a pit lamp which, on the endeavour of a workman to open it, would suddenly be extinguished. Has there been any sufficient encouragement given, of late years, for the production of an efficient lamp such as this? Pitmen who risk their own and fellow workmen's lives by opening lamps, or even using lucifer matches, for the purpose of pipe-lighting, should be subjected to both fine and imprisonment. In like manner, if it can be shown that these lamentable accidents can be lessened by improvements in the mines, and by care or additional expense, the proprietors and managers should not be allowed to go

scathless. Some suggest that, if a substantial fine were levied on the proprietors for each life lost, we would soon hear much less of these calamities. We know that many who are engaged in the mining business would, if possible, do right,—that in many instances there are now making exertions for the moral and social improvement of those in their employ; but, in the majority of cases, they do not personally supervise.

#### ARCHITECTURAL EXAMINATIONS AND THE ARCHITECTURAL ASSOCIATION.

THE ordinary meeting of members of the Architectural Association was held on Friday evening (the 7th inst.), at the house, in Conduit-street. The President (Mr. Roger Smith) occupied the chair.

Mr. Arthur Smith (Honorary Secretary) read the minutes of the last meeting, which were confirmed.

The following gentlemen were, on ballot, elected members of the Association:—Messrs. Georgi, Paraire, Weib, Taylor, and J. G. Goldsmith.

The president said he had to remind the meeting of the course of business, with reference to the question of architectural examinations, to which their attention had been invited by the circular of the Royal Institute of British Architects. At their last meeting, on the 23rd ult., Mr. Arthur Smith moved a resolution, which was in effect that the establishment of an architectural examination might be rendered advantageous to art, and improve the standing of the profession. A debate ensued on that proposition; and, as there appeared to be no prospect of discussing it without going into other points incidental to the subject, the meeting agreed to postpone the consideration of Mr. Smith's motion, in order to consider another bearing on details submitted by Mr. Blashill.

Mr. Blashill observed that when, at the last meeting, he ventured to submit a resolution, that, in the event of a professional examination being insisted upon, it should be confined to subjects connected with the practice of the profession, and that the Association did not consider it desirable that matters of general education should be introduced, he did so from a conviction that the object of the proposed examination ought not to be to test the scholastic acquirements of the candidates in a general sense, but should have reference only to those matters immediately connected with the profession of the architect. He would therefore, at the meeting to pass his resolution, the effect of which would be not to disqualify anybody, but to enable gentlemen so disposed to come in to offer themselves for examination in subjects of a purely professional and scientific character, without reference to those abstruse questions which too often formed a stumbling-block to competitive examination in other branches of learning. Since the last evening of meeting he had made a slight alteration in the wording of his motion, which he now begged to move in the following terms:—"That, in the event of a professional examination being insisted upon, it should be limited to those subjects which bear directly upon the practice of the profession, and should not include matters of general education; and this Association is apprehensive that an examination in the principles of beauty would lead to results unfavourable to the progress of art." Appendix to this resolution he wished to propose a list of subjects for examination, which should include the properties of materials, the theory and practice of construction, the construction of buildings, and the sanitary and structural clauses of the Building Act, and such matters. The history and character of the various styles of art might, perhaps, be added, and an examination into the elementary branches of geology, mensuration, mathematics, and chemistry. A knowledge of the outlines of chemistry would include the nature and quality of materials, and their mechanical properties. Geology would also have a certain reference to kindred subjects,—stone, sand, brick, earth, &c.; and an acquaintance with geometry would be necessary, in order to understand and apply the theory and practice of construction.

Mr. Arthur Alton said that he, for one, would protest against an examination in subjects which would involve what might be termed academical education. He feared that, as no examination but a voluntary one could be instituted, the whole affair would prove a failure.

The president reminded Mr. Alton that the question before the chair was—not whether there should or should not be an examination—but what should form the subject of a proposed examination.

Mr. Alton said that his object in coming to the meeting was to learn the opinions of others, and to give his own. With regard to the subjects named by Mr. Blashill, he was of opinion that many of them embraced matters which it was not absolutely necessary for young men to become masters of. It seemed to him that the whole principle blinged upon the fact, that the cry for improvement came from below instead of from above. The agitation had come from architectural pupils, who maintained that the education offered them was not sufficient to make them competent. The question, therefore, was, not whether they followed the associates of the Royal Institute were to be examined, because there were associates who were as old as follows; so that if the Institute were to attempt to force a compulsory examination upon its associates, they would be bound to attend the whole question of examination. He thought the Institute was perfectly right in asking for the opinion of the entire body of architects, for the only way to deal with such a subject was to put it up to the architects as possible tests.

Mr. Kerr (as a visitor, being called on) said he wished to explain the motive which had induced him to attend that evening as a visitor. For many years he had taken a deep interest in the question, and he reminded the meeting that, when the Architectural Association was founded, it was formed upon this very question; and, having reason to think that, owing to ambiguity in the programme of the Royal Institute, their precise intentions were not

thoroughly understood, he had made a suggestion that he should esteem it an honour to be allowed to further the objects of the Association by stating what he considered to be the views of the Institute, whether the latter opinion might not, so to speak, be misled and prove abortive. At the last meeting of the Institute it was proposed and the resolution of the question should be adjourned for an indefinite period, as they were waiting for the decision of the Architectural Association and for the Association in Scotland. It was clear, therefore, that the Institute could not discuss the matter until after the Christmas holidays were over, and he then explained the position in which the Institute stood, he hoped the Association would not arrive at any ill-advised conclusion, but give due attention to the subject. The object of the Institute in moving was, that they were of opinion that the time had arrived for the introduction of the educational element into the qualification of an architect. They proposed that this introduction of the educational element should be commenced in a very small manner, in order that they might feel their way, and have nothing to retract or retreat, but go forward. The members of the Association, however, were of opinion that they would not doubt feel that it was desirable to creep before commencing to run. The council of the Royal Institute had put their views in a very decided form, and the first proposition laid down, on their understanding of the matter, was never anticipated. The idea of confining the proposed examination to associates and those who might hereafter become fellows of the Institute was no integral portion of the proposition. The resolution decided that the examination should be established, the profession, as a whole, had no particular care about what the Institute might do, he hoped, therefore, that gentlemen would not waste time in considering that portion of the subject. The President said we consider that the Institute has abandoned that by their vote.

Mr. Kerr—When the proposition was first brought forward opposition was offered to it, and then the gentleman who proposed it said it should be taken as a whole or rejected as a whole. The Institute, however, refused to do that, but, for they considered that it was desirable that the proposed examination should be voluntary. The Institute had, in fact, abandoned the compulsory and now confined itself to recommending a voluntary examination, and he regretted that he had gone so much into detail as the third and fourth propositions with regard to the curriculum, now somewhat confused, and he had no doubt had, in some extent, misled the minds of the profession, in such language as "pure arithmetic and applied mathematics," and such expressions as "the theory of the beautiful" and "analysis of styles of art composition." They might well be misled. As far as he knew, the objects of the Institute was to make a complete list, containing not only the propositions made by Mr. Blashill, but other collateral subjects bearing indubitably on the subject, but that the candidates for examination should have the right to select non-essential subjects. He thought gentlemen might perhaps be relieved in their minds when he announced that he had authority for the statement of the members of the committee of the scheme. He agreed with Mr. Blashill that, if an examination be the test of competency, it ought to be confined to essential subjects, because he feared that supplementary or collateral subjects might lead to heartburnings and dissatisfactions, and that gentlemen otherwise well qualified might complain that candidates took higher marks in subjects in which they had not prepared themselves, and so created the introduction of details, and he assured the meeting that the Institute had the matter so much at heart that, in order to prevent misconception, it was quite willing to begin *de novo*. The main matter would be left to the candidates to prepare the curriculum; and, although the task would have to be undertaken sooner or later, depend upon it, here it was that the Institute would be left. He therefore advised gentlemen not to trouble themselves to walk patiently to the end of the road until the curriculum was settled. The Royal Institute was now founded upon what might be called the element of reality, and it was a pity that twenty-five years ago it was the only way to bring the members of the profession together; and it must be admitted that it had succeeded in a very honourable manner, and that it commanded the esteem and respect of the representatives of a very large number of the profession. The Architectural Association, on the other hand, was formed on the principle of self-improvement; the students and assistants were introduced into the ranks of the profession, and the education placed within their reach. They therefore determined to found an association which should for the most part be confined to young men who would endeavour by a system of mutual instruction, to make up the deficiency of which they complained. Since that time the Association, like most other young societies, had passed through various vicissitudes. He was happy to find that it still commanded the confidence of the junior members of the profession; but he took leave to remind them that their future progress would much depend upon the course which they might adopt that evening. The architectural institutions were, in fact, on their trial. The policy of the Architectural Association had always been education, and the possibility of the success of the Institute was not necessary there (in the Association), and consequently there was no rivalry between the two bodies. The profession was not so far gone as to require a diploma to be given to a student, or to require a register and the irregular dustman; but what it wanted was that its members should be known by education in their practice. Now with regard to the reply to be given to the Institute, there were three courses open to the Association. One course would be, if they did not see their way clearly, to consult caution, and not reply at all. Another would be to go thoroughly into the matter; and the third would be to treat the question in the abstract, and leave details until a future time, probably a year hence. He thought the Association would best consult its own dignity by dealing with the matter on the ground in detail, but generally, in the first instance. He totally objected to the Royal Institute of Architects confining the examination to applicants for its own membership. The profession at large had nothing to do with the matter, and he had already dealt with that there should be an examination for the public benefit, which should include the whole profession. He had never opposed the scheme of examination; but he thought the council of the Institute ought not to take upon itself functions which belonged to the profession generally. Holding this opinion, he was in favour of leaving the matter to the hands of a special committee, who would investigate the matter, and report, and report upon it. He felt persuaded the Institute would have to come to that in the end; for he thought the profession

would say, "This is a public question, and should be treated by a committee especially appointed with a view to its public character." If this course were adopted, the council of the Royal Institute would get rid of a good deal of the odium attaching to the subject, and the public would be far more satisfied in the end.

Mr. Baker said, he thought the Association had reason to be grateful to Mr. Kerr for attending to the present occasion; for, on their last evening of meeting, there was an opinion prevalent in the room that the examination was to be compulsory, and that any person who did not pass it would be ejected from or taboored by the profession.

Mr. Paraire complained that Mr. Kerr had come down and told them what they were to do,—a course which he feared would retard the action of the Association, and interrupt that good feeling which had previously existed between the Association and the Institute. He (Mr. Paraire) held in his hand the papers showing the description of examination for candidates for district surveyorships. It seemed to him that they would not be following a bad example if they were to adopt that examination as a guide. On that subject, for instance, descriptive geometry was an invariable subject of examination, and in his opinion a knowledge of algebra was equally indispensable. He should therefore move, as an addendum to the list of subjects mentioned by Mr. Blashill, arithmetic, algebra, descriptive geometry, drawing,—plan, elevation, and section,—applicable to architectural subjects, and freehand drawing.

Mr. Gates said that, as he had taken a prominent part in promoting a petition to the Institute on the subject, his opinions were pretty well known. He, therefore, merely rose to suggest whether it might be possible to attach the whole of the subjects from the resolution of Mr. Blashill, because it seemed to him that, taking arithmetic alone, an examination into that science might be so conducted that scarcely a single architect in London might be found competent enough to pass it. He did not oppose so much to the subjects themselves as to the limit to which the examination into them might be carried, for it would be easy to make an examination so abstract that it would be impossible for any one to pass it who had not devoted immense labour to that particular branch of study. The examination for a district surveyor could be very different, the list of subjects, yet it was well known that the manner in which the examination was conducted made it competent for almost any gentleman out of his articles to comply with it. He therefore proposed to express an opinion upon the subject, any objection to omit from his resolution the list of subjects altogether, as such a course would very much facilitate the object which they had met to accomplish.

Mr. B. A. C. Herring remarked that, on the last evening of meeting, he had expressed himself strongly against examination; but that, in consequence of the explanation given by Mr. Blashill, he had changed his mind, and modified. He begged, therefore, to propose, as an amendment to the resolution of Mr. Blashill, "That it is the opinion of the Architectural Association that a strictly voluntary examination should be instituted, which has a view of guiding the student of architecture to such a course of study as would enable him to arrive at competence in his profession."

Mr. Rickman seconded the amendment. Mr. Rickman supported the amendment proposed by Mr. Herring. He had never entertained a doubt as to the propriety of instituting an examination for young men coming out of their articles, and that it would sooner or later become a necessity, not in consequence of any law of the land, but *ex necessitate rei*,—as an incentive to improvement. If to propose an examination would answer that end, it would be impossible to deny its advantages. Had he been present on the last evening of discussion, he would have suggested the appointment of a committee to select the subjects to be included in the examination, and many of the subjects enumerated by Mr. Blashill ought to be gone into. The subject, however, was one which, in his opinion, ought to be left to those who were naturally the most competent to express an opinion upon it. Some desultory conversation ensued; and ultimately Mr. Blashill consented to withdraw his motion for the time, so that Mr. Herring's amendment might be carried; and Mr. A. Smith withdrew the resolution.

Mr. Herring's amendment was then carried without a dissentient voice. Mr. Blashill next moved his resolution, which, after one or two amendments, ran as follows:—"That, in the event of a professional examination being insisted upon, it should be limited to those subjects which bear directly upon the practice of the profession, and should not include matters of general education. And this Association is apprehensive that any examination upon the principles of taste might lead to results unfavourable to the progress of art."

After some discussion the resolution was passed, omitting the words,—"And should not include matters of general education." The schedule including the subjects suggested for examination was withdrawn.

On the motion of Mr. Rickman a resolution was also agreed to,—That it be an instruction to the secretary to transmit the resolutions passed that evening to the secretary of the Royal Institute of British Architects, and to express the willingness of the Association to enter into the other portions and details of the subject as soon as the Institute should have come to a decision on the essential points of the intended measure.

The President said he entirely approved of the resolution, and congratulated the meeting on the progress which had been made. It was then announced that at the next meeting (on the 21st instant) a paper would be read by Mr. Blomfield on "The Arrangement of Churches," and that the next subject for the Class of Design would be a grand staircase to a mansion.

Classes for modeling and for instruction in botany have been organized in connection with the Association, and gentlemen desirous of joining are requested to communicate with Mr. H. A. Reeves, 28, Brunswick-square.

FALL OF TWO HOUSES AT KENNINGTON.—On Thursday afternoon two houses in course of erection at the back of Kennington-park fell to the ground with a fearful crash, burying several workmen beneath the ruins. As soon as possible three men were extricated, when they were found to be much injured.

CONNECTION OF HEALTH AND DISEASE WITH THE ELECTRICAL STATE OF THE ATMOSPHERE.

In a paper by Mr. Thomas Moffat, M.D., "On the Prevalence of certain Forms of Disease in connection with Hail and Snow Showers, and the Electric Condition of the Atmosphere," read at a recent meeting of the Manchester Literary and Philosophical Society, it is stated that in 1852, while deducing results from the meteorological observations of the two previous years, the author observed that an intimate connection existed between falls of snow and hail and diseases of the nervous centres, such as apoplexy, epilepsy, paralysis, and vertigo; and that the results of eight more years bear out the truth of the observation. All observers, he remarks, agree that the air is negative on the approach of great storms, and negative or alternately negative and positive in unsettled weather; and he finds that such storms are almost invariably accompanied by convulsive diseases, or diseases of the nervous centres in some form, as well as by such other forms of disease as premature uterine action, epistaxis and diarrhoea, with vomiting and cramps. Negative electricity, he concludes, plays an important part in these atmospheric conditions and morbid actions. Hail and snow, he adds, are formed under the influence of opposite electrical conditions.

The subject is highly important, and merits further investigation. We have long been convinced that even common colds are produced by some electrical state of the atmosphere inhaled, and that the action of draughts on the skin is electrical, the continued friction of the current exciting electricity rather than merely producing coldness directly, though the positive electricity, as we are persuaded, is analogous to cold in its contractile tendencies, while the negative is probably relaxing. Ozone and antozone, which are just the vital air oppositely electrified, are believed to have something to do with the production of diseases of different classes, such as influenza and cholera; and it is many years since Mr. John Hay, we recollect, published a series of scientific papers at Leith, near Edinburgh, titled "The Seafield Bath Reports," in which he compared the electrical states of the atmosphere with the varying phases of the virulent cholera then prevalent. Were it fully proved what species of diseases (if any) the positive electricity tends to aggravate or to produce, and what the negative, we might perhaps be soon enabled to prevent as well as to cure such diseases, by means of the opposite electricity to that exciting the evil influence. In cholera seasons, if it be the electricity which excites the oxygen of the air into the ozonized state which is defective, thus weakening the scavenging powers, as well as probably acting directly to the injury of the human body,—might not the worst localities, such as close courts and dwellings, be even frequently re-electrified, directly, by means of so potent an agent as the electrical steam boiler of Sir William Armstrong's invention? Electricity of the right kind could, of course, be still more readily applied to the patient's body; and it might be that even those "colds" which are often so difficult to remove, and so deadly in their ulterior effects, would thus be removable, as if by magic. The medical and scientific worlds do seem to be here on the brink of important discoveries.

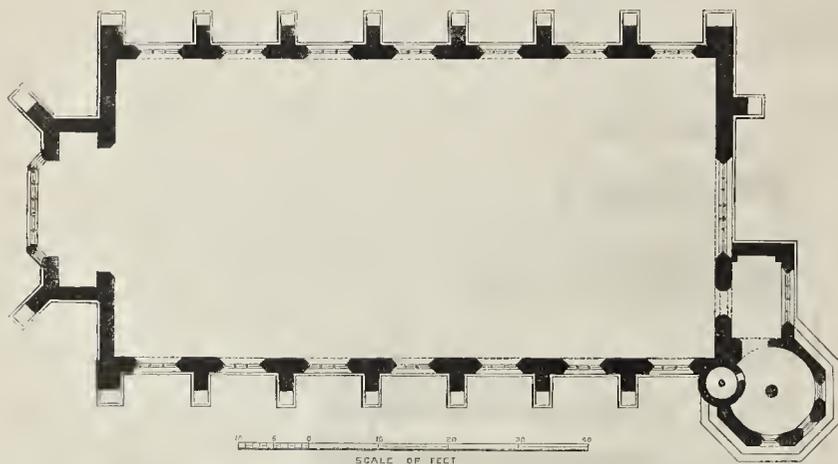

FRANCE.

THE Monceaux Park, the greater portion of which is about to disappear, was at the end of the last century one of the wonders of the capital: the Parisian folk delighted in admiring its pavilions of all sorts of architecture, grottoes, kiosks, imitations of rivers, ruins, islands, Greek temples, winter gardens, &c. In one portion of the park there was a windmill, with a rustic habitation for the miller; this fantastic but contained a dairy, with all the milk-pans in the finest porcelain, and the walls were lined with Carrara marble. Of all this nothing now remains but the *débris* of a colonnade, which formerly constituted a rotunda without covering, an ancient statue standing in the centre.

Henceforth, says the *Silole*, this park will be for the most part cut up into small lots, whose limits are already set out; but that portion which borders on the Rue de Courcelles will form a square likely to rival any of the metropolises.

The "Impasse des Peintres," and the adjoining house, which is to be cleared away, for certain proposed improvements, are on the site of one of the gateways of the town under Philip-Augustus. This portal, known under the name of Porte Saint Denys (in olden times), took another

NEW LIBRARY, MIDDLE TEMPLE.—Plan of principal Floor.

under Charles V. It was decorated, as well as the other gates of Paris, with a statue of the Virgin.

The *Impasse des Peintres* derives its name, according to Sauval, from the fresco painters inhabiting the locality: others say that a master-painter, Guyon Ledoux, built there, in 1535, a house with a corbelled turret: some existing documents, however, show that, in 1303, the *Maison de l'Arbalite* belonged to the descendants of one Gilles Lepeintre.

Of the thirty-one properties expropriated three were arranged amicably; out of 113 shops of different sorts and industrial establishments, seven were compensated by mutual contract. In summing up the following figures occur: offers by the town of Paris, 4,003,620*fr.*; claimed by owners and tenants, &c., 9,703,812*fr.*; awarded by jury, 5,972,700*fr.*; difference between demands and awards, 3,821,112*fr.*; difference between offers and awards, 1,360,080*fr.*

At *Lux-Saint-Sauveur* the works for the construction of the new Napoleon bridge are actively progressing. The Minister of Public Works has obtained the services of one of the British colonists near *Bagnères-de-Bigorre*, Mr. Lyte, an artist and skilful photographer, and has engaged him to make proofs of the works at different stages. These photographs are despatched at once to the Minister, who can report on the general progress without going into details only to be arrived at by complicated measurements and a mass of descriptions.

#### THE MOVEMENT ON THE CONTINENT FOR IMPROVING THE DWELLINGS OF THE WORKING CLASSES.

The following is an extract of a letter from Professor V. A. Haber, of Wernigerode, in Prussia, addressed to Mr. Henry Roberts, F.S.A.:

The best thing by far on the Continent in this direction is the *cité ouvrière* at Mulhouse, in France, which, in October, 1860, had not fewer than 560 excellent dwellings, with gardens, and of which 36½ have been sold to working men, after the excellent system by which the occupier may become the owner of his dwelling. Besides the houses there are a washhouse and bath, restaurant, reading-room, bakehouse, lodging-house for single men, a school for children, an inn, or house of call for working men on the tramp; and it is in contemplation to provide the *cité* with a physician and a nurse. There is not the least difficulty in getting 5 per cent. on the capital, though the shares pay only 4 per cent.: the capital raised by loan is at 4½ per cent.

To see this neat suburb of Mulhouse rising like an enchantment in a few years,—to see it on a fine summer Sunday, with the gardens in full blossom, roses without end, and the people as decently and homely merry as heart can wish,—and to compare this with the condition in which the writer has known them, some twelve years

since, and in which the large mass of the mill-people may still be seen here and elsewhere,—to see the 364 mere proletarian *ouvriers* transformed (with their families) into thriving *ouvriers propriétaires*—is a grand sight indeed. One peculiarly French trait is, that not a few young men, after having served their time, or not being yet called, enlist as *remplagants*, and with the money they get buy a house in the *cité* for their aged parents.

#### ARBITRATION, SHEFFIELD WORKHOUSE.

A DIFFERENCE arose between the Sheffield Guardians and Mr. Harrison with regard to his contract for joiner's work in the workhouse alterations. The amount of the charge in dispute was 200*l.* An arbitration was agreed on and the award has been made. The arbitrators' costs and charges amount to 100*l.* 10*s.* The arbitrators have given a decision adverse to the guardians. Mr. Harrison's original contract was 1,020*l.*, and during the progress of the work he appears to have drawn 800*l.*, leaving a balance of 220*l.* From this sum the guardians proposed to make a reduction of 200*l.*, leaving 20*l.* only as due to the contractor. Mr. Harrison objected to this; and the result was that Mr. Charles Unwin, Mr. John Frith, and Mr. T. J. Flockton were called in as arbitrators. We are informed that they decide that the guardians are to pay 313*l.* 1*s.* 10*d.*, being 93*l.* 1*s.* 10*d.* in excess of Mr. Harrison's original account. The award also fixes the guardians with the costs of the proceedings, making a total order of 414*l.* 4*s.* 10*d.*, exclusive of the charges of their own solicitors, and other items, which the arbitrators order each party to pay on their own account.

#### IRELAND.

A NEW Gothic drinking-fountain is in course of erection on the Custom-house quay, Dublin. His excellency the lord lieutenant is the donor. Messrs. Purdy & Outhwaite are the contractors.

The new Decorated chapel and other extensive works in connection with St. Vincent's hospital, Stephen-green, have just been finished at a cost of 1,200*l.* Mr. J. Beardwood, was the contractor.

The building surveyors of Dublin are about to form an association for the purpose of "protecting themselves against the irregularities of unqualified practitioners, whose proceedings are calculated to bring the profession into disrepute."

A new R. C. church is about to be built in the parish of St. Michael's, Limerick.

The Berwick drinking-fountain in Cork, and that in Limerick, presented by Mr. Ryan, the late mayor of that city, have been erected. Another, the gift of Mr. Malcomson, is in progress.

On Wednesday, November 21st, the opening of the new orphanage of St. Vincent de Paul, at Glasnevin, took place. The architect was Mr. S. J. Butler; and the builder, Mr. P. Myers.

The new building for the Jesuits at Miltonpark, near Dromybrook, has just been completed. The building stands on 25 acres of land, and consists of two four-story wings, 40 feet by 65 feet, connected by a two-story building, 64 feet long, containing a chapel and refectory. The height of the wings from the ground level to the coping of parapet is 50 feet. The designs show a front of Italian character, but in the erection of the building they have been departed from. The total cost of new works was about 4,700*l.* The designs were furnished and the works carried out under the superintendence of Mr. Charles Geoghegan; Mr. John Rooney, builder.

A new lunatic asylum is about to be built near the town of Letterkenny, co. Donegal.

A bronze statue is about to be erected in Cork to the late Alderman Fitzgibbon. The town council are to grant a site in Patrick-street, or some other suitable spot. A drinking-fountain is also to be constructed in connection with the statue.

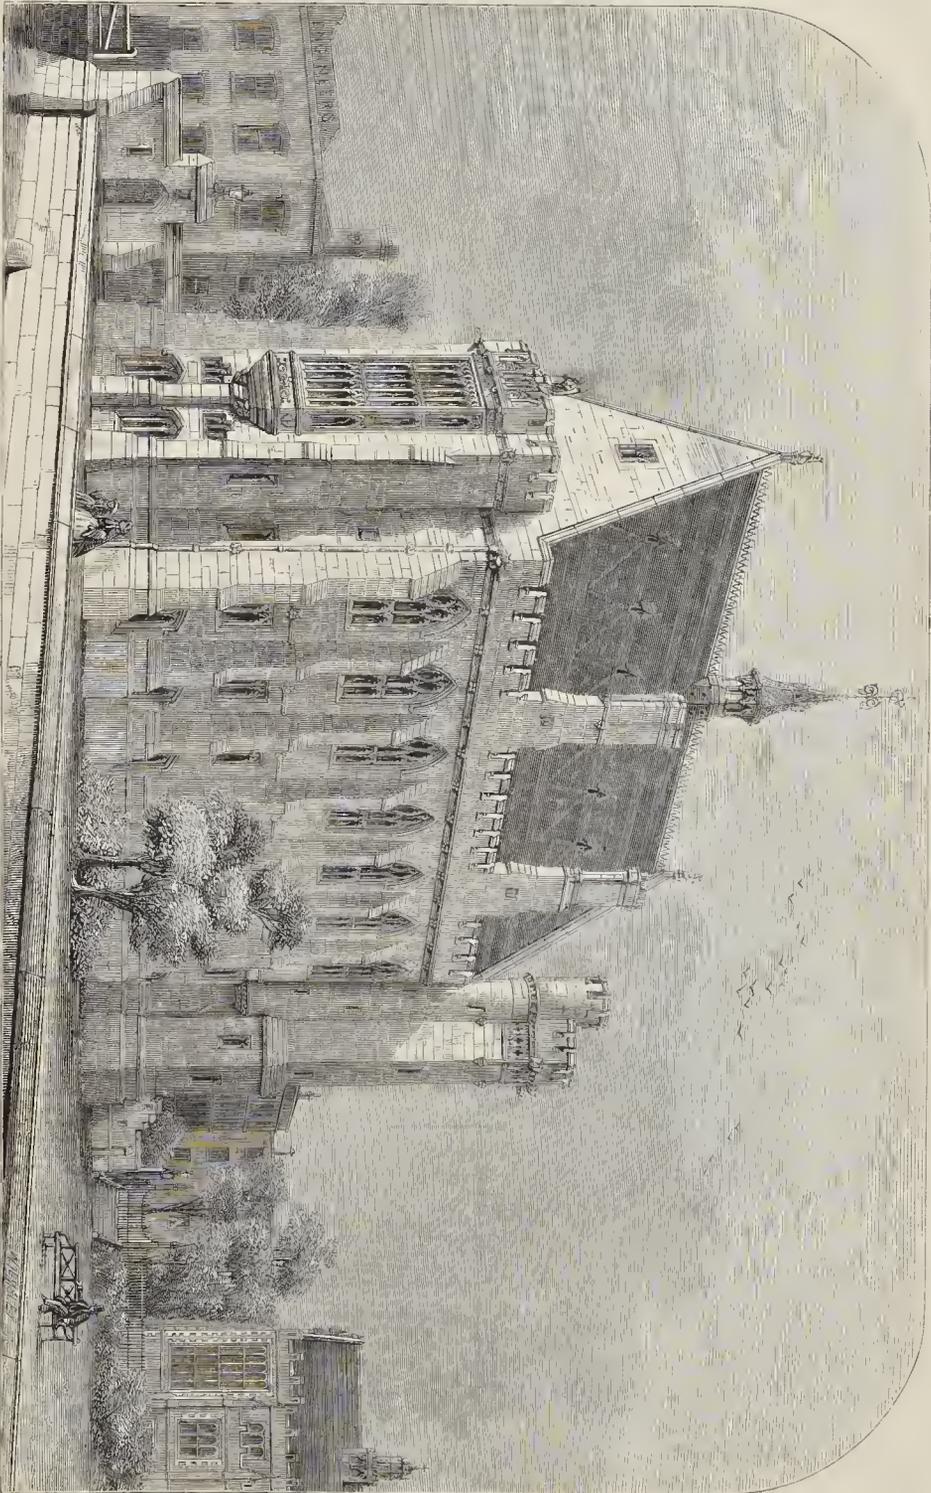

#### NEW LIBRARY, MIDDLE TEMPLE, LONDON.

In our volume for 1858 (p. 567), it is recorded, with other particulars, that the first stone of the New Library was laid by the late Sir Fortunatus Durrant, on the 16th of August of that year. The strike delayed the works, but the building is now nearly completed, and we give in our present number a view of it, and the plan of the principal floor,—the library proper. This apartment, which may be called 96 feet long, including the oriel, 42 feet wide, and 63 feet in height, to the underside of the ridge, is covered with a bummer-beam roof, after the fashion of that in Westminster Hall. In fact, when it is looked at from the south end, the window in the north end, not seen in our view, being also very like the great window in Westminster, the likeness is disagreeably striking. The library is warmed with Perkins's hot-water pipes, and the floor is laid with cement, in stone margins. The side windows and that in the northern end are filled with stained glass, by Messrs. Ward. The latter, containing the arms of Templars, is a rich piece of colour.

Below the library are two stories, introduced as a commercial speculation, with more advantage in a pecuniary point of view than to the appearance of the building externally. These chambers are not, as is generally supposed, for the temporary reception of persons overcome in the library by the somnifera influence of study; but will be let to any parties who wish to reside or carry on business in the Temple.

Mr. H. R. Abraham, it will be remembered, is the architect; Mr. Geo. Myers the contractor. The carving was executed by Mr. Ruddick. Mr. Brodie (who succeeded the late James Rowland) is clerk of the works.

The building is wholly of Bath stone externally; and the cost, including the book-cases, will be something under 13,000*l.*

NEW LIBRARY, MIDDLE TEMPLE, LONDON.—MR. H. R. ABRAHAM, ARCHT.

## CHANGES IN TRADE.

## THE FRENCH TARIFF.

GREAT distress, it is to be regretted, exists at the present time amongst the ribbon weavers of Coventry, and those engaged in departments of the silk trade, in Spitalfields: some other branches of trade are also depressed. Nevertheless, the general trade of the country is in a satisfactory state; and, doubtless, the new Anglo-French treaty will be the means of giving increased scope to British industry. It is, therefore, most desirable, at the present time, that both masters and workmen should endeavour, as far as possible, to take the opportunity which is presented by the reduction of duty on many articles of British manufacture.

Amongst some of the most important items of this treaty, it may be noticed that the duty has been entirely taken off, from between forty and fifty chemicals: amongst them are the various acids, dyes of iron, copper, various preparations of tin, including tiles of all kinds, bricks, fire-bricks, gas-retorts, drainage-pipes, and others; crucibles of all sorts, including those of plumbago, or black-lead; clay-pipes, glazed or not, of all shapes.\* Stoneware utensils, and apparatus used in the manufacture of chemical products, are all to be admitted into France duty free. Common ware of all sorts, flat and hollow ware, including bottles, flasks, household articles, kitchen utensils, &c., will be charged 4 francs per 100 kilos. This will cause increase in trade. Amongst the other articles from which the duty has been removed are broken glass and cullet; rock crystal, rough or worked, if unmounted; wool, raw, Australian, imported from British entrepôts; cotton, raw, imported direct from British India, and from British entrepôts, in British or French vessels. Several vegetable fibres are also free; as is silk in cocoons, raw or thrown. Slates for roofing are charged 4 francs per 1,000; in squares or slabs, 10 francs per 100.

Tissues, hosiery, and lace, of pure silk, are free: crapes, called English unbleached, and lace of silk, black or coloured, and net, are reduced to 10 per cent. in 1860; in 1864 they will be free. In connection with other matters, a considerable reduction of the French duty will open a market which has hitherto been closed by the old restrictions; and such will be the mutual advantages, that a still further decrease will be soon found desirable. So great a change cannot be made without for a time pressing on some classes; the evil will, however, not be met by the opposition or disputes of masters and workmen. The strike of the ribbon weavers, at Coventry, has led to no good result: on the contrary, we fear that it has been partly the means of bringing distress upon a large number of respectable and industrious families. Many blame the new tariff for this. It should, however, be remembered, that it is the change of fashion which has been the chief cause of this trouble. At the present time ribbons in the bonnets and dresses of the ladies are but little used in comparison with the quantity in demand a few years ago; velvets, feathers, and other kinds of ornamentation being employed instead. Otherwise, we believe that, by improvement of our skill in the design of the patterns of these articles, with the advantage of steam machinery, &c., we should soon have been able to compete in this way with the French. It has been suggested, in order to check the distress of the ribbon-weavers, that, if every woman in England were to purchase but one yard of ribbon, it would make a vast improvement in the trade. No doubt the ladies of Great Britain feel heartily disposed to relieve the sufferings of this or any other body of honest workpeople: it may, however, be feared that this plan will not be of any permanent benefit, for it is difficult to turn the tide of fashion.

Many remember the days when brass buttons of several descriptions were so generally in use. Some thousands of persons depended on this production for a living. Covered buttons became the rage, and in a very short time there was scarcely a brass button to be seen. Deputations from the unemployed workmen were received by personages of distinction, presents of brass buttons were offered, and benevolent gentlemen persisted for a time in wearing the old style. This, however, was of but little avail. The trade of the brass button maker became profitless, and many were reduced from a comfortable position to one of poverty. It may be hoped

\* Glazed pipes, with decorations, in relief, of one or more colours, flat or hollow, are charged 5 francs per 100 kilos.

that the cloud which has come over the ribbon trade is but temporary. The season has been unfavourable; and other things are to be taken into account which should encourage brighter hopes for the future. There is unfortunately a want of inclination on the part of workmen, when the demand for a particular kind of labour has ceased, to undertake some other. At the time of the change from stage coaches to railway carriages many of the most respectable of the guards and coachmen were offered situations in connection with the railways: only a few accepted them; and, in many cases, these poor fellows ended their days in the workhouse.

## THE LONDON COSTERMONGERS.

So officious and troublesome has become the persecution of these street dealers by certain authorities in the City, that a meeting of the costermongers and their friends has been held, at which their grievances were very fairly argued. It appears that there are about 50,000 of these dealers in London; that about 10,000 of them are married, and have an average of five children each; so that if we add 50,000 children, 10,000 wives, and 50,000 others, we find that the number of persons depending on this street trade amount to 110,000. We have had many opportunities of judging the character of this large body of the London population, who have generally been driven to this kind of life, and we have noted the great industry of the majority.

As a matter of certainty, there are some of these men and women very rough in manners, and perhaps not very fastidious in certain matters; yet generally we have seen much to be commended in the class; and to them not only the dealers in the market, but the dwellers in the poorer districts, are much beholden. Therefore, while it is necessary to keep the thoroughfares clear, we should be sorry to see a spiteful spirit shown towards them.

## PROVINCIAL NEWS.

*Stewkley (Bucks).*—The new schools lately built here, at a cost amounting to nearly 1,000*l.*, have been opened by the Bishop of Oxford.

*Brighton.*—The prospectus has been issued of a Brighton Hotel Company, with a capital of 75,000*l.*, in shares of 5*l.* each, the promoters being in negotiation for an eligible site on the West Cliff. The hotel will contain 200 bed-rooms, and accommodation for private families.

*Parkhurst.*—Improvements have been made at these barracks. A gallery has been erected, besides other improvements having been effected. The contractor for erecting the married soldiers' quarters, according to the plan of the Secretary-at-War, Mr. Sidney Herbert, has commenced preparing for the foundation for the building, which is to be placed at the western end, and facing the parade ground, which is also in the course of restoration. A well for the new barracks is now digging, and which it is calculated will require to be carried to the depth of 300 feet before a sufficient supply of water will be obtained.

*Worcester.*—Another step in the progress of our street architecture, says the local *Herald*, has been taken by the erection of a shop at the corner of Broad-street and the Cross. The proprietors are Messrs. Spriggs & Co. It has been erected by Mr. Hemming, builder, Lowesmoor, from the designs of Mr. Rowe, of this city, architect, and is of brick, with stone dressings. The shop has a long front, occupying the corner of Broad-street and the Cross. It is composed of plate-glass set in brass frames, and forming a series of windows in both streets, with an entrance in the angle. The shop and principal room above are illuminated at night by circles of gas-jets, disposed in sunlight pattern, with cut crystal pendants. The house is probably the loveliest in the city, and Mr. Spriggs has given the public the benefit of a considerable addition to the width of the footpath.

*Malton.*—The works for laying down a system of large drainage pipes along the streets of Malton are being proceeded with. The drainage, from the nature of the ground on which the town is built, has a great inclination to the river, and the trunk drains are being laid 12 feet deep, in order that the cellars and kitchens may be drained if required. The work is estimated to cost about 1,500*l.* The adjoining town of Norton is also under a survey by Mr. Jno. C. Wise, who is nearly ready with the sections, &c., with a view to the drainage of that place, which at present is very defective. Both schemes are under the control of the Malton Board of Health.

*Bristol.*—New schools connected with St. Clement's Church have been opened. The build-

ings consist of schoolroom, 70 feet by 22 feet; class-room, 16 feet by 14 feet; with teachers' residence, all in the Early Decorated style of architecture, from the designs of Mr. S. D. Gabriel, of Bristol, architect, and cost 1,400*l.* The design has been carried out by the following contractors,—King, mason; Lawrence, carpenter; Melsom, plasterer and painter.

*Leeds.*—An extraordinary general meeting of the Leeds Philosophical and Literary Society has been held, to receive the report of their building committee, and to decide upon some means for carrying out the proposed additions to and alterations in the hall of the society. The chairman explained that two sets of plans had been submitted to the committee, and one had been chosen. According to the selected plan the estimated expense, in all, was 2,682*l.* The committee, however, felt strongly that a new elevation would be required, the cost of which would amount to 540*l.* Thus there were 3,222*l.* for the inside and outside of the old and new buildings. In order to carry out the plan an additional sum of 1,200*l.* would be wanted. After some discussion the following resolutions were carried:—"That it would be desirable to carry out the plans produced, and adopt the improved exterior elevation as well as the internal arrangements, provided the requisite funds can be obtained; and that for that purpose the subscriptions should, if possible, be raised to 8,000*l.*;" and "That the general committee be requested to continue their services, and, if the required fund can be raised, to proceed with the execution of the work." The plans selected have been proposed by Messrs. Dobson & Chorley.

*Hull.*—The Hull Park Committee have decided that the People's Park should be laid out at a cost not exceeding 5,000*l.*, exclusive of planting the trees. Mr. Pearson (ex-mayor) has made arrangements with Mr. Earle, the sculptor, for a marble statue of her Majesty, to be erected in the park. A subscription is at present on foot in Hull for raising a statue to Mr. Pearson, the donor of the park.—A new company has been formed here, in order to construct a large dock on the west side of the town. The old dock company have issued a report, in which they virtually announce their intention to oppose the scheme in Parliament, and to apply for power to construct a dock themselves of a similar character.

## CHURCH-BUILDING NEWS.

*Walton (Bucks).*—The church of Walton St. Michael has undergone a general reparation, and been reopened. The restoration of the nave was entrusted to Mr. Scott, that of the chancel to Mr. William White, under whose auspices also the ancient rectory has received enlargement and some interior polychromatic decoration. The old unsightly pewing, which crowded up the nave of the church, has given way to open benches. The choir has been simply fitted in oak. The pavements of the sacrum and chancel have been relaid with tiles in plain colours, intermixed with the old stone paving. A new communion-table, rail, and sedilia have been provided. The east window has been repaired and glazed with stencilled quarries by Messrs. Lavers & Barrand; a new vestry added on the north side of the chancel; and a choir organ, by Mr. H. Willis, erected—partially recessed in the wall—with the key-board fitted into the stall-desk.

*Wolverton.*—The new church at Stantonbury, which has recently been erected for the accommodation of the large population connected with the works of the London and North-Western Railway at Wolverton, has been consecrated. The edifice is situated about three-quarters of a mile from the Wolverton station, on the west side, and is built of stone, in the Decorated Gothic style of architecture, from the designs of Mr. Street, of London. The tower and spire, which are intended to be raised to a height of 150 feet, are left unfinished from want of funds. The interior is without galleries, and has an open-timbered roof, with aisles, and unenclosed seats, instead of pews. The walls are of Cosgrove stone, with Ancaster dressings, the marble plasters supporting the arches being of a dark red colour. The stone pulpit occupies a kind of recess on one side, and bears an inscription to the effect that it was presented by the foreman and workmen at the Wolverton factory. There is also an octagonal stone font, the gift of the Marchioness of Chandos, the wife of the chairman of the North-Western. The entrances and floor are paved with tiles. Mr. Mills, of Stratford-on-Avon, is the builder of the church, which, it may be added, contains sittings for nearly 500 persons. The cost of the structure, so far as it is now completed, has been 4,430*l.*, of which

sum the shareholders of the London and North-Western Railway have contributed 2,560*l.*, and persons locally interested, and others, 1,870*l.* A further sum of 1,000*l.* will be required to complete the spire and the upper part of the tower. A burial-ground surrounds the church; and nearly contiguous to it are school-rooms, large enough for 400 children, which have now been in use for a considerable period.

**Southborough.**—St. Thomas's Church, erected at a cost of 2,400*l.*, has been consecrated. The edifice was completed about fourteen months ago. The design is in the Early Pointed style of architecture, and the materials used are the Kentish rag and Bath stone. The building consists of a nave, north and south aisles, and chancel with north and south aisles, an organ-chamber, south porch, and vestry. A clerestory, with eight cinquefoil windows, serves to light the upper part of the nave, and terminates at the west end of the building in a doublebell gable, beneath which is a couplet of lancet windows divided by a massive buttress extending from the bell gable downward, and terminating at the base in a western doorway. The remaining windows throughout are of a simple character, disposed in lancets, trefoil-headed and soffit-cusped. The roofs are covered with slates from the Bangor and Talero quarries, disposed in ornamental patterns. Internally the church is of Calverley stone, with alternated round and octangular piers, arches and dressings, of that material. It is arranged to accommodate upwards of 300 on the ground-floor, with open seats of deal, stained and varnished, as are the exposed timbers of the open roof. The architect is Mr. F. Hyde Pownall, of London; and the works were executed by Messrs. Jackson & Shaw, of Westminster.

**Salisbury.**—The memorial church to George Herbert, the poet, has at length been erected, in his own parish, Bemerton (a village in close contiguity to the city of Salisbury). The church stands on a site near the edifice where he formerly ministered and lived, and beneath the altar of which he was buried. Thursday, the 13th of the present month, is fixed for the consecration. It is not intended, for obvious reasons, to remove the old edifice, which is a small and ruinous structure, only about 45 feet long by 18 feet wide, without any architectural pretensions. The new church is in the Early Decorated style, and is to be dedicated to St. John the Evangelist. It is built of Bath, Fishbury, Melbury, and other stone, and consists of a nave, north and south aisles, and a chancel, on the north side of which is a tower, surmounted by a pointed bell-turret. The interior is about 104 feet in length, and 53 feet in width, and is fitted up with open stained deal benches to accommodate 365 persons. The pulpit and font are alike of stone, carved, and the general effect of the interior is enhanced by a stained glass east window. Mr. Wyatt, of London, was the architect; Mr. Miles, of Shaftesbury, the builder; and Mr. Howitt, of Wilton, clerk of the works.

**Chreacester.**—The new church of the Holy Trinity at Watermoor has been enlarged, and the unfinished designs of Mr. Scott have been completed. Dr. Warneford's trustees and the Diocesan Association made grants of 200*l.* and 70*l.* to insure free and open seats, which now accommodate 130 more persons, and the church has been re-opened. The church has been warmed by hot-air apparatus, furnished by Haden, of Trowbridge, at the cost of an anonymous benefactor, who presented 100*l.* for the purpose. There is some artistic carved work by Getflows, of Liverpool, in fruit, foliage, angelic figures, &c.

#### COUNTRY COTTAGES.—OVERCROWDED AND UNDRAINED.

A BERKSHIRE magistrate, in a statement made at a recent dinner of the Faringdon Agricultural Library, gives particulars of a special examination into the state of the cottages of agricultural labourers of the district, which fully corroborates all we have said on the subject of such cottages generally; and he himself remarks that he is firmly convinced that this is but a fair sample of the condition of the agricultural labouring population of England. "Indeed," he adds, "I have been assured by farmers that the want of decent accommodation has for some time past been driving the superior class of peasantry to emigrate; and that, unless some reformation be brought about, none but the feeble and most ignorant will remain in places where decent lodging is not to be procured." So totally inadequate is the accommodation in most of these cottages, that it is quite common to find fathers and mothers, with grown-up, as well as younger, sons and daughters,

the last of these with one, two, and even four illegitimate children, sleeping together, "pell-mell," as is remarked, in numbers varying from 5 or 6 to 8, and even 12, in one room!! Drains are generally a-wanting, or when laid, even worse than if a-wanting, as in flowing into a sitting-room, or emitting stench at a front door. The whole state of matters is fearful, and, moreover it is most disgraceful to land-owners. In one instance, that of Longworth, it is said that "Most of the cottages in this village are very old, some of them scarcely fit to live in. (Said to be ecclesiastical property.)" At a time when so much attention is being paid to the breed, keep, and condition of horses, and other beasts, it is shocking to think of such neglect of human beings. Would not many land-owners and farmers find it to the advantage of their much-loved pockets were they to turn their ploughmen and their farm-women into the well built and ventilated, drained and cleaved stables and cow-houses, there to enjoy the society of the sleek, fat, and spirited animals of which they are so proud? The magistrate referred to (Mr. H. Tucker) suggests that "Surely the Act of Parliament which authorizes the Government to advance money to lauded proprietors for the draining of land, erecting farm buildings, &c., might extend its provisions to the more important duty of housing the poor, if it were only with even half the comfort in which we house our cattle and our horses."

#### LINCOLN GRAMMAR-SCHOOL COMPETITION.

DESIGNS have been sought for master's new residence. In reply ten were sent in, out of which five were selected for further consideration, bearing the following names and mottoes:—"Beta" (Mr. Giles); Mr. Drury, Lincoln; Mr. Goddard, Lincoln; "Ides" London (name not known); and one marked "Justice." The last was accepted by the visitors, and proved to be by Messrs. Bellamy & Hardy, of Lincoln.

#### CLIFTON COLLEGE COMPETITION.

THE council having decided to confine the competition to the architects of Clifton and Bristol, issued their "instructions" in the first week of October, and invited all architects whose names appeared in the local directory to send in designs. The sum to be expended on the college alone is 10,000*l.* The author of the best design is to carry out the works at the usual per centage; and the authors of the second, third, and fourth-best designs are to receive respectively 50*l.*, 30*l.*, and 20*l.* In response to this invitation, upwards of twenty designs were sent in on the 28th ultimo. A sub-committee of the council was appointed to examine and report upon the designs submitted, and they afterwards called in the assistance of Mr. Benjamin Ferrey, architect. Ultimately the design of Mr. Charles Hanson was selected as the best. The second premium was awarded to Mr. Norton, the third to Mr. E. W. Godwin, and the fourth to Mr. T. R. Lysaght.

#### GLASGOW ARCHAEOLOGICAL SOCIETY.

At the usual monthly meeting of the Glasgow Archaeological Society Mr. Robert Hart read a paper on "The Remains of an Ancient British Village near Busby, in Cathcart Parish." Numerous traces of these pit-houses are said to be found in Aberdeenshire, and on the bank of Lochfine, and other places. These are found rarely to exceed 8 feet in diameter. Those found at Overbe were of the kind called "Piet's houses" by Wilson and others. They were arranged in a convex crescent round the foot of the small hill—thirty-six in number—and on the flat top of it, six, also in a curve. Those round the base of the hill were dug about 4½ feet deep into the hill, and averaged about 12 feet square. The sides of some were lined with a thin wall of stone: one or two had slabs of thin undressed stone set on end to support the earth sides: others had nothing but the natural soil for walls. There was a passage or entrance in the centre of one side in each, going in upon a level with the floor; but those on the top of the hill had an inclined passage down into them. The floors of them all were paved with irregular-shaped thin flag-stones, such as might be got in the bottom of the Cart. In the centre of the floor there was a hole or space left to hold the fire, and the remains of the fires were found in them.

Mr. James Fleming read a paper "On Certain Peculiarities of Scottish Heraldry;" and Dr. D. P. Stewart read the first of a paper "On a re-

markable Drinking Cup used by the old Viscounts of Kilsyth; and on Arms used by a Glasgow Family, of the name of Muir, at the Battle of Prestonpans."

#### LONDON AND COUNTY BANK, LOMBARD STREET.

THE contract for the superstructure of the proposed new building for the London and County Banking Company has been undertaken by Messrs. Jackson & Shaw, for the sum of 14,830*l.*, exclusive of the fittings. The basement, with its range of strong rooms, stationary departments, and lavatories, has been already completed by Messrs. Myers up to the street-level. The banking department will be fire-proof. The elevation in Lombard-street will be of Portland-stone, with rusticated Doric columns, as will also that in Nicholas-lane, up to the first floor, above which Jennings's patent facing bricks will be used, an experiment which will be worth watching. It should also be remarked that the whole of the stone to be employed will be obtained from old Westminster Bridge. Mr. C. Parnell is the architect.

#### THE HULL DBAINAGE QUESTION.

A RATHER stormy debate has taken place in the Hull Board of Health on the long mooted question of the west district drainage and the merits of the plan of Mr. Hawksley (supported by the local surveyor, Mr. Marillier), and that of Mr. C. F. Butler, the assistant surveyor, which, as our readers may recollect, is on the gravitating principle.

The debate arose upon a motion,—

"That the plan of Mr. Hawksley, C.E., for the drainage of the west district of this borough, together with his report of the 1st October, 1856, thereon, and presented to this Board on the 28th day of the same month of October, be, and the same are hereby adopted; and that all previous resolutions of this Board adopting any other plan of or for such drainage, and inconsistent with this resolution, be, and the same are hereby rescinded."

and on an amendment to the effect,—

"That it be a direction to the Committee of Works to submit Mr. Butler's plan for the drainage of the west district of this borough to T. Page, esq., G.E., late Government Inspector for Croydon, with instructions to report to the Committee on the following points, or on such of them as he may deem requisite, namely:—First—Whether in his judgment Mr. Butler's plan for the drainage of the west district, if carried out in the manner proposed by him, would prove efficient. Secondly—In his opinion it would not,—whether he can suggest any alteration therein by which it might be made so. Thirdly—In the event of his coming to the conclusion that Mr. Butler's plan does not, in its present form, and cannot, be so amended as to afford a reasonable prospect of its result being satisfactory,—whether he can himself furnish the Committee with an independent plan for the effectual drainage of the west district on the principle of gravitation. Lastly—If able to supply such plan, what would be its general character, and the approximate cost of carrying it into execution; and that all other resolutions of the Board to the contrary be, and the same are hereby rescinded."

Another form of amendment was proposed, embodying a suggestion that Mr. Hawksley's plan, as well as that of Mr. Butler, should be submitted to Mr. Page; that whatever decision Mr. Page might give with regard to either of them, should be final and binding upon the Board; and that, immediately upon receipt of Mr. Page's decision, the work should be proceeded with according to his report as to which was the best scheme.

In course of the debate it was asserted that there was in fact no plan other than a written one by Mr. Hawksley before the meeting, and that what plan there was had been so indefinite, that Mr. Marillier, the surveyor, had "mistaken the top for the bottom of it." This the surveyor denied; and it appeared that some slight misunderstanding only had occurred with regard to the invert and the crown of one of the sewers.

Very different opinions seemed to be entertained as to the cast district drainage (on Mr. Butler's plan), some maintaining that it was very imperfect, and that the new Pearson park could not be properly drained by it.

After much talk and no little reiteration, the previous question was supported, and the clerk, on being appealed to on the effect of carrying this question, said that they would be in precisely the same position as they were before. There was a resolution on the books approving of Mr. Butler's plan, and another giving instruction to the Works Committee to carry it out. If they carried the previous question these resolutions would remain, and it would be for future action to be taken on them.

Finally the previous question was carried by a majority of 27 to 15.

## ADULTERATION OF LINSÉED OIL.

We continue to receive letters showing the great want of pure oil. One correspondent says,—“They are now putting common resin in it, which is very injurious to paint, and becomes tacky in a warm atmosphere. The white lead you generally get, no doubt, is ground up with had oil. You cannot depend upon making a good job of flat painting: it will become glossy and pately in a short time after it is done, though nothing but turpentine is used. The oil question is really a matter of importance. For inside work, the only sure mode of making a good job of plain painting is by using a little good elastic varnish and turpentine, instead of oil; but this is too expensive for work generally; although, if done in this manner, the work would last two or three times as long as the ordinary process of painting, and look much superior. It would be a good thing for the tradesmen and public if any one would publish the true and best mode of testing whether the oil is genuine or not.”

THOMAS KERSHAW.

## COMPETITIONS FOR STAINED GLASS.

I WAS glad to see in your number of the 1st. instance some attention had been drawn to your extract of my letter, which appeared in your issue of the 10th ult., with reference to the making designs for stained glass more publicly competitive.

But the more I think what the effect of such a plan would be, the more I feel convinced that it would tend to raise the art of stained-glass designing, greatly higher than it at present stands.

I think it would give a great impetus to advanced students in Government Schools of Design, to have such a means open to them of showing their powers in designing; and even to attempt designs of this kind for other art manufacturers would also add to such impetus. To have a knowledge of the practical working out of such designs is, of course, very necessary; but I believe, generally speaking, with opportunities for learning, there is no great difficulty in attaining this knowledge, but often very much the reverse.

Another good that would result is, that it would allow young men to think and act more for themselves in this, and not be in any way hampered, as one so often hears they are, by what their employers may think or wish to do. At all events the plan is not likely to do any harm, and it might do much good. Why, then, should it not be attempted?

I still do not think the choosing out of such designers for stained glass, the best idealist, colourist, and delineator, and if possible combining them to produce the window, would make the “miserable jumble” which your correspondent, “Peter,” imagines. If good ideas, colour, and drawing are found to exist most in one design, the designer thereof is certainly the man to be employed for the work; and a more satisfactory thing is likely to result than if three were employed at it. But such a man is as rarely to be found as hidden treasures. I believe more artists do possess these qualities than we are apt to suppose; but, in order to arrive at extraordinary perfection in one or two of them, the other one or two are neglected. Many aim at drawing, to the exclusion of the other two qualities, power at chiaro-scuro and colouring, and many fewer at idea.

Of modern painters, Turner perhaps combined these three qualities to most perfection; but even his drawing seems to have been sometimes neglected so as to excel the more in idea and colour.

But to return. Out of many designs which might be submitted for a stained-glass window, let us suppose that none of them combined all the three qualities specified, or even two of them: my plan for making the most out of the number would be the following:—

Discover which design showed the most harmonious colouring, in doing which there would be no great difficulty; next that which showed the most correct drawing, in discovering which there would be more difficulty; and next, that which was the most rich in idea, to discover which might possibly be exceedingly difficult, for the richest ideas are very often the most subtle. For that reason a plain description of the artists' ideas would be necessary to accompany such a work, in order to avoid unnecessary delay in discovering the best idealist. It would also be essential, that those destined to decide on the merits of such works should either be artists, or men well versed in art.

Let the general arrangement and ideas of the idealist be submitted to the correct delineator, and I think a subject rich in drawing and idea would result. If this, then, were submitted to the man who shows the innate quality of producing harmonious colouring—a quality so rarely seen in our enlightened age,—I believe a very perfect window would be the consequence.

Mr. Ruskin, in “Modern Painters,” says,—“That art is greatest which conveys to the mind of the spectator, by any means whatsoever, the greatest number of the greatest ideas.” This is true with regard to all works of fine art; and no doubt, properly to convey these ideas, proper execution is required; but I maintain that these ideas may be, and often are, conveyed by inferior execution; and it is to obviate such deficiency that, where it is practicable, I would ask the assistance of another.

A STUDENT IN ART.

## IMPROVEMENT OF IPSWICH.

I BEG leave to second the proposition of your correspondent respecting the improvement of Brook-street; and I have no doubt that all who look to Ipswich as the capital of their native county will, with the usual patriotism, concur in the same. A similar improvement is wanting at the east end of the butter-market, where it enters Brook-street; more especially now that the west end of the butter-market opens into the line of streets leading from the Eastern Counties Station. It is worth making a public subscription for, which would certainly be responded to in Ipswich; for a still greater improvement was effected in Colechester by the same means, though the population of this town is little more than one-half that of Ipswich.

W. SCARGILL.

## BUILDING STONES.

In your recent notice of Mr. Hunt's Statistics of Building Stones you do not mention an excellent Bath stone from *Murhill Down* quarry, which has lately come under my notice, and has been used in several of the buildings in Gloucester—the markets, the corn exchange, &c. For outside works it is the best weather stone that I have seen under the name of Bath stone, being composed chiefly of shelly or flinty-looking particles, very equally disposed throughout.

I should hope that his work makes mention of Painswick stone, dug from the Coteswold hills, about six miles south-east of Gloucester. I may describe it as an oolitic freestone, resembling wrought Caen stone in appearance, but with far better wearing properties: it is excellent for indoor-finished work, as well as for outdoor-work, when not used in projections such as bases, string courses, hutch slopes, label mouldings, &c., in which positions *Murhill Down Bath* is preferable, or a stone called *Bisley* in this neighbourhood, which is also used for the ashlar work on the ground line, “between wind and water,” as the sailors would term it. The fine central tower, and other parts, of Gloucester Cathedral are built in this manner with the two stones, *Painswick* and *Bisley*.

If the Great Western Railway Company were to make a small branch-line from Stroud or Cirencester to Painswick and Bisley quarries, close at hand, these valuable building stones might rival the supplies of Caen and Bath stones in the London market.

W. H. E.

Mr. J. J. Roeluck, who writes to us to urge the goodness of the stone from the hills west of Huddersfield, remarks, with much truth, “When decay has taken place in a building such as Westminster Palace, the permanent remedy I believe to be in introducing carefully selected stones from the best quarries in the district from which the stone of the New Palace was supplied, rather than from any coating whatever applied to the whole building indiscriminately.”

## EXPERIMENTS ON THE PURIFICATION OF SEWAGE, AT CROYDON.

AFTER the discussions that have taken place, I need hardly say that the most effectual method by which the sewer water from large towns should be purified, before it passes into the rivers, has now become a matter of great and vital importance.

A correct and detailed account of the experiments which have been carried out during the last two years by the Croydon Local Board, under my direction, on a large scale and at much expense, may be of value to many other towns, which are probably now in equally difficult cir-

cumstances to those in which this rapidly-increasing district has been placed.

I will first state that no mechanical means have been adopted to mix the different deodorizing and disinfecting agents, hereinafter described, with the sewer water; but, as they were all applied in a liquid state, the intermixture was in most cases rapidly effected.

The flow of sewage water at Croydon varies with the state of the weather, from 600 to 1,400 gallons per minute; the whole amount discharged being from 800,000 to 1,400,000 gallons during the twenty-four hours;—a part of this, discharged during the night, being clean water.

The apparatus used during these experiments was of the simplest kind, consisting of two wooden cisterns, holding 600 gallons each, and two precipitating and filtering tanks, lined with brick, being each in length 320 feet; width, 45 feet; and depth, from  $\frac{1}{2}$  feet to 3 feet; each holding about 250,000 gallons. These tanks are subdivided by one longitudinal wall, and three transverse walls, besides perforated iron-plates, so placed as to contain a thickness of straw, gravel, and coke. They were generally worked alternately, so as to give time for substances held in suspension to precipitate, and also to facilitate the action of any chemical agents used to fix or separate the matter held in solution.

The water passes from these tanks into a culvert one-quarter of a mile long; and, at the time these experiments were made, also through about  $1\frac{1}{2}$  mile of open ditches before it entered the river. The water now passes over fields intersected with irrigating channels, to which I will not further allude,—a statement respecting these having already appeared in one of the daily papers.

In the following account of the different experiments, a statement of the peculiar effect produced by each is given: the general effect common to all is afterwards stated:—

The first trial was made with lime-water. 1,250 lbs. of lime were slaked daily in the cisterns, and then passed into a manhole situate in the sewer, 300 feet before it entered the tanks: this effectually deodorized the water passing into and from them, but gave a clouded and milky appearance to it; and before it reached the river there was a smell clearly perceptible, and a white deposit left on the sides of ditches. The expense of this process was about one guinea per day.

The second trial was made with perchloride of iron, made under the direction of Mr. Way, by dissolving iron rust in muriatic acid: this was applied at the same place, in quantities varying from 60 to 120 gallons per day, at a cost of 8d. per gallon. When the larger quantity was used the water near the surface, after passing halfway down the tanks, became quite clear, and flowed from the end of the filters free from colour and smell: there was, however, a deposit formed on the weeds and branches on the side of the ditches which became offensive. The water taken from the ditches was in a very different state from that taken at the end of filters; and this occasioned conflicting statements, as to its purity, which greatly perplexed those before whom the most contradictory evidence was given, by men of the highest character and respectability. The cost of this process was, on the average, four pounds per day.

The third trial was made with a deodorizing composition from the Walker Alkali Works, at Newcastle, consisting of a mixture of chloride of manganese and persulphate of iron, which was dissolved in the cisterns, and run into the manhole. This composition was very effectual in deodorizing, but did not clarify the waters so well as the perchloride of iron; but I think this was attributable to a defect in the temporary manufacturing apparatus fitted up hastily at Newcastle, which failed to give the proportion of perchloride of iron that was intended by the makers. The cost of this process was two pounds per day.

The fourth trial was made with limewater and fifty gallons of perchloride of iron. This was effectual in clarifying the water, but the same offensive matter was formed in the lower part of the ditches. The cost of this process was 2s. 10s. per day.

The fifth trial was made with Dale's magnetic muriate of iron, of which 100 gallons per day were used. The water, as it passed from the filter works, was nearly clear, but the same deposit was apparent in the ditches as previously described. The cost of this process was 4s. per day.

The sixth and last trial was made with one gallon of MacDougal's carbolic acid and lime to 40,000 gallons of sewer water. This removes all smell, and disinfects but does not clarify the water; this defect, being now, however, effectually remedied by the system of irrigation, is, in our case, of no consequence. The cost of this process is 18s. per day.

There is one general effect produced by all these agents, of a remarkable character. A large part of the solid matter, instead of subsiding to the bottom of the tanks, forms a floating crust on the surface of the first divisions, about 100 feet in length, which, in about six weeks, becomes 15 inches thick, and so solid that it is necessary to use spades and harrows for its removal; and if this is done at short intervals, the solid matter at the bottom of the tanks accumulates very slowly.

The manure from the surface just described is very valuable, and has been used this summer by our farmers in this neighbourhood, on meadow land and turnips, producing in one case four times

amusing, if not quite correct; and besides, it treats scientifically, as well as popularly, of the chemistry of all the fifty known metallic elements.

The results of Mr. Pepper's visits to coal mines are interesting, as they shed a light on the dark position of the poor miners, female as well as male, and show how such deadly explosions as those of recent occurrence take place, and how they could and should be prevented. He enters very fully into the peculiarities of such mining works, and illustrates what he says by rough but seemingly truthful sketches. We observe that he points special attention to the self-extinguishing safety-lamp (Simons's) of which we have ourselves just been speaking, as a hopeful aid in obviating explosions.

On the subject of iron the author treats no less fully, as well as of copper, lead, and tin, telling us all about their mines and their manufacture into market metals: of gold and silver, too, and of aluminium; and, indeed, of all the more important metals, there is abundant information, both interesting and instructive.

While treating of iron, the Bessemer process is described, and the author, we observe, expresses an opinion quite in accordance with that taken by us from the first; that, notwithstanding undue laudation in the outset, and undue depreciation in the long run, this process "will, in time, effect great improvements in the iron manufacture."

Under the head of lead is a *résumé* of what is known of the influence of water on lead, and lead on water, a subject which we were the first to bring before the public in a way to excite attention and lead to care and caution in the use of lead in water-supply.

Under the head of gold the author, while alluding to its modern abundance, takes care to prevent us running away with the idea that it is only in recent times that gold has been got in at least considerable abundance; King Solomon, as we are told in the Bible, having worked up 27 tons weight of gold, as the produce of a single year, on the adorning of the temple; and the tomb of Simandius, according to Diodorus, having been envired with a circle of gold 350 cubits about, and a foot and a half thick, a mass of gold of enormous value even at the present time: Semiramis, again, erected in Babylon three statues of gold, one 50 feet high, and weighing 1,000 Babylonian talents, with a table of gold 40 feet long and 12 feet broad, and weighing 50 talents. Gold, therefore, though probably not so very abundant as now that new accumulations have been added to the old (may not some of the gold of Solomon and Semiramis, by the way, be even now in circulation?) was by no means a scarce or rare article in times of old.

While treating of mercury and the beautiful colours which it yields, the author regrets, as every artist must do, the unstable nature of these colours. Vermilion, however, or sulphuret of mercury, is not so changeable as the iodide, neither is the red oxide. The iodide is the most beautiful of all, whether in its primrose robe or its scarlet attire. It is of a beautiful pale yellow while hot, but generally changes, in a very curious way, to a vivid scarlet, as it cools, or when it is even touched; yet we have obtained it ourselves of a yellow hue even while cold; and this yellow colour, as we have found, may be rendered comparatively fixed by repeatedly subliming the iodide of mercury on metallic zinc. A black colour will first be thus produced, but finally the beautiful pale yellow; and probably the scarlet colour may also be fixable in some such way, although we have not tried to do so. We may add, however, in aid of those artists or others who are personally in search of means to fix mercurial colours, that the bromide of mercury retains the yellow hue, though not so fixedly as the double iodide of mercury and zinc; but, by considerable pressure, it may be made scarlet, though only where pressed; and that a series of curious colours, ranging from pale yellow to deep sage-green, can be produced by combinations of mercury with iodine and phosphorus together. There is a somewhat curious fact with regard to colours produced from iron, which we some time since happened to discover, and which we may here note while on the subject of colours. Observing an artist-friend of some mark, on one occasion, looking (as we may call it), some red oxide of iron on his parlour fire, the idea recurred to us that in precipitating oxide of iron from its muriate, by means of an alkali, the first precipitation had appeared to be very crude by comparison with a second precipitation of the same oxide, after being taken up again by muriatic acid, as it happened to be; and, on retrying the experiment, we found that, at each of several precipitations,

the powder of red oxide of iron became finer and more subtle as well as more vivid in colour. How professional chemists would account for this curious fact we cannot imagine: it appears to be inconsistent with prevalent theory: nevertheless, it can be easily verified as a fact, and may lead those interested to further discoveries in the same direction,—a very interesting one when we keep in view the magnificent hues of subtle oxidation obtained—but only so obtained—on the surface of polished steel implements in the fire; and the beautiful prismatic hues which Bergmann got by forcibly subliming, in a strong heat, a little proto-muriate of iron. In repeating Bergmann's forgotten experiment, we may here add, as a curious circumstance, that we obtained round translucent scales, tough and bendable like talc, and scarcely distinguishable in appearance even from those of a fish. The sublimation was only got at a full red heat.

But we must have done with Mr. Pepper's "Play-book of Science," or rather with our own little Christmas by-play, in which its suggestive pages have led us to indulge. There are only one or two hints, as to correction of errors in old lore, which we may append to our otherwise unqualified approval of the volume. Bichloride of tin was not known among the old chymists as "liquor of Lebarius," but as "liquor of Lihavius." Prince Gebar was not merely said to have converted mercury into a solid, consisting, in fact, of oxide of mercury; but was said to have converted it into another solid, namely, gold; and he himself says that gold consists of pure quicksilver, "clear fixture," and "sulphur changed from what it was," as the "finger" of the other elements. If he were not an alchymist, how did he come to know or believe that? After the opinions given by eminent modern chemists, from Davy downwards, as to the possibility of transmutation, the probable correctness of the idea or principle, and the also probable constitution of the metals in general, as actual compounds (see Graham, the present master of the Mint, in his "Chemistry" on the subject), rather than elements, which no eminent modern chemist has ever conceived them in reality to be, though obliged to regard them as such *ill analysed*,—in the face of all this, we may remark, Mr. Pepper's ridicule of the principle of transmutation is rather stale and antiquated; and he ought to reconsider the subject, without allowing himself to be biased by the unquestionable impostures of so-called alchymists. On one other point we may add, that Dr. Dece did not consult his crystal while Kelly digested the revelations: it was Kelly who acted as Dece's "Scrier," describer, or seer, and who saw the visions in the crystal; while Dece, as the master-magician, noted them down. Mr. Pepper wonders "how he could look into the stone," as the "crystal" was "a polished piece of cannel coal." What Kelly really looked into, however, was the depths of his own imaging faculty; and any fixed point, almost, for the eye to gaze upon, would have done nearly equally well.

Finally, let us add, Paterfamilias, who is meditating the perennial Christmas hock-gift to his young hopefuls, cannot do better than place Mr. Pepper's "Play-book of Metals" on the list; and take a dip into it himself, too, on Christmas eve.

### Miscellaneous.

THE POST-OFFICE.—In the last financial year the expenditure was 1,905,568*l.*, besides 41,489*l.* for superannuation and compensation allowances, as compared with 1,854,808*l.* and 40,108*l.* in 1858-9; 1,776,911*l.* and 36,400*l.* in 1857-8; 1,610,325*l.* and 26,861*l.* in 1856-7; and 1,291,550*l.* and 23,500*l.* in 1855-6. The growth of expenditure in the five years consequently amounted to 579,866*l.* In the same period the income advanced from 2,767,201*l.* to 3,310,655*l.*, showing an advance of 543,454*l.*

STATUE OF AMERICA.—Mr. Edward Kuntze, of whose medallion portraits we spoke some time ago, has produced a statue of America which deserves a word of notice. America is represented as a female figure leaning upon a shield bearing an eagle, the shield resting upon the stump of a hewn tree, to indicate clearance, on the root of which are piled up fruits and other products of the country. The head-dress is a tiara of thirteen stars, representing the thirteen original States. She has a young, fresh countenance, with an air of beneficence, and with outstretched hand offers welcome to all. The arms, judging from photographs before us, are somewhat short. Mr. Kuntze's countrymen in England should aid him in the work.

LIVERPOOL CEMETERY COMPETITION.—Through want of indication, and under pressure of intimation on the part of an official that note-taking was forbidden, our reviewer did not see the whole of the designs. It appears there was a second room "elsewhere," containing nine sets of designs, some of them very good.

BROMPTON REFORM.—The ground has been cleared in Brompton-road of a block of dull, heavy houses with palings on the south side, and a large piece of vacant ground now exists for a new square between Knightbridge and the Museum, which is being laid out with considerable energy. A correspondent writes,—“This square will present two permanent sanitary adjuncts, a livery stable and dung-yard at one corner, and a busy slaughter-house at another.”

THE SEWAGE QUESTION.—An experiment has, it is said, been submitted, to practical test during the last eighteen months in Hyde, near Manchester, under a patent of Mr. B. Standen, of Salford, for deodorising and concentrating the material collected from potties and ashpits. It now assumes the shape, it appears, of "The Eureka Manure Essence," and is produced at Messrs. Standen & Co.'s agricultural chemical works, in Hyde. The manure collected is said to be greatly reduced in bulk and weight, and thus a saving effected in the cost of transport to the farmers, who receive it in a state of powder resembling guano. Joint-stock companies are to be established, it is said, to work the process in towns desirous of adopting it. The material seems to be similar to the Parisian *podrette*, if we rightly understand this account of it.

THE FIRE BRICK TRADE AND THE FRENCH TREATY.—In the spring of this year a meeting of the various fire-brick and clay-retort manufacturers in Durham and Northumberland was held in the Chamber of Commerce in this town, to consider the probable effects of the commercial treaty with France on this now large and important branch of our local manufactures. Mr. Jos. Cowen, chairman of the Tyne Commissioners, was appointed a representative of the trade to visit Paris, and lay the case of the fire-brick makers before the commissioners. He did so, and we are now glad to learn, by the publication of the details of the treaty, that all the concessions asked for by Mr. Cowen have been granted. Fire-bricks, clay retorts, pipes, and all other articles usually made by fire-brick makers, are henceforth to be allowed to enter France entirely free of all duty. This will be a great boon to this branch of local industry, as hitherto some of the fire-clay goods entering France were charged with a duty of ninety per cent. Now they are free. — *Newcastle Chronicle*.

OPENING OF THE BOTANIC GARDEN AT DUBLIN TO THE PUBLIC.—A treatise has been printed and circulated under the title of "The Royal Dublin Society and the Citizens of Dublin. Why should Exclusiveness and Sabbatarianism be the Rule at the Glasnevin Botanic Garden, whilst under Her Majesty, at Kew, Free Admission is the Rule on all the Days of the Week, and on Sunday?" Issued by a Preliminary Committee formed for Promoting the Freer Opening of the Glasnevin Botanic Garden. The committee propose to memorialize the governmental department which has the supervision of the Royal Dublin Society, in the event of the Society refusing to the public privileges which they themselves exercise; but they are hopeful that an expression of the public feeling on the matter is all that will be required to place the Glasnevin Garden on some such footing as that at Kew.

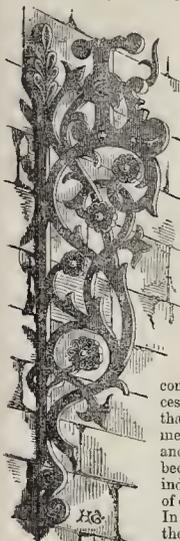

THE LEICESTER ARCHITECTURAL AND ARCHAEOLOGICAL SOCIETY.—A *soirée* has been held by this society at Leicester, under the presidency of Lord John Manners, M.P. The assembly was a numerous one. The large room of the Temperance-hall, where the *soirée* was held, contained many objects of interest. Lord John Manners made some remarks on the development of archaeological and architectural knowledge, and suggested that local architectural societies should give their formal opinion as to the style of the new Foreign Office. The Rev. Charles Boutell, M.A., delivered a lecture on "Medieval Costume as Illustrated by Monumental Brasses." The lecture was illustrated by rubbings from brasses. A paper from Mr. F. W. Ordish, on "The Objects of Architectural and Archaeological Societies," was then read. The Rev. I. H. Hill, of Cranoe, read a paper, from the pen of Mr. J. Gough Nichols, the historian, on "The State of Leicester in the Early Part of the Seventeenth Century." Mr. Thompson also read a paper on "Recent Discoveries illustrative of Roman Leicester."

# The Builder.

VOL. XVIII.—No. 933.

Condition of our large Towns. Leeds.

LEEDS, speaking broadly, is a filthy and ill-contrived town. In some of the streets it is impossible for a person unaccustomed to impure air to remain for even a short time without becoming sick and ill. The stench is overpowering, and the sights equally so. The paucity of private accommodation is such that in the side streets and open places no delicacy whatever is felt concerning

compliance with the necessities of nature; so that even young persons merging into manhood and womanhood have become from habit totally indifferent to the sense of decency in this matter. In many of these streets there is no superficial drainage. If the street be concave, the rain and slops soak down the middle to some lower level; if convex, the liquid refuse runs to the sides of the road, near the pavement, and not unfrequently overflows the latter. Some of the streets in the neighbourhood of Quarry-hill and the York-road are without any road pavement whatever. A week ago the cart-ruts in the roads were 9 inches deep, where the mud was solid enough to allow of an impression in it being left; and in others the cart-road was a narrow channel of liquid mud. Add to this, that with a few exceptions the streets are narrow, tortuous, and badly lighted; and that the air is afflicted with factory smoke; and that side of the picture, it will be seen, is not an attractive one.

Yet Leeds is wealthy and flourishing, and has spent money liberally and nobly. Let us look first, then, on this side of it.

The prosperity of Leeds may be indicated by the following table, showing the amount of money expended on public buildings and public works within the last few years:—

1847. Borough Gaol, cost .....	£40,000
1855. Kirkgate Market .....	14,000
1858. Townhall (exclusive of fittings, organ, &c.) .....	51,625
1859. New Grammar School .....	14,000
1860. New Workhouse .....	17,000
„ New Overseers' Offices.....	4,500

In addition to these there are numerous works of district property, such as cemeteries and chapels, also places of public worship, statues of Peel, Wellington, E. Baines, M.P., and a portrait statue of her Majesty, all of recent date.

At the present time sums of 8,000*l.* for the Philosophical Hall, and 16,000*l.* for the Schools of Science and Art, and Mechanics' Institutions, are being raised in the town, and the buildings will be proceeded with almost immediately. The extensive Infirmary is about to undergo thorough renovation, and additions are to be made to its accommodation; whilst a new theatre is to be built in a short time. But perhaps what will give the best idea of the resources of this town is the extent of the corporation loans under the Improvement Amendment Act of 1848, which in 1856 amounted to the sum of 512,000*l.*

The public spirit shown in these extensive outlays of money for improvements and addi-

tions to its public buildings and works is very great. A large part of this corporation loan is being devoted to the drainage of the town; and it is well that it is so, for few places of equal wealth and importance have been hitherto so miserably drained.

Perhaps it would be impossible to find a town in all England where the house accommodation for the labouring populations has so unequally kept pace with the increase of population as in Leeds. This is not altogether inexplicable when we consider the rate at which the increase of population has proceeded.

We give this table to explain the demand which has existed for the last fifty years for increased house-room in Leeds and its immediate suburbs:—

Population.					
A.D. 1801.	A.D. 1811.	A.D. 1821.	A.D. 1831.	A.D. 1841.	A.D. 1851.
53,342	62,665	83,943	123,548	150,234	174,270

It is believed also that in the census of 1861, the population will have reached 200,000. Thus it will be seen that in fifty years the population has been nearly quadrupled, and between the two last decades of years, above 20,000 inhabitants have been added in each decade.

This enormous increase has occurred chiefly in the labouring classes, mill-hands, mechanics, and artisans. There are a few streets built to accommodate the middle class of householders, which necessarily accompany so vast a labouring population. But the decent and comfortable houses of clerks and professional men, bear a very slight proportion to the miles of squalid tenements in dirty, badly drained streets, erected for the artisans and mill-hands. The courts and alleys, and pestilential dens into which the latter have been gradually driven; the filthy habits, the vicious appearance of the lower classes, all these are a foul blot on the town which calls itself the metropolis of the West Riding. And yet, naturally, the working classes of Yorkshire are, perhaps, the most intelligent in England. They are a well-formed, powerfully-built, and healthy race of men—hard workers and shrewd thinkers. Subject to such demoralizing influences as Mr. Hole has noticed in his account of the social condition of the labouring classes of Leeds,\* we hold it to be impossible for working men with large families, to keep themselves in even a tolerable condition of health or morals. The forest of factory chimneys vomiting forth their clouds of sooty smoke, such a plague to housewives as even to compel them to dry their washed linen before the fires of their single dwelling-rooms; the dye-houses and cleansing-rooms of cloth and other mills, poisoning and defiling every stream, and turning the river into a dense and blackened stinking drain; the narrow and over-crowded streets, the closely-packed dwelling-houses, the imperfect drainage; all these are influences which, acting together on the working man's health and happiness, have made a very considerable impression on his physical and social condition and his appearance.

One very serious evil in the construction of modern houses in Leeds is that of building houses back to back. In this case the houses are placed between two streets or approaches, the entrances being on opposite sides of the block,—each tenement going half way through the whole block. This arrangement results in the evil of an impossibility to get a draught of pure air through the house, and the consequence of very imperfect ventilation. The commonest deficiencies of life are totally disregarded, but we will let Mr. Hole speak for himself on this point:—

“The physical condition of the majority of the working classes of the town would have been good, had it been subjected to proper municipal regulations during the last thirty years. Decent houses and well-drained streets are scarcely less important than good wages, or day and Sunday schools:

\* “Light more Light!” an able essay on the present state of education amongst the working classes of Leeds, and the means of improving it; by Mr. James Hole, Hon. Sec. of the Yorkshire Union of Mechanics' Institutions, recently published by Longman & Co. To this work a premium offered by the Dean of Chester, before he left Leeds, for the best essay connected with the social advancement of the working classes, was awarded.

but notwithstanding an enormous sum expended in making drains, there are many miles of houses, yards, and streets unconnected with the main drainage. In Leeds, the reprehensible mode of building cottages back to back, has been almost universally the custom, and in spite of its known evils, it is allowed to go on, no steps being even contemplated to check its growth. The unfortunate dwellers in miserable streets so constructed, sometimes struggle for a while to maintain an aspect of decency about their little dwellings, but at last the accumulating filth renders it impracticable, and they give up the contest in despair. One privy to four cottages, has been settled to be the legitimate allowance in Leeds; but this liberality of supply has been by no means universally attained. A favourite plan, and almost inevitable on the back-to-back system of building, is to plant the privies for a number of houses in the centre of the row, with a sleeping-chamber over them! Every question of convenience, or even of common decency, seems sacrificed to the one consideration of getting the largest possible return for the money invested.”

This is the calm statement of a man, who, perhaps, knows more of the working classes of Leeds, than any other man in the town. We will ask the wealthy manufacturers of Leeds—the men whose riches and luxuries are the product of these dwellers in dens of fever and filth,—whether they approve of such a dreadful state of things? Revelling in the beautiful suburbs of Kirkstall and Headingley, surrounded by every luxury that boundless wealth can procure, it would yet be well if these woolen lords would realize the fact, that upon them devolves a responsibility in this matter. They live upon the industry of their armies of workmen and work-women. Is there to be no reciprocal feeling between them? We well feed and cleanly house the horse which carries us, and does our work well; are we to leave these other animals, these men who do our bidding and create our riches, in a worse case than the soulless brute? You, millionaires of Leeds, have no slight responsibility. Ask not yourselves, in a tone of contempt, “Are we our brothers' keepers,” for society has determined that you are. In so far as you derive your wealth from their labours, so far are you debtors to them, and they are claimants upon you for the righteous treatment which you willingly bestow on your horses,—if for no better.

It is impossible that the working men themselves can remedy the evil condition of their dwelling-places. The artisans may get well paid, but they marry early, and generally have large families. But supposing them to begin life with a virtuous determination to do well, and keep themselves respectable, it is easy to see how the struggle is maintained. Universal filth around them, and stench about and above them; companions who have long since given up the struggle in despair, whose various pleasures and demoralizing recreations alone seem to modify their evil plight,—all these gradually coerce their resolutions, and sap away their good intentions. Where it is impossible to give even the opposite sexes the common decencies of privacy in their houses and sleeping apartments, we must expect immorality, and the result to be regarded as a matter of course, and as nothing wrong. Where dirty streets, and crowded houses make men feel that their self-respect is gone, and that they are part and parcel of the system which includes these evils, we must expect them to fly to public-houses, and escape for awhile the miseries of home; though by this they are only perpetuating the evil, and entailing it with all its dread consequences on their children. Consequently, we find the low public-houses and beer-shops, and cheap places of amusement in Leeds, crowded in every part. The houses of recreation are brilliantly lighted, and music offers its attractions also to a music-loving population. The working man is well paid, and in these places he gets all the indulgences which money can procure him. In one den of so-called amusement, we are told that there is a greater average nightly attendance, than at the evening classes of the seventeen Mechanics' Institutes put together. The low beer-shops and public-houses are so numerous in the neighbourhoods of the artisans' houses,

that every twentieth house seems to be one of them.

We do not wonder that Leeds has to build enormous gaols, and workhouses, and reformatories. We cannot be surprised that Leeds should exhibit her criminal list, and demand that the assizes for the West Riding should be held in her Town Hall. But we will suggest to this metropolis of the West Riding, that her great men most imperfectly understand the very elements of political economy. They build a grand townhall in which assize courts can be held; they build an enormous gaol in which to incarcerate the convicted criminal; they add workhouse to workhouse where the spirit-broken pauper may decline and die at the public expense; they build a reformatory where young thieves who have graduated in the profession are prevented the practice of it,—and we are willing to allow these are, one and all, very excellent correctives,—but where are the preventives? The seed-beds of the crimes are allowed to exist and flourish in all their rank luxuriance. We do not hesitate in affirming that if proper control were held over the building of houses for the working classes; that if the streets were kept clean, and the river, streams, and canals were restored to their original purity; that if the drainage were properly carried out, and the dens of infamy and demoralization kept sternly in check, there would be a vast change and improvement in the condition of the town. It is never too late to begin. The town has already been saddled with the expense of correctives, let it now devote some attention to preventive measures. The municipal authorities may do a vast deal of good by exercising an undeviating control over the building of dwelling-houses for the poor. They will find that cheerful, roomy cottages, well ventilated and thoroughly drained, with proper accommodation for division of the sexes, and private offices for each house; all these are powerful antagonising influences against the crime and pauperism which now cost them such enormous annual outlays. If for each reformatory a dozen schools were built,—for each gaol a town were drained,—for each workhouse a Building Act enforced healthy cottages,—we should show our knowledge of political economy, and social science would triumph over police statistics.

Light, air, clean water, and elevating elegance in our streets, are in the end cheaper than gaols, reformatories, and workhouses. You must let men have the former with the addition also of room, or they will qualify themselves for the latter; and in any case the public has to pay, either for the preventives or the correctives, the happiness or the misery.

It was a natural remark which we heard a visitor make, whilst gasping the vitiated atmosphere of Leeds, "Surely these people have not enough air to live upon." One is almost willing to believe this, literally. It is a wonderful sight to see the chief approach to Woodhouse-moor on a Sunday afternoon and evening in summer. Woodhouse-lane becomes one huge footpath; pavement and horse-road are crowded with eager pedestrians, hastening upwards to the moor to get a breathing of un-heated, un-smoked pure air. In Holbeck also, where dwell many thousands of operatives, there is a general exodus to Holbeck-moor. Every outlet into the country is crowded with persons to whom the luxury of pure air is denied during the week. If you ascend any of the ridges or eminences which surround Leeds, and thence, on a Sunday morning or afternoon, regard the prospect, you will see the whole landscape dotted over with groups of figures; and would find it difficult to cast the eye on a country footpath or green field for miles around, where families and friends are not luxuriating in the blessings of a clear atmosphere. We see something like this exodus to the country in the suburbs of London on a Sunday. Leeds is a terribly rainy place, the atmosphere is dense and heavy, and retains perennially the smoke and sulphureous stonches of factory chimneys, iron foundries, dye shops, and cleaning houses, with which the town is crowded. The streets are narrow and not well lighted, except in instances which could be counted on the fin-

gers. Even in London we know nothing like the narrowness of the ways, whilst the traffic in many of them is only surpassed in important streets in the metropolis, Liverpool, or Manchester.

We have surely said enough to show that great changes are needed in Leeds, and we earnestly call on the right-thinking, intelligent, shrewd, and wealthy inhabitants of the place to set about the work.

*Millionaires of Leeds!* you are your brothers' keepers.

#### ON CHURCH AND CONVENTUAL ARRANGEMENTS.\*

*Cistercian.*†—The characteristics of the churches of the Cistercians, like the Cluniacs, a reformed congregation of the Benedictine order, is an extreme simplicity in outline—absence of triforium and pinnacles, a single central tower, a simple west front, and plain undivided windows—for no ornament of any sort, not even of painted glass, was admitted—and a flight of stairs led from the transept into the dormitory. Clairvaux had a chevet, with nine radiating square-ended chapels; two east chapels in each wing of the transept, and two in each of the western aisles of the transept. There was a large west porch; stalls for the clergy were set on the west of the transept, and for the servants at the lower end of the nave. Pontigny, c. 1150-70, where Lanfranc, Anselm, and a Becket, took refuge, had a chevet with seven square-ended chapels, and side chapels to the choir aisles, and west and east aisles to the transept; and Altenburg (c. 1255) has a chevet with seven polygonal chapels; the only English instance of such a termination is said to be indicated at Beaulieu, which, probably, resembled Clairvaux. Atohaça, in Portugal—1148-1222—has a three-aisled nave, and a chevet with nine chapels. Notre Dame Buremond, begun 1218, is of the Rhenish type, having pentagonal apses to the choir and apses, a cupola, with two flanking central towers; and a large west transept and narthex (Schayes, iii. 50). In the twelfth century the order distinguished themselves from the Benedictines by the choice of a secluded spot and the simplicity of their ground plan, which, in its earliest type, was marked by a short square-ended choir, as at Holy Cross, Here, Boyle, &c., except at Rievall and Fountains; often aisleless, as at Pluseardine, St. Mary Sweet Heart, Kirkstall, Roche, Furness, &c.; and by having chapels (usually four) on a line with the choir, and opening like an eastern aisle into the transept, as at Sybacone, c. 1147 (Lenoir, ii. 47). Fontenay (c. 1119), Sereny (c. 1128), Clairvaux, and Noriac, built by St. Bernard, and St. Vincent at Rome. Cîteaux was square-ended, but had apses to the transeptal chapels. Vaux de Sereny (c. 1128) was square-ended, with four apsidal transeptal chapels. Fontenay had a square apse, with square-ended transeptal chapels. This arrangement, which was adopted in the fifteenth and sixteenth centuries at Florence and Romo, appears in England at Kirkstall, Roche, Furness, Netley, Buildwas, Tutern, and Fountains, &c.; and in Ireland, at Dumbrody and Boyle. No Lady-chapel protrudes at the east end. The eastern aisle of the transept was always parted off into chapels (Arch. Jour., xi. 136). The exceptional instance of towers (both Perpendicular) occur at the west end of Furness, and on the north-west angle of the transept at Fountains. At Clairvaux (Viollet le Duc, i. 267), and ordinarily in Cistercian houses where the choir was aisleless, the whole space under the lantern was left open, so as to leave free access to all the eastern altars. The number of four transeptal chapels was sometimes increased to six, as at Rievall, Fountains (Proc. Ass. Soc., i. 263; iii. 54), Furness, Kirkstall, Dumbrody, and Graig-na-managh. Jorevella in 1154, presents an advance in the arrangement, having choir aisles; and Byland, which has western aisles to the transept. In France there was a large west porch.

*Friars.*‡—The churches of the Friars—Franciscan (e.g. Kilconnel), Dominican (e.g. St. Andrew's, Norwich), and Carmelite, e.g. Hulne, were oblong and of unbroken length, destitute of a triforium, and generally provided with only a single aisle or rarely flat-ended; but a Franciscan ruin at Winchelsea has an apse. The Franciscan church at Stirling has an octagonal apse. In the fourteenth

\* By the Rev. Mackenzie E. C. Walcott, M.A. See p. 793, ante.

† Jour. Arch. Ass., vi. 390, 312; Ecclesiologist, cxxxiii.; Viollet le Duc, 207, 250, 264, 269; Fosbrooke, Brit. Mon., 112.

‡ Fosbrooke, Brit. Mon., 117, 121.

and fifteenth centuries, tall, narrow towers, as at Roswick, Moyne, Multifernan, Adare, and Kilconnel, were inserted between the nave and choir. Ardirt has a west tower; the cloister is on the north at Moyne, Muekross, and Adare, on the south at Kilconnel. Kilconnel and Muekross have a south transept; Castle Dermot has a north aisle and transept. Reading has a nave and aisles.

St. Andrew's, Norwich (Jour. Arch. Ass., xiv. 60; Harrod's "Gleanings") and the Dominican Friary (Schayes, iii. 153-4), at Louvaine, c. 1230, and at Gloucester, had a nave with aisles; that at Ghent is a square-ended oblong, c. 1240; so is Roseomon, but with a north nave aisle. Conventual buildings were arranged by the Dominicans, as at Sligo and Kilmallock, on the north; and their preaching-yard laid out on the west or south side. Hulne, a Carmelite church, is a mere oblong (Arch. Jour., iii. 141).

The Friars (Lenoir, ii. 205; Viollet le Duc, i. 237; Ecclesiologist, No. cxxxiii.), owing to their destination as preachers, required to place their houses in the midst of a surrounding population; and had to adapt them to the irregularity of the site, large spaces of ground not being attainable. The stalls of the brotherhood occupied the nave, and the congregation occupied the parallel aisle. The cloister of the Jacobins of Paris and Agen were on the north side. The churches in those towns, as at Toulouse, were oblongs of two aisles, but the latter, of the latter part of the thirteenth century, has a chevet with five chapels. Chapels were not ordinarily added until the fourteenth and fifteenth centuries. The refectory at Toulouse and Paris stood out at right angles to the church. The Austin Friars' house at St. Marie des Vaux Verts, near Brussels, exhibits an oblong church without towers. On the north side of the cloister was the library, on the west the dormitory, on the south the refectory, on the east the day dormitory for the "meridian." On the north and south of the eastern cloister were the guest houses. The infirmary was detached on the south-west of the great cloister.

*Præmonstratensians.*§—Two of the most deformed ground-plans, in England, belong to the Præmonstratensian Regular Canons, a reformed branch of the same order as the Austin Canons. Easthy (Proc. Ass. Soc., ii. 317), with its long, aisleless choir, and nave wanting a south aisle, and Bayham, with an aisleless nave and lateral galleries to the transept. The choir is aisleless, but ends in a polygonal apse.

*Cluniacs.*¶—The original Abbey of Clugny bears a marked resemblance to Lincoln Cathedral, built by John de Noiers for Hugh of Burgundy. A peculiarity of Cluniac churches in England is the position of the sacristy, which at Tintford and Castle Acre is attached to the north wall of the transept. In France a narthex, or outer church for penitents, was a distinctive feature (Viollet le Duc, i. 185, 207, 259), as at Clugny, c. 1220; Yzeval, c. 1160; and Charité-sur-Loire, of the twelfth century, with two towers above the porch, four towers flanking the transept, and a central tower formed the lantern. The Abbey of Clugny was composed of a church with a nave with double aisles; a main and choir transepts, each with four apsidal chapels; an ante-church, a chevet with five chapels, and a cloister on the south. Above the great porch in Cluniac churches in France, a chapel of St. Michael was built. At Daventry and Tykford, the outer or firm-court was of considerable size (Monasticon, v. 206, 184).

*West Front.*—The ordinary west front in a fine building presented a gable between two towers. In the church of a nunnery, as at Romsey, there was no west door. The west fronts presented high-pitched roofs and gables, when stone walls replaced the old flat wooden roofs, and were especially useful in the snowy and rainy North. The mystic triangle of the Trinity in the pediment was replaced by the gable cross; and triumphant angels, apostles, evangelists, saints, and stories from Holy Writ and legends, arranged over the front, formed a guide of Christian life and vast systems of instruction. Occasionally, on a German type, in the central compartment there was a western tower, as at Belvoir, Ely, Hereford; imitated afterwards at Bolton, Wimborne, Christchurch, Hants, Shrewsbury, and Waltham. The same plan is observed at Mechnin, Limerick, Dantzig, Roeskildo, St. Vincent's, Soignies; St. Gertrude's, Nivelles; at Fribourg, St. Germain des Prés; St. Savin's, and St. Benoit-sur-Loire; but they were soon placed at the angles to show the

§ Lenoir, ii. 478; Fosbrooke, Brit. Mon. 115.

¶ Fosbrooke, Brit. Mon., p. iii.; Viollet le Duc, i. 237, 250.

arcading and windows of the front. We also find a western church attached, as at Sherborne, Glastonbury, and Tynemouth (Mon., iii. 311; Collinson's Somerset, i. 263; Harston's Sherborne); and similar instances in the Cluniac churches, and St. Front's, Périgueux.

**Porches.**—A Galilee (Duceage, s. v., Lenoir ii. 50) occurs at Durham, Ely, and Snettisham: it may have derived its name from being the most distant portion of the church from the altar, or from the circumstance of its being used like a lych-porch for the dead, with a touching allusion to the fact that our Saviour, after His resurrection, showed himself so frequently to His disciples in Galilee. The third week after Easter by the Greeks, and Wednesday in Easter week by the Latins, was called Galilee from this circumstance. This porch was used as their last station by processions. It is found on the south side of the transept at Lincoln. The porch was probably a vestige of the narthex of the primitive church. In it the children of the abbey serfs were baptised, and the office was said, at which the domestics assisted. It was also used on Palm Sunday to arrange the procession, and to receive great personages in bad weather. At Clugny it was as large as a church. It was often a sanctuary, containing a ring which the fugitive clung to, as at Durham (Fosbrooke, Brit. Mon., ch. xix.) and at Cologne, where there was an inscription, "Hic stetit magnus reus." It was also used as a parlour for conversation with persons who were permitted to enter the actual monastery. On the stones the measurements of weight and length were sometimes carved, as on a nave pier at Old St. Paul's.

In the twelfth century porches were often interspersed by grand portals. There are large porches at the west end of Peterborough and Chichester, south transept of York, and the north transept of Westminster. Large northern porches were added on the town side at Salisbury, Wells, Hereford, Christchurch, Worcester, Wells, Durham, &c.

**Galleries.**—The gallery in front of churches took its origin from the necessity of accommodating the choir, who sang "Lauds, Gloria," &c., when the procession on Palm Sunday returned from carrying the sacrament to the cemetery. Frequently windows were groned closely for this purpose, and this may have been the design of the huge west arch at Tewkesbury. In bad weather the ceremonial was held before the altar of the Cross, under the choir-screen, and this custom may have led to the construction of minstrel galleries at Winchester, Exeter, and Malmsbury. Galleries are found at the west end of the nave at Le Mans and Jumièges in the north transept, and in the north nave aisle at Winchester, in both transepts at Bechoverley, in the south transept at Westminster, Hexham, and Cerisy, and like a small arcade at Elgin.

**Doors.**—The north nave door was allotted to the laity, that on the south opened into the cloister, the exceptions are where the conventual buildings were on the north side of the church. Romsey, being the minister of a nunnery, has no west door.

**Towers.**—Towers had frequently an altar of St. Gabriel or St. Michael, the conductor of souls (perhaps in allusion to the Paradise below, or the legend of his apparition, c. 490 and 706), (Johnson's Notes, Ethelred's Eccl. Laws, 1014, c. 2), and the interior was frequently covered with sepulchral inscriptions. A chapel of St. Michael, in Cluniac houses, was built above the great door. The great tower of St. Benoit-sur-Loire, c. 1026, was called St. Michael's; the central tower of Canterbury is called the Angel tower; and on the highest gables of Wykeham's colleges are statues of St. Gabriel or St. Michael. Three towers were built at Canterbury, York, Wells, Lincoln, Durham, Llanthony, Southwell, and Ripon, as at Westminster, built by Edward the Confessor (Publ. Rec. Comm. 1855, p. 214); Liehfield alone retains its three spires. Ely and Peterborough have central lanterns; Salisbury, Norwich, Chichester, and Oxford have central spires. Two western towers were designed at Norwich and Chichester. At Chichester, as once at St. Paul's, Salisbury, and Westminster, Worcester (Arch. Inst. Wore., 103; and Crowland, Proc. Ass. Soc., iii. 273), there is a detached helmy-tower. At Rochester it is attached to the north transept; at Donlunne to the south transept. At Wyndham (Monast., iii. 328; Arch. Inst. Norfolk, vol. 1851, p. 115), the abbey steeple, built over the three eastern nave-hays, served as all communication with the nave, which served as a parish church. Aberden and St. Andrew's have two west towers. Elgin had three towers, with large turrets flanking the east end. Fortrose has a single west tower. At Exeter the towers

form transepts—a very convenient arrangement for the monks (Viollet le Duc, i. 168), when tolling the bells for the night offices, or when a large congregation filled the nave. The same arrangement prevailed at St. Germain des Prés, Clugny, Vézelay, and Chalons-sur-Marne. The western towers contained the bells rung on fast days, and as a summons of the laity to service. There are towers to the choir transepts at Canterbury, and tower-turrets at the west end of Salisbury, and Peterborough, and Rochester, to the east end of Chichester, and Exeter, and Norwich, to the west and end of Winchester. Turrets flank the choir of Peterborough.

**Transept.**—There are aisleless transepts at Canterbury, Norwich, Carlisle, Worcester, Gloucester, Exeter, Rochester, Kilkenny, Romsey, and Bristol; but the place of an aisle was ordinarily supplied by the erection of eastern apsidal chapels or square, as at Exeter. St. Patrick's has a quasi-aisle. St. Stephen's, Caen, as Canterbury had, has an internally formed lateral aisle. Scotland, like France, ordinarily presents only a quasi-transept. Transepts with east aisles for chapels are found at Peterborough, Hereford, Liehfield, Selby, Whithy, Ripon, Lincoln, Roche, Jorevalle, and Howden. Double aisles flank the transepts of Winchester, Ely, York, Wells, and Byland. One of the compartments at Winchester retains its name of the caleyatory, the place for lighting the censers. A stone confessional chair remains in the south transept of Gloucester, and confessionals are to be seen at Maig-Aidair (Fosbrooke, Ency., i. 122). The revery, as at Westminster, Gloucester, and Christchurch, was attached to the transept; it contained a press for vestments (one remains at Winchester), an altar, and a bell to announce the coming of the celebrant. Transept towers occur at Exeter and St. Mary Ottery, and in Cormac's chapel, on the rock of Armagh, consecrated 1134, as at St. Stephen's, Vienna, Narbonne, and Chalons-sur-Marne. At Angoulême there are towers at the ends of the transept. At St. Lambert's, Liege, there was a south transept tower (Schayes, iii. 136). Choir transepts are added at Salisbury, Lincoln, &c., as at Clugny and Nivelles. In the sixth century St. Germain built chapels in the transepts of St. Vincent's. The chapels were usually founded as sepulchral charities, and supported by families of distinction, or by bequest of ecclesiastics. There are superb western transepts at Ely, Lincoln, and Peterborough.

The word choir\* is first used by writers of the western church, and Isidore, of Seville, derives it from the (corona) circle of clergy and singers who surrounded the altar (Orig., lib. i. c. 3); it occurs in the c. 13 of the 4th Council of Toledo. The position of the ritual choir in the nave may be ascertained by a difference in the shape or ornamentation of the pillars, the presence of a piscina, or marks of the rood-beam. Priests' rooms are found over the vaulting of the nave and choir at McIlfont, Holy Cross, and Kilkenny. In abbeys the choir (Viollet le Duc, iii. 227), raised by steps above the level of the rest of the building, usually extended into the nave, from which it was divided by a rood-screen; and on this side of the transept was the altar for matins and lauds, the nave being left for the guests, pilgrims, &c. Romsey has a raised platform in the nave aisles for the stalls of the nuns. In the cathedral the choir usually commenced on the other side of the transept, which was given up to the congregation; the large aisles were for their accommodation on the same level with the choir, and no stalls obstructed their view. Between the high altar and the bishop's throne, which was placed in the apse, stood a low or matin altar, with the vestment of the celebrant on a stand, and a brazier for kindling the incense. On each side of the entrance of the sanctuary stood a seven-branched candlestick. (Comp. Fosbrooke, Encycl., i. 124.)

The apse or chevet took its origin in the junction of the common circular tomb-house of the east end, found behind the altar with the basilica, by the removal of the intermediate walls. The tomb-house is still existing, under the name of Becket's Crown, at Canterbury, an imitation of the east chapel of Scus, and like Henry VIII's chapel at Westminster; Trondhjem, Batalha, Burgos, and Mureia. Romsey has apsidal terminations to the choir aisles: the central compartment once formed probably an apse (Proc. Arch. Inst., Winchester volume). The choir is disproportionately short at Westminster, Brecon, Brinkburne, and in several Cistercian abbeys.

Stalls were introduced at the close of the thirteenth century (Schayes, iii. 125), when the choirs were lengthened and arranged in two tiers. The earliest instances of wooden seats occur in a constitution of Grosstete. Three-legged stools were an earlier substitute; there is a mention of their use in the fifteenth century, and of choir-stalls in the Black Book of Swaffham. Lenoir mentions that Romanesque stone stalls remain at Ratzburg (ii. 135). The choir in cathedrals, following the monastic usage, was previously walled off from the aisles by a low partition (Schayes, Hist. de l'Arch., iii. 126), as at Canterbury, Alby, Chartres, Bourges, St. Denis, Amiens, and Notre Dame; in the two latter instances carved with figures. A solid wall still incloses Rochester. The bishop's throne was, when stalls were introduced, removed to a seat in the choir. Sick and straggle monks sat in the retro-choir.

**Lady-chapel.**—The earliest Lady-chapel was built at the west end of Canterbury, and re-erected in the north nave aisle by Lanfranc, but did not assume a prominent position till the thirteenth century (in Belgium, in the fourteenth century—Schayes, iii. 106), and then was usually placed eastward of the choir. It occupied the south choir aisle at Elgin, and the north at Thetford, Hulne, Belvoir, Bristol, Oxford, Llanthony, Wyndhamton (Monasticon, iii. 328), and Canterbury; but was detached at Ely and St. Martin des Champs; is on the north side of the nave at Waltham and Rochester; on the south of the choir at Ripon (over the chapter-house) and Kilkenny; in the south transept at Wimborne; at Lincoln and Gloucester it is cruciform; at Liehfield and Wells it has a polygonal apse; is in the galilee at Durham, and in the south transept of Wimborne. At Christchurch there is a chantry over the Lady-chapel.

An inclosed baptistery, like that at Luton, is found at Cividade de Friuli, of the eighth or ninth century. At Canterbury it forms a round building near the choir.

At Fontaines the marshalling of processions was marked out by stones along the nave, and a line of demarcation to women drawn across it at Durham, as at Canterbury and York formerly (Fosbrooke, Encycl., i. 125). A curious acoustic arrangement of pottery was found under the wood-screen at Fontaines. The pulpit (Duceage, vi. 263; Lenoir, i. 98, 217; ii. 76; Viollet le Duc, ii. 406) was on the south side of the nave. In Italy stone pulpits are found of the thirteenth and fourteenth centuries, as at Siena and St. Miniato, Florence.

In the twelfth century, as at St. Augustine's, Canterbury, and Bury St. Edmund's, pulpits were used in French churches, but probably were only movable wooden lecterns. In the thirteenth century they became usual, owing to the establishment of the preaching friars, and their employment in the refectory; the earliest is that of Beaulieu. In the fourteenth and fifteenth centuries we find an open-air pulpit in the cloisters or court; as at St. Die, at the Friary, Hereford, and Magdalen College, Oxford; Bishop Latimer preached in Priory-gardens, and his contemporaries at Paul's Cross. In churches they appear first in the Perpendicular period. There is a stone pulpit at Wells. The bishop's throne (Lenoir, i. 205; ii. 115, 239; Viollet le Duc, ii. 22, 279, 414; Duceage, s. v., Cathedra) was formerly of stone, as at Canterbury, Norwich, Avignon, St. Vigor, and Rheims. At the close of the fifteenth century they began to be of wood. Sedilia, rare in France, are found in Normandy and Brittany, and appear in England at the close of the twelfth century. There are generally three seats connected with a piscina in England, but four occur at Firmess and Paisley, and five at Southwell. In place of the triumphal arch of the basilica, a trines (Lenoir, i. 185) was set up, richly carved and adorned with tapers. An altar of the crucified, used in the ceremonies of Palm Sunday, was erected in the nave of St. Gall, round which the sick monks on All Saints' Day took their place. The most ancient in Belgium is that of Louvaine (Schayes, iii. 127), of the sixteenth century. The finest in France is in the Madelaine, Troyes.

At St. Ambrose's, at Milan, and St. Miniato's, at Florence, altars, as was usual in Roman churches, were placed in front of the choir. A screen was added in the thirteenth century, and this addition was multiplied in the two following centuries (Schayes, iii. 126). It was used for reading the Epistles, Gospel, certain lessons, letters of commendation, edicts of bishops, and acts of councils, and in some places for the benediction of the bishop, whence its name of jube. At Clugny the lady were communicated at the rood-loft through a grill. They took the place of the ambo and lectern of the basilica, and were used for the reading

\* Lenoir, ii. 73.

\* Wal. Strabo, l. c. 139; Durand, l. 1—18; Lenoir, l. 183; h. 249; Honorius, l. 149; Duceage, ii. 336.

of the Gospel and Epistle, and at a later date for the organ and singers. They were composed generally of a central door, closed by a curtain during the celebration, as the ciborium had been veiled, and in the lateral arches were placed altars.

*Screens.*—The rood-screen took its origin in the necessity of protecting the monks from draughts of cold air. As a compensation to the laity for their exclusion, two kinds of screens were introduced, identical in principle, though varying in position and arrangement. One was the choir-screen, in which, as at Chichester, Exeter, and St. David's, an altar was placed on either side of the great entrance from the nave. The second was the nave-screen, in which there was a central altar, forming the main altar and high altar of the laity, set between the two rood-doors, as that of St. Cuthbert's at St. Alban's. At Guilden Morden (Lysons's Brit., ii. 59) there is a double rood-screen. At St. Alban's they formed a loft used as a dormitory by twelve monks. The rood stood over the choir-screen at Canterbury, but at St. Alban's over the presbytery-screen, a piece of furniture the original of altar-rails, which is still found at St. David's (Jones and Freeman's St. David's, p. 89). At Christchurch, Hants, the screen stood in the first compartment of the nave westward of the lantern, as at Tintern, Fountains, and Winchester. The screen is placed in the second bay westward of the lantern at Buildwas and Norwich; at Westminster and St. Alban's, in the third bay; in the sixth bay at Tynemouth; and in the fourth bay at Jorevalle. Various parcels screened off chapels in the nave, transepts, and aisles; often, as at Fountains and St. Alban's, blocking up the nave. Against these enclosures and between arches, the tombs of bishops and abbots were placed, but at length were developed into distinct chantries; the earliest instance being that of Idyngdon, at Winchester.

The reredos behind the altar is found at St. Mary's Overy, Winchester, Westminster, St. Alban's, and Christchurch. Immediately behind it, in a retro-choir, was the shrine of the Patron Saint, as that of Hugh at Clugny; St. Louis at St. Denis; at Winchester, St. Alban's, Bury, Durham, Brighthelmton, Lincoln, Lichfield, Westminster and Canterbury, where the east processional path is on a level with the chapel, but with the floor of the nave at Durham and Westminster. The shrines of saints were in subordinate positions: at Rochester, choir transept; Chichester, south transept; St. David's, north side of choir; and Oxford, in a north chapel.

Watching lofts to observe the shrine, remain at Oxford, St. Alban's, Westminster, Worcester, and Canterbury. Chambers for the watchers of the church may be seen at Lincoln (Fosbrooke, Brit. Mon., p. 283), and over the north porch of Exeter. Minstrel's galleries are found at Exeter, Malmesbury, Winchester, St. Mary Ottery, Gloucester, and, perhaps, Westminster. The cell of a recluse remains at Norwich (Proc. Ass. Soc., ii. 349).

*Wall Passages.*—The triforium (Ducauge, vi. 669), which at a later period was treated merely as a portion of the clerestory window, was at first designed to combine (Lenoir, ii. 103), additional height with constructional security, and was used for purposes of accommodation, for a passage, and for hanging tapestries on festivals; it is locally called the numeraries at Christchurch, Durham, and Westminster, where the great size of this gallery was a continuation of the plan of this story in the Confessor's church (Vita S. Edw., Puhl. Rec. Comm. 1858, p. 417), which contained altars, and was retained, probably, for the accommodation of spectators on grand ceremonials. It is a feature never found in a Cistercian church. The peculiar wall passages in the lower story in the same church were used by the abbot for the purpose of supervising the monks. The prior's gallery still remains at St. Bartholomew's, Smithfield, and was probably of a similar destination. The wall passages of the clerestory were probably used by the sciscian when he went round to secure the shutters of the windows, then unglazed or merely latticed, in case of rain or storms. The windows were formed of stone, pierced with circles or tracery, like trellis-work in the early churches of the West and East. Glass windows are mentioned at an early date. Gregory, of Tours, speaks of wooden sashes glazed in France (Glor. Mart., i. c. lix.), and in 1052, stained glass is described at St. Benigne de Dijon. A labyrinth (Lenoir, i. 184; Arch., Jour. xv.

\* Viollet le Duc, lii. 465; Darandou, iv. c. xxiv. ; Hier. Angl., p. 66.  
† S. Chrys. t. viii. p. 354; Lact. de Opif. Dei., c. viii.; Fortunatus; Carm., ii. p. 11.

218), to thread which was a compensation for a pilgrimage to Jerusalem, is found at Canterbury, and St. Bertin's, St. Omer's; St. Michele, Pavia; St. Quentin's; Aix; Chartres; St. Maria in Aquino; Lucca, and St. Maria in Trastevere, was introduced in Belgium in the thirteenth century (Shayes, iii. 118). The fridstool, or chair of sanctuary, remains at Beverley and Hexham. The tabernacle is often an ambyrie near the high altar, on the north side. A credence-table remains at St. Cross. After the thirteenth century credences (Viollet le Duc, iv. 372), were introduced in Belgium (Schayes, iii. 123), generally on the right and often on the left of the altar: the latter, divided by a slab, held a basin and cruets, and was furnished with a water-drain below; that on the right was an ambyrie, and held the books and ornaments of the altar. An additional ambyrie served to keep the holy oil. The piscina was ordained by Pope Leo IV. for cleansing the chalice. It became an important piece of furniture in the thirteenth century, and was provided with a stone bracket for the sacred vessels, and two drains, one for common water, the other for the rinsings of the chalice. Ambyries for the books and processional crosses also remain. An ancient clock brought from Glastonbury, is found at Wells. The "horloge à roues" is attributed to Gerbert, Archbishop of Rheims, or to Pope Sylvester II., c. 1003. The Cistercian rule xxi. prescribed their use, though sundials continued in use. The altars had no retables or crucifix, until the end of the thirteenth century (Shayes, iii. 121; Walafrid Strabo, i. c. 139).

The *sacristy* (Ducauge, v. 759; vi. 148; Lenoir, ii. 287, 367) ordinarily intervened between the chapter-house and the church; but is found on the north side of the choir at Thornton; south side of the choir at St. Mary's, York; Lichfield, Leicester, Hulne, Selby, and Furness; and at the east end of the choir at St. Mary's, Warwick, and Malvern; in conjunction with an almonry on the north side of the north transept at Castle Acre and Thetford; and on the south of the south transept at Westminster. It is very possible that the name of the so-called castellan's rooms at Christchurch was a corruption of sacristan's rooms, they being situated on the north-east angle of the nave. The sacristy at Noyon was a two-storied circular building, opening on the east side of the transept.

*Conventual Arrangement.*—There was a generally understood rule and an evident similarity in the ordinary mode of conventual arrangement. Where exceptions occur they may be readily traced to some easily assignable cause: (1) the retention of earlier buildings; (2) the habits and requirements of a particular order of monks, or their transfer as architects, or bishops over another order; (3) the nature of the site, existing streets, or old town buildings; (4) defence in exposed situations; (5) modifications of the primitive rule and rearrangement of the buildings at a subsequent period, from emulation with others, from the love of reconstruction, for convenience, grandeur, or imitation of adjoining churches; (6) the perpetuation of the plan of the mother church and convent, by imitation in its cells; (7) the confusion in arrangement, owing to the necessity of providing accommodation for kings, nobles, and guests of distinction, for synods, and sometimes parliaments.

In the case of the lonely Cistercian houses (Viollet le Duc, i. 307; De Canmont, Abec., 178; Monasticon, vi. p. 9),—for instance, Mount Grace,—the oratory and cloister were tomb-like. The brethren lived apart in little cells, each provided with three little rooms and a garden; and only left them three daily for church, or refectory on certain days; while they assembled in the cloister-court on evens to read over the lessons appointed for the matins of festivals. At Clermont there was an outer court with cattle stalls and a watch-tower on the west, the guest-house on the south, barns on the north, and the prior's lodge on the east, and the apsidal oblong church, flanked with chapels; to the south of the church was the cloister, with the refectory on the south and the chapter-house on the east. To the east of the church was a large garth, surrounded by separate cells.

Each monastery included (1) a cloister-court; (2) an inner court, with the infirmary, guest-house, kitchen, servants' hall, library, &c.; (3) the larger arch being designed for carts, granary,

stables, store-rooms, grange-hall, servants' rooms, tribunal, prison, and the abbot's lodge; a remarkable instance occurs in the Promonstratensian Abbey of Ardaines, near Caen; (4) the court of the church, or close, open to the public; and (5) mills, gardens, orchards, &c. There was a court called Ronneland—probably from rone, roony, as in Romney, Romney, &c.—in front of St. Alban's; the Forbury (Monasticon, iv. 39) at Reading; and at Norwich Tombland, at least since 1302 (Blanford's Norfolk, iii. 67). By the Benedictine rule (Fosbrooke, Brit. Mon., 112; Fleury, xxiii. 14, 19; v. 207, 213; Monasticon, i. pr.), where six hours were assigned daily to manual labour, every trade and occupation necessary to the convenience of the community were domesticated within the walls.

In the plan of St. Gall, of the ninth century, the library abuts on the north wall, the sacristy on the south wall of the choir. The abbot's house, outer school, and guest-house lie parallel to the north transept and north nave-aisle. To the east of the church are the garden, cemetery, infirmary, and novices' house; to the south is the cloister, with the dormitory on the east, the refectory on the south, and the cellarge with a ladder above it on the west. The poor man's hospice, composed of chambers enclosing a common-room, fronts the guest-house. To the west and south were farm-buildings and workshops. The hospice for stranger monks had a common room and a dormitory. The guest-house comprised a large refectory, sleeping chambers, stables, servants' rooms, and domestic offices. The almoner's rooms were on the north-west side, those of the porter on the south-west of the church. The outer school, to which a master's house was attached, contained a large room, parted by a screen, and opening on the bed-rooms of the scholars. The infirmary and novices' house each comprised a cloister, refectory, dormitory, and a chapel, which separated the two courts. The abbot's lodge, of two stories, contained in the base tier his sitting and bed-rooms, under his solar and oratory. The servants' house was detached. Between the church and the cellarge were the parlour and vestibule for the reception of visitors, and giving orders to servants. In the sacristy the lower story contained presses, chests, and the altar plate; the upper room held the vestments, and communicated with a room used for baking the sacred bread and preparing the consecrated oil. The library stood over the scriptorium, which was provided with desks. Under the dormitory, from which one staircase led into the transept and a second to the cloister, was the common-room, with a fireplace, and connected with the bath-house. The refectory was provided with a vestry for the ordinary robes of the brotherhood. The abbot's triclinium stood at the top of the room; the brothers sat along the side walls on benches; the guests' table occupied the centre, and faced the reader's pulpit. The kitchen and buttery communicated with this room.

The earliest plan extant of an English monastery (Lenoir, i. 28; Hasted's Kent, iv. 259) is that of Canterbury, made c. 1130-74. It embraces in the cloister court, which was on the north of the church, a chapter-house on the east, with the dormitory in a continuous line with it, the refectory on the north, and on the west the cellarge and store-rooms. Behind the refectory was the kitchen, southward of a second court, in which the guest-house was on the west, the parlour on the north, and on the east a gate. To the east of the dormitory was a cloister ranged round a herbery garden, and connected with the infirmary, which lay again to the eastward. The court-gate adjoined the guest-house, forming the principal entrance. In the herbery court the prior's lodgings were on the east; and to the north of the bakery, granaries and offices, which occupied another court.

At the close of the twelfth century Clairvaux, Cistercian (Viollet le Duc, i. 269) had the following plan—A cloister on the south side of the church, with a lavatory; on the east side of the garth the sacristy, preceded by a little library next the south transept, with the great library above it approached by stairs out of the transept; the chapter-house of three alleys, with the parlour and old abbot's lodge extending southward under the dormitory; on the south side the parlour, the refectory of three alleys, and kitchen; on the west side, but detached, the cellarge; on the south-east of the choir was a small cloister, with carols for the copyists in the north alley, and a large hall for conference on the south. To the east again were the infirmary and novitiate, and more to the southward were the abbot's lodge and infirmary cloister. The stables were on the north-west side of the church. At Cîteaux, the mother of the

\* Jour. Arch. Ass., xiv. 87; Canute's Ecc. Can., 2; Althelm's Trans., Ps. ix. 9, xciv. 22.  
† Proc. Ass. Soc., i. 177, 293; Churton's Monastic Remains; Schayes, iii. 134; Viollet le Duc, i. 282, 283, 279, 302, 305, 409; iii. 409; Lenoir, ii. 197, 201.

order, the arrangements were much the same. A little chapel adjoining the gate, to which the abbot conducted all guests before entering the monastery, and a stable conveniently adjoined it. The great cloister contained the cellars on the west, slightly detached by a passage, with the guest-house and abbot's lodge to the southward; on the south were the kitchen, the refectory, and parlour; on the east the dormitory, chapter-house, and sacristy; in a second cloister to the east was the library above the carols of the copyists at the north, and the infirmary on the east. Pontigny had its cloister on the north, with cellars of two alleys, and the rooms of the conversi above; on the north the refectory, kitchen, and calefactory; on the east the sacristy, chapter-house, novitiate, and wine and oil presses; on the west of the church were the abbot's lodge and guest-house. The cellars was on the west at Vaux de Senay.

The Clugnia Monastery of St. Martin-des-Champs has its cloister on the north side; the refectory and parlour on the north; cellars on the west; the sacristy, chapter-house, and large halls, under the dormitory on the east; a detached Lady-chapel on the north of the choir, the small dormitory running parallel to it, more northward. At St. Genevieve the refectory is on the west, with the kitchen on the south. At St. Germain-des-Prés the refectory is on the north, the chapter-house on the east under the dormitory, and the cellars on the west.

**Cloisters.**—The Eastern monasteries had an enclosure, round which the houses of the community were ranged, and connected by a colonnade, as at St. Laura, Mount Athos, and St. John's, Constantinople. But in the West, where the churches were of far larger dimensions, and frequented by women, a different arrangement was inevitable. There were ordinarily two cloisters; the common, or great court of the religious; and the smaller or private court, used for conversation, by the copyists, for the residence of the abbot and dignitaries, and adjoining the library, cemetery, and infirmary. At Abingdon the earliest cloister was a mere enclosed space within walls (Chron. Abingd., ii. p. 272); that of St. Cutbert, at Durham, was circular; while in the reign of Charlemagne, St. Angilbert gave a triangular form, for symbolical reasons, to the court of Centula, which contained two chapels of SS. Mary and Benedict. The cloister appears to M. de Caumont (Abec. Arch. iv. 4), and Fleury, to have been framed on the model of the peristyle of the Roman city house; the outer or farm court on that of the country villa. The triclennium reappears in the refectory, in the garth the xystus; the church in the atrium; and the exedra in the chapter-house; the kitchens and lesser rooms, hospitium, hyernaculum, tablinum, &c., preserve their original position in the monastery; the walled park, gardens, servants' and store rooms are equally familiar features to the classical student.

Cloisters were originally built of wood; until the twelfth century, and even at a later period, a timber roof was employed, and the corbels which supported it remain at Beaulieu, and in other places. The cloister is mentioned by Brakelond, c. 1173. It is wanting at Fountains, Kirkstall, Jorevalle, Stoneleigh, and Wroxhall. In the thirteenth century, alleys surrounding the garth are found at Salisbury and at Peterborough; and in the fourteenth century at Norwich, Wells, Chester, and Chichester, and Hereford had only three alleys. The cloister occupied the north side at Canterbury, St. David's, Chester, Gloucester, Buildwas, Milton Abbas, Sherborne, Tintern, Paris, Noyon, Rheims, Rouen, Beauvais, Sez, Bayeux, Puy-en-Velay, Cartmel, and Magdalen College, Oxford; and on the west at New College, in the same university; on the north of the choir at Lincoln; and on the south of the choir at Rochester. In cathedrals the bishops often took the south side as the best, and left the northerly to the canons. The church invariably formed one entire side of the cloister, which nearly always was to the south in northern countries, in order to secure as much sunshine as possible.

The cloister-close in Cathedrals was surrounded by the houses of the canons. In the twelfth century the canons built private houses round the close (Viollet le Duc, iii. 410; Lenoir, ii. 495; Schayes, iii. 133; Monasticon, vi. 39, 141). It must be borne in mind that Winchester, Canterbury, Durham, Norwich, Rochester, Worcester, Chester, Gloucester, Peterborough, and Westminster, continued to be Benedictine abbeys, and Bristol, Oxford, and Carlisle as Austin Canons' houses, until the reign of Henry VIII. In the

former, out of deference to the bishop, the superior bore the name of prior, and not of abbot. At Ely the bishop occupied the abbot's seat. With the exception of St. David's, the Welsh, the Irish, and Scotch cathedrals, and collegiate churches, as Lichfield, Ripon, Manchester (Jour. Arch. Ass., vi. 191); Wilmshere (May's Wilmshere, 1860); Beverley, Lindisfarne, Perth, Southwell (Jour. Arch. Ass., viii.; Arch. Inst. Lincoln, 214); York, and Wolverhampton, had no cloister. Maidstone (J. Whichcord's Maidstone) preserves its collegiate arrangement. The caputular buildings included a chapter-house, refectory, cellars, schools, a vicar's close, as at Hereford and Wells (Jour. Arch. Ass., xiii. 34), library, audit-hall, bursary, prison, and tribunal.

The common monastic arrangement was the following:—On the north were two doors into the church; on the east of the great cloister were the sacristy, chapter-house, and the calefactory, with the dormitory, approached by a separate staircase above them; on the west were the cellars and store-rooms and the guest-house; on the south, fronting, but thus removed as far as possible from the church, to secure it from noise and the smell of dinner, was the refectory, connected with the kitchen. Such is the description given in some old Latin verses preserved by Du Cange; and the arrangement is found towards the close of the eighth century at St. Wandrill's, Foutenelle, Upper Normandy; and at Beauport, Côtés du Nord, at the commencement of the thirteenth century. Boyle and Netley present the anomaly of a wall and gate occupying one side of the great cloister.

In the north alley at Beaulieu, Melrose, and Gloucester, the carols of the monks, recesses for copying books still remain. In the foreign abbeys they were usually in the smaller cloisters. In Cistercian houses this alley was appropriated to moral collations or lectures. Peter de Blois says the west side was allotted to the novices, and the east walk to prelections; the latter were selected from profane authors. Lanfranc mentions that the cloister was designed for conversation at certain hours of the day. The Benedictines used the cloister, and the Carthusians, Cistercians, Trappists, and Carmelites the garth, for internments. The cloister was under the control of the prior, sub-prior, and several other officers. It is observable that at Winchester, until a recent period comparatively, the scholars in summer time studied in the cloisters. In the centre of the garth, which was planted with trees and flowers, was generally a fountain, and sometimes a pulpit used in the festival of All Souls.

**The Chapter House.**—It was so called, according to Papias, because the rubrics of the statutes of the order were daily read over to the monks in this room. In the ninth century the alley next the church was used as a chapter-house. In 966, Herlevy, wife of Duke Robert of Normandy, built a separate chamber for the purpose at Fontenelle. Edward the Confessor built "a vaulted and round" chapter-house at Westminster (Vit. S. Edw., Publ. Rec. Comm. l. 2309). In the twelfth century one in the form of a parallelogram was built at Bocheville; a square or oblong is found at Buildwas, Castle Acre, Shrewsbury, Wenlock, Stoneleigh, Glastonbury, St. Mary's (York), Oxford, Bristol, Chester, Exeter, Gloucester, and Dunkeeld. From the commencement of the thirteenth century a polygonal shape was adopted, and of this and the following century we find a decagon at Lincoln, Bridlington, and Lichfield; and an octagon at Westminster, Howden, Kenilworth, Cokeresand, York, Sarum, Elgin, Plusecardine, Thornton, and Wells; and a round at Worcester. It is two-storied at Glasgow. In the thirteenth century it was sometimes divided into aisles; there are two at St. Pierre-sur-Dives, Dadeix, and Kirkstall; and three at Tintern, Netley, Fountains, Beaulieu, Jorevalle, and Buildwas. It was in this country probably a Cistercian; and certainly, as it is found at Fontenay at the close of the twelfth century, a French arrangement which was followed in Belgium (Schayes, iii. 134). At Wells and Westminster it is built above a crypt; it stands on the north side of the church at Wells. At Dunblane it occupies the east end of the north nave-aisle. It was provided with a stone bench along the walls, and with a seat for the abbot at the east end. Occasionally a chapel was adjoined, as at Batalha, and the apsidal termination found in the House of the Jacobins at Toulouse, Reading, Lanthony, Durham, Ripon, Houghmond, and Norwich may have served for a similar purpose. The chapter-house chapel at Tongres retains its stone altar (Schayes, ii. 148). As it was the place of

judgment on refractory monks, cells (Proc. Ass. Soc. ii. 230) are sometimes found adjoining it, as at Durham and Norwich. It was regarded as inferior only to the church in its sacred character, and a light not uncommonly burned perpetually in it. Bishops were interred in it at Durham, and persons of distinction at Gloucester. It frequently had two large openings on either side of the west door, as at Combe, Houghmond, Bristol, and Beaulieu, to admit light, and to enable the priors and monks of dependent cells to take part in the proceedings on important occasions. It is approached through a vestibule at Chester, Bristol, St. Mary's (York), and Kirkstall; and by a passage at Wells, Southwell, York, and Lichfield; at Belvoir (Nichols's Leicester, ii. 80) it stood in the centre of the cloister.

The *Slype* was a narrow passage between the transept and the chapter-bowse, which occurs in the Benedictine houses of Winchester, Gloucester, Durham, Finchale, and St. Alban's, where it led to the monks' cemetery. Its place is supplied by the *Sacristy* in Cistercian houses. It occurs in the Clugnia convent of Bromholme, and in that of Austin Canons at Newstead.

The *Dormitory*\* invariably adjoined the church, as the monks had, on the mornings of certain festivals, to sing matins at an early hour. For this purpose the Cistercians constructed a staircase out of the south transept leading to the dortor, and it usually extends in their houses over the chapter-house. It appears in the same position at Beldigh (Premonstratensian). The ordinary position was the east side of the cloister, as in fourteen abbeys of France mentioned by M. de Caumont; but it was built on the west at Durham, Chester, Worcester, Shrewsbury, Laocok, and St. Alban's, by Benedictines; at Fountains, Kirkstall, and Rievale, by Cistercians; at Hexham and Thornton (Proc. Ass. Soc., ii. 119; Arch. Jour., ii. 357), by Austin Canons; at Leiston and Eastby (where it is of two alleys, and detached by Premonstratensians. At Thourout and Senanques it is over the east walk of the cloister. It occupied at Crowland the east side of a second court, in which the refectory was to the north, the granaries being on the south-west, and the guest-house on the south. Cellars are frequently found under the dormitory, as at Westminster, Durham, and Sherborne, St. Mary's (York), Finchale and Shrewsbury (Benedictine), Bromholme (Clugnia), White Friars, Coventry, Thornton and Bolton (Austin Canons), Kirkstall, Rievale, and Farness (Cistercian). One portion of this substructure was the *calefactory*, a chamber warmed with a stove or long heating-pipes, serving as a place to provide fire for the censers, and warmth to the monks in cold weather; the chapter occasionally met here. There were two at St. Gall, one for the brethren, and a second for the sick and novices. The dormitory stood over the south aisle at Wenlock and Wymondham. Twelve monks slept in the roof-loft at St. Alban's, as watchers. The beds were ranged along the walls under the windows; the abbot, by the Benedictines (r. xxi.), Clugnia, and Austin Canons' rule, slept in the centre of the room. The cellarer then only had a separate chamber; but in later times the abbot or prior possessed his lodge, and the dortor was subdivided into separate cells, with doors made three-parts of trellis-work, so that the chief official could exercise a supervision of the whole. This plan was advantageous for silence, retreat, and devotion; and it is found in 1370 at Noyon, and, a century earlier, in the Black Friars, at Gloucester (Gent. Mag. 1860, p. 340), where the cells had stone partitions. A lamp burned all night in the dortor. At Tykford (Monasticon, v. 206) there were five cells. The dormitory of the conversi remains at Wenlock (Clugnia), (Potter's Mon. Rem.).

The chamberlain had charge of all the beds and furniture in a convent. The monks took their meridian (Monast., ii. 230) and changed their shoes before and after prayers in the dortor by day; in cold weather, when the spring in the cloister was frozen, they used hot water in the dortor; an additional reason for building the calefactory at no great distance from it.

The *Refectory*† ordinarily occupied the south side of the cloister, for reasons already assigned. At Sherborne, an exceptional case, it is to the west. Of course, where the cloister was on the north of the church, the refectory was on the north, but still almost invariably fronting the church, with Premonstratensians, Benedictines, Cistercians, Clugnians, and Austin Canons. The other deviations from the rule are at St. Augus-

tine's, Canterbury, where it was on the east; at Joreville (Cistercian) on the south-east, beyond the dormitory; and on the west in the Black Friars, Gloucester. In the House of the Bernardines at Paris, at Nately, Furness, and in the Marvel of Mont St. Michel, and apparently at La Luzerne, the refectory was below the dormitory. It was above a cellarage Dunfermline, Battle, Reading, Beauport, Sherborne (Benedictine), Eastly and Leiston (Præmonstratensian), and Kirkstall (Cistercian). At Clairvaux, Savigny, and Bonport, at Tynemouth, Fountains, Vaux de Senay, Beaulieu, and Rievale, it stood north and south, at right angles to the cloister. The wall pulpits, which formed the guest table, remain at Chester, Eastly, Beaulieu, Shrewsbury, and St. Martin des Champs, and were used by the reader of holy books during dinner. At Winchester College to this day the Gospel is read at election dinner. The pulpit of St. Laura, Mont Athos, is of wood. The refectory of Fountains, Nately, Eastly, Villers (Schayes, iii. 40) in Belgium, and St. Martin des Champs, has two aisles; those of St. Mary's, York, the Bernardines, at Paris, of the fourteenth century, and of Alcobaca, have three. Mural paintings enriched the refectory, as at Villers, Clugny, Fontenelle, Luxueil, St. Germain de Flais, St. Michael, Antwerp, and St. Martin's, Dover. Leonardo da Vinci painted his "Last Supper" for the refectory of St. Dominic, at Milan. Adjoining the refectory was the torgema, or dresser, for cups, plates, &c. In the thirteenth century the refectory was sometimes apsidal; and the early form of the Eastern refectory, and those of Palermo, with three apses; and St. John Lateran, built by Pope Leo III., was an imitation of the Roman triclinium. (Lenoir, ii. 229). At St. Laura, Mont Athos, the refectory is in the shape of a Greek cross.

There were four kinds of refectory.—1. The summer. 2. The winter (as at Villers and St. Beatus's, St. Omer). 3. That of conversation; and 4. The misericord, for eating flesh meat (Fosbrooke, Brit. Mon., ch. xlv., xviii.; Ducange, s. v.; Monasticon, v. 206). At Tynemouth, we find a common hall on the west, and the new hall on the south of the cloister (Monast., iii. 311).

The *Kitchen* was, of course, an indispensable adjunct of the refectory, and invariably adjoined it, although, as at Durham, it occasionally stood behind it; its ordinary position was on the side. There were two—one for the convent, and a second for the infirmary. Our statements refer to the former. That of Marmontier was shaped like a bottle; those of St. Florence Vendome, Saumur, Villers, and St. Pierre de Chartres (thirteenth century) were round; those of Pontlevois, Fontevault, Durham, and Glastonbury, were octagonal; and those of St. Ouen at Rouen, St. Gall, and Fountains, square. The kitchen took charge of the hutchery and fishpouids; and the leibomadarius presided over the kitchen, entering for a week, each monk taking his course in turn. The kitchen of Fontevault had small apses in each face.

The *Lavatory* is found in the thirteenth century near the refectory of the Génovévans at Paris and at Clairvaux, and in the south cloister walk at Westminster, Wells, Chester, and Gloucester; at Durham it was a detached building in the garth, probably built over the spring, which formed the first simple lavatory. Near the lavatory is often found a long laundry for the towels.

The *Cellarage* usually formed the west side of the cloister, and sometimes joined the guest-house. A magnificent substructure of two aisles remains at Vincellottes, Fountains, and at Beaulieu; the cellars included granaries, beer, wine, and oil vats. On this side were the guest-house at five French abbeys mentioned by M. de Caumont, and magazines at seven others, also described by the same distinguished author. They were usually vaulted and divided into aisles: a good specimen remains, but on the east side of the cloister extending southward, of the time of Edward the Confessor, at Westminster; inferior, however, to the grand buildings of Vaucilar and Eberbach. The same purpose was served by the large granges, buildings divided into three aisles, as at Ardennes, Maubisson, and St. Vigor, for the convenience of having one alley free for the passage of carts.

The *Treasury*, sometimes called also the refectory, was generally near, or, as at Westminster, as at Canterbury; in the transept at Chichester; and there is frequently a deep recess in a crypt, to hide the sacred plate in time of danger, as at Canterbury. At Clermont, Limoges, and Nur-

bonne, the treasury and sacristy occupy two of the choir chapels.

The *Exchequer*\* derived its name from the chequered cloth divided into squares, for the convenience of casting up accounts. With the offices of the chamberlain and cellarer, it ordinarily stood in the great court, adjoining the cross round which the conventual market was held.

The *Library* at St. Gaul was over the scriptorium and adjoined the Presbytery, and was generally placed towards the north to preserve the contents from insects. Those of Wells and the Grey Friars, London, were of considerable length. At Septuagesima an inventory was taken. It is next the slype at Finchale; south of the choir at Wimbome; over the chapter-house at Dunfermline, Eastly, and Lichfield; and in an upper room near the south transept at Westminster, and near the north transept at Hereford.

The *Scriptorium* (Lenoir, ii. 374; Fosbrooke, Brit. Mon., ch. xlv.) was usually in the cloister or adjoining the church, but in the foreign Cistercian houses in the second or inner cloister; the preceptor had the charge and furnished materials to the librarii, who made new books, and the antiquarii, who copied or repaired the old books.

The *Archive* or *Muniment-room* (Lenoir, ii. 69, 375) was sometimes over the church-porch, as at Peterborough and Fontenelle; in the south-western tower at Clugny, where the north-western was the prison; in an isolated tower, as at Martin-des-Champs and Vaux de Senay. It contained the matriculation lists, chartularies, terriers, and registers. The provost kept the key. It was occasionally built over the sacristy; it is near the south transept at Chichester, and is of large dimensions, adjoining the choir at Salisbury.

The *Parlour* (Fosbrooke, Brit. Mon., ch. xli.; Dneange, iv. 142; Lenoir, ii. 327), common or reception-room, where the monks gave directions to the servants, traded with merchants, or conversed with friends, adjoined the gate or refectory; it was on the east of the cloister at Clairvaux, St. Mary's, York, Walsingham, Beaulieu, on the north at Clugny; on the south at Fountains and Cîteaux; south-east at Shrewsbury; west at Durham; north-west at Newstead. The Cistercians had three parlours; (1) for visitors; (2) for conversation; (3) for confession.

The *Abbot's or Prior's Lodge* is called the palace in the plan of St. Gall. Suger, in the twelfth century, and the prior of Canterbury before 1120, lived in a single lodge. In the ninth century it was a large building at Pontenelle; at Pontigny it contained four rooms; at St. Gall it consisted of a mansion, including a bed-room and solar, and servants' offices, kitchen, bath-room, and cellar. It often was provided with a chapel, as at Ely. It adjoined the church usually in Benedictine houses, was detached by Cistercians, and by the Austin Canons was connected on the west side of the cloister with the nave, generally on the south-west by a staircase, and adjoining the novices' hall, as at Haughmond, &c. It was on the south-east of the cloister at Durham, Kirkstall, Leiston, and Newstead; on the south-west at Westminster, Crowland, Hulne, and Bridlington; on the east at Shrewsbury, on the north at Sherborne, on the north-west at Tynemouth, on the south at Finchale, and north of the north transept at Eastly and Castle Acre; on the north-east at Wenlock, and of two stories.

The *Infirmary* was among the Cistercians a large hall for exercise, with separate cells like a dormitory, as at Ousecamp, near Noyon, founded 1130. At St. Gall it contained a chapel, dormitory, refectory, and consultation-room, standing to the north behind the church, and ranged round a cloister. In England it was on the east of a small cloister, and furnished with a hall and chapel at Canterbury, Westminster, and Gloucester; south-west of the nave at St. Alban's; detached on the south-west at Hulne and Shrewsbury; west of the dormitory at Durham and Worcester; south-east of the cloisters at Castle Acre and Peterborough; and on the east at Rievale, Binham, and Bridlington.

The *Guest-houses* were usually near the gate. One was built at Fontenelle at the close of the seventeenth century. It was not always a detached building, and frequently formed a hall, of two alleys at Beaulieu and Fountains, with bed-rooms opening off it. At St. Gall, in the ninth century, it consisted of two large buildings, with every convenience and servants' rooms. At St. Alban's it was an enormous range of rooms, with

stabling for three hundred horses. It was on the west side of the cloister at Fontenelle and St. Germain-des-Prés, at Newstead, Beaulieu, Eastly, and in the Norfolk houses (Hirrod's Gleasings); on the west of the great court at Durham, Finchale, and Eastly; on the north at Tynemouth, and Bridlington; over the great gate at Thornton; south of the cloister at St. Alban's; south-east at St. Mary's, York; east of the chapter-house, Worcester; south of the refectory at Shrewsbury; detached southward in the great or outer close at Furness and Hulne; north-east of the cloister at Tintern; on the north, over cellarage, at St. Martin's, Dover; and parallel to the refectory at Glastonbury (Collinson's Somerset, ii. 263). The Hospice, called Salle des Gardes, remains at Caen.

There were also guest-houses for travelling religious, and the poor, and pilgrims.

The *Tribunal*, or *Court*, and *Prisons*.—The tribunal and prison usually adjoined the great gate, as at St. Stephen's, Caen; or occupied the chamber above it, as at St. Alban's, Tewkesbury, Westminster, Malling (Mou., 118, 383), Hexham, and other abbeys. The dungeon is under a tower at St. Gabriel Calvados; near the transept at Berne; on the south of the chapter-house at Durham; at Clugny it had neither stair, door, nor window; at St. Martin des Champs was subterranean; and at Hirschau barely permitted the prisoner to lie down.

*Other Buildings*.—The gate-house was sometimes provided with a chapel in the upper story. A charnel was a frequent adjunct to an abbey, with a chapel over the arnary. The novices and choristers had a separate building and inner school. Glastonbury and St. Victor, and other houses, furnished seminaries or public schools, held in the outer school, usually divided by a screen or wall, to mark distinction of rank or attainments; besides these were the alms-house, surgery, dispensary, herbarium, industrial buildings, and workshops, mills, stalls, and stables, barns and sheds for agricultural produce and implements; while Hulne exhibits all the features of a fortified position, and others had on the coast, as at Furness, watch-towers. Battle has a fortified gate (Lenoir, i. 77; De Caumont, *Abécédnaire*, 178). Strong walls still remain at St. Stephen's, Caen, and St. Germain Auxerre; and forts defended the abbeys of Montpeyrnux and Condat. In the thirteenth and fourteenth centuries nearly all the French abbeys and Cathedrals, as at Alby, Beziers, and Narbonne, were fortified, owing to the continual wars (Viollet le Duc, i. 227, 262; ii. 376; Lenoir, ii. 491). At Casnel a castle forms the west end of the cathedral. Holy Cross, Beative, and Crossagnel were fortified. The alms-house (Fosbrooke, Brit. Mon., ch. xlii.) of Westminster stood on the west side; the sanctuary occupied the enclosure on the north side of the abbey. The alms-house of St. Stephen's, Caen, is detached at some distance on the north side. Charnels occurred at Steinen, Hereford, Hythe, Worcester, Norwich, St. Peter's-in-the-East, Oxford, Ripon, and Lynn (Gent. Mag. N.S. vii. 156).

In conclusion, the old distich informs us that the Franciscan loved the town, the Jesuit (the worst of architects) the great city, the Cistercian the valley, and the Benedictine the mountain. In England, the Benedictine was the citizen and most learned of monks; the Austin Canons, with their long-drawn aisles, were proverbial for their love of preaching and logic—the term, doing Austins, i.e., disputing with these monks, was long a proverbial exercise at Oxford; the Cistercian, with his secluded convent, the educator of the poor, an eminent friend of the labourer, a class which he employed in large numbers as conversi, was a recluse devoted to industrial pursuits in works and farming; the Clugniae combined the fine arts, reading, and study, with bodily labour and agriculture; while the cells of the Carthusian, a gloomy brotherhood, the Dominican was the preacher, eager for the development of intelligence, the champion of orthodoxy, and the devotee of philosophy; the Franciscan Minor, a name harkening all the brothers were equal by their vow of poverty, was the preacher of equality. It was a fatal error at the Reformation not to have converted their beautiful and stately houses to charitable uses, study, and prayer; but we may still glean from them all that they held of good and beneficial to humanity, agriculture, and art, and go forward ourselves with a firmer foot by retaining the lesson in our hearts; and, however widely our opinions in religion may differ from many of

the tenets of those who built them, we shall do well to remember that in their sacred enclosures he buried the enmities of many generations.

ON ACOUSTICS.\*

The subject to which I venture to invite your attention is that of acoustics, or the science of sound; in reference (of course) to its bearing on the arrangement and construction of those buildings where the free transmission of sound is of importance.

It will not, I think, be deemed necessary that I should advance any apology for the subject itself. The proper construction of buildings intended for music or public speaking, is a point of vital interest to every architect, as under this category may be comprehended all the more important works that come into our hands; and such buildings (however excellent in other respects) cannot certainly be said to have fulfilled the design with which they were erected, unless they have been made favourable to the easy transmission of sound. A knowledge of the laws that regulate this transmission, and of the methods necessary to bring a building into conformity with those laws, is then most desirable to us.

A very considerable time has elapsed since a paper on this subject was read before the Institute; and this consideration, coupled with the fact that even such books as exist on the subject are not generally known, induces me to hope that it may be possible to lay before you some already-ascertained facts of interest, but which are not so familiar as they deserve to be.

I must disclaim, however, the ability to present anything new, in any other sense than the one just indicated. The subject has always occupied a share of my attention as a reader, but not as an experimental philosopher; and lately, it has become my duty to search very thoroughly for all accessible information that relates to it, and it has been the difficulty of collecting scattered facts, and of obtaining even the titles of books, that has principally made me feel that an account of the books and other sources of information accessible, and a condensed exposition of the most important points to be gleaned from them, might be of use to others.

In the commencement of an inquiry into the laws governing the distribution of sound in buildings, a student would naturally seek information on the nature of sound and the laws of acoustics, from treatises on physical science. The works best worth consulting are the following, and I name them now, to avoid interrupting the main subject afterwards:—

"The Treatise on Sound," by Sir John Herschel, published in the "Encyclopædia Metropolitana," and since issued separately. This is the best work on the subject in English; but it has the drawback that it does not contain any account of the discoveries of the last thirty years, having been published in 1830.

Mrs. Somerville's "Connection of the Physical Sciences."

Detached Papers by Professor Wheatstone.

The article "Acoustics," in the "Encyclopædia Metropolitana."

Arnott's "Elements of Physics."

Brewer on Sound.

"The Cours de Physique" of Mons. Biot.

"Cours de Physique" of Pouillet.

"Traité d'Acoustique," by Chladni; a standard work; also published in German.

And the writings of Savart and Biot, and others, published in the "Annales de Physique et de Chimie," and the lectures of Savart, reported in the "Institut."

On the special subject of buildings, we have, published in England,—

Saunders on Theatres.

Wyatt on Theatres, quoted in "Gwilt's Encyclopædia."

Iman's abstract of evidence connected with the rebuilding of the Houses of Parliament.

A considerable number of papers scattered through the *Builder*, from 1846 to the present day, especially those by Mr. Scott Russell, before the Royal Society and this Institute, in 1847, and a few small pamphlets and incidental notices in books on other subjects. It is right to add that this is not a complete list, but only a selection.

Published abroad, we have,—

"L'Acoustique et Acoustique des Salles de Réunion Publiques," a very practical and sensible little book.

"Rhode, Theorie der Verbreitung des Schalles

für Bunknster," a small but very valuable pamphlet.

Observations by Chladni in his book, and in contributions to the "Allgemeine Musikalische Zeitung;" and a few other papers and hooks.

I am, moreover, informed that a French work of great value on this subject exists, different from any of these, but the title of which I have been unable to learn.

From almost any one of the first-named books a general knowledge of acoustics can be obtained; and if we make an attempt to sum up briefly what is known about sound, leaving out, as not essential to our present purpose, both the refinements of mathematical calculation and the elegant results of experiments on undulation, vibration, the pitch of musical notes, and other departments of the science, we arrive at a few definite results of philosophical inquiry which can be briefly stated, and will be enough for the present purpose.

Sound, then, may be regarded as motion made sensible to our ears; and the sense of hearing as a very refined sensitive and delicate sense of touch. A moment's thought will suffice to remind you, if this description seem at first sight startling, that there is no sound unaccompanied by motion, that there is but very little motion without audible sound; and lastly, that if motion exist, but he so cut off from our ears that no communication can take place, we hear no sound.

Sound is not, like light, conveyed through an imponderable medium; it, on the contrary, travels through all the substances, solid, liquid, and ætiform, that surround us; and it is precisely that class of substances best suited to convey motion, which forms the best conductors of sound; while those bodies that deaden and destroy motion, render sound also. For example, a rod of elastic wood, or of iron, will convey readily any motion, from one end of it to the other, and such a rod forms one of the best known conductors of sound.

A heap of sand will, be it only thick enough, check the force of the most powerful cannon-ball, and, were there no means of hearing round it, such a heap would equally deaden the report of the cannon; unless, indeed, the air lurking between the grains of sand conveyed some faint impressions to the listener.

We are, however, more familiar with the atmosphere as the conductor of the sounds that reach our ears than with any other medium, and as it is through the atmosphere alone that the sounds heard in large rooms are transmitted, we shall have little occasion again to refer to the conducting properties of other media.

The atmosphere, under favourable circumstances, will transmit to great distances any agitation that is roused in it. As an instance of this we may refer to the experiments of M. Biot. This gentleman having an opportunity of operating with a very long cast-iron pipe forming part of an aqueduct in course of construction at Paris, found that even when the pipe was 1,040 yards, or more than half a mile long, the explosion of a pistol fired into it at one end would blow out a candle at the other, and that the lowest whisper at one end was as distinctly audible at the other as to the speaker himself. This experiment succeeded better at night than in the day-time.

Although, however, the air in a tube where any lateral escape is impossible shows this marvellous sensitiveness, we do not find a similar result from speaking in open, unconfined air. It is a matter of familiar experience that sound under these circumstances decays and dies away, till at last it ceases to become audible. This decay is only the natural consequence of the fact that the original force is constantly spreading through a wider and wider space, and is getting (so to speak) diluted.

A familiar illustration to you all will be the gradually widening circles that spread on the surface of smooth water from a spot where you drop in a pebble, and which, weakening as they widen, at last fairly vanish into the flat unbroken lake.

The analogy between the progress of sound and that of water-waves thus roused, is, however, less complete than is ordinarily supposed, for it usually happens that, from the first, sounds have an initial direction impressed upon them, and that they travel further in this direction than in any other. The most familiar instance to us all is that of the human voice, which is always heard very much further in front of the speaker than it is at his sides or behind him. The human voice is not, however, an exceptional case; it is well to know that the larger number of sounds have something of this propensity. A good example is a tuning-

fork: when the sound of this is excited it will be audible to a much greater distance square than otherwise; that is to say, you will hear it better if the ear is in a line with the two arms, or in a line at right angles to one joining the two arms, than it will if the fork is turned a quarter round, so that a line joining the two arms would be at an angle of 45° to one drawn from the ear to the fork.

The decay of sound is very much prevented not only by any initial direction it may receive, but also by any accidental circumstance that prevents the agitations in the air from spreading laterally, even if it be only one side that is confined. Thus sound will travel a long distance along the ground, and it will be very audible along a wall, because the angle formed by the wall and the ground forms two sides of a sort of tube, and thus prevents part of the lateral escape. There is an instance of this sort recorded in Dr. Hutton's Dictionary, that has been often quoted: a garden wall exists in Dorsetshire that will, be states, convey in this way a whisper 200 feet, without loss of distinctness.

Sound in an open atmosphere travels in a straight line; should it, however, encounter an obstacle, or pass the limit of any boundary, it always spreads to some extent behind that obstacle or boundary. For instance, in a church an auditor exactly behind a stone pier and close to it will probably hear worse than if nothing were between him and the clergyman; but still, even close to the pier he will hear; and, if keeping always the pier between him and the speaker, he moves further back, he will soon reach a point where he will hear as well as if his ears as if there were no obstacle. I use the words "with his ears" advisedly, because the eyes always assist us in our attention to public speaking, and, of course, this assistance would be lost in the situation I have supposed.

Sound, when it encounters an obstacle directly opposed to it is, however, beaten back, or reflected; the phenomenon of echo is familiar to all, and is the result of such a reflection, sending back the sound from a considerable distance. It was laid down by Mr. Scott Russell, in the paper read by him before you on this subject, in 1817, that in the case of sound, the movements of which are closely allied to water-waves, reflection does not take place except where the wave impinges on the obstacle at an angle greater than about 30 degrees.

Where the angle is less than this, the sound does not again leave the obstacle, but simply runs along the face of it,—in fact, is conducted along it, in the manner we have just had occasion to mention. All, or almost all, whispering galleries are examples of this conduction, that at St. Paul's being a very good one.

Should the angle, however, at which the sound falls approach nearer to a right angle, it will be reflected back, and will follow the same law as the reflection of light; that is to say, the angle of reflection will equal the angle of incidence, so that all sounds to be heard, as echoes by the speakers, must fall on a reflecting surface exactly at a right angle, and if a sound reaches any surface at an angle of, say 45 or 60 degrees, from the right, it will be thrown off at the same angle, 45 or 60 degrees, but to the left.

It will be familiar to all that there are some echoes that can repeat one syllable, some two, some three, and so on, simply because in the one case longer time elapses than in the other before the echo gets back; and it will always be found when the sound takes longer time to make its journey to the reflector and back, it is because it has had a greater distance to go over. From this we gather that the speed at which sound travels, rapid though it be, is not so great but that the effect of even a moderate addition of length is quite perceptible in the longer time it takes to reach the ear. In this particular sound differs from light and electricity, which travel so fast, that unless with great distance, the time they consume in going cannot be detected.

The speed of sound in the atmosphere varies with the greater or less density of the medium. It has been very frequently measured, and Herschel gives, as the results of the best investigations, that sound in dry air at the temperature of 62 degrees travels over 9,000 feet in eight seconds. This statement is easily remembered, but it may be useful to add that 9,000 feet, or 3,000 yards in eight seconds, equals 1,125 feet, or 375 yards in one second, or 12½ miles in a minute.

As a practical application of this fact, I may extract from the same author the remark, that if music were performed in a room 53 feet long, with an echo in the extremity, each reflected note, should

\* Read by Mr. T. Roger Smith, as elsewhere mentioned.

there happen to be a passage with as many as ten notes in a second, would exactly interfere with the following note sounded by the musician. Passages as rapid as this constantly occur in modern music, and it is not a very uncommon thing to hear them thus spoiled.

The varieties in the nature of sounds are very great. Thus we have music, articulate speech, and noise; we have variations of pitch, of quality, of loudness, of volume, of intensity, and of distinctness. We have in music combinations of sounds in succession to form melody, and simultaneously as harmony; and of sounds heard together, we have some combinations that are harmonious, and some that are discordant.

As an illustration of some of these peculiarities, let us suppose the string of a harp struck and left to sound. We hear a long, definite note gradually dying away, but which, faint though it becomes, still retains its pitch. If, now, we examine the harp-string, we find it constantly vibrating to and fro with great rapidity; as it gets to rest, its excursions on each side of the line of repose grow shorter and shorter, but they neither become more nor less frequent than when they were most violent. It is clear that each movement of the string must rouse a movement in the air, in fact, strike a blow upon it; and we begin now to trace some connection as likely to exist between the regular recurrence of these blows and the equable pitch of the note the string gives out, and also between their diminishing vigour and the fading loudness of the sound. It is, in fact, as I dare say you all know, the regular recurrence of distinct impressions which occasions all prolonged sounds, and with one or two exceptions, this is always a consequence of vibrations. The way in which the separate shocks on the ear produced by the vibrations get fused into one sound corresponds very closely to what happens to the sight when a spark of fire is swung round so rapidly as to appear a fiery circle: the impression of the sound on the ear, like that of the spark on the eye, does not die away the very instant the exciting cause stops; and if that impression be renewed before the recollection of it has had time to vanish, the sense of hearing loses the consciousness that any intermission has taken place.

Very bright lights remain longer impressed on the eye than the image of ordinary objects, and similarly very intense sounds remain longer in the ear, and consequently fewer repetitions of them in a second are required to produce a continuous note: so that though it is impossible to hear sounds from an ordinary cord making fewer than 30 vibrations in a second; yet Savart has succeeded in making audible a sound composed of only 14 pulses, or 7 complete vibrations, in a second; and, at the other extremity of the scale, in rendering audible sounds up to 24,000 vibrations, or 48,000 pulses, per second. The greater or less frequency of the vibrations occasions the sound to be more or less sharp, and the actual correspondence between the number of vibrations in two notes determines their concord or discord when sounded together.

For example, the lowest C on a grand piano is said by Brewer,\* to require 32 pulses in a second for its production; the sound most accordant with that is its octave, the number of whose vibrations always bears the relation of two to one to those of the original sound. Thus, in the instance just selected, 64 vibrations in a second are required to produce the C an octave above the one we started from. If the dots in the diagram represent pulses, it will be seen that when a note and its octave are sounded together, every vibration of the fundamental note coincides with a vibration of the higher one.

If G, the fifth above this C, had been substituted for the octave, we should have struck a note containing 48 pulses in a second along with the C containing 32 such pulses; that is to say, three pulsations of the higher note to every two of the lower one; and, as the diagram shows, only every other pulse of the fundamental note would have coincided with one of the upper one. This is the next most accordant interval.

The relation between a note and its major third is expressed by that of 4 to 5, or 32 to 40, so that this interval is less perfectly consonant.

Two notes the pulses of which hardly ever coincide, sounded together, produce a discord. For instance, the seventh above any note bears the relation to it of 15 to 8, and this is consequently a very imperfectly consonant interval.

Beyond just stating that all natural sustained sounds are produced by the vibrations of elastic

\* Whose numbers do not precisely correspond with those given by some of the French writers.

substances, it is impossible to enter upon the very complicated and very interesting investigations that Chladni, Savart, Wheatstone, and others, have conducted upon undulation and vibration in all its forms, or to describe to you the elegant experiments by which the motions of vibrating bodies are rendered visible.

The transmission of these vibrations through the air is, however, a matter of some moment to our subject. Each impulse of the vibrating body makes an impression on the air immediately adjoining it, which impression instantly passes onwards and outwards, leaving the atmosphere behind in a state of quiescence. A wave of sound is, in fact, a state of momentary compression travelling with the speed of the wind away from its exciting cause into space; and it is accompanied by a displacement of particles, slight, indeed, but still actual, and, in fact, when the impulse has lost the power of moving the air at all it ceases to exist.

Should this wave meet with an obstacle that reflects it, it will travel back through the atmosphere to any point to which it may be directed by the reflecting body. Any agitation of the air which from circumstances, such as reflection, for example, is made to take the form of regular pulses, will, if these are but frequent enough, become an audible sound. Take a familiar instance.

Suppose that we have a pipe, of any length shorter than about 35 feet, closed at one end, and make an agitation in the air at the open end. As that the separate movements are so far apart that the impulses leave long intervals between them, no sound is heard; but as soon as the movement is brisk enough for a pulse the moment it has travelled to the bottom of the pipe and back, to be followed at once by another, an audible sound will result, the pitch of which depends on the length of the journey each pulse has to make down the pipe and back again. If we go on making the agitation more brisk for a time, no alteration, except in loudness, will be audible, the pipe seeming, so to speak, to keep the agitation that wants to enter it waiting till the one that is there emerges.

But suddenly the sound heard will jump an octave, and we shall find, if we take the proper means of investigating, that the air in the pipe has divided itself into two vibrating lengths. Increase the agitation, and soon another jump takes place, the air in the tube dividing itself into three portions, and so on,—the points of division being termed nodes. Thus, for example, by blowing more or less violently into an organ-pipe, we can produce either its fundamental note, or the octave above that note, which is the sound proper to a pipe of half the length, or to the original pipe divided into two portions by one node, or the twelfth above, which is the sound proper to a pipe one-third the length; or to the original pipe divided into three portions by two nodes, and so on.

These divisions equally occur in vibrating strings, and it is remarkable that even where a string or a pipe is sounding the gravest note it variably coexists along with the primary ones, giving out the octave, twelfth, &c. These sounds are called *harmonies* of the principal sound, and an acute ear can detect their presence constantly; perhaps nowhere so readily as in the note of a large bell.

It becomes of importance to us to know all these circumstances, if we reflect that any room may be regarded as nothing else than a great organ-pipe, in which, if a suitable agitation be roused, sounds, no doubt, will be emitted by the air. Nor is there any safeguard in the size of the room; for, although a room be too large for what would be its primary note to be audible, the harmonies of that note, some of them, will be quite appreciable; and it is the presence of these, that causes what is known as the *note* proper to a room.

As this note cannot be ordinarily avoided, the only thing to be done in relation to it, is to see that the dimensions of the room, each way, bear some simple numerical relation to one another: so that if undulations are roused that travel from end to end, and others that travel from side to side, the sounds due to the two may blend harmoniously, and not clash discordantly.

The last point to which I have to draw your attention, is the sympathetic vibrations that sounds can excite in sonorous bodies. If a tuning-fork is sounded in the air, its note is extremely feeble, but if it be rested upon a pianoforte, or a table, a marked alteration in sound is audible.

Half a dozen tuning-forks, of different pitch, tried in succession, will all rouse the same pheno-

menon, and the truth is, that small as they are, each one has set the entire material of the pianoforte or the table in vibration, and that, too, in accordance with its own rate of motion, so that the whole table or the whole piano has become, for the moment, a part of the tuning-fork, and is emitting sound in unison with it.

If we now vary the experiment, and hold our different tuning-forks near the open end of an organ-pipe or a flute, we shall not get the same uniform result. Those forks which emit the sound the pipe or flute would emit if blown into, or one of its harmonies, will be found to set the air in the tube into sonorous agitation, and the note they emit will be greatly reinforced; but the other tuning-forks, whose note is not related to that of the pipe in question, will be found to have only a trifling influence, if any, over the air in the tube, and this sound will not be perceptibly reinforced.

Thus we arrive at a fact of the greatest importance, namely, that some vibratory bodies will move in unison with almost any sound, while others, voiced to emit a particular note, will reinforce that note, or those related to it, but will be useless, or almost useless, as regards other notes.

It now becomes desirable, having considered some points relating to the nature of sound and its transmission, to ask, "What means have we of influencing sound in a building? and what obstacles is it likely to encounter there, compared with what it would meet with in the open air?"

There are two familiar instruments in everyday use, and a third some forms of which are also well known, which supply a sufficient answer almost without words to the first question, namely, "What means have we of influencing sound in a building?"

The two instruments I first alluded to are the violin and the speaking-trumpet. The third is any common reflector, say the sounding-board of a pulpit.

If we take any familiar sounding object, such as, for instance, a watch, and note how far its beat can be heard in a room, and then place it successively in the mouthpiece of a speaking-trumpet, in the focus of a parabolic reflector, or against the body of a violin, we shall find that in each case we have influenced the sound; and so far as I know, we have no possible means of influencing the sounds emitted in buildings, except such as bear an analogy to one of these three.

There will be something to be said by hand-and-foot upon impediments, and the avoidance of them; for, after all, except in extraordinary cases, the whole secret of success in building, for sound, lies in simply doing as little harm as possible; but as far as assistance to sound goes, I repeat, we cannot get beyond the teaching of the mirror, the speaking-trumpet, or the violin.

To return to the watch, we shall find that both the reflector and the speaking-trumpet cause its tick to be heard much more loudly at the same distance, or to be audible to a much greater distance than when uninfluenced; but only in one direction. The person to whom the trumpet is pointed, or towards whom the mirror faces, gets more sound; but a person at the side gets less.

Were the sound of such a nature as to be capable of being closely examined, it would be found in both cases to be deteriorated in quality of tone; and I am inclined to think more so by the reflector than by the speaking-trumpet, and in each case, if articulate, or otherwise very sharp and defined, it will have lost a little of its distinctness.

If, now, we take the violin and place upon it the watch, we shall find that the sound will be audible to a greater distance than when the watch is by itself; but will not be (as in the other cases) confined to one direction only. It will not, probably, extend in any direction so far as the trumpet would throw it, but will be much more equally heard; while, and this is the great point, whatever change takes place in its character, is entirely for the better. None of its distinctness is lost, but its tone is improved; and should the violin be a very fine one, and something with musical sounds he substituted for a watch, the effect on the quality of the sound will be very marked. A string, for example, stretched to sound a certain note, and excited by a violin bow, will give out its proper note, indeed, but its voice will be poor, thin, and weak. Transfer the string to the instrument, draw the same how across it in the same way, and the note of the string, re-inforced by the vibrations of the body of the instrument, will be something totally different, incomparably firm, and yet identical in pitch and sharpness.

We ought, then, in building for sound, to take

a lesson from each of these instruments. What are their peculiarities? In the reflector and the speaking trumpet, the influence upon sound is almost wholly a matter of form. In the violin it is also, no doubt, a matter of form, but as much if not more a matter of materials combined with form.

We gather, then, that we may, as in the speaking trumpet, impress an initial direction on sound as emitted, and guide it forward, or that we may aid its progress by reflectors behind or above the speaker, but that if we want to support or improve it, we must have recourse to the resonance, or sympathetic vibrations of some sonorous body, capable of lending itself to all the varieties of sound produced near it.

The common sounding-board often fixed over pulpits, acts as a reflector, but usually (being made of thin wood), as a resonant reflector, a much less dangerous neighbour than a hard smooth surface of plaster or stone, which has the disadvantage, that it reflects a sharp and somewhat spoiled echo, that travels in the same direction, indeed, as the primary sound, but is a little behind it, and seems often to mar its distinctness.

It will be readily understood that a slanting reflector overhead, to beat downward and forward rays of sound that would otherwise escape towards the ceiling and be lost, is likely always to do good, and can in no case be so injurious as one behind the speaker; and it need scarcely, I think, be added that the only reflectors that can be of advantage are those that throw the sound forwards in the same direction as that in which the speaker is speaking. An echo reflected down from a high ceiling, or worst of all, back from an opposite wall, will always be disagreeable.

It may be more appropriate here than afterwards, to notice a curious application of the reflector to pulpits, which was some years ago rather extensively made use of, and is illustrated in the model before you.

It appears from a pamphlet published by Rivington in 1829, entitled "Description of a Parabolic Sounding Board erected in Attercliff Church, by the Rev. John Blackburn," that this church is a parallelogram, 95 feet by 72, and 56 feet high, with an elliptical recess 32 feet wide by 10 deep for chancel, and the pulpit placed in the centre of the centre aisle, in front of the chancel. There is no clerestory, but there are pillars supporting a gallery. In this church it was impossible for the preacher to make himself heard, and after shifting about the pulpit in various directions with no marked advantage, he determined to erect behind the pulpit a sounding-board like a hood—parabolic in section with his head in about the focus of the parabola. He relied upon the property of that curve to reflect as parallel a series of rays diverging at the focus, and he adds, that the result exceeded his most sanguine expectations.

The congregation were now able to bear the preacher, and the remote seats of the church became some of the best. The inventor of this expedient was Mr. Blackburn himself, and he brought it before the public in this pamphlet, which is admirably and scientifically written, and also laid it before the Royal Society and the Society of Arts. With the last-named Society he deposited a model, which has since passed into the possession of the London University College, and it is by the courtesy of the secretary of that college, and of Professor Potter, that this model, which is the one before you, is intrusted to me for this evening's paper.

To proceed, however. In the Society of Arts Transactions I find two letters from Mr. Farish, the Jacksonian Professor at Cambridge, who had had one of these reflectors put up in his church. He reports most favourably both upon Mr. Blackburn's reflector and his own, saying that the sound is improved in every part of the church, and especially that of the more distant parts; but he alludes casually to inconveniences that had been supposed to exist, and says they are of no consequence.

This seemed like a flaw in the case, and as the point appeared of great practical interest, I obtained, through the kindness of Mr. Holland, of Sheffield, full particulars of the subsequent history of the reflectors, and, not to trouble you with all the details, found the main facts relating to them to be these.

First, I find the reflector has been pulled down from Attercliff Church, partly because it was unsightly, partly because the present incumbent can do without it, and partly because the inconveniences attending it were felt very trying by most preachers; though the inventor either was not annoyed by them, or endured them cheerfully for the sake of the real benefit he

derived from the reflector, but some of the casual occupants of the pulpit found them so trying that they used to prefer preaching from the reading-desk.

The disadvantages were,—first, that the speaker heard every word uttered in every part of the church; and, secondly, what was worse, had every word be himself uttered diaped into his own ear; and, lastly, that to do any good with the reflector he was obliged to keep still, with his head in or near the focus of the parabola. One of the neighbouring clergy preaching in the Cambridge Church states that he was at once amazed and amused at the distinctness with which he heard the whisperings of the charity children in the remotest part of the west gallery; and the converse of this transmission was true, for a watch placed at the focus of the parabola could be heard to the very end of the church.

As regards the general application of these instruments, I find that the carpenter who made the original one himself made and fixed no fewer than twenty-nine of them, including two at Oxford, one at Cambridge, one at Trinity Church, Huddersfield; one at Dackensfield, near Manchester; and one at St. Sepulchre's Church, Smithfield;—perhaps members present can inform us of the fate of some of these. Also, I find that at Darnall, near Attercliff, the end of the church was built in a parabolic shape, and the pulpit fixed in the focus. The preacher in this church is satisfied with the effect, but occasional preachers, some of them, dislike it. Lastly, I got information of one other church at Sheffield, where the reflector was put up and made use of, and satisfied the clergyman and those persons who sat in the centre and at the ends of the church, but the people at the sides heard worse than before, and complained accordingly; so much so that it had to be removed.

From these facts, which I hope I have not unduly extended, we may gather that the parabolic reflector possesses such disadvantages that it would never be safe to build the end of a room of that shape, and that, in most instances, it will be inadmissible, even as a palliative, in bad cases; but that, on the other hand, it does enable persons remote from the speaker to hear well, and therefore, in a church or room that was long and not wide, it might be valuable, if the speaker is not nervous, and does not employ much action. I need not add that it can hardly fail to be always frightfully ugly.

We pass now to consider the speaking-trumpet, and the analogy it may bear to a room. The action of the speaking-trumpet was for long attempted to be explained by the theory that the sounds were reflected across and across from side to side of the tube, and somehow got ejected nearly or quite parallel in direction from its mouth. But this theory fails in many ways to account for the phenomena of the speaking-trumpet, and M. Hasselwitz, the great authority on that instrument, declares that all his experiments led him to the conclusion that the effects on sound produced by the speaking-trumpet are due to a different cause. The air contained in the interior of the instrument, he maintains, being enclosed by its walls, is compressed by the vibrations of the sonorous body in a more vigorous manner than would be the case if the walls had no resistance; consequently, each individual particle of this air contracts a greater amplitude of vibration, and is capable of transmitting that action to a greater distance before it becomes entirely lost, than it would in the open air.

Now all this applies, *mutatis mutandis*, to a public speaker in a room. If you set him up in a spot where a great height over his head swallows up the sound above him, and vast spaces open on either side of him and behind him, the power of his voice is wasted in communicating vibratory motion to these masses of air, as well as to that mass which lies in the direction where the auditors are.

If now, avoiding the extreme of cramping and confining the space too much, you set your speaker under a low roof, which rises as it goes away from him, and in a recess that widens as it joins the main building, you procure him the advantages of the speaking-trumpet, and throw his voice forward by preventing it from losing itself. And it must further be remarked that if you want your speaker to be able to address a very numerous audience indeed, you must effect it, not by enlarging the building very greatly in every dimension, but by extending it in the direction towards which speech is directed—namely, forwards—with only such additions of height and breadth as are necessary to prevent the structure from falling through disproportion.

Turning now to the violin, we find its peculiar effects are due to resonance. As to the methods of procuring resonance, we have seen that a body of air in a room will reciprocate certain sounds, and we find in certain buildings that the air will reciprocate any musical sounds emitted, but with the disadvantage that it continues to sound them for some time after the original musical notes have ceased. Canterbury Cathedral is the finest instance of this sort of resonance I have heard of. Westminster shows it also. Beautiful as is the blending of sounds and richness of tone due to this cause, it is of more advantage to church music than to reading or speaking, as you will readily notice at Westminster. In ordinary public buildings, therefore, a large mass of empty space is to be avoided, not only because the air in it absorbs part of the power of the voice, but because it may be resonant in an undesirable way. The employment of thin planks of wood for procuring resonance is not open to the same objection, and nearly all the most celebrated acoustic buildings known will have been found to be fitted up to a great extent with wooden lining.

A floor on columns, with a hollow space under it, and a ceiling with a hollow space above it, are both adjuncts to resonance. It is to be remarked, that the presence of auditors in a room deadens the sound so much that if a building be such as to afford, when full, the greatest possible assistance to music and to the human voice, it is more than likely to have a very decided reverberation when empty.

Let us now for a moment ask what *harm* we can do to sound; what impediments a building may present to its propagation; and how far, in a new building, we may avoid these impediments, or, in one where they already exist, may neutralize or remove them.

The principal cause that will have an unfavourable influence on sound in buildings are echo, reverberation, obstacles, and unshapeliness or bad proportions.

Echo is, where it exists, one of the most formidable blemishes possible in a room, for it asserts its unwelcome presence with every word that is spoken. The presence of a flat surface at a considerable distance from the speaker or musician, and facing him, is very much to be avoided, as apt to echo, and consequently in almost all good public rooms the end farthest from the platform is curved, or recessed, or otherwise broken up, or has a gallery thrown across it, the front of that gallery being carefully arranged, so that either it shall not echo or shall reflect the sound to where there is no auditory. In case of an existing echo, the best remedy no doubt is to break up the surface of the reflecting wall in some such way as this. Where expense or other difficulties prevent this remedy being applicable, to hang up draperies, which may mask and break up the reflecting surface, is good.

In over-loud rooms an echo is often perceived from the ceiling downwards. Such a one exists very decidedly in the new reading-room at the British Museum.

Should the echo, however, be indistinct, or very much broken up, or should there, indeed, be a noise, but not amounting to a regular echo, the disturbance is called reverberation.

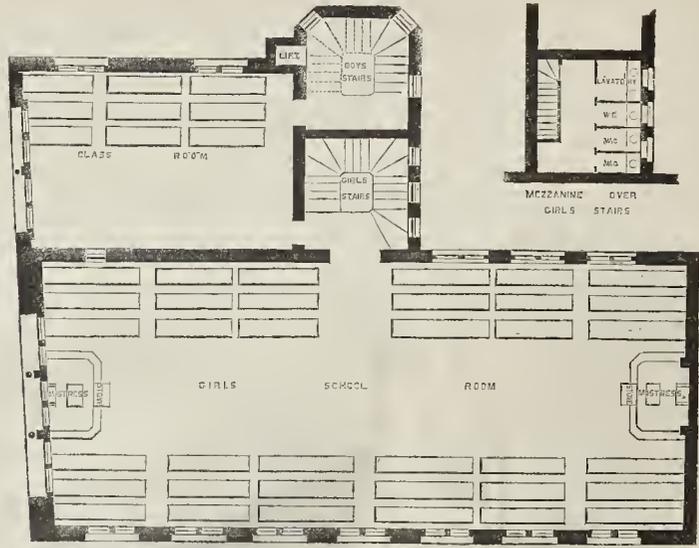

The excess of resonance in an empty room often causes reverberation, and may be generally cured by covering those surfaces which reflect sound with soft substances. The audience frequently do it, but if not, the gradual addition of carpets or matting, or hanging up drapery, will proportionally deaden the excess of sonority in the room till a proper pitch of distinctness is gained. In a church in the north, where the reverberation was unpleasant, even when there was a full congregation, the desired quiet was, I am told, quite gained by laying down matting over the aisles and other open spaces.

Open skylights are very apt to reverberate, so are deep and square window recesses, and both ought to be avoided where sound is of great importance.

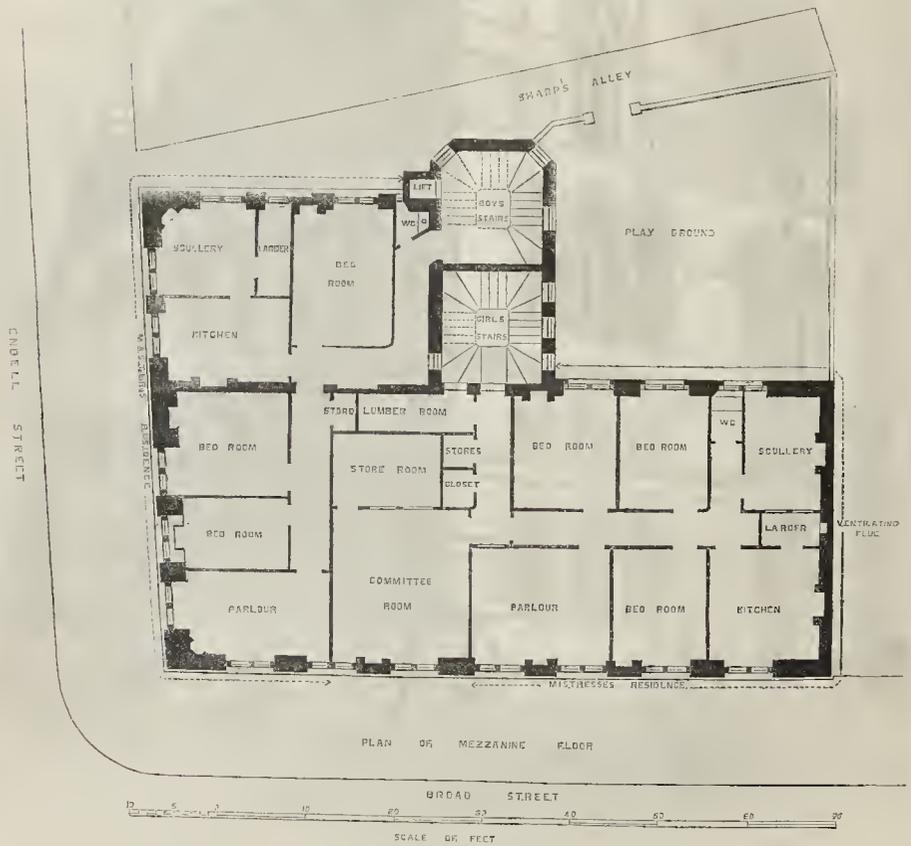

Lastly, damp walls reverberate much more than dry ones, and in a new building it may often be as well to hang up a little drapery for a few months, which can be safely taken down, when all gets quite dry.\*

**NATIONAL PROLIFERATION INSTITUTION BUILDING, LONDON.**—The foundation-stone of a new building, at the corner of Gracechurch-street and Bostons, intended for this life-office, has been laid by the chairman, to whom the board presented the silver trowel used on the occasion.

\* To be continued.

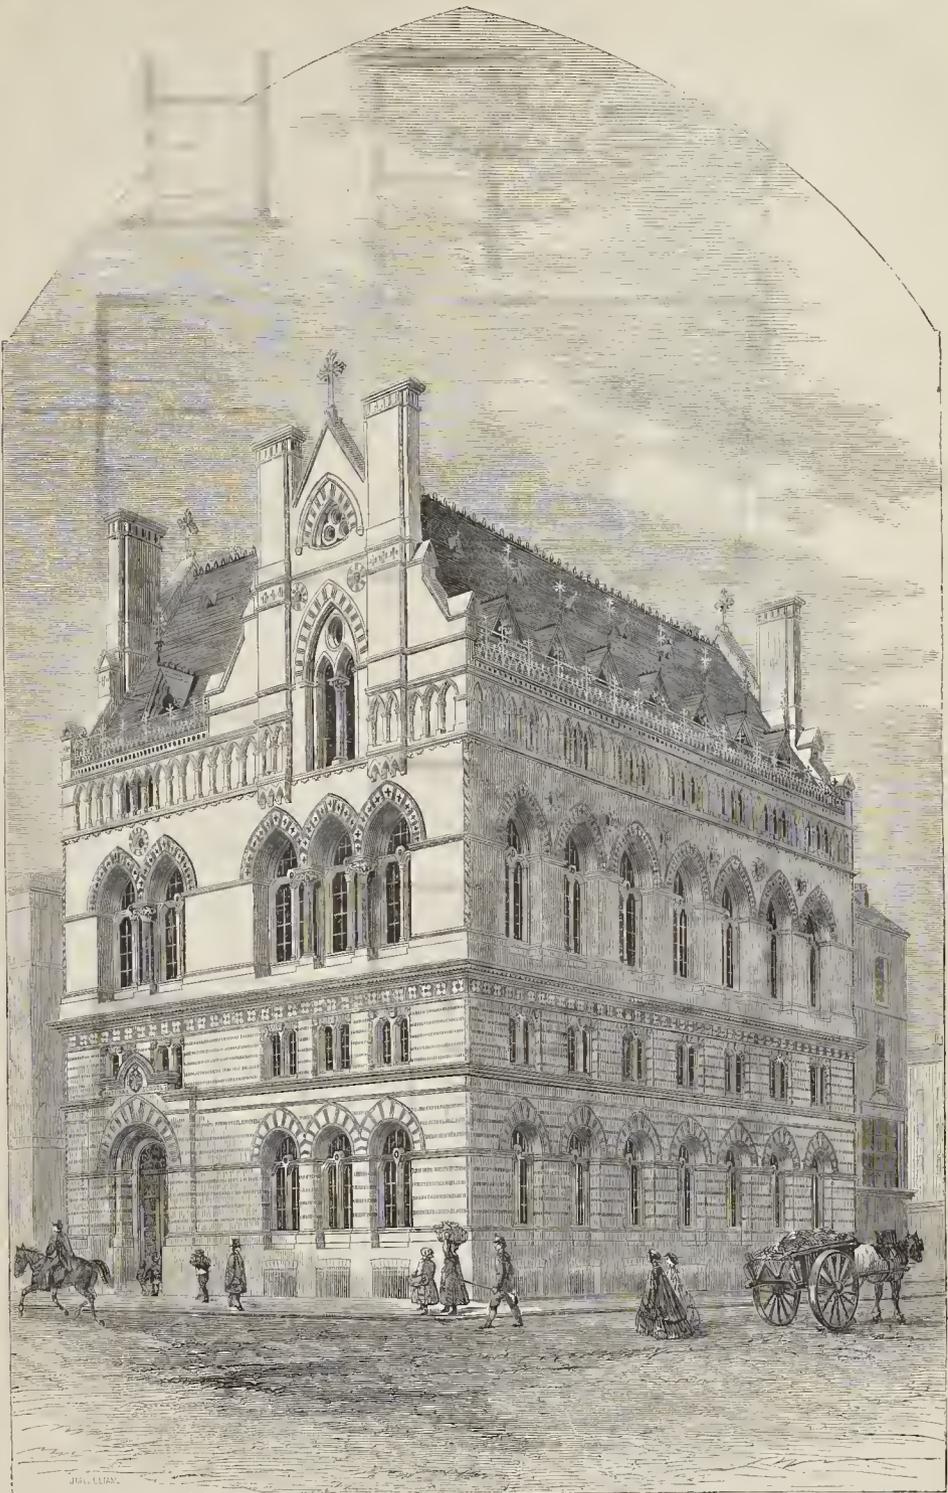

PLAN OF FIRST FLOOR GIRLS

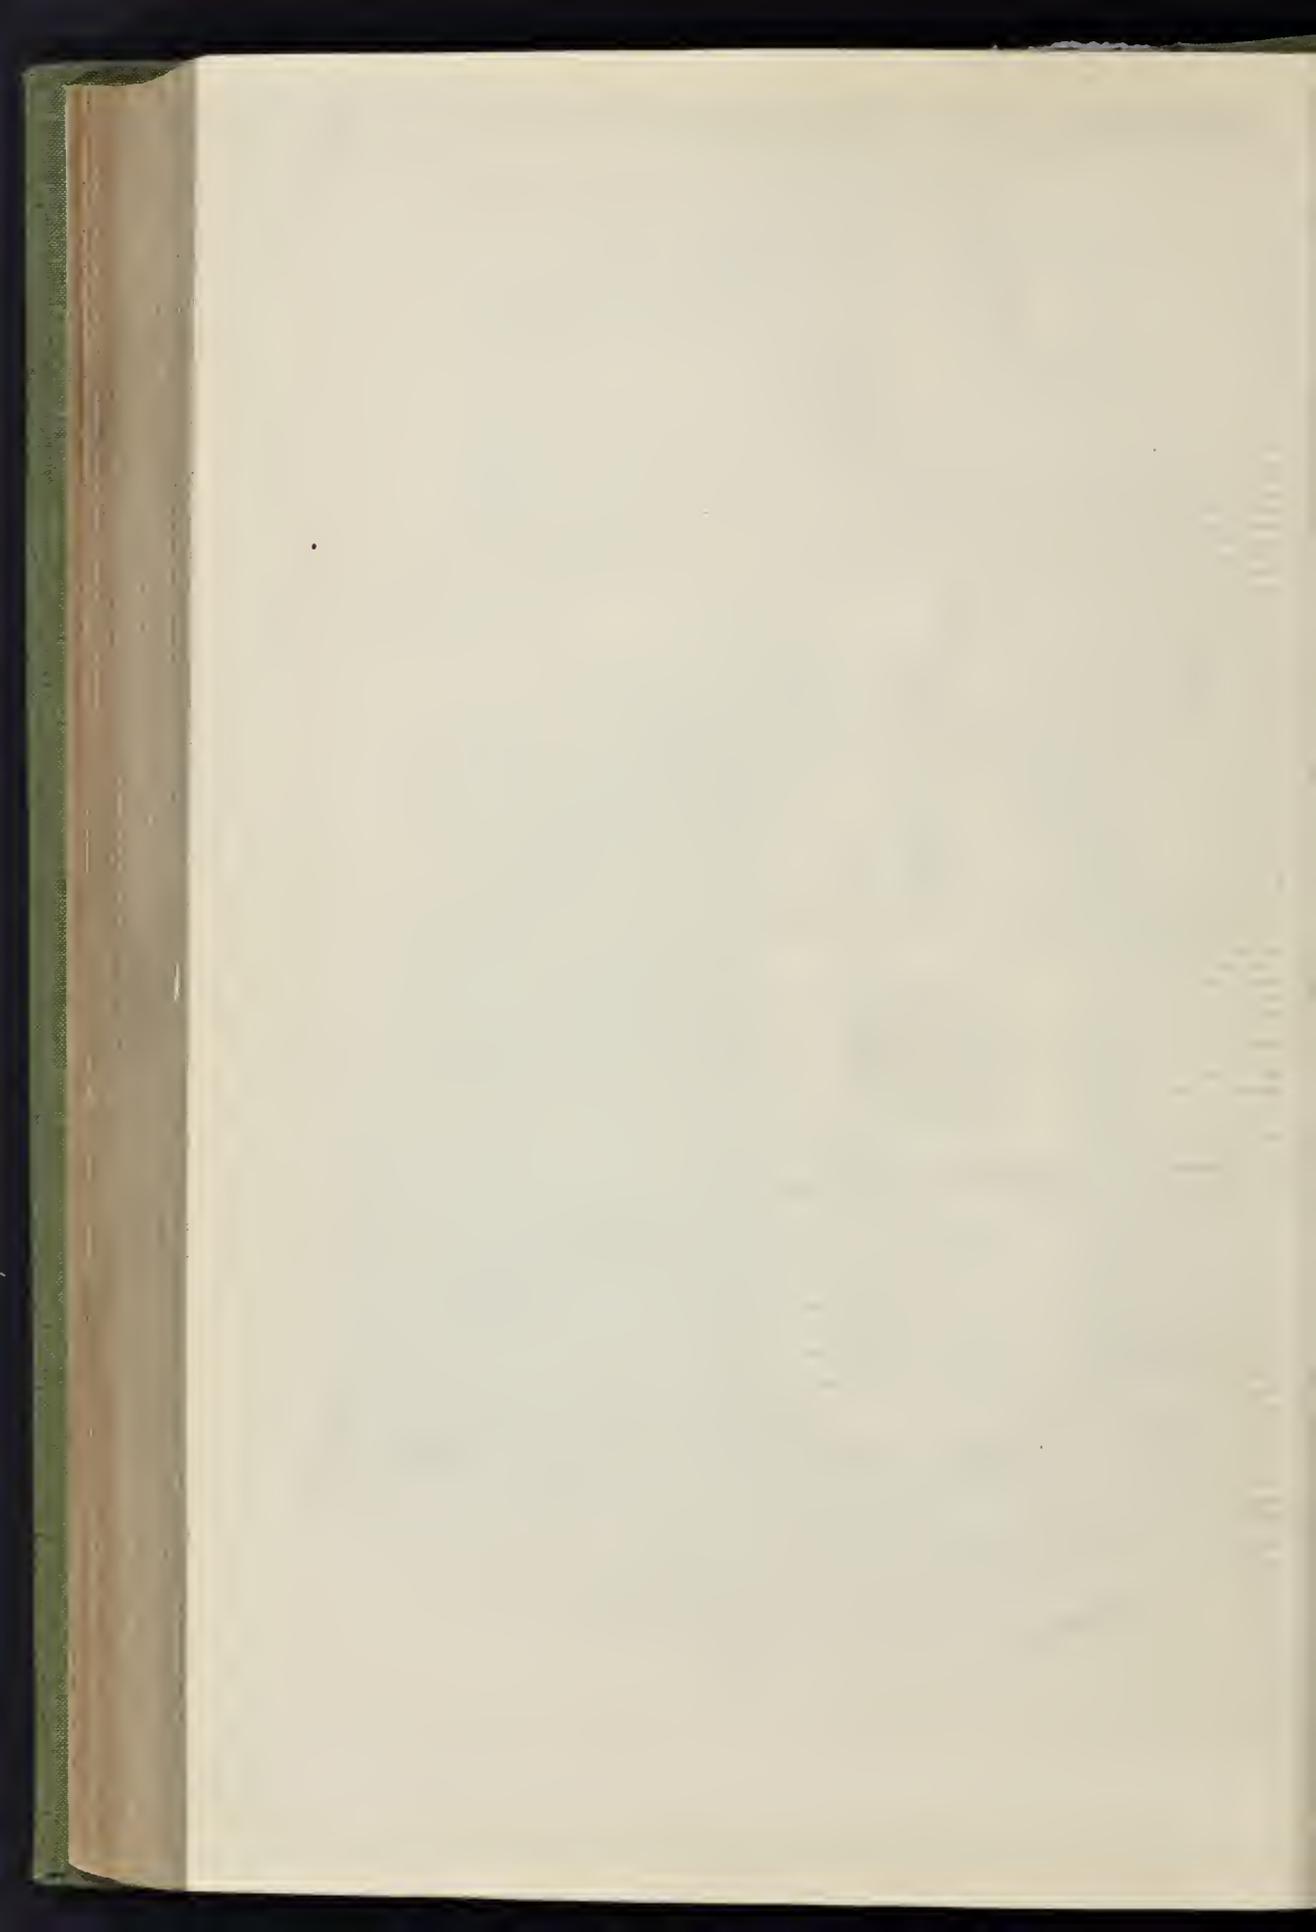

PLAN OF MEZZANINE FLOOR

ST. GILES'S NATIONAL SCHOOLS.

ST. GILES'S NATIONAL SCHOOLS, BLOOMSBURY, LONDON.—MR. E. M. BARRY, ARCHITECT.

## NATIONAL SCHOOLS, ST. GILES'S-IN-THE FIELDS.

SOME of our readers may have noticed a lofty brick structure in course of erection at the corner of Endell-street, where the latter enters Broad-street. The building is now completed, and on Wednesday last was formally opened, by the Hon. A. Kinnaird, M.P., in the absence of the Right Hon. Lord John Russell, as the National Schools of St. Giles's-in-the-Fields, having accommodation for nearly 1,500 children. Such an establishment, we need hardly remark, is greatly wanted where it is placed, as the neighbourhood is one of the worst in London. Great exertions have been made by the parishioners, headed by the present indefatigable vicar of St. Giles's, the Rev. A. W. Thorold, to supply the educational deficiencies of the parish; and the edifice just erected from the designs of Mr. Edward M. Barry is the first fruit of their anxious labours. We now give a view of the exterior, and plans of the principal and mezzanine floors. The building and its appurtenances occupy a site 75 feet long, with an average width of 60 feet; while a portion of the land, about 30 feet square, is set apart as a playground and a means of obtaining light and air, at the back of the building.

There are four floors, besides the mezzanines and attics over the staircases. The basement is proposed to be used for a soup kitchen, or for an industrial school. It is abundantly lighted by means of windows in the plinth of the elevations towards Broad-street and Endell-street. The ground floor is devoted to the infants' school, and contains a large schoolroom, 62 feet long and 23 feet wide, as well as a private class-room and other conveniences. Immediately over the ground story is a mezzanine floor, 9 feet high in the clear; and here are placed residences for the schoolmaster and schoolmistress, and a committee-room, with store and lumber rooms. The master's residence is entered from the boys' staircase, and the mistress will have access to her house from the girls' department. The latter is in the principal floor, which is 18 feet high.

The girls' schoolroom is 72 feet long by 28 feet wide; and the class-room in connection with it is 30 feet long by 20 feet wide. It is intended to use the large room for lectures and other parochial purposes, in the hours when it will not be required for scholastic uses. The boys' department is over the girls' floor, and the arrangements are in all respects similar. Access is given to the boys' floor, by a separate staircase and entrance from Sharp's-alley. The girls and infants will enter by the principal door in Endell-street. A lift is constructed in connection with the boys' staircase, giving the means of hoisting from the basement to the highest part of the building. The lift finishes, externally, as a bell-turret, and is a conspicuous object from Endell-street. The materials employed, are brick, tiles, and slate; the last forming eills, weatherings, and copings. The prevailing colours are a warm yellow and red, but a few black bricks are also used. Black and red Minton's tiles form the string-courses between the mezzanine and principal stories. All the strings, and moulded work, of all kinds, are of red brick. The windows of the principal floor towards Endell-street are grouped together, and only divided from each other by columns of red polished granite, with boldly carved capitals.

The gutters are of cast iron, and so arranged that lead flashings are dispensed with. There is a railing of ornamental character fixed to the gutter to prevent snow, broken slates, &c., from slipping over into the streets, and to act as a parapet in giving protection to men who may be required to clear the gutter, or to repair the roof. The dormers, bell-turret, and hips of the roof, have ornamental finials of wrought iron, and cast-iron crosses are placed on the three gables. The roof is covered with green and blue slates, arranged in bands; and the ridge is formed of slate, perforated with trefoils.

The internal construction is very simple. The stairs are of Yorkshire stone, and the floors are supported by rivetted wrought-iron beams. All the floors are pugged, and a space is left between the floor and the ceiling joists below them, to prevent the transmission of sound. The roof, which has a space of 28 feet, is composed of principals formed by a semicircular arch, and collar over the same. The principals carry purlins and rafters in the usual way. All the internal woodwork is stained and varnished. The window-frames are so designed as to constitute important features in the elevations. Each arch-headed window has a transom across the springing of the arch, and a mullion connecting the sill with the transom.

The windows in the part below the transom open internally as casements, and the part which fills the arch is hinged to the transom, to open inwards at any angle desired for ventilation. The rain-water pipes are of cast iron, and appear externally at the corners of the building. They are placed in the position so often occupied by a shaft in Venetian buildings; and their upper portions are ornamented by a twisted band cast on to the pipe. Means are adopted for admitting the external air to the school-rooms and class-rooms through the dado, and vitiated air-flues are built in the walls, and carried up into the chimney shafts, which are of great height, and are placed on the gable walls of the building.

The workmanship displayed about the whole of the building is very good, and reflects credit upon Messrs. Mansfield & Son, the contractors, and Mr. Dale, the clerk of works, to whom we must give credit also for an ingenious arrangement of the desks and forms.\*

We congratulate the rector, Mr. Thorold, on having set up such a powerful means for good in his neighbourhood as these schools present; and Mr. Edward Barry on having produced one of the most successful brick-buildings of which our own time can boast.

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The ordinary general meeting of members was held on Monday evening at the House in Conduit-street.

The chair was occupied by Mr. F. W. Porter. The minutes of the last meeting having been read and confirmed.

Mr. T. Hayter Lewis (hon. secretary) read a list of donations to the library, including a copy of the illuminated volume by Mr. Owen Jones and Mr. H. Warren (published by Day & Son), entitled "Paradise and the Peri."

The Chairman, having announced that the next ordinary meeting of the Institute would be held on Monday, the 7th of January, when a paper would be read by Mr. G. E. Street, stated that, on an early evening, a discussion would be taken (at the instance of Mr. Tite, M.P.) on the various processes for the preservation of stone.

Mr. Penrose (hon. secretary for foreign correspondence) said it was with deep regret that he had to announce the death of two distinguished members of the Institute. The first was one of the most eloquent writers on art, the venerable and lamented Earl of Aberdeen. The deceased nobleman travelled in Greece long before the termination of the great war, and, in the year 1822, published a work which produced a great effect at the time, entitled, "An Inquiry into the Principles of Beauty in Grecian Architecture." His lordship was a member of the Dilettanti Society, and during his long life had done everything in his power to encourage classic art. The other member whose death they had to deplore was Mr. Samuel Ware, the author of a well-known treatise on arches and their abutments, published in the year 1809.

Mr. Kerr said he wished to call the attention of the members to something more than a formal recognition of the merits of the late Earl of Aberdeen. He would do so in no disparagement of the statement of Mr. Penrose, but, from a profound admiration of the high merits of the deceased nobleman. He (Mr. Kerr) had been brought up in the office of which the Earl of Aberdeen was the most distinguished client; and he was of opinion that his lordship had occupied the first place in the list of their vice-presidents. When the noble earl first came before the public in connection with art, the Gothic school (modern) was in its infancy, and that Baroual style of architecture, so to speak, was coming into vogue which had led the way to the Mediæval revivals of the present day. The Classical style of architecture had not then arrived at maturity; and, at that time, when such men as Professor Cockerell came before the public with Greek remains, Lord Aberdeen also presented himself, with perhaps more profound learning and acute judgment; because, from his position, he was enabled to devote more time and attention to the abstract principles of Greek style than any professional architect could be supposed to do. Since that time the Gothic school had arrived at a high position; and, although the architectural body were divided upon the subject and split into two camps, one advocating (as he

himself did) the Classic, and the other the Gothic; still he thought they might combine, on an occasion like the present, and express their opinion on the loss of a high-minded and cultivated nobleman, whose writings on art were as eloquent as his knowledge was profound, and his taste pure and elevated.

Mr. C. H. Smith observed that, on the return of the noble earl from Greece, fifty years ago, Argyll House was subjected to very extensive repair and alterations. Although the building looked mean, and the elevation, perhaps, paltry, it contained some of the finest rooms of any private mansion in London, especially upon the ground-floor, some of which were 20 feet in height. The mansion was, he believed, built by Gibbs, and was decorated in the Roman and Italian style. The cornices of the rooms were very beautiful, and the ceilings were rich with elaborate ornaments, in the style of Sir Christopher Wren. When the Earl of Aberdeen bought the house from the Duke of Argyll, he had just concluded a lengthened tour in Greece, whither he had been accompanied by Mr. Wilkins, the architect; and he returned home imbued with a taste for Grecian art. The beautiful rooms to which he referred were forthwith stripped of the bold decorations in the style of Wren and Gibbs; and, in their stead, trifling and insignificant-looking cornices were put up, abounding in honeysuckles, after the manner of pure Greek art; and the elaborate ceilings gave place to a style of ornamentation plainer even than that of the room in which they were then assembled. This innovation was made, as he understood, in deference to the desire of the Earl of Aberdeen, who could bear nothing that was not Grecian.

The Chairman said he quite agreed in the tribute which Mr. Kerr had paid to the memory of the late earl, who was one of their most distinguished members. With regard to the observations of Mr. Smith, in reference to the internal decorations of Argyll House, the question was one of taste, upon which, of course, there would be diversity of opinion. He had now to announce that the council had fixed the 14th of January for a special general meeting of members, to consider the question of architectural examinations.

Mr. T. Roger Smith then read a paper on "Acoustics;" a part of which will be found on another page.

At the conclusion,

Mr. Scott Russell, in responding to an invitation, said he had very little to add to the almost encyclopedic paper which they had just heard, and which he felt had very nearly exhausted the subject. He would be chargeable with ingratitude, however, if he did not express his individual thanks to Mr. Roger Smith for the information contained in his essay. Mr. R. Smith had admitted with modesty that he laid no claim to be the discoverer of any new laws of nature, but he had done what perhaps was more valuable; for, instead of discovering one law of nature, and endeavouring to account for everything by that principle (which quacks often assumed to do), he had thrown a philosophical light over the entire subject. Although he could add nothing new to what Mr. Smith had said, he would venture to refer to a few instances which had come under his own observation, in illustration of the practical hints which he had thrown out. Certainly a great difficulty was to convert an ordinary room into a good sounding room. There was a radical difficulty between the necessities of a big room and those of a little one. A little room was infested with abominations which arose out of its littleness, and no doctor or quack could get rid of them. The public generally insisted upon getting a parallelogram, large flat surfaces and a flat ceiling, and there was really no cure for such a building. Under these circumstances all that could be done was to choose a tolerably good proportion, and make the room near to it, but not exactly it. He differed from Mr. Smith in thinking that we had not yet got the exact proportions for acoustic purposes, for he thought that if they took the ordinary harmonic numbers,—2, 3, 4, and 5 (all of which were good acoustic numbers),—and took them in breadth and height, they would procure a room which would speak easily, and resound to the human voice. If on the other hand they were only to come near to these numbers, the result would be a room which would neither speak nor sound. He believed that when they had the choice, if they kept the roof high, they would simply avoid echo; but that, if they wanted an audience to hear the speaker or singer, they must keep the ceiling low. If the

\* The form and desk are in one; and, when required, the top of the desk turns over and serves as a back to the seat, or, the back edge of two desks being placed together, they form a table and seats.

room were low, and the speaker placed himself high, his voice would soon cease to strike the room at a reflecting angle. He had first noticed this in rather a remarkable manner. In Scotland, as they all know, half the church went out from the other half, and had no place to go to. The general assembly met in a building in which no one could hear what anybody else said. They then went to a low building where the ceiling was 15 feet high, and the floor about an area of an acre, where the audience (consisting of half the ministers in Scotland and their congregations) heard each other very distinctly, because the sound sensibly travelled along the low roof. The difficulties of echo would beset all large parallelograms. In theatres an attempt was made to get rid of them by breaking up the space with boxes and partitions; but he believed that the best form of building for 1,500 or 2,000 persons would be one pretty nearly a circular or an octagon, or a circle with four parallelograms. One of the best churches for hearing which he knew of in this style was that of St. Stephen, at Edinburgh, which was an enormous octagon, and in which from 2,000 to 3,000 persons could hear very distinctly a clergyman who had not a loud voice. In this church there were no echoes. The best form that he knew of for hearing and seeing was a circle, with the seats rising one above another, and covering as much of the bare wall as possible. The worst form was that nearest it, namely, a semicircle, with a great flat wall to echo the voice. The courts of justice, for instance, were built in this manner; and he could point to at least half a dozen of them in which nobody could see or hear anybody he wanted to see or hear. There was another point to which he would refer in reference to this subject. It should be borne in mind that there was one set of noises which it was desirable to hear, and another which it was undesirable to hear; and the great desideratum was to make a building in which what it was desirable to hear would be audible, and that which it was undesirable to hear would be inaudible. No one, for instance, wanted to hear, either in a church, a concert-room, or a theatre, fidgeting, rubbing of feet, or tittering. These were noises which no one particularly wished to hear; and theatres were generally so well constructed for hearing what passed on the stage alone, that the audience were very seldom disturbed by the not infrequent loud conversation of persons in the boxes. Her Majesty's Theatre was the most wonderful building for hearing and seeing in, and he did not think he could suggest anything better, although it had faults which might be corrected very easily. He did not think the difficulties to be overcome were so great with a large building; for, where the building was very large, there was no bother on the score of resonance; and, if the building were raised behind, and the wall covered with heads to swallow the sound, the probability was that it would answer very well. The great secret of success in making a large building hear was to cover it with heads; for in a large building the voice required to be assisted. In a small building, on the contrary, the difficulty was to suppress the echo. He could personally speak to the accuracy of Mr. Smith's statements with regard to the parabolic reflector, for he had tried it when he was a guest at the house of Mr. Blackburn, and was frightened at his house. It was also, as represented by Mr. Smith, "villainously ugly," and, moreover, prevented the congregation at either side of the preacher from hearing him. He therefore hoped that it would never be generally adopted in our churches. He also agreed with Mr. Smith in thinking that resonant roofs were great aids to hearing; that the roofs of churches should be of wood; that the top of the pulpit should be of the same material, and as large as possible; as, if this precaution were not taken, it would be impossible to prevent the speaker's voice from being lost. He did not believe in the parabolic form, but he believed that if the end of a building were narrowed near the speaker, the roof inclined, and the walls covered as evenly as possible, every auditor would get his share of the sound; and that, by attending to these principles of construction, all would be done that human nature could do to assist the voice. He begged to propose a vote of thanks to Mr. Smith for his excellent and instructive paper.

Mr. White, in seconding the vote, said he had devoted a good deal of time to the consideration of this particular subject; and that there were one or two points in the paper to which he wished to refer as briefly as possible. One of these was the proportioning of a room to given ratios. To determine exactly what these should be, would perhaps require a paper as long and elaborate as

that which had been read that evening on the general principles of acoustics. Mr. Smith had, he thought, suggested those which were favourable to the transmission of sound, and in this respect he (Mr. White) believed that old churches were built with greater regard to the ratio than was generally supposed. On a late occasion Dr. Barlow, in lecturing on symbolism, had referred to a paper by him (Mr. White) on the geometrical proportions of Mediaeval churches, but he begged to say that his paper had nothing whatever to do with symbolism as such. From the observations which he had been able to make, he had arrived at the conclusion that buildings which were the most beautiful in proportion were the best also for sound. Again, with regard to the general form of buildings, low aisles and lofty naves were best for sound. In reference to flat surfaces behind a speaker, as referred to by Mr. Scott Russell, in our courts of justice, he might state that on one occasion he remembered the Bishop of Lincoln preaching in the open air; when, instead of turning his back to the wall, he faced about towards it, and the result was that he was heard distinctly by several hundred persons. At Dorchester church, in Oxfordshire, the building was lofty, but with low aisles; and there, although the area was very spacious, every word uttered in the pulpit could be distinctly heard from one end of the church to the other.

Mr. Frazer, referring to the use of sounding-boards, mentioned the case of the great church of Amsterdam, formerly a Roman Catholic but now a Protestant building, in which the sounding-board was from four to six times the size of the pulpit. With regard to what had fallen from Mr. Roger Smith, it seemed to him that his paper contained perhaps too much theory without those deductions which would enable the architect to arrive at the proportions which would give certain effects. Mr. Smith had pointed out the descriptions of buildings which were unfavourable to the transmission of sound, but he had not given the actual proportions of a perfect building. Professor Donaldson, of Edinburgh, whose lectures on the theory of sound showed the attention which he had devoted to the subject, was at present building a music-hall in connection with the University, and the proportions which he had adopted were 30 feet wide, 45 in height, and 90 in length. He had tried various experiments, and the above proportions were the best he could devise. The building was now all but complete, and he (Mr. Frazer), understood that Professor Donaldson had been completely successful in making what might be termed a model music-hall.

Mr. Scott Russell said that Mr. Frazer was not quite correct in the enumeration of the proportions chosen by Professor Donaldson. The music-room in question was 66 feet long, 48 feet high, and 32 feet wide, and these were the three proportionate numbers of musical harmony which would make a good room.

Mr. C. H. Smith said that, if all the conditions of a room were equal, the sound would be heard more distinctly in winter than in summer, the density of the atmosphere making the difference. Some substances, it was known, absorbed sound, while others reflected it. Mr. Scott Russell had suggested that a wall should be covered with human heads, but he (Mr. Smith) took leave to suggest that they should be bald heads, because anything in the nature of hair or wool was antagonistic to the transmission of sound. This was proved at once by reference to a carpet warehouse, in which it was extremely difficult to hear. Experiments with regard to acoustics should always be made when the room was full. At the room of the Royal Society, the difficulty of hearing was so great that they were obliged to hang woollens across it to absorb the sound. The admission of the outer air, in cold draughts, had also a good deal to do with sound; for, in the orchestra of a theatre, it was known that if the door were suddenly opened so that the cold air rushed in, the musical instruments were all put out of order for the moment.

Mr. Morris said, one of the most important subjects in architecture was church building; and the exact position of the pulpit was an essential consideration. It was, in his opinion, essential that the pulpit should be placed very near a communion service was always better heard than any other part of the service, in consequence of the reflector formed by the recess in which the table stood, and which produced that abatement in the ceiling, and narrowing of the walls, necessary for perfect hearing. When, many years ago, he built a church, he went with the minister

and made various experiments with the view of determining the site for the pulpit, and they found that the greatest effect was produced by placing it as near the wall as possible. At Westminster Abbey the sermons for the people were preached under the lofty cross, and the consequence was that those only heard who had the good fortune to get very close to the preacher; while those behind him could scarcely hear a word. On the previous day he attended Divine service in a church where the pulpit and the reading-desk were on the old plan. The result was, that the reader, who stood with his back to the pulpit, was distinctly heard; for the pulpit served as a sounding-board; but, when the minister came to preach, his voice was completely lost.

Mr. Penrose said the Institute would be anxious to have Mr. Smith's paper printed as soon as possible, in order to make experiments, for it was well worthy of illustration; and when the profession were in possession of it, it might assist them to remove an accusation often brought against them, namely, that they did not understand the principles of acoustics. On this subject an anecdote was told of the late Mr. Justice Maule, who, on being shown by a friend the plan of a room which he intended to build, and which he believed would be very good for sound, said, "Then you won't tell your architect!" He (Mr. Penrose) could corroborate the testimony of Mr. Smith in reference to the superiority of a wood ceiling, even in a room but 30 feet long. At St. Paul's Cathedral it became necessary, in consequence of the echo from the dome, to place something to prevent the sound going up, and with that view he had prepared a sounding-board, hyperparabolic in its sections, which he found had the effect of stopping the echo and propelling the sound. A preacher, speaking distinctly and slowly, might now be heard at a distance of 120 feet. There was a building at Athens which might be mentioned as having been constructed especially with a view to hearing, as the walls were made to radiate from an angle close to which the speaker stood. There was one building which he could mention of the parallelogram shape, which had been found favourable to sound, and that was the new church of St. Pancras, in which 3,000 persons could hear with distinctness. It was understood that semicircular roofs were very bad for sound, generally speaking, but this was not the case when the roof was very lofty, as in the case of St. Paul's Cathedral. There was one objection to a low building, and that was, that the ventilation would be imperfect, and there could be no doubt that the quality of the air had a good deal to do with the transmission of sound.

Mr. Hansard inquired whether any new effects had been produced at St. Paul's by the removal of the screen?

Mr. Penrose replied, that the music and preaching were now heard much better, and that the congregation in the transept were able to hear the sermon, which they could not do before.

The vote of thanks was then passed unanimously.

Mr. Arthur Shean Newman, of Tooley-street, was, on ballot, elected a fellow of the Institute.

Mr. Baister Fletcher, of 6, Oregon-terrace, Peckham-rye, was also elected an associate.

#### PROPOSED ARCHITECTURAL ALLIANCE.

GROWING out of a suggestion which appeared in our columns, and a pertinent paper "On the Evils of our Present Practice, and the best Way to Remedy them," read by Mr. J. P. Pritchett, before the Northern Architectural Association, the latter body addressed a letter by their secretary, Mr. Oliver, as our readers know, to various architectural societies. The letter said:—

"The object of the Northern Architectural Association set forth in this resolution, is to establish an alliance or general association between the several architectural bodies in the Kingdom, so that when any question arises touching the interests of the profession, such as a proposed legislative enactment, any important competition, or any growing evil, the views of the profession at large may, by such an organization, be at once ascertained, and immediate action taken thereon.

Should the proposal be favourably received by the existing associations, the details of the plan will, of course, require the consideration of the various associations joining in the alliance; but I may just mention that in promulgating this idea the Northern Architectural Association do not wish to inaugurate an additional society, entailing expense and labour on its members. They merely wish to establish a bond of union amongst the several societies now existing, but which, under the present circumstances, are totally isolated from each other; and they think by the interchange of reports of proceedings, by correspondence on passing events, and by meetings of delegates on important matters, much service may be done to the profession, as good feeling will thereby be promoted between distant members of the profession, and united action can be at once taken concerning any matters affecting their joint interests."

We are informed that replies favourable to

the proposal have been received from the council of the Royal Institute of British Architects; the Institute of Scotland; the Liverpool Architectural Society; the Birmingham Architectural Society; and the Glasgow Architectural Society.

A scheme of action has now to be prepared and discussed by the various bodies.

#### THE ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of members was held, as mentioned last week, on Wednesday, the 12th, at 9, Conduit-street. Mr. P. Anson presided.

Mr. Moody, the curator, read the report of the committee, which included the following:—

"A sub-committee having carefully examined and valued the whole of the stock of photographs, amounting to about 1,300, and having selected more than 500 to be retained, in conformity with Clause No. 2 of the Objects of the Association, the committee are prepared to dispose of the remainder at a very moderate rate to subscribers for the current year, Schools of Art, and similar educational societies. The photographs will be open to inspection on application to the curator, Mr. Moody, at 9, Conduit-street, W. The uncertainty so publicly expressed last year as to the continuance of the Association, the partial derangement of its operations, the late period at which it opened, and the short duration of the exhibition, held in a new locality, naturally operated prejudicially, as is made manifest by the great diminution of the number of subscribers from that of the year 1859. But the committee confidently hope, from the numerous expressions of satisfaction which have been received, that subscribers will be induced, by the excellent quality and the extremely low cost of the photographs issued, to assist by drawing the attention of their friends to the advantages offered by the Association,—as the larger the number of subscribers, the smaller the proportion of expenses to be met, and consequently the greater advantages to each individual subscriber."

"The forthcoming exhibition, which will open on the 1st of January, will be an unusually interesting one—many artists having taken subjects expressly for it; and it has been sought, by inviting suggestions for the works which shall form the subject of photographs, and the directing of photographers to these subjects, to advance as much as possible the practical character of the subjects exhibited."

"To Mr. F. G. Penrose the best thanks of the committee are due, he having acted in his capacity as Honorary Foreign Secretary to the Royal Institute of British Architects, a circular letter to the foreign and corresponding members of that Institute, requesting them to make known the objects and advantages of the Association to photographers resident in their respective towns—a measure from which the committee anticipate the most favourable results."

"The following gentlemen have kindly undertaken the office of Local Honorary Secretaries:—Mr. Dawson, of Bradford; Mr. Suter, Brighton; Mr. P. M. Phipson, Norwich; Mr. McGibbon, Edinburgh; Mr. W. H. Reid, Plymouth. The committee will be glad to receive the names of gentlemen in other towns willing to act in the same capacity. They have the pleasure to announce that Mr. Beresford Hope has consented to act as the third trustee."

"The following gentlemen are the retiring members of the Committee:—Messrs. Aitchison, Clifton, Gariing, Morgan, and Whitehead, of whom Mr. Morgan offers himself for re-election."

"The following have expressed their willingness to serve on the Committee. We have the pleasure of proposing them, to make up the full number of twenty-five:—Mr. E. R. Baker, George Truett, J. P. Seddon, Roger Smith, and W. S. Barber."

"The general account of receipts and expenditure from the 30th of November, 1859, to the 30th of November, 1860, showed that the Association had received 1,015*l.*, as follows:—Balance from previous year, 112*l.*; subscriptions received in 1860, 508*l.*; ditto for future years, 4*l.* 4*s.*; ditto for photographs in excess of subscriptions, 339*l.*; admissions, 33*l.*; season tickets, 3*l.*; sale of catalogue, 7*l.*; illustrated ditto, 6*l.* The expenditure included the following items:—Liability from former years, 89*l.*; dilapidations at Suffolk-street, &c., 23*l.*; rent of Conduit-street Gallery, and expenses of exhibition, 80*l.*; advertisements, 72*l.*; paid to photographers, 410*l.*; curator's salary, 30*l.*; balance in the hands of curator and in the bank, 217*l.*—total, 1015*l.* The statement of assets and liabilities showed an estimated balance in favour of the Association of 181*l.* 19*s.*

The Chairman, in moving that the report and statement of accounts be received and adopted, stated that the committee wished to be empowered at a general meeting to dispose of their surplus stock. It had been examined by the Committee with great care, and an estimate of its value had been carefully made. From this examination the committee were enabled to state that the value was fully equal to that of last year.

Mr. C. C. Nelson seconded the motion.

Mr. Baker commented upon the expenditure, which he stated was larger than the receipts. He hoped, however, that the Association would be enabled, by the sale of their photographs in stock, to balance the account; and that in future years either a larger income would be obtained, or some means devised of economising the expenditure.

Mr. Lightly said that the expenditure last year was to some extent exceptional, as there was a heavy charge for advertisements, &c., consequent

upon what might be termed the reconstruction or revival of the Association. Moreover, the number of subscribers estimated was 1,200, whereas 500 were all that were obtained. He had no doubt, however, that from the satisfaction so generally expressed by the subscribers, they would interest their friends, so that a large measure of success would attend the operations of the Association during the coming year.

The motion was then put and agreed to.

On the motion of Mr. Lightly, a resolution was passed empowering the Association to dispose of the surplus stock of photographs.

Mr. George Truett was elected an auditor in the room of Mr. Webb, deceased.

Mr. W. Beresford Hope was elected one of the trustees.

The retiring members of the committee having been re-elected, thanks were voted to them, to the trustees, auditors, and honorary secretary (Mr. Lightly), for their services.

The Chairman, in acknowledging the usual compliment passed to himself for presiding at the meeting, expressed his hope that the next exhibition would continue to give satisfaction to the subscribers. He admitted that the expenditure was large compared to the receipts, but he hoped this anomalous state of things would not exist another year.

#### ART AND ITS CRITICS.

##### LIVERPOOL ARCHITECTURAL SOCIETY.

THE 11th meeting of the session was held on Wednesday evening, the 12th; Mr. James Hay, the president, in the chair.

Mr. W. H. Pieton, the hon. secretary, having announced various donations,

The Chairman presented Mr. Doyle with "Fergusson's Hand-book of Architecture," as a prize for the best set of drawings made during the summer.

Mr. Frank Howard then proceeded to read the paper for the evening, which was entitled, "A History of Art, and its Critics."

After some prefatory observations, he said the first specimens of painting on sculpture which we found consisted of rows of these simple, simple figures, either standing, sitting, or walking in procession. From this rude mode the art proceeded to the formation of groups, and hence originated one of the first principles. When a number of figures were introduced into one subject, it was found necessary to distinguish the principal figure in the piece. This was done by making the god, the hero, or the king, much larger than the subordinate figures, and this practice was adopted at the Parthenon, in Athens. In the subsequent progress of art, the principal figure was distinguished by being more elaborately finished than the subordinate characters. The next desire was to distinguish figures by character. Polydorus wrote the names of the deities he meant to represent under the figures, and the same practice appears to have been adopted in some of the Etruscan vases. Phidias had the credit of individualising character, for he fixed the forms of his gods, in which, it was said, no Greek ever after departed. With the name of Homer we were introduced to the earliest criticism in art. (How far he read *in extenso* the passage in which Homer describes the figures on the shield of Hercules, or the shield of the shield of Hercules. In each criticism, he contended, there was exactly the same description: record, and nothing else was held up. The next step in the art was the perception of form. Pericles called in Phidias to decorate the Parthenon. These wonderful productions of Phidias and his pupils, the remains of which now were by the name of the Egin marbles, had been acknowledged as unapproached, if not unapproachable. Phidias was ranked as the foremost sculptor of the world. It was left to Mr. Ruskin to make such use of himself as to say that he would rather see the Egin marbles in fragments in the museum than have seen them in their perfection in the Parthenon. The next step was the imitation of objects, and here the dangers of art commenced. Zeuxis followed Phidias in idealising form. When he painted the picture of Helen, he required seven beautiful virgins as models, and out of them he made his "Helen of Troy." Subject was lost sight of in the object, and Zeuxis painted a man eating figs and grapes; and, when it was hung out, the grapes were so natural that the birds came and pecked at them. A contemporary painted a curtain so perfectly that Zeuxis asked him to pull the curtain aside that he might see the picture; and when he learnt the truth, "Zeuxis has deceived birds, but you have deceived Zeuxis." Zeuxis then painted a picture of art, and painted a subject piece of art. The public only admired the glossy skin of a lion's cub in the picture; and, in disgust at their taste, Zeuxis ordered it to be removed. "The public," added Mr. Howard, "only admire the clay of a cart." Landseer attracted more by the fine gloss of his bay horses than by any other quality in his pictures. He was told of Andsell and Landseer that they had dogs and horses rubbed over with bear's grease to make them gloss when they were seen from them. This was what painting for the public inevitably led to. Public opinion had never been so satisfactory as when it was convinced of its own ignorance, and was wise only to know that it knew nothing.

Mr. Howard then went on to the revival of art in Italy, tracing the progress down to the present day, and giving criticisms of the works of the great masters. The principles, however, upon which artists are judged were always the same,—invention first, then taste, and last execution. The public reversed them, and put execution first

and invention last. As to artists, it was only in the application of the principles that differences arose. The whole of art had not been settled. There were some questions of science yet to be solved. But should it be urged upon the strength of these unsettled questions that the uneducated public were as qualified to judge as those who had made these matters the study and even the experiment of their lives? Because artists doubted, were the public to decide? If so, the severe censure of Pope would be justified, "that fools rush in where angels fear to tread."

A discussion ensued, some of the members maintaining that in the long run public opinion on art was, on the whole, sounder and more correct than that of artists,—a very defensible position, inasmuch as it says in other words that the ultimate deduction from the opinions of the many is more likely to be sound than the opinion of an individual.

#### SITES FOR PUBLIC STATUES.

NOTWITHSTANDING that we can with justice claim the honour of having had, amongst us, men most eminent in literature and science, it is remarkable that, with the exception of Jenner, we have no street monuments, in the metropolis, of those worthies who, in peaceful, scientific and literary pursuits, have shed lustre on this land.

In various directions,—in the streets and squares,—there are memorials of naval and military heroes, statesmen, and persons of rank; but we look in vain for such marks of esteem,—placed in the sight of the multitude,—in honour of those who have been national benefactors in science or literature, and who have thereby acquired a world-wide fame. Neither Shakespeare, nor Sir Isaac Newton, nor Milton, for example, has an open-air monument. This is a matter not creditable to the present state of our intelligence and advancement. In most foreign capitals, a better spirit than this is shown.

It has often occurred to us that many of the statues which have been placed in London seem not to be in the right situations. Generally, there has been a disposition shown, if we except Trafalgar-square, to place the street monuments in as isolated positions as could be contrived; and in few instances, in the metropolis, has monumental statuary been made accessible to our public buildings, as we have often urged; and notwithstanding that this might often be done with advantage. It is to be hoped that, in the arrangements of the new law courts, there may be ample opportunity afforded for placing in front of the buildings, in prominent situations, representations of worthy lawyers who have done honour to the bench. Connected with the exterior of the College of Surgeons, or Physicians, we would like to see effigies of Hervey and John Hunter. In front of the British Museum, why have we not the figures of some of our most famous philosophers and poets? What place so fit for memorials of Shakspeare and Milton as the bases or pedestals which seem to have been made for the express purpose on each side of the central portico? An avenue of statues, stretching from the metal gateway to the main entrance of the Museum, would have an excellent effect; and ample space might be found here for at least twenty memorials; and amongst these we might expect to find such men as Caxton, Sir Christopher Wren, Sir Joshua Reynolds,—who was both a painter and author,—Sir Isaac Newton, Oliver Goldsmith, Dr. Johnson, and others whose names will come to recollection.

When we reflect how powerless the efforts of the wisest general, or the bravest soldier, would be against those modern cannon and rifled muskets and other means which science has brought into use; and on the civilizing effect of literature; it would seem that the time has arrived when equal honour should be shown to peaceful benefactors of the state, with that which has been shown to the mighty men of the sword.

#### KING GEORGE III. AND ART.

HOWEVER great may have been the mental deficiencies of this monarch, and obstinate his disposition, it is but just to say that art, science, and literature were beholden to him for judicious encouragement and assistance: although himself of imperfect education, and no great reader, he was ready to admire the talent of others. With great judgment and much munificence, under the direction of this king, the famous library which forms such an important feature of the British Museum was gathered together. The collection of topographical prints, the mugs and plans, are both curious and valuable, and show that they were purchased *en amore*. This seems to have been his majesty's favourite study; and, probably, several of the plans are the work of George III's

own hands, for good authority states that he copied every capital abart, took the models of celebrated fortifications, and the soundings of the chief harbours in Europe. In 1820, there was in the Queen's library, at Frogmore, a portfolio of drawings—about fifty in number—done by George III. when Prince of Wales: they are problems worked out from a work on practical geometry, with vignettes to each, drawn in Indian ink, on small folio paper. His majesty had an early predilection for the study of architecture; and this preparatory department was probably the groundwork of his knowledge of the art. It is probable that these drawings were made with Mr. Kirby, as that artist was the instructor of his majesty in the science of linear perspective. A celebrated antiquary and virtuoso, writing from Rome, on Dec. 16, 1762, says, "Nothing gives me more satisfaction than to find so many fine things purchased for the King of Great Britain. He is now master of the best collection of drawings in the world, having purchased two or three capital collections in this city, the last (belonging to Cardinal Albani) for 14,000 crowns; one kind of which are original drawings, by the first masters; the others, collections of the most capital engravings; and lately there has been purchased for his majesty all the museum of Mr. Smith, at Venice, consisting of his library, prints, drawings, designs, &c."

The king was remarkable for his free and kindly bearing to men of genius. To Reynolds and West he showed particular favour, and his support of the Royal Academy from its commencement is well known. It is said that the king first suggested to Mr. West the professional study of Scripture history, and desired him to bring his drawings to the palace for inspection. Mr. West did so, and came at a time when the sovereign had with him some dignified clergymen. The company were all gratified with the sketches and with their accuracy to the Scripture text, affording proof of the painter's acquaintance with the Scriptures. "And do you know how that was?" said his majesty to the prelate who made the remark. "Not exactly, your majesty." "Why, my lord, I will tell you. Mr. West's parents are Quakers, and they teach their children to read the Bible very young. I wish that was more the case with you, my lord."

It was in conversation with Joseph Lancaster that the king expressed the worthy sentiment that "he hoped the day would come when every poor child in his kingdom would be taught to read his Bible."

George III.'s appreciation of Handel should not be overlooked, and, as an evidence of his generosity, it is worth while to state that, during his illness in 1789, a committee, appointed to examine the state of the privy purse, found that, out of an income of 60,000*l.* per annum, his majesty never gave less than 14,000*l.* a year in charity.

However much all must regret the general events—the bloodshed and expenditure—of this reign, it should be remembered that both art and science emerged, as it were, in England, at this time; and that manufacture, commerce, and education all became extended in a most remarkable manner.

#### MISS COUTTS'S DRINKING FOUNTAIN.

The most important drinking-fountain yet designed for London is being erected through the munificence of Miss Durdett Coutts, in Victoria-park. It includes a colonnade around four fountains, covered with a dome, and will be constructed of Aubigny stone and green and red marble. There will be figures of Sicilian marble, and bronzo appliances. The height will be 57 feet, and the diameter of the structure 26 feet, while the steps around the whole will extend to 40 feet. Mr. H. A. Darbishire is the architect; Mr. George Smith, of Plinico, the contractor; and the cost will be about 5,000*l.* Miss Coutts does nothing by halves.

#### THE MYDDLETON STATUE AND FOUNTAIN FOR ISLINGTON.

The old police-station at the corner of Islington Green is at last cleared away, and the site will be prepared for a statue and fountain, which are being executed by Mr. John Thomas, the sculptor. The design consists of a statue of Sir Hugh Myddleton, proposed to be in Sicilian marble, 8 feet 6 inches high, in the picturesque costume of the period, raised on a rich pedestal, with sculptured dolphins and shell, supported on console-shaped trusses, at the angles, which are intended for fountains. Marble panels are on each face of the pedestal, which is also enriched with festoons of shells and water-flowers. The pedestal stands in

the centre of a basin for water, with an ornamental curb, 3 feet 6 inches high, of an Italian-shaped plan, 24 feet in diameter. On pedestals on each side of the curb to basin are sculptured boys with vases, from which will spring jets for drinking fountains, falling into marble shells, supported on corbels.

Sir Morton Peto, Bart., M.P., presents the marble statue: the other portion is to be erected by subscription.

#### THE ROYAL ACADEMY MEDALS.

ON Monday, the 10th inst., being the ninety-second anniversary of the foundation of the Royal Academy of Arts, the following silver medals were awarded, at a general assembly of the academicians.

To Mr. Thomas Henry Watson for the best architectural drawings,—the Morning Chapel, St. Paul's Cathedral.

To Mr. James Turpin Hart for the best drawing from the antique.

To Mr. Charles J. T. Smith for the best model from the antique.

To Mr. Thomas Henry Watson for the best perspective drawing,—the Royal Exchange.

To Mr. Thomas Henry Watson for the best drawing illustrating sciography.

The President, Sir Charles Eastlake, justly complimented Mr. Watson on the zeal, industry, and talent displayed by him, and stated that the medal for the best architectural drawing was to be considered a first-class medal, conferring upon him the privilege of a student for life; and that in addition a book handsomely bound and inscribed would be sent him.

We add our congratulations to those of the president. Mr. Watson's father has been long known to many members of the profession.

#### THE FEMALE SCHOOL OF ART.

As we mention that an exhibition of paintings, drawings, sculpture, and other works of art, will be opened early in June, 1861, the proceeds of such exhibition, and sale of pictures, to be appropriated to the fund now raising for a building for the permanent establishment of "The Female School of Art;" and that the exhibition will terminate with a bazaar, for which contributions are solicited; we may, perhaps, lead some of our readers to interest themselves in the undertaking. The contributions will be thankfully received by the superintendent, Miss Louisa Gann, between this time and the 1st of May, 1861.

The school is at present carried on in a house in Queen-square, Bloomsbury (No. 43). These premises are in many respects better adapted for the school than those in Gower-street; but what is needed is, that the school should be rent free, and that its permanency should be established.

The students are doing their utmost: they have formed an evening working party, and an afternoon painting and sketching party, to make suitable articles for the bazaar—a praiseworthy course, as their time is valuable to them for study, and they have already subscribed to the fund, besides now paying a raised fee for instruction.

#### CHURCH-BUILDING NEWS.

**Luffenham.**—The tender of Messrs. Cave, of Oakham, and Halliday, of Greetham, builders, has been accepted for the restoration of South Luffenham Church.

**Saffron Walden.**—The church here has been opened after extensive repair. The entire works have been completed by Mr. Wm. Brown, of Lynn, builder, who has lately carried out similar restorations at Newport, High Roothing, and other churches in Essex.

**Buckland.**—The parish church of St. Mary, at Buckland, near Reigate, has been restored. The glazing of the east window is by Mr. Hardman: "The Crucifixion" occupies the centre light, the figure on the cross being thrown out from a ruby vesica. In the side lights are the figures of the Virgin Mary and St. John. The tracery in the upper part centres in a circular cusped light, in which is the Lamb, and exhibits angels in adoration. The two other windows in the sanctuary are—one, representing the visit of the holy women to the sepulchre; the other, the raising of Lazarus. The roof is of oak, in panels, the last row of which over the altar is decorated with tracery, painted and gilt, and bears, in the centres of each, shields with a cross of fleur-de-lis. Over the altar and on either side, are the emblems of the Evangelists; while, at the intersections of the ribs, are carved and gilt bosses and shields bearing the names and

emblems of the apostles. The pavement is a green trellis with black spots at the intersections, the interstices of the trellis being filled with tiles, increasing in richness as they approach the altar. On the north side of the chancel is a four-centred arch, moulded and filled up to the capital with an open oak screen for an organ. The pulpit occupies the north-east corner of the nave, and is octagonal in shape. A large three-light window is filled in with the subject of the Nativity, with attendant angels in adoration. A newell staircase of open work leads up to the ringing-chamber in the tower, where there are five bells. The fittings throughout are of English oak. The works have been carried out under Mr. H. Woodyer, architect, by Mr. Wm. Shearburn, builder, Dorking.

**Stanton (near Tewkesbury).**—The church of St. James, Stanton, has been restored, on plans furnished by Mr. G. R. Clarke, of London, architect, at a cost of 720*l.* The chancel has been rebuilt, a vestry erected, a new roof placed on the north aisle, the old nave roof unceiled, a porch erected, and a final and lightning-conductor added to the spire. The old chancel arch, also, has been replaced, open seats provided throughout (the old bench ends, which exhibit specimens of carved tracery, being preserved). Three new windows have been placed on the south and north sides of the church, and a stained-glass window at the west end of the nave. The subjects illustrated in the three compartments are the texts, "Rise, take up thy bed and walk" (John, v. 8), "When he looketh upon it he shall live" (Numbers, xxi. 8), and "Receive thy sight" (Luke, xviii. 42). The whole of the works have been completed by Mr. Griffiths, of Eldersfield, builder.

**Dawley.**—A new Wesleyan chapel has been opened here. The new edifice, built upon the site of the old one, occupies a conspicuous situation. Mr. Griffiths, of Bridgnorth, was the architect. Mr. Bray was the builder. The style is Italian. Fronting the street is a tower of white, blue, and red brick; the crown mouldings, strings, and cornices being of Bath stone. It is finished with deep corbel cornice, hipped roof, and weather-vane, and has openings for a clock. The main roof is carried higher than the sides, in order to obtain light by means of nine clerestory windows, in consequence of buildings blocking up the back. The chief entrance is beneath the tower, up which a stone staircase also leads to the end and one of the side galleries. The centre is divided from the aisles by white brick pillars, and semicircular arches of the same material (blue and white), and finished with label moulding—the whole painted. The total cost will be about 1,200*l.*

**Marden (Herefordshire).**—The church here has been restored. The old plan has been adhered to, according to the *Hereford Times*, and everything valuable as mere material, or as archaeologically or architecturally interesting, preserved and re-adapted in the new edifice, such as the pillars and arches, the well and niche of St. Ethelbert, &c., and the old type has likewise suggested the character of the new work. In taking down the old roofs and walls, it became a subject of wonderment how they could have held together. The timbers of the roof were found to be in many important parts perfectly pulverized with decay, and the mortar worthless. In re-building, the nave pillars have been set at their original elevation. The nave is separated from the aisles by arcades of four bays on each side, and is surmounted by a simple clerestory, pierced with quatrefoil and trefoil apertures. The west facade of the church is composed of a three-light window in the centre, with cinque-foils at the ends of the aisles, and a sexfoil in the gable. The aisles are lighted with eight two-light windows of various designs. There is a stone porch on the south side, with a moulded archway, the inner doorway being a restoration of the old one. The framing of the roof is visible internally. The benches have been restored. The aisles are laid with encaustic tiles, supplied by Mr. Godwin, of Lugwardine. The works have been carried out from the designs and under the superintendence of Mr. Thomas Nicholson, of Hereford, the diocesan architect, Mr. Crittenden acting as clerk of the works, and Mr. Noden, of Leominster, being the builder.

**Canon Frome.**—A new church has just been erected for this parish, the tower of the old one only being retained. Mr. Bodley was the architect, and the work is in the Early English style. The walls are of the local red stone, left free from plaster. Bath stone has been employed in the windows and pillars. The floor is laid throughout with tiles, the chancel floor being enriched with marble bands and four marble steps. The

chancel stalls, altar, and pulpit, are of oak, carved. The eastern wall is adorned with a reredos of alabaster, inlaid with marble, displaying the cross above the table, while a window (the work of Messrs. Clayton & Bell) represents in three compartments the Nativity, Crucifixion, and Resurrection of our Saviour. The nave and aisles are furnished with movable oak benches and chairs. Mr. T. Collins, of Tewkesbury, was the builder; and the reopening took place on the 6th inst.

**Upton.**—A new Independent chapel at Upton, near Chester, has been erected and opened for divine service. The design was furnished by Mr. Thomas Lockwood, of Bolton, architect, and has been carried out by Messrs. Lockwood and Farrimond, of Chester, builders.

**Leicester.**—The lofty stone spire of St. Martin's Church is a spire no longer, and the crazy old tower is now eased of its weight. The difficult task of taking it down was entrusted to Mr. William Neale, carpenter, Leicester, who has accomplished the work without mishap or accident, in little more than three weeks. The sort of crow's-nest scaffold thrown out of the four upper windows of the spire, and by which the most dangerous part of the work was to be performed, was a noticeable feature in the work of demolition. It is to be hoped, when the tower is taken down in the ensuing spring, the whole being to be rebuilt, on a design by Mr. R. Brandon, of London, architect, that funds will not be wanting to carry it out in its entirety, and once more to make the lofty spire of St. Martin's worthy the fine old church to which it is to be an appendage.—The foundation-stone of the new church of St. Andrew has been laid by the Duke of Rutland. Mr. Scott is the architect; Messrs. Osborn, of Leicester, are the builders; and Mr. J. Firth, the stonemason.

**Derby.**—The foundation-stone of a new Wesleyan chapel has been laid at the top of Canal-street, London-road, Derby. The new edifice will accommodate 900 persons. It is to be 80 feet long by 47 feet wide, and the total height on the walls 30 feet. Means are provided by four staircases for entrance to and exit from the galleries, which will be circular in form, a space being left for an organ and singers. A basement story below the chapel, in height 10 feet, will contain a room for school or public meetings, 60 feet long and 20 feet wide, besides four vestries, &c. The building is to be faced with bricks with stone dressings. Facing London-road there will be two octagonal turrets, surmounted with perforated stone pinnacles, relieved with tracery and canopies: they will be about 66 feet high. The front windows will also be relieved with tracery, labels, and carved terminations, and construction arches formed with blue and white bricks. The sides will have battresses and plain lancet windows, with labels and arches the same as to the front windows. The design is by Messrs. Giles & Brookhouse, of this town, and was selected in competition. The tender of Mr. Wm. Bridgitt has been accepted, and will now be carried out. It is estimated that the total cost on completion will be about 3,000l.

#### STAINED GLASS.

**Albury Church.**—A stained glass window has been placed in this church, painted by Lady Rokewood Gage, of Albury-park. The subject is St. Peter. The glass was provided by Messrs. Powell. Lady Gage intends, we understand, to paint the other windows of the chancel in turn.

**Salisbury Cathedral.**—A painted window has been placed in the chapter-house of this cathedral by Miss Wickens, of the Close, as a memorial to the late Mr. James Wickens and his relict, the parents of Miss Wickens.

**Christ Church, Heaton Norris.**—Another memorial window by Messrs. Edmundson & Son, of Manchester, has been put up in this church, making the fifth. The subjects, which are in three medallions, are,—“The Raising of Dorcas,” “The Raising of the Widow's Son,” and “The Raising of Jairus's Daughter,” with diapered grounds and border.

**Warrington Church.**—Mr. R. B. Edmundson has erected in this church a window in memory of his own parents. It is the west window in the north aisle, consisting of four principal lights and tracery in the Decorated style, and is one of the new windows of the recent restoration by Messrs. J. & H. Francis, of London, architects. The principal subjects are Simon with the infant Jesus in his arms, in the Temple; Mary and Martha; Mary seated at the feet of Jesus hearing His teaching; the Resurrection, and the Ascension. Below are four angels, bearing scrolls inscribed with suitable texts. Each subject is

surmounted with canopy work. In the large opening in the tracery is a representation of the Good Shepherd. The remainder is filled up with angels, emblems, &c., with the following inscription at the bottom of the window:—“This window was erected to the honour and glory of God in affectionate remembrance of James and Elizabeth Edmundson, by their son, R. B. Edmundson. Also in memory of Barbara Edmundson, his sister, and Ralph B. Edmundson, his son. A.D. 1860.”

**Manchester Cathedral.**—An unknown individual has had completed, and erected, in the west end of the south aisle, a stained and painted window. This window is of four principal lights, with tracery. The subject represents Aaron and Hur staying up the hands of Moses during the battle with the Amalekites, and occupies the four large lights. There are three small subjects in the tracery, which represent, on the left, “The finding of Moses; on the right, “The Destruction of Pharaoh's Host in the Red Sea; and, in the centre, “Moses holding up the brazen serpent in the Wilderness.” Angels with palm branches, &c., fill up the remainder of the tracery. Messrs. Edmundson & Son were the artists.

**Christ Church, Blackburn.**—A memorial window, in stained glass, has been erected in Christ Church, Grimshaw-park, Blackburn, to the memory of the late Robert Hopwood, esq., of that town, a donor to that and other churches. The window is 16 feet high by 8 feet wide. The style is Decorated Gothic. The subject, extending over all the lower lights, is “The Last Supper.” The treatment of this subject, from designs furnished and executed by Messrs. Baillie, of London, is peculiar. The Saviour, as if to mark his special affection for “that disciple whom Jesus loved,” has risen from His seat, and is administering the holy communion to the youthful communicant, who meekly receives the symbols of his Saviour's death on his bended knees, to the surprise of the other disciples, more especially of St. Peter. In the tracery lights, in the first row above the subject, on the right and left, are the bread and wine. Above these are angels in the act of adoration, and the whole is surmounted by a celestial crown.

#### PROVINCIAL NEWS.

**Barnard Castle.**—The Mechanics' New Hall here has been inaugurated. The new building is an addition to the Witham Testimonial, erected some fifteen years since, for the use of the Mechanics' Institution, and comprises a large hall capable of seating 700 people, an orchestra or proscenium, to accommodate fifty or more speakers or performers, with two side rooms, and another apartment, with a separate entrance for the use of the savings bank. The whole was designed by Mr. Bryson, architect, and carried out by Mr. Appleby, contractor; the entire cost being about 900l.

**Liverpool.**—The finance committee of the town-council have been empowered to sell to Messrs. Lightbody & Boulton, on behalf of persons not named, a portion of land in Dale-street, belonging to the corporation, at the sum of 40,000l. This land was originally offered for the sum named to Government as a site for a post-office. The persons taking it bind themselves to expend 70,000l. in erecting a building on the site. It is said that the intention is to erect a leviathan hotel on the American principle.

**Southport.**—Twenty million of bricks, says the *Ormskirk Advertiser*, are now wanted in Southport, for the building of 100 more houses.

#### IRISH BUILDING NEWS.

The town of Balbriggan has been lighted with gas by Mr. Daniel, of Mary-street.

A new wing is being erected to the Royal School, Dungannon, adjoining the Armagh road, which will nearly double the accommodation of that edifice. Mr. McCurdy is the architect; Mr. William Geatens, of Dungannon, the contractor.

The works at the new Protestant Hall, Waterford, are progressing rapidly: one of the towers is entirely finished. The main building is roofed in, and the ceiling nearly completed: it is lighted by means of two very efficient gas deflectors. Mr. Fitzpatrick is the contractor.

A new cross has been presented to the inhabitants of Garey, by the Right Hon. Sir P. Esmond. It is erected in front of the Parochial Church of St. Michael. It is of granite, and is 25 feet high from the base. The lowest stone of the shaft weighs 3 tons. On each of its sides are deeply sculptured recesses, containing four figures, representing SS. Peter, Thomas, Bartholomew, and James. Higher up on the shaft are figures, life

size, of St. John and the three Marys. From this rises a cross, on which is sculptured the dying Christ. The whole has been executed by Mr. Fegan, sculptor, of Sallystown, county Wexford, at a cost of 256l.

#### THE PATENT PAINTED AND GILDED LEATHER CLOTH.

THE majority of our readers have, doubtless, met with the patent leather cloth used to cover seats and otherwise, and many have seen it in its painted and gilded shape as manufactured by the Leather Cloth Company; nevertheless, they would probably be surprised, as we certainly were ourselves, to find a large warehouse in Cannon-street West, filled with rolls of it. In France it has long been extensively supplied by this company, but here as yet it has only been occasionally used. In the new Westminster Palace Hotel, for example, it is hung in the smoking-room; and, at the Royal Hotel, Bridge-street, Blackfriars, in the billiard and reading rooms. Many of the designs already produced are very elegant; and it may be made to present all the elegance of gilded leather, the *cuir doré* and the *cuir argenté* of the Middle Ages, while its cost is but trifling as compared with those hangings with which, as we know, in the sixteenth and seventeenth centuries all the houses of the Venetian nobles and gentry were hung. In England, too, it was greatly used, and examples may still be found in old houses. The cost of the painted and gilded leather cloth may be called about 2s. 6d. a yard square, being enamelled by a patent process, which preserves the original beauty of the gilding, and allows it to be washed without injury. It is very durable, and it could be hung on new walls, on which it would not be safe to paint or put paper.

This company, who have manufactories also in France and Belgium, have large works at West Ham, where they employ about 150 men. Looking over their warehouse, we saw large quantities also of their vulcanized India-rubber belting, which, as being more durable, appears to be fast superseding the leather belting.

#### CESSPOOLS IN SALFORD.

SIR,—I send you some extracts from the Salford paper, by which you will see that while you good folks in the south are spending your hundreds of thousands of pounds in endeavouring to alter your system of drainage, we in the north are following out the good old plan of cesspools, and are in a fair way to obtain a profit from that which is a source of great expense and trouble to you.

The following is the system pursued here:—Nearly all the houses are built with a passage, called an “entry,” running the whole length of the backs of the houses: a large cesspool, or “midden,” is constructed between every two houses, with an open space for ashes between, closed with doors in the walls of the entry, through which it is emptied regularly, under the direction of the police, by the town scavengers, in the night time; the only deodorizing material used here being the ashes and other refuse thrown down the cesspool.

Of the successful operation of the above system, which seems to be so highly spoken of and recommended by our local authorities, I leave you to judge when you have read the annexed papers.

T. J.

\*.\* The pith of the statements is to the effect that there are districts in Salford where a pestilential air predominates, and which give an average (per annum, we conclude) of 47 deaths in a thousand! If this be correct, the authorities are permitting the perpetration of wholesale murder under their very eyes, and in spite of their very noses.

#### TOWN SEWAGE OUTLET WORKS.

THE experiments made at Croydon in attempting to purify sewage are only valuable in so far as they furnish actual results. In each case, as described, the sewage seems only to have had the solids of the sewage intercepted; and, I believe, recent chemical analyses prove that the result of any known process of so-called disinfection or purification of sewage is merely a separation of the solids, and is not in any degree a chemical purifying. The effluent water remains true sewage water, full of the soluble salts of sewage, as if mechanical filtration alone had been used. This effluent water, however bright to sight and pure to smell, is true sewage; and, as such, ought to be conveyed to agricultural land for purposes of vegetation. Even after passing through 6 feet

vertical of land under cultivation, water escaping from the land drains will be found, on analysis, to contain manure in solution, not so strong as at first, but strong enough, in many instances, to warrant a second use in irrigation, and sometimes, probably, a third and fourth application, if the site is favourable for this form of irrigation.

The cost of sewage works ought to be kept down, as also the cost of working. Tanks constructed with brickwork are not, in all cases, necessary. Canals or tanks may be formed with side slopes of say one to one in earth, at a very light cost; and in such tanks or canals the sewage may be strained free from all solid and flocculent matter, by hurdles, in which gorse has been secured, so as to stop all floating matters. Simple liming will hasten deposition; but, excepting in hot weather, this may not be necessary. The "floating crust" found on the surface of the sewage in the tank at Croydon is not all due to the chemicals used, but is partly due to the oxygen of the atmosphere. Such a scum or crust is found on the foul rivers and canals in and near Manchester, and other places, at all times; but most during warm weather. The Croydon sewage tanks might probably have been made as effective without brick side-walls; and, if so, the cost would have been saved. At several places expensive tanks of brickwork for filtering sewage have utterly failed, as at Lugby, for instance. Let our engineers try simple and inexpensive means to free sewage from its solids, and then to get the clear-liquor water conveyed to land in the cheapest possible manner, and all parties will be benefited. If the sewage cannot go to the land it must go, without its solids, into the nearest water-course, river, or the sea.

CIVIL ENGINEER.

#### ARCHITECTURAL EXAMINATION.

I CANNOT refrain from offering an observation on the proposed examination of those who contemplate following the profession of an architect. Whether the examination should be compulsory or voluntary, I believe it would be a great advantage to the rising generation if those who are competent to form an opinion, and who have suffered in early life in an architect's office by having received little or no instruction, would suggest a proper routine for study to be followed. Many have not the advantage of a classical education; but still there are many subjects to which their attention might be drawn for their study and consideration, and which would prove, and they would derive, an advantage in future life. For instance, if the student were told it would be to his advantage to have a correct insight into arithmetic, geometry, algebra, mensuration, leveling, land-surveying, estimating, perspective shadows, geology, trigonometry, together with a general historical knowledge of the profession, a young man would then have before him a system laid down for his general instruction, which I regret to say never was the system adopted in an architect's office many years since. A heavy premium was paid for six or seven years, and during that time not one word of instruction was imparted, no opportunity afforded to see the progress of construction, and neither in drawing, perspective, nor any of the useful requirements in following the profession in after life. Therefore I feel for the rising generation, if a proper system of instruction were laid down, it would prove a great boon to many, whether they might feel disposed or not to pass an examination; at all events, they would be generally qualified, and feel better satisfied with themselves, and feel grateful to those who had put them in the right road for preferment. I should therefore be an advocate for examination, which need not be so strict as to deter young men from such a course or dishearten them in their prospects in life.

A FRIEND TO THE YOUNG ARCHITECT.

#### NEWCASTLE SAVINGS BANK COMPETITION.

At the adjourned annual meeting of this institution the members proceeded to select one of nine sets of plans sent in for new Bank premises. It was arranged that voting should be on all the nine, and that the mode be by ballot. The result of the first scrutiny was,—Mr. Johnstone, five votes; Messrs. Oliver & Lamb, three votes; Mr. Watson, nine votes; Mr. Wardle, two votes; Anima non, one vote. Mr. Watson not having an absolute majority of all the votes, a ballot was again taken between him and Mr. Johnstone, with the following result:—Mr. Johnstone, six votes; Mr. Watson, fifteen votes; consequently the premium of 50l.

was awarded to Mr. Watson. A building committee for the purpose of carrying into effect all such measures respecting the proposed new building as may, from time to time, be referred to them by the General Board of Management, was then appointed.

#### NORTHAMPTON TOWNHALL COMPETITION.

SIR,—It may perhaps ease the mind of "A Competitor" to know that one of the sons of one of the architects of Northampton does not intend (nor has he at any time mentioned his intention) to compete for the new townhall.

W. HULL, Jun.

#### APPLICATION OF SEWAGE.

CARLISLE.

SIR,—I quite agree with the writer of the article in your number for the 18th inst., headed "The Sewage for the Soil," that the public may obtain valuable information from all schemes for the application of sewage to the soil which may be carried out.

I send this communication in order to contribute some information on the Carlisle experiment, and also to correct an error into which the writer has fallen as to the engineers of these works.

Considerable alarm was felt by many persons in Carlisle when it was first understood that the low-lying land in the vicinity of the town was to be irrigated with the sewage; but I can unhesitatingly state that, during the past year, there has been no inconvenience felt therefrom, and no complaint from any person on this account, while it has been equally obvious to the eye that a powerful stimulant had been applied to the growth of grass. So far the experiment has been a highly satisfactory one in a sanitary point of view, and I should rejoice to hear that it has been equally successful financially.

The error in the article is the statement that Mr. McDougall was the engineer of these works. He is the lessee of the sewage of Carlisle, and the inventor of the distinctive used, but Messrs. McKie & Mansergh were employed by him as the engineers of the works, and had the sole responsibility of practically carrying them out.

ISAAC CARLISLE.

#### MASTERS AND WORKMEN.

Mrs. Brown, and Mr. O'Brien v. Bennett.—This was an action, tried in the Marylebone County Court, to recover wages for work done and loss of time. Mr. Lewis, instructed by the London Amalgamated Association of Operative House Painters, said the claim involved a principle whether the employer is not liable for loss of time incurred by workmen when kept waiting for materials. The plaintiffs are journeymen glaziers, lately employed by the defendant at the New Railway Station, Finsbury. They were engaged on the 2nd of October, and commenced work. On the following day, being short of glass, the defendant told them not to leave the job, for he expected more glass to arrive every minute. Therefore, complying with the request of defendant, no deduction ought to be made from their wages. The plaintiffs corroborated the above statement.

The defendant admitted the want of glass, but did not consider he was liable for the men's loss of time. Several witnesses having been examined, his Honour was of opinion that, if employers through neglect kept workmen short of materials, and a loss of time occurred, it would be unreasonable to deduct the loss from the wages of the workmen.

Verdict for plaintiffs, with costs.

#### LIGHT AND AIR CASES.

Cutler v. Hedges.—This was a motion heard in the Vice-Chancellor's Court on behalf of the lessee of No. 15, New Burlington-street, for an injunction to restrain the defendants, Messrs. Hedges & Butler, of Regent-street, from increasing the height of a building at the rear of the plaintiff's house, and from erecting dormer windows on the roof thereof, so as to prevent the plaintiff from enjoying the same amount of fresh air and light through his windows as he has hitherto and of old been accustomed to enjoy. The plaintiff complained that the defendants had raised a building at the rear of his house, about a foot in height, and that they had placed on the roof thereof, which slanted northwards, dormers (which were windows projecting from a slanting roof), and that the raising of such building and the placing of such dormers materially diminished the amount of light in the rooms, or some of them, at the rear of his house. It was stated that before the suit was instituted the plaintiff had said that he would be content if the dormers only were removed, and that the roof might remain at its present height.

Mr. Mallin and Mr. Cutler were for the plaintiff; and Mr. Bacon and Mr. G. Simpson for the defendants.

After the case had occupied the court a considerable portion of the day, the Vice-Chancellor suggested that the dormer windows should be removed from the north to the south side of the defendant's building; that such building should remain at its present height; and that there should be no dormers on either side; and an order to that effect was accordingly made by consent.

#### PATENTS CONNECTED WITH BUILDING.\*

CHIMNEY-POLES.—R. Atkinson, Southampton-court, Tottenham-court-road, London. Dated 11th April, 1860.—On the outside of the pipe or tube forming the chimney-top is fixed a series of vertical ribs, with tapering cross-pieces attached to the edge thereof, forming a series of T-shaped ribs round the said pipe or tube. When the wind strikes the chimney-top it enters between these T-shaped ribs, and its egress being prevented by

the overhanging edges of the said ribs, it is forced to travel upwards, through openings provided into the interior of the chimney-top, and thus causes an upward current. A series of chambers are also provided round the exterior of the chimney-tube or pipe, and communicating with the interior, for the purpose of increasing the upward current of air; and there are also short exterior tubes or flat rings for directing and dividing the currents.

ATTACHING KNOBS TO SPINDLES OF DOORS.—W. Bate, Wolverhampton. Dated 26th April, 1860.—This invention consists in a new and peculiar method of connecting and attaching the spindles to the knobs of locks and latches, so as to permit of their being used with doors of different and varying thickness, which the patentee accomplishes by providing a series of holes one quarter of an inch apart, through one of which a screw is passed from side to side of the neck of the knob. By this means he obtains a rough adjustment of the length of spindle. At the opposite end of the spindle he provides another set of holes, but only one-sixteenth of an inch, or less, apart; and by securing the other knob, by means of a similar screw passed through one of the closer-placed holes, he is enabled to correctly adjust the length of spindle as required.

IRON OR GLAZED STRUCTURES FOR HORTICULTURAL OR OTHER PURPOSES.—T. H. P. Dennis, Chelmsford. Dated 11th April, 1860.—The patentee uses wrought or cast-iron pillars for the main supports, attached to which are bosses having dovetail, mortises, or joints arranged to receive horizontal plates. The dovetails to fit these mortises are formed from the solid wrought or cast-iron plates, either on one or both sides. The end rafters are attached to the ridge by a sliding bolt; the sash-bar or intermediate rafters are also fixed to the ridge and front plate, either by forming a hook from the end of the sash-bar or rafter, or by affixing iron clips thereto. In the latter arrangement, distant pieces are necessary. The end bars or lights of a house are fixed, either with iron clips, having a mortise in the upper side to receive the bars, or by cutting mortises from the bars to fit up to and clip the plates. The iron clips are made suitable for wooden structures where iron sash-bars are required. The pivots upon which the front sashes hang are formed from their own frames, and swing upon the iron mullion of the house; the sashes can be drawn entirely out. The dovetail joints and fastenings, by which the sash-bars or rafters are held in place, are applicable to any shaped building.

FLOORINGS AND ROOFINGS, AND OTHER PARTS OF BUILDINGS.—A. Taaffe, Rue de l'Union, and W. Toovey, Rue de la Pompe, Brussels. Dated 25th April, 1860.—To obtain lightness, strength, and freedom from fire in construction, there are formed eight framings of wrought metal, which are covered on the upper, and, if desired, on the lower sides with plates of sheet metal, the whole being united together by nuts or screws, or other suitable bolts. When for floorings, the upper surface of these constructions may be covered with wood, or any other suitable material, and the under surface with lath and plaster, or any other suitable material to form a ceiling. Sometimes the surfaces are formed by means of plates laid in angular channels, and connected together across the upper and lower angles by transverse straps or plates, or by the aid of blocks of wood when for roofing. The invention cannot be described without reference to the drawings.

#### Books Received.

Fairbairn's Crests of the Families of Great Britain and Ireland. Compiled from the best authorities, by JAMES FAIRBAIRN, and revised by LAWRENCE BUTTERS, Seal Engraver in Ordinary to the Queen for Scotland. Edited by JOSEPH MACLAREN. In 2 vols. Edinburgh: Thomas C. Jack. London: Hamilton, Adams, & Co.

The first volume of this useful work contains an alphabetical list of more than 30,000 families, with their respective crests, as they may be found on the rolls of the Herald's College, and another of nearly 5,000 mottoes, with translations from alien or obsolete languages. There is also a Glossary of heraldic terms. The second volume is occupied chiefly with nearly two thousand well-executed plates of different crests. Most of these are common to many families, no less than 162 bearing the stag-head, while 181 are distinguished by the same, *erased and attired*; but many others, such as the Pegasus, appear to be claimed by one family only. There are few materials for com-

\* From the *Engineer's* lists.

mentary, further than to recommend the work to those who may not be acquainted with its contents, as a depository of valuable information for all interested in tracing the descent of families.

Many of the crests, we may remark, record, as is very well known, a very savage state of things as the boasted origin of families; but a few even excel in this regard; one, for example, consisting of a tattooed savage; another of a grisly head stuck on a dagger. Very absurd, too, in appearance, are some of these crests. The Vandye family, for example, have an eagle stuck into a harrel, with one of its wings torn off; or, in heraldic language, it consists of "an eagle's head and neck in a tun, dexter wing elevated, sinister cut off and lying on wreath."

As a whole, however, family crests are full of interest and significance: it is only to be regretted that this well got up and useful work contains little or no information as to the history or origin of, or reasons for, the adoption of such symbols, as denotive of families, and their names and deeds. A third volume, with a mass of explanatory but condensed references, would soon be called for, in order to render the work complete. A single word would very often suffice to explain what is now a mystery to all but a few.

A very useful art-feature in the second volume is a series of plates of monograms, for the use of family-plate manufacturers and others. There are also specimens of lettering, crests, and scrolls and garters with mottoes, heraldic illustrations for chargings, &c.; British and foreign crowns and coronets, regalia, orders, chaplets, and helmets; city arms, and flags of all nations. This second volume also contains a glossary, key to plates, &c.

In the preface the editor regrets the decline and fall of heraldic influence and heraldic studies, which he ascribes to the unquestionable fact that "the honours due to genius, valour, patriotism, and industry, have been bestowed too much in the spirit of party."

*The British Almanac and Companion for 1861.*

Knight & Co., Fleet-street.  
MR. CHARLES KNIGHT contributes to "The Companion" an interesting and valuable paper, "Localized Handicrafts in South Midland Agricultural Districts." These are chiefly non-factory employments, such as refer, for example, to straw-plait, lace, and shoes, concerning which the statistical knowledge possessed is not precise. The social position of the females engaged in the straw-plait trade is a matter of serious interest. Thames Embankments, Refractories and Ragged Schools, and the South Kensington Museum, afford subjects for other papers.

"The Companion" has, as usual, its article on "Architecture and Public Improvements," but on the present occasion it calls for no observation from us beyond this, perhaps,—that inasmuch as it could not have been written but for the *Builder*, the fact that the *Builder* is not once mentioned may be placed in the category of things "cool."

#### VARIORUM.

BEETON'S "Christmas Annual" (248, Strand) gives for a shilling such a variety that it can scarcely fail to command a large sale,—a detached illuminated almanack (with flowers of monstrous size, by the way), a sheet of puzzles, and a book of tales, conundrums, charades, tricks, and what not, the whole illustrated with wood-cuts.—And, talking of wood-cuts, we must again praise those in "The British Workman," the sixth yearly part of which has just been issued. It is a miracle of cheapness, and is doing much good.—"Stanford's New London Guide" (6, Charing-cross), contains a large amount of useful information; but it should be revised by a competent hand, to prevent the appearance of such an erroneous assertion, for example, as that Westminster Hall, the crypt of "old St. Paul's," that of St. Stephen's Chapel within the Palace of Westminster, and the entrance to St. Bartholomew's Church, are remains of the Norman period!—The Christmas number of "The Welcome Guest" titled *Snow-bound*, is an amusing bundle of stories told in a railway station while waiting for a train stopped by the snow. The fault is an over abundance of robbery and murder. Perhaps, however, at Christmas, people look for spice.—A third edition has been published of Dr. Lankester's valuable and comprehensive "Guide to the Food Collection in the South Kensington Museum."—Viollet-le-Duc's "Essay on the Military Architecture of the Middle Ages" (J. H. & J. Parker); and Mr. Miles's "General Remarks on Stables, and Examples of Stable Fittings" (Longman & Co.), will receive early notice.

#### Miscellaneous.

**MEMORIAL OF CROMPTON.**—The people of Bolton have subscribed to erect a statue of Samuel Crompton, who invented the "mule" which has given fortunes to hundreds, and bread to thousands. After some discussion the commission has been given to Mr. W. Calder Marshall, R.A.

**STREET TRAMWAYS.**—Mr. Train has received permission from the vestries of St. John's, Hackney, and St. Leonard's, Shoreditch, to lay down a line from Ball's-pond, along Bridport-place, Pool-street, Dorchester-street, New North-road, Pitfield-street, Old-street-road, and City-road, towards the City.

**BRITISH ARCHAEOLOGICAL ASSOCIATION.**—At the second meeting of the session, held on Wednesday, the 12th instant, Mr. G. Godwin, V.P., in the chair, Mr. T. J. Pettigrew read an elaborate paper "On a Seal of Richard Duke of Gloucester, as Admiral of England and Earl of Dorset and Somerset,"—showing that he received that appointment in the 2nd and in the 11th Edward IV., and that the seal must have been, from the titles expressed on it, executed between the years 1474 and 1475. Afterwards, Mr. Syers Cumming read an interesting paper "On the Employment of Tubes and Hollow Bricks in Ancient Buildings." The Chairman made some general observations on the subject as affecting cottage-building.

**ROYAL ENGLISH OPERA, COVENT-GARDEN.**—Mr. Balfe's new opera, "Bianca, the Bravo's Bride," is pursuing a successful career, but must be stopped for a night or two because of the time that will be occupied, in the first instance, by the forthcoming pantomime. "Bianca" contains some of Mr. Balfe's best music, and is sung by Miss Pyne admirably. Mr. Harrison, too, does all that need be done, and the chorus is excellent; but, with these exceptions, the opera is not efficiently sung. To Miss Pyne and Mr. Harrison the English public are indebted for the establishment of an English opera-house on sound grounds; but, if they would maintain their position, they must strengthen their company.

**THE NEW ORPHAN HOUSES AT ASHLEY DOWN, BRISTOL.**—Another annual report, by Mr. Mullar, the founder and conductor of this extraordinary establishment, has been given; from which it appears that he is now building accommodation for an increase of the number of orphans to be provided for, from 700 to 1,150, at a cost, for building, of 23,000*l.*, and an additional yearly expense of about 5,200*l.* For the current year, he states that 50*l.* a day is required, and more as the work proceeds. It is a scarcely credible fact that it is almost entirely by what may be called a "hand-to-mouth" system that these many hundreds of poor orphans are being fed,—a system which has, to a constantly progressing extent, been successfully pursued for the last quarter of a century, by the same singular man, who attributes his success to the power of daily and believing prayer alone; whereby, from day to day, contributions come tumbling in from all quarters, tradesmen giving percentages on all their profits, professional men a share of their income, in one case amounting to nearly one-half, ladies their jewels, clothing, &c., all for behoof of the poor little orphans. Mr. Mullar, it appears, has always enough coming in to keep him going without either credit or debt, but seldom much more; and at times he scarcely knows, from day to day, where the means are to come from for the next day's provision, yet it never fails to come. This is certainly a wonderful phenomenon; but it is also a fearful risk: still, we dare say, in case of any sudden short-coming, at least for a time, no difficulty, on the score of credit, would arise. The greatest risk, perhaps, is that of the sudden or unexpected death of the devoted and remarkable head of the institution. The new building, as noted, will cost some 23,000*l.*: of this sum he has already 21,282*l.* on hand, and "every day brings him fresh supplies," often in very small sums. Of the general expenses, he has a balance of 9,358*l.* to begin the year with; but, besides the orphans, he has schools, missionaries, Scripture circulation, &c., to provide for, in a similar way; and, for all this, he has a separate income of about 10,000*l.* a year, of which there was a balance of 2,392*l.* in hand. In all, the sum in hand, when the report was made, amounted to 35,033*l.*; and the grand total of annual expenditure to 72,182*l.*; out of which sum he allows himself—nothing per annum, by way of salary; or rather perhaps, we should say that he has a salary of 72,000*l.* a year, and spends it all on his little orphan family.

**FALL OF AN IRON ROOF AT LILLYBURY.**—The skeleton iron roof of the new building in course of erection at the Lillybury Copper Works has suddenly given way, bringing with it three workmen. One fell 18 feet, but escaped unhurt; while the other two fell from the height of from 30 to 35 feet, and were very much injured. The span of the roof is nearly 60 feet, and the weight of the iron which fell, being fifteen iron girders, was not far from twenty tons.

**READING.**—The Abbey Gateway, according to the local *Mercury*, "daily manifests further indications of a fall on its northern side;" and, he adds, "if the further consideration of the restoring is made over to Mr. Scott, it is quite clear that all difficulties will be removed long before any decision is arrived at."—The new Assize and Police Courts approach completion. The civil and nisi prius courts are in a forward state. As respects the position of the grand jury gallery, the paper just named says, "We believe it will be found that very few judges will be able to make themselves heard at such a distance, and there will also be some awkwardness discovered in conveying the hills to and from." The floor of the large hall is being paved with Pocol tiles of various colours; but, on the occasion of halls, a temporary boarded floor might be laid down at a small cost. There are a large number of offices connected with the courts. The grand jury room is fitted with a "sun light." A hot air apparatus is carried throughout both the police and assize departments, and is introduced into every office.

**OPENING OF A NEW CATTLE MARKET AT NEWCASTLE-UPON-TYNE.**—The new cattle market recently opened, and which is situated at no great distance from the old one, will afford accommodation for about 3,000 head of cattle, or about three times the number hitherto adequately provided for. The site of the new market is immediately on the west side of the Infirmary. The area is about two acres and three quarters, surrounded by a stone wall surmounted by iron palisading. The entrance is through gates in Marlborough-street, and one at the east end of the market. The pens are accessible from five alleys running parallel with Marlborough-street, the whole length of the market, and 17 feet in width; these again being intersected by two cross alleys of 30 feet in width. The pens are constructed of oak, and forty of them are appropriated as stands for bulls, being of great strength, with ring-holts, &c. All the alleys and the two principal crossings are paved with blue whin Pifo-stone, and the pens with freestone. There are seven entrance-gates; and, as soon as the new street is formed to the south of the market, another will be formed on that side. The market is fitted up with gas; and with water from the Whittle Dean, and also from the Bath Lane.

**ELECTRO-TELEGRAPHIC PROGRESS.**—All the metropolitan police stations are said to be now connected by telegraphs, and the fire-engine stations will very shortly be in similar communication. The wires are all carried over the houses, and are in many instances supported by the church steeples. Many of the newspaper offices are about to be supplied with wires from Mr. Renter's office, and in one case a newspaper in Fleet-street will have private wires to the Houses of Parliament. Mr. Renter has made a proposition to the London daily papers to report the whole of the proceedings of both Houses of Parliament. He proposes to have one corps, and, as we have said, to have wires laid to each office, so that the report can be printed from a copy written out by a telegraph clerk.—One of the first acts of Count Persigny's administration, it is said, will be the completion of the telegraphic wires by which the chief towns in eachondissement will be placed in communication with each other and with the more important centres of population in the empire. The reduction of the price paid for transmitting telegraphic messages likewise occupies the Count's attention. Although the original price charged by the Government has been reduced, the transmission of telegraphic messages is still beyond the reach of the majority of the public. The consequence is that the annual produce of the telegraphic department is much less than it might be, and the country in general is deprived of the advantages of the telegraph.—Experiments are at present being made with a newly-invented electro-telegraphic apparatus which transmits messages textually, giving a perfect *fac-simile* of the handwriting. The reproduction is said to be so faithfully executed by this new apparatus that any description of portrait or drawing may be forwarded with as much facility as a simple message. It is of this invention we presume that the *Journal de Havre* speaks as an Italian one.

**THE TYNDALE MONUMENT: CURIOUS PROPOSAL.**—Earl Ducie proposes that the column to be erected to the memory of Tyndale, should be surmounted by a parabolic reflector or mirror of some kind, which might be so constructed as to reflect the sun's rays through a large angle and be visible at a great distance, across the Severn, and up and down the line of the Midland Railway. "This reflector would," it is said, "have a very beautiful effect, during many hours of the morning and evening in summer, and throughout the whole period of sunshine on a winter's day, and would strikingly illustrate the great event of Tyndale's life which it is proposed to commemorate."

**MONUMENTAL.**—The proposal to erect a statue to the late Lord Macaulay in Trinity College, Cambridge, has met with a hearty response. The Prince Consort, Chancellor of the University, has headed the subscription with 100*l.* An influential committee of "residents," with Dr. Whewell, the Master of Trinity, at its head, has been formed for the purpose of carrying out the arrangements.

—A monument has been erected on Southsea Common to commemorate the late Sir William Peel, who died in India at the head of the Naval Brigade during the Sepoy mutiny.—Lord Dundonald, it seems, is to have a monument at Liverpool, and several subscriptions, headed by the Mayor, have already been announced for the purpose.—We regret to hear so little said of Admiral Napier, who surely merited a place in St. Paul's, with something monumental to remind us of the bluff old sailor, who did some brilliant deeds in his lifetime.

**CENTRAL RAILWAY STATION IN THE CITY.**—The Court of Common Council have adopted a report of their Improvement Committee relative to the establishment of a central railway station in the City of London. The report stated that it was absolutely necessary that there should be a central railway station in the City, and that the best site for it would be Farringdon-street,—that the effect of having the station at this spot would be to materially improve Holborn-hill and Skinner-street, and reduce the gradient from 1 foot in 19 to 1 foot in 40 in the case of Holborn-hill, and 1 foot in 46 in Skinner-street, which alone would be a most important improvement,—that it would also greatly improve the City property in Farringdon-street and Victoria-street, and be of very great importance in connection with the proposed new market in Smithfield. The report concluded with a recommendation that the court should continue their powers to carry out the proposed plan.

**"NEEDFUL REPAIRS" OF A HOUSE.**—In the Court of Common Pleas, last week, was tried the case of *Scates v. Lawrence*. It was an action for breach of covenant to repair and make "all needful reparations" reasonable wear and tear excepted. 30*l.* were paid into court. The plaintiff's estimate was 60*l.*, the defendant's, 16*l.* The house is the Swiss Cottage, at Tottenham, which had been built 150 years ago. The case for the defendant was that it was dilapidated when he entered it, and that seven years before the close of the term he had put it into repair. The plaintiff's answer was, that the rent (50*l.*) was low. The house contained three sitting-rooms, four bed-rooms, the usual offices, a large garden, a field, stable, conservatory, &c., and that the defendant took the house, knowing its condition. Mr. Justice Willes: On such a covenant a tenant is bound to put the premises into good repair if out of repair when he entered, and to keep it in repair, having regard to its general character and condition; but he is not liable for new papering, which is purely ornamental, and not expressed in the covenant. It is a matter to be decided by the jury. According to common sense, rather than the strict construction of law, if the tenant had painted the outside within three years, and the inside within seven years, and there had only been fair wear and tear since, he was only bound to cleanse the old paint, &c., and not to repaint. So, as to other repairs; the tenant was not bound to give the landlord a new house, but the old house in reasonable repair, with reference to fair wear and tear. The maxim, "give and take," must in such cases be applied; and a landlord ought not to claim for every crack in the glass or every scratch on the paint. The question was whether there had been a substantial performance of the covenant. The tenant was entitled to have the benefit of repairs he did, and was not bound to make them just before he left, so as to let his landlord have the whole advantage of it, and have none of it himself; for the landlord, not the tenant, had to bear the burden of fair wear and tear.—The jury immediately returned a verdict for the defendant.

**CO-OPERATIVE PROFITS.**—The Wardle Co-operative Manufacturing Company, we hear, has declared a dividend of 60 per cent. on the past half-year; and other companies in the Rossendale district are in so flourishing a condition, that large dividends will be paid to the shareholders.

**FALL OF A WAREHOUSE IN LIVERPOOL.**—On Saturday before last, about three o'clock p.m., a large portion of tenement, situated at the corner of Jordan-street and Chaloner-street, suddenly gave way; and, with a rush, the front and corner walls, beams, floors, and roof, with the contents of the different apartments, settled down in the street. The portion of the warehouse which fell is almost new, having been recently rebuilt after a fire which occurred on the premises about twelve months ago. It was four stories in height.

**LINCOLN GRAMMAR SCHOOL COMPETITION.**—Sir,—I your notice of the Lincoln Grammar-School competition you mention one of the five designs selected for further consideration, with the motto "Ideas," with names unknown; so I beg to inform you that the unknown authors of that design were myself and Mr. James Thomson. Our names were attached as usual in such cases, but I suppose overlooked; hence the only means of making the unknown known will be by your courtesy through your wide-spread journal.—**GEORGE SIMMONS.**

**LINSEED OIL.**—Allow me to thank a "Friend to the Unemployed" for his remarks respecting the adulteration of linseed oil. I would suggest that the manufacturers or merchants should be subjected to a similar ordeal as the *Lancet* uses towards different tradesmen, viz., to purchase samples from each, and publish the result of an analysis, giving the name of the firm that sold the genuine article. If linseed oil is scarce, let us have what there is genuine, at the market price, because it must be genuine to answer our purpose. The present substitute will not do.—**A. B.**

**FALL OF HOUSES IN KENNINGTON.**—Sir: You mentioned briefly the fall of houses in course of erection near Kennington-park. If the poor fellows who were buried beneath the falling materials, and almost crushed to death, should not survive, an investigation will take place, and show how inadequate are the powers of district surveyors in preventing speculative builders erecting such dangerous structures as those in question. There are several of a similar description, in close proximity, now erecting, and equally dangerous. Mortar of lime and mould from the excavations; joints to brickwork averaging 3-inch and 1 inch; arches without skewbacks; neither iron nor other bond; spruce deal joists, 7 inches by 1½ inch; lintels, 4½ inches by 3 inches, carrying the floor; joists over openings, 4 feet 6 inches wide, without discharging arches or any other support but the head of sash-frames. They will vie with houses at Brighton, which are the climax of scamping.—**A. CLEGG, OF WORKS.**

**THE COVENTRY RIBBON TRADE.**—An excellent example, so far as regards the distressed weavers of Coventry, has been charitably set by the Baroness Brunow, who, as Messrs. Grant & Gask, of 60, Oxford-street, inform us, has ordered, through their firm, a dress, to be made principally of Coventry ribbon, and for the completion of which about 500 yards will be required. It is to be hoped so excellent an example will be widely followed by other ladies. A suggestive one at our elbow (while giving her vote—a plumper, of course—in favour of the ribbon dresses, one of which she wishes she may get, just to see how it would look), says she knows of a desideratum which might also perhaps be of considerable service, at least at a future time, to the ribbon weavers; while it would be "a real blessing" to milliners and mantua-makers, both amateur and professional, could it only be realized by some inventive brain. From what we can understand as to this desideratum, it appears that, in the making of bonnets, dresses, cloaks, &c., the cut materials are often required to be what are called "on the cross," in order that they may set or fit more handsomely; and that, for this purpose, such materials are cut crosswise,—or slopingly, rather,—out of webs of silk, or velvet; but that, in doing so, there is not only very little economy, and some disfigurement by frequent joinings, but often great waste, and considerable additional have what I shall call "cross ribbons," broad and narrow, so woven as to imitate the cut material "on the cross," an end would be put to a great deal of waste slashing, against silk and velvet webs, and rejoining of the materials so cut; and a new branch of the ribbon trade might thus arise, to replace, so far at least, that which has fallen into disuse.

**THE SEWAGE OF CANTERBURY.**—The subject of utilizing sewage is about to be taken up at Canterbury. Some gentlemen connected with agriculture have met to discuss a plan for irrigating the Sturry marshes with the Canterbury sewage.

**THE GLASGOW QUEEN'S PARK.**—The Glasgow Town Council have resolved to devote 8,000*l.* in laying out the main roads and walks on the plan of the Queen's or South Side Park, as modified by Mr. Carrick, the city architect. A long discussion has taken place upon the method of laying out the park. Some members are in favour of its being laid out in the Italian style of gardening, others preferring that it be laid out as an airing and recreation ground for the people.

**HOW TO BRING DOWN RAIN.**—Mr. Weeks, of Sandwich, writes as follows to Mr. Rowell, who, at the British Association, suggested the possibility of bringing down rain from the clouds at pleasure:—"I have from very early life been an assiduous experimenter with electric kites, atmospheric exploring wires, &c. Now I beg to assure you that it has several times happened that, when my kite has been raised immediately under a distended, light, fleecy cloud, at moderate elevation, a free current of sparks has passed from the apparatus during some ten or twelve minutes. I have suddenly found myself bedewed with a descent of fine misty rain; and, on looking up, have seen the cloud upon which I was operating surprisingly reduced in magnitude."

## TENDERS

For setting out, excavating for, and forming, roads, foot-paths, and sewers, on land east side of railway, for the Great Malvern Hotel Company. Mr. E. W. Elmist, architect:—

Hayes & Warrington	£1,350 0 0
Edwards	850 0 0
Holt (accepted)	928 0 0

For two villas at Spareshook, Essex. Mr. Read, architect. Quantities supplied by Mr. Baggett:—

Macey	£3,700 0 0
Hedges	3,587 0 0
Lawrence & Sons	3,548 0 0
Coleman	3,389 0 0
Hill	3,284 0 0
F. & F. T. Wood (accepted)	3,280 0 0

For the erection of a public-house, the "Rose and Crown," High-street, Wapping, for Messrs. Taylor, Walker, & Co. Mr. Charles Dunch, architect. Quantities by Mr. Curtis:—

Perry	£1,490 0 0
Hedges	1,387 0 0
W. Hill	1,350 0 0
Hack & Son	1,339 0 0
Wood, Brothers	1,259 0 0
Blackburn	1,209 0 0
Emmott	1,205 0 0
Stewart	1,188 0 0
Brown (accepted)	1,141 10 0

The accepted tenders for warehouses for Mr. W. P. Edwards, St. Stephen's, Norwich. Mr. John Daymond Ellis, architect, Norwich:—

*Bricklayer, Plumber, Mason, Slater, and Tiler.*

J. W. Lacey ..... £492 0 0

*Carpenter and Joiner.*

T. Brooks ..... £647 10 0

*Smith and Founder.*

Pinson ..... £347 0 0

*Plumber, Painter, and Glazier.*

J. & J. King ..... £218 10 0

Total ..... £1,705 0 0

For public-house, Approach-road, Victoria-park, Messrs. Hannack & Lambert, architects:—

Brown & Robinson ..... £2,160 0 0

Case ..... 2,150 0 0

Page ..... 2,050 0 0

Blackburn ..... 1,909 0 0

Forrest ..... 1,689 0 0

Hedges ..... 1,685 0 0

Perry ..... 1,633 0 0

For building new offices for the Commissioners of Sewers of the City of London, at Gullinall. Quantities supplied:—

Sawyer ..... £6,070 0 0

Harding ..... 6,800 0 0

Bartley, Brothers ..... 6,586 0 0

Cowley ..... 6,459 0 0

Longmore & Barge ..... 6,375 0 0

Brage ..... 6,286 0 0

Garnison ..... 5,751 0 0

Little ..... 5,711 0 0

Cushing ..... 5,657 0 0

Axford & Co. .... 5,592 0 0

J. J. & F. Coleman ..... 5,459 0 0

Mellor ..... 5,363 0 0

Wills ..... 5,342 0 0

Wilson ..... 5,347 0 0

Batterbury ..... 5,235 0 0

Stevenson ..... 5,219 0 0

Patman & Fotheringham ..... 5,167 0 0

Colls ..... 5,160 0 0

Rider ..... 4,966 0 0

Myers ..... 4,940 0 0

Hill (accepted) ..... 4,892 0 0

Perry ..... 4,728 0 0

# The Builder.

VOL. XVIII.—No. 934.

Shades and Lights in London. St. Luke's: Whalstone Park: St. Clement's Dances.

**ITH CHRISTMAS,** which brings with it the termination of our volume for 1860, comes the repetition, in numerous quarters, of statements made by us years ago as to the condition of the homes of the labouring and poorer classes in various parts of London. Thus, Mr. Harvey, chairman of the West London Union, writes to the leading journal to describe the state of parts of Holborn. He says the relieving officer and one of the guardians of the union recently visited Plumtree-court, Holborn, which contains twenty-seven houses, without back yards, and, with few exceptions, without back lights. These houses were occupied by 676

men, women, and children. In one room, 10 feet by 13 feet, and 8 feet 6 inches high, there were thirteen persons living and sleeping, viz., two men, five women, and six children. In another house, 17 feet long and 16 feet wide (including the passage), with ground-floor, first-floor, and attic, there were sixty-nine persons living and sleeping, with only one convenience in the basement. On another occasion, when the officer visited a house in this court, between twelve and one o'clock in the morning, for the apprehension of a man who had deserted his wife; in attempting to go into one room he was compelled to wait until the inmates had risen from the floor behind the door, so that the door could be opened. The people lay so thick on the floor that he had to be cautious in stepping between them. In this room there

was one child suffering from the measles and another from the small-pox. On opening the door, he goes on to state, the stench was so great that the police officer who accompanied him was obliged to withdraw.

Seven years ago we described this same place in words differing little from those now used by Mr. Harvey:—

“Leaving Field-lane,” our account ran, “and crossing Holborn into Shoe-lane, opposite the wall of St. Andrew’s Churchyard, you reach the entrance to Plumtree-court, which has long been the haunt of fever: this court extends a considerable distance towards Farringdon-street, when it goes off at right angles to Holborn: the court is very narrow, and the drainage very imperfect. A sink at the bottom of this pestilential hole receives the greater part of the refuse of the place: it is often stopped, and then a pool of considerable extent is formed. Pulling the latch of the outer door of one of the houses here, and then entering the room on the left, with the assent of its occupants, we found an atmosphere so stifling that we were forced for a moment to retreat. There were two beds in the room: in one, which seemed to have heads all round it, were no fewer than nine women and children. They were stowed so oddly and so thickly, that it was not an easy matter to count them even by the strong light of the policeman’s lantern. In the other bed were a man and a lad, and in a small room, or closet, leading from this room, three other persons were sleeping. There was little ventilation. Had there been none, assuming that each respiration is 40 cubic inches (Menzies), the respirations twenty a minute (Haller), and that the existence of .08ths of carbonic acid is destructive (Lichig),\* the occupants of the front room must have died in eight hours! We will not trouble our readers with the inference, nor need we give them further details of this quarter. Pondering on what we had seen, and weighing the possibility of improvement before the infant-school has done its work, we were glad to make our way homeward to freer air.”†

We have engraved views by the dozen, showing to the eye the overcrowded state of houses now again pointed to as full of danger because of the number of their inhabitants, nothing having been done to bring about a change: indeed, in some of the London parishes, we have reason to believe that the overcrowding is greater than it was five years ago. Parish authorities do not seem to be aware that the Removal of Nuisances Act requires that whenever the medical officer of health, if there be one, or if none, whenever two qualified medical practitioners shall certify

\* See First Report of Metropolitan Sanitary Commission, page 137.  
† See, also, “London Shadows,” by George Godwin; page 15. 1854.

that any house is so overcrowded as to be dangerous or prejudicial to the health of the inhabitants, these inhabitants consisting of more than one family, the local authority shall (not *may*) cause proceedings to be taken before the justices, to abate such overcrowding, and the person permitting it is rendered liable to a penalty.

Leaving the authorities, then, to do their duty, while we venture to pursue the course we believe to be ours; we would give a few particulars of a parish little known to the majority of readers,—St. Luke’s in the central portion of London. Many have heard of the benighted condition of Golden-lane and its neighbourhood, from the often-repeated appeals of Mr. Rogers, the incumbent of St. Bartholomew’s district; while others of an antiquarian turn may remember accounts of the time when Golden-lane and its surrounding parts were a fashionable locality,—when the theatre of Queen Elizabeth’s days existed, and green trees and fields stood in the place of the endless rows of houses and other buildings which now exist. Generally, however, except to the immediate dwellers, little is known of this, perhaps one of the poorest and most neglected parts of the metropolis. It is most densely populated. From Old-street, an important thoroughfare (“the old highway from Aldersgate for the north-east parts of England, before Bishopsgate was built”), branch on both sides many streets, most of them narrow: from these run courts and alleys teeming with an immense population, chiefly in a poor and forlorn condition. Strange and dreary is the appearance of these avenues, in spite of the bright sunshine. Let us, however, make a more minute examination,—walk to Golden-lane and its tributaries, and see how these are cared for. Leading from the lane in Cherry-tree-court, a place barely 4 feet in width, are seven houses on one side and a high wall on the other. Externally the houses are not in bad repair, but in the interior their dirty and dilapidated condition is remarkable. In one small back room was a little boy nine years of age, and a girl some years younger, who had scarcely a rag of covering on them: there were two other children out, we were told, working in the street. Those at home crouching over the fire were altogether un instructed. Their mother made a living in the markets, they told us, and their father had run away. A wretched bundle of rags in a corner served for bedding. In a back yard, rupaved and broken, was the overflow water from cesspools, the closets stopped and in a bad condition: there was only surface-drainage, and that of an incomplete description, and yet every room of these premises is occu-

Fig. 3. Home Comfort.

ped by a family, some of them consisting of seven, eight, or nine persons. In most of the houses the water "ran short;" on Sundays "the water is turned on for about five minutes, but sometimes it does not reach them." The landlord of this and a large extent of property here and in other quarters has been asked times out of number to put the place into a little better order; he, however, receives the rent, promises attention, but does nothing. The whitewashing of the narrow, dark staircases of these houses and of the walls, which are at present black with accumulated smoke and dirt, would entail but a trifling outlay. We trust that the day is not far distant when compulsory drainage, *thoroughly carried out*, will be made a rule in connection with the dwellings of the poor. Remarking that the scavengers of St. Luke's perform their duty very badly, we pass on to Harshorn-court, a singular locality, which, with the parts adjoining, is inhabited to a great extent by thieves and the most dangerous characters. This is the entrance to a labyrinth of courts which, like the intricate workings of a Gloucestershire iron-mine, lead in all manner of curious and mysterious directions. In front of five houses is a kind of square, which formerly has probably been occupied as gardens; here swarms of children peer curiously out, neglected little creatures, so forlorn, so seemingly helpless for good, that the first impulse is to ask—What is to become of them? What business, according to present arrangements, are they fitted for? What, except by chance, is there for them but beggary or the prison?

The houses mentioned are single houses (one room deep), without any openings at the back. Like those previously alluded to, these dwellings are, so far as exterior is concerned, not in bad repair, but anything worse than the interiors cannot be easily imagined. Let us step up one of the dark narrow staircases: in one room, on the door being opened, a man had risen hastily from his bed; a strong active-looking woman was there, and from the mass of rags swarmed a number of children (it was about ten o'clock in the morning). Few could look at these helpless little things without an aching heart; the faces, not ill-shaped, were massed with dirt, and they had on scarcely a rag of covering; there was no furniture in the room, the window was plastered with mud; and the floor, although this able woman was here, had probably not been washed for months. The tenant complained of the landlord's neglect. Modestly, we ventured to hint that if the wife were thoroughly to clean even the broken glass of the windows, and maybe, give the floor a good washing, when the landlord next called for his rent, he would be so much astonished at the contrast that he would set some one to put the walls in order immediately. The tenant stated that his wages for working in the market are small and uncertain, and with a number of children "I cannot pay much rent," he said, "or do you think that I would stop in such a place as this? The dirt you speak of is the least evil, from night till early morning the place has no peace, at times it would take a dozen policemen to quell the tumult." This is no doubt true, for most lawless and defiant is the population here.

In all parts there are apartments in a similar condition; no attempt is made at ventilation, there are no hack windows, no openings to the roof; dirt and crowding, particularly in the upper rooms, produce an atmosphere unpleasantly visible.

A great portion of the open space is occupied by a large dust-heap, which consists of the worst kinds of refuse, that, we are told, has been in the course of collection for several years, and which is daily added to by such matters as the costermongers may not find convenient to sell. There are no dust-bins provided, so that, as a necessity, the refuse of the houses is added to this putrid heap, which is made a sort of *play-ground* for the children, who, in their way, enjoy what seems to them a remarkable benefit.

For a population of ninety and more persons, there are only two closets, in a most filthy condition, over which is the water-tank. How can people be clean or decent under such circumstances? Refuse is left in all

directions, and the roadways, in other weather than this, are deep with poisonous and stagnant water. Turning sharply to the left of the *play-ground*, we come to Little Chicapside. In this and other places, close by, may be seen groups of houses without proper accommodation; even the surface drainage is not good; the pavement abominable, and the whole of the space around is polluted with cesspools.

We look into many houses and tenements, and hundreds might be described so much alike, that an account of one would almost serve for the other. Range after range of houses, badly constructed; the roads and yards unpaved, are patched in such a manner as to be of but little use; the soil saturated with the most unwholesome matters, to a considerable depth; room after room, to the extent of thousands, all loaded with dirt; the same pictures of broken ceilings and walls; half-naked and half-fed children; old wick-like women, crouching by the fire-grates; men entirely or partially drunk, lying on shavings, or rags, on the floors, nearly all without furniture,—these form the picture. Without particularizing, we will jot down slightly a few characteristic features.

Twelve houses form a narrow court, sunk below the regular surface; there are two closets only for all those—there was, a short time ago, only one. Here dwell persons who might give information respecting missing dogs; others who collect in the streets; and there is more than suspicion that some of the persons who have lived here, have been engaged in the horrible employment of skinning cats alive. Gladly do we escape from the din of barking dogs, and the unpleasant physiognomy of the inhabitants. Let us proceed to a fresh spot.

Another narrow court, in which are several houses, having cellars below them. In passing, had as have been the smells already experienced, they seem faint in comparison with that which rises from the grating. By means of the open windows above this we see a sickly woman, and a child lying in a corner still more sadly stricken. This is not to be wondered at, for descending into the cellar will be found an untrapped and dirty closet (Fig. 1), the water-cask close to it, and an accumulation of other refuse, which had been allowed by the scavengers to remain for six months. Up the staircase, by the crevices of the floors, by the open windows, the fever-bringing gases make their way into the rooms.

In one of these houses, similarly situated, where the people seemed better off than usual, we asked a woman if she thought that water kept in such condition could be fit for use. The reply was,—*"It's excellent water, sir; I would not mind drinking a gallon of it."* On endeavouring to explain how soon water is rendered unwholesome by the action of bad air, she said,—*"I am sure I don't know, sir, but it is beautiful water though."* This ignorance is one of the difficulties to be encountered, and stops the way of improvement.

Let us make another sketch. It is a square room, the walls of which we can touch either way by stretching out the arms; close to the window is a closet, untrapped, and cesspool (Fig. 2). In rooms like this a family of six persons may be found. Such is the unpleasant effluvia which arises from the back premises, that people cannot, particularly in summer time, open the window.

We peeped into another interior, dirty beyond description,—a man on the floor asleep,—the children out at *work*, which probably consists of turning "catherine-wheels," or some less honest employment. Onions and other vegetables are lying about to be got ready for sale. The atmosphere, if possible, worse than usual; the ceiling and walls, black as the back of a chimney. The fireplace and chimney project, and a large portion of the upper part of the bricks has been removed; so that the smoke, in a great measure, spreads over the walls and roof. (Fig. 3.) On the person here waking up, and some remarks having been made that it would be better for health to have a little ventilation, he at once said, "certainly," and bodily lifted out the window-frame, and placed it against the wall.

Words and sketches fail to give an idea of what is going on around us. Nothing but a personal inspection can afford a just notion of the state in which these poor and often ignorant people are allowed to be.

In one small room, without any separation, live nine grown-up persons and two children,—eleven in all. There are the mother, and married sons and daughters, and the children, all living in this promiscuous manner.

In some parishes their sanitary arrangements are much more effective than others. In St. Luke's the relative state is not good; when saying so, we must, however, not omit to add that the district is overrun by poor, and that the chief body of ratepayers are but ill able to meet the heavy demands made upon them. There are, however, matters which depend on more sanitary inspection; and where the forcing of the proprietors of houses to do what is right, might not only be beneficial to the inhabitants, but, by preserving health, be a saving in the poor-rates. As one example of the inefficiency of the parish officers of health, we will mention Wood's-place, Chequer-alley, leading to Whitecross-street. Here, at a very short distance from the houses, is a water-closet, which, at the time of our visit, was overflowing on the ground. The people say that the effect upon them is very bad, and that maggots crawl from the court into the houses. This state of affairs has continued for a long time, and the parish authorities have had notice of it for more than eight months, yet nothing has been done. In other cases it is complained that half-measures are used, and that when improvement has been made, there is not enough attention shown to see that order is kept. To this important question we may return at another opportunity. Weary, oppressed, and pained beyond expression by the poisoned air and the sad sights which have come to view, we will now only look at one more group of houses. In an ill-paved yard is a closet, the cesspool is overflowing, standing in pools, and running down the gutter, and into a smith's premises. The smith says that at times he is quite flooded with it, and that at the last attack of cholera, himself and two sons were in the hospital ill with this disease at the same time, and that deaths happened in the adjoining houses. "But see," said a respectable-looking old man, "the state of the place a little way to the back. I have a large family, which in a measure forces me to live in such a place. Look at the house adjoining; a drunken man, if he fell, would knock the wall out; there are two closets overflowing, the dust and other refuse are inundated; close to this is the window of my bedroom; no one would credit the atmosphere we breathe. I have been to the country to work, and when I returned last Saturday night, I thought I should have been poisoned; and complaint is useless." Mr. Rogers' schools, excellent in their arrangements and good in their management, and a harbour for the houseless in Playhouse-yard, are bright spots in this darkness.

In Whitecross-street—a wonderful market for the poor at mid-day—the crowd is enormous, but on a Saturday night you might almost walk on the people's heads.

Various interests are antagonistic to the rapid improvement of the dwellings of the poor to which we have referred; but the statesman will be a benefactor to his country, who will with firmness and vigour grapple with the monstrous evils which so much need remedy. The important points to be aimed at are—

- 1st. Power to overlook houses let in tenements.
- 2nd. The power of preventing the letting of such houses to more persons than the amount of space will healthfully admit of.
- 3rd. The enforcement of the removal or improvement of houses which are shown to be arranged on wrong sanitary principles, or where drainage is in such state as above referred to; and
- 4th. The establishment of Ragged Schools—the provision of means for the removal of the youth of both sexes who are placed in situations which leave no hope, and other measures which have been often referred to by us before.

It seems, however, clear, that in order to give parishes such as St. Luke's fair play, we should have an amalgamation of all the parishes of the metropolis, rich and poor, so that those which are ill-conducted may be assisted by others more prosperous.

That our review may not be wholly a dark one, we must not omit to note some of the good things that are in progress in various parts of the metropolis. In St. Giles's, once in such evil repute, the schools and other buildings which have been reared during the last twenty years are creditable to all who have been concerned. In other directions we are glad to note improvement, and that in various neighbourhoods, schools, churches, and improved buildings are springing up. Every one has heard of Whetstone-park, a place heretofore always infamous. It consists of a row of houses, between Lincoln's Inn and Holborn. These buildings are of much older date than any portion of Lincoln's-inn-fields. We well remember the place some years since, when its badly-paved, dirty, and evil state was notorious. We now find the place carefully swept; boards are posted with directions to prevent the throwing out of refuse, and in the centre of this once-neglected spot a Ragged School has been established.

Great alterations have taken place here in a comparatively short period. In 1735, the few persons who inhabited Lincoln's-inn-fields were obliged to apply to the Legislature for permission to rate themselves, for the purpose of getting rid of several nuisances. On this occasion evidence was given that, forty years before, the site had been all in grass. About 1705, that part which bounds the Terrace-walk of the society of Lincoln's-inn, was raised; but in 1734, quantities of rubbish were brought from all quarters, and thrown there. The space near the Turnstile was infested by persons who let wretched horses for a half-penny a ride. The riders' limbs frequently came to damage. Besides, the fields were used as a place of exercise for the horses of richer persons, and in consequence accidents were of frequent occurrence.

The *Loyal and Impartial Mercury*, of September 1, 1682, has the following paragraph:—"On Saturday last, about 500 apprentices and such like having got together in Smithfield, went into Lincoln's-inn-fields, where they drew up, and, marching into Whetstone-park, fell upon the land-houses there, when having broken open the doors, they made great spoil of the goods: of which the constables having notice, and not finding themselves strong enough to quell the tumult, procured a party of the King's Guards, who dispersed them, and took eleven, who were committed to the new prison. Yet on Sunday night they came again, and made worse havoc than before, breaking down all the doors and windows, cutting the feather-beds and other furniture to pieces."

The Ragged School which has been opened here is very useful, and is well attended,—some evenings of the week by boys, and on the other evenings by girls. It is most desirable that the school should be open during the day; and this could be readily managed, should sufficient funds be provided.

Close by, namely, in Clare-market, a more important establishment has been opened through the exertions of the Rev. C. M. Robins, the incumbent of the district. A row of six houses, known as the Colonnade, has been taken, put into good repair, made to communicate, and decorated with texts and otherwise.

On entering the place we find ourselves in a commodious room, comfortably furnished. Some very good engravings hang upon the walls. In the upper story is a sleeping-room, in which are several beds. The fittings of this apartment are remarkable for their neatness and good taste. This part of the building is a refuge for orphan and destitute boys, which, in a spot close by, has been in operation more than twelve months, and has been the means of rescuing from misery and ruin many boys who, but for this institution, would have been left to sink. They are now earning an honest livelihood, some as errand-boys, some in shops,

while others have been sent to sea, where they are doing well, and bear a very good character.

In the sitting-room set apart for these boys is a fireplace fitted for cooking. Here sick people may have broth, puddings, and other things cooked for them free of charge. Something of this sort is greatly needed in all the poor districts of London, for many have very little idea of cooking properly; and in illness this is more than ever the case, to say nothing of the trouble and expense of cooking at home. Instruction could, at the same time, be given to some older girls, who might assist in this kitchen. A trap-door and some descending steps lead where a large boiler has been provided for making soup in the winter time. Good soup is made and sold to the poor at 2d. per quart, cost price. This will supply a want that has been greatly felt in the parish: the prospect of a rise in the price of provisions during the winter will make this and other soup-kitchens of great value. Passing through the apartments of the superintendent, a room is found neatly papered, and hung with good prints. The floor is carpeted, and the place has the aspect of a drawing-room. This is the club-room, provided for working men, where they may smoke their pipes, have the opportunity of enjoying a gossip, or reading books, newspapers, and other periodicals, in a well warmed and well lighted apartment. Above this is a library.

Next is a club-room for women, which is provided in the same way as the men's club. Here, from six until ten o'clock in the evening, aged and other women may come to read, work, and talk. When we remember the conditions of some of the wretched homes which those persons are forced to occupy, the advantage of this provision is evident.

In the Working Men's club, we learn that already eighty subscribers have entered their names. The payment is 2d. a-week, and it is considered that this is more than sufficient to meet all the expenses of rent, light, fire, publications, &c. It is worthy of notice, that the club is under the management of the working men themselves, who will thus have a direct interest in its success.

One room is occupied by the Parochial Mission women, who are employed amongst the poor in performing various kind offices for them when in distress. There is also a clothing establishment in the same house, where persons living in the neighbourhood may procure articles at cost price. There is also a registry for servants out of place, nurses, and charwomen.

On the ground-floor a large apartment has been contrived, which is intended as an adult school for boys and young men, who are able to pay a small sum weekly for their schooling; and here it is proposed to give lectures and cheap concerts. Several inhabitants of the district have offered their services in carrying out this praiseworthy object. Here persons living in the neighbourhood will have the opportunity of spending an evening in a comfortable room—a greater boon to hard working men than many imagine, who are not aware of the conditions of their homes. In order that the most may be made of the premises, the upper part of two of the houses has been put into good order, and is let out at a reasonable rate to persons of a good character desirous of living in a quiet and respectable manner. We direct attention to this excellent work with pleasure, and recommend those who are willing to benefit the neglected masses of the metropolis and our large towns to pay the institution a visit.

The Swamps still abound; but the Bridges are building.

We have made arrangements by means of which we hope to be able to place before our readers in the coming year articles of more than usual interest illustrative of architectural and social progress abroad. We shall, further, continue the review we have commenced of some of our large towns, with special reference to their deficiencies and requirements.

#### COMPETITION DESIGNS FOR THE LEEDS MECHANICS' INSTITUTION AND SCHOOL OF ART.

THE exhibition of competing designs for this institution commenced on Thursday, December 20, in one of the side galleries of the Mnsic Hall, in Albion-street. This exhibition has been looked forward to with great interest by many persons. The union of a mechanics' institution, school of art, and picture gallery, boys' school and girls' school, and school of science; and the sum, 13,000*l.*, to be expended on the building which was to accommodate all these institutions, gave great scope to the architect's powers, and grand designs were expected from the competitors. This expectation was enhanced by the eulogiums which have been passed on the plans at every public meeting in Leeds for the past two months. Those who were interested in the cause of architectural beauty looked forward to a display of originality at least, and probably of some genius. It is true that the sum of money to be expended was small, and the ground to be covered large; but then the site of the building was grand; and it was certain that good men were working hard in this competition.

We have been accustomed to regard mechanics' institutions as standing illustrations of the utter sacrifice of feeling to apparent use; of beauty and elegance to commodious utility. This is necessarily the case in the management of these institutions, and unnecessarily, though almost invariably, evident in the architectural features of the buildings erected for, or adapted to, mechanics' institutions. But, in Leeds, the Town-hall has created a revolution. A building sufficiently good to please the Leeds people ten years ago will not pass muster now. The warehouses erected latterly, whose chief requirements are room and light, have added to these two necessities grandeur and architectural beauty. The Town-hall and the Wellington-street warehouses act as a standard by which all new buildings are tested; and great dissatisfaction is expressed when new works fall short of these common standards. Thus, the Overseer's Offices in East Parade, which are now being erected, are loudly and universally condemned by all men of taste and by the public generally. Yet we would remind the Leeds people that it is better by far than any municipal building or any private building erected more than ten years ago in Leeds. It is the standard which has been raised, and the public taste elevated; and the architect of the Overseer's Offices has not kept pace with this rapid improvement in both.

Being cognizant of these circumstances, it may be expected that no public body will venture to erect a bad public building in Leeds; particularly when the completion of the undertaking depends upon subscriptions from the inhabitants of the town. So that we were glad to hear the oft-repeated praises of the plans for the art schools, picture gallery, and mechanics' institution; and believed that, in proposing to erect a building which should be a credit to the town, the committee was doing the wisest thing possible, and making a powerful claim on the generosity of subscribers and friends of the institution.

Our first introduction to these plans on Thursday morning showed us that the committee has not been able to exercise much choice in the matter. There are only three plans out of the seventeen competing which could be adopted with any degree of credit. In two of these there are several obviously objectionable parts, and the third might be very considerably improved. But we shall notice the whole of the plans; and, after remarking upon each, give our own opinion on the plans generally, and the selected plan in particular.

The drawings are arranged in sets, but not numbered, and the names of the architects competing are not attached to them. It has been stated that three plans out of the whole were selected for ultimate comparison and choice, and that the authors of these three were Mr. Brodick, Messrs. Perkins & Backhouse, and Mr. Shaw; all, oddly enough, Leeds architects. It is, moreover, no secret as to who are the authors of the majority of the designs; and, whilst examining the plans for this criticism, we invariably heard the spectators speak of the designs as Mr. So-and-so's, and not by the motto attached to them. We shall, however, only refer to the selected three under the names of the authors: the rest we shall notice by motto.\*

\* We should here remark that the principal conditions of the competition were,—1st. That the building should be so arranged that the school of art, the art gallery, and class-rooms for boys and girls might be erected first; leaving the Mechanics' Institution, library, hall, and reading-room to be erected afterwards. 2nd. That certain specified rooms, with dimensions given, should be kept in one block or wing; and that other rooms should be kept in the other block or wing to be erected afterwards.

"M.I.B.A."—The selected design of Mr. C. Brodrick, architect of the Town-hall, is on the plan of a rectangle, and is one of the few that are so treated. The site of the new building is not itself rectangular, one of the angles of the oblong being reduced, making a trapezoidal form.

The plan chosen has a façade to the three streets by which the site will be surrounded. It is in the Italian style. The entrance in the centre of the principal front is elaborately decorated. It is approached by several blocks of steps; and, on each side of the site, is a recumbent lion. The doorway itself contains elaborate carvings, both of mouldings, caryatides, &c.; and the two pilasters which break the façade and rise to the top of the building are surmounted by a segmental pediment, filled richly with sculpture. The general character of the elevation is that of a large unbroken rectangular block, relieved only by the before-mentioned pediment and the vase-like forms surmounting the pilasters on each side. A very noble tier of windows runs round the whole of the three fronts of the building on the ground floor, and gives abundance of light to the rooms in it. The whole of the first floor (the building consists of basement, ground, and first floors) is lighted from the roof, being appropriated to the school of art, picture gallery, and school of science. The lecture-hall is in the centre of the building, and is circular on the model (so the accompanying statement says) of the Rotunda at Dublin, and is 77 feet in diameter. The picture gallery and schools of art and science surround this great central hall on three sides; and, on the fourth (the back), the hall occupies the ground to the extent of the site. The ground floor is devoted to the reading-room, library, and offices on one side, and on the other to the girls' school. The basement is occupied on one side by the boys' school, dwelling-rooms for porter, and waiting-rooms, &c.; whilst beneath the hall is a large room of the same form as above, to be devoted to tea-parties.

So much for the internal arrangements, which appear, except in some slight particulars, all that could be desired. Let us now glance at the exterior. It has been noticed that the whole of the first-floor is lighted from the roof: there are, consequently, no windows above the ground-floor windows. Thus it will be seen that the whole of the top of the building, for one-third its entire height, is a dead wall, which, unbroken except by a cornice, gives a heavy leaden appearance to an otherwise grand and well-designed structure. The roof is low, and surmounted by a picturesque cresting, in some degree helping to relieve the weight of the dead-wall. We would suggest that a parapet should surmount the cornice instead of the present flat wall; and, instead of the flat space between the cornice and the ground-floor windows, the wall should be broken up at intervals by bas-reliefs or other sculpture. A smooth stone building as this is would, in a few years, become blackened by the factory smoke, like the Philosophical Hall, in Park-row, Leeds; and then this third of the elevation, which is unbroken, will be like a huge leaden coffin, sepulchral, heavy, and excessively ugly.

"Prodesse civibus," the second selected design (by Messrs. Perkins & Backhouse), claims to be in the Tudor style, though there are not wanting features in it which are of any style but Tudor. This design has been described as being Classical on the ground-floor, and Gothic above; the windows on the ground-floor being circular-headed and plain, whilst the first-floor windows are bowed, with tracery. The top of the building is surmounted by a fifteenth-century parapet. At the angle of the principal front is a huge dome. The lecture-hall is 92 feet by 61 feet, of very good form, and will accommodate 2,087 persons. The picture-gallery is 84 feet by 30 feet, and a good room. The decoration of the hall, which is shown in a separate drawing, is most unsatisfactory.

"Spes" (now labelled as being by Messrs. Shaw & Sons), is the third plan selected out of the competition. It is Tudor in style, the principal feature being an octagonal lantern-tower—not altogether destitute of character in itself, but wholly out of place here. The hall, or lecture theatre, is 116 feet by 50 feet, an absurd plan, considering the distance some of the audience must be from the lecturer. There are two galleries, one above the other in the hall, which have a bad effect. The general effect of the exterior is trifling and petty, and the windows are small.

"Fortiter et Fideliter" gives us an exterior like a reduced segment of the Coliseum, excessively classical, yet possessing considerable power. There can be no question but that the arrangements of this plan are infinitely superior to all the other

plans in competition. It complies with the conditions most scrupulously. The lecture-hall is 90 feet by 70 feet: the picture-gallery is constructed on the South Kensington model: the accommodation for the class-rooms, both for the school of art and other classes, is admirable. The plan possesses one feature peculiar to itself: the great hall is in the angle of the plan, and stretches diagonally across the site, whilst on one side is a separate entrance to the school of art and picture-gallery; and on the other side a separate entrance to the day schools. No other competitor has coped with the difficulty of the site as the author of this plan has. It is undoubtedly the most masterly arrangement in the competition. The cost of the building is estimated at 13,000*l.*; the sum to be expended.

Red Cross in a Circle,—a device.—This is the most highly and elaborately wrought of the Gothic plans. In a series of nine powerfully executed drawings, the author gives us most detailed and minute plans, elevations, and perspective. The general character of the elevation is simple: the entrance is flanked by two towers with high-pitched roofs; that of the school of art is also high-pitched; that of the lecture-theatre semi-circular. The author makes the most of the dead wall of the picture-gallery, by constructional brickwork.

The internal arrangements of this plan seem very successful, and proceed from an intimate knowledge of the various departments, especially of the art department; which, judging from the accompanying statement, the author seems to have studied, and taken much pains about. The lecture-theatre, designed to seat 2,000 persons, is 107 feet by 64 feet, and is a noble Gothic hall. It is surrounded on three sides by a gallery. The plans include an elaborate system of warming by means of hot air, and of ventilation by a shaft in a central courtyard. The decoration of the hall is effective. We would suggest to the author of these plans that his design is considerably marred by heavy penwork in his perspective; though this seems a fault of haste, for the workmanship in all the others is masterly. And if the author will allow us, we will remind him that thirteenth-century costumes are not common in Leeds at present, and that his perspective is not improved by them. Also, that the spiral column of the human figure is a continuous joint at intervals of an inch and a half, or less, and not a pocket-knife. A memorandum of this sort will be valuable to all the other architects engaged in this competition, as well as to our *Gougesque* friend.

Red Cross in a Blue Circle,—a device.—The chief feature in the elevation is a very high-pitched roof and dome. We will not be responsible for describing the style of this design: the best characteristic of it is, that real brick is used. The arrangements, however, are not good. Great pains have been taken to make the most of the design, which has fourteen drawings to explain it, and is very creditably executed. The lecture-hall is 100 feet by 60 feet, and not a bad room.

Three Concentric Circles,—a device.—The internal arrangements of this plan are really good, but the exterior is so unfortunate that we shall not consider the design at any length. It is a stone building, and, in the upper story, has clustered shafts of green and red, the only colours in it, which look like small wax tapers borrowed from a Christmas tree. The author is evidently not at home in the style he adopts, which is a sort of Italian.

We will here deviate from our task, to protest against the use of monograms of a simple character. The last three designs have all concentric circles as a monogram, and two have internal crosses. This is confusing, and may be of disadvantage to a competitor. We also protest against long Latin sentences, as in the next design we notice, though we only give the commencement of it. Surely architects can find one word, or two at the most, of sufficient character to individualize their designs; and, if they only can avoid "Excelsior" and "Amicus" they are safe.

"Secretur ad imam," &c., &c., &c.—This Gothic plan is indicative of great practice in cottage architecture, which the author must have had; and that is not a good preparation for the designing of a large building. On the right is an immense hall with high-pitched roof, like a Belgian Hotel de Ville, without the dormers and gables. On the left are clusters of gables, small, and dwarfed by the large hall. The arrangements in this plan are admirable. The details of the windows are exceedingly beautiful, and thoroughly well drawn.

The hall is of a bad form. Few architects seem to take the trouble to make such perspectives as the author has executed.

"Sit Lux, et Lux Fuit."—Another Gothic plan, the principle characteristic being a picturesque tower of great elegance. The lecture-hall, 60 feet by 105 feet. The other internal arrangements are both good and commodious.

"Art and Science."—In seven drawings the author gives a detailed plan of arrangements, which (judging, as we have invariably done, from the printed instructions) are not of the best possible character, much space being lost in corridors and passages. The exterior is Italian, and heavy. The lecture-hall, 92 feet by 50 feet, is better in form than in the majority of plans, the prevailing error being to make the hall too long for its breadth.

"An Old Friend."—An Italian design. The author of this design, whom we suppose to be a Leeds man, proposes to devote 400*l.* of the architect's commission to the external carving, of which there is abundance. This, no doubt, is a delicate bait, but has been signally unsuccessful. The most original part of the plan is a large corner dome, the lower part of which acts as a vestibule to the lecture-theatre.

"Connoissance" submits six drawings of a red brick design, with a corner lantern-tower, not without character. The author laments the haste with which he has had to produce his drawings, and having to send them in incomplete. We notice this design for no other reason than to propose to the author that he should get some one to write his description of competition works for him. There are not two lines of the description without four or five words wrongly spelt: the author dispenses with full stops, and is not very luxuriant of commas. The ridiculous verbiage, bad spelling, and absurd composition of this description disgrace the competitor. If "Connoissance" is a forger, we apologise for our remarks; but, if an Englishman, we are sorry for him.

"Ars et Scientia."—Elevation classical and meagre, not necessary accompaniments of each other. The lecture-hall has two galleries—a bad feature. The internal arrangements good and commodious. The picture-gallery is 80 feet by 30 feet, and built on the South Kensington model, which, by the way, seems to be the model for a large number of competitors.

"Ut Prosim."—Italian, with portico and central dome. A bad and minute edition of the Leeds Town-hall.

"Per Ardua."—A Gothic design. Totally insignificant; no unity or subordination of parts. Cottage architecture applied to a large building must be unsuccessful.

"Intent."—This is a design which seems to have cost the author little trouble. The elevation, in a pseudo-Italian style, is so unsatisfactory in point of design, that no excellence of arrangement could possibly compensate for it.

Having glanced at all the designs, we must now say a few words concerning the competition itself. There are eleven Classical and five Gothic designs, three only of which seem to us worthy of consideration. These are—"Fortiter et Fideliter," Red Cross in a Circle, and Mr. Brodrick's. We have carefully compared all the plans, room with room, judging in all cases by the printed instructions. Concerning the two first: both are so good that it seems to us merely the question of Classic or Gothic as to which should be selected. Both not only comply with all conditions, but show, in provisionary rooms not asked for, a very close knowledge of the subject. All the rooms are well lighted: the arrangements are simple and distinct; no space is lost in either; the central courtyard, in the Gothic design, being most valuable as a means of access for built-in two parts—the art department first, and the hall of the Mechanics' Institution afterwards. Both can be built for the money (13,000*l.*) as the designs now stand.

Concerning Mr. Brodrick's design, we have only to say that, if it suits the committee of the Mechanics' Institution, the committee has entirely misled all the other competitors by the issue of the printed conditions. Mr. Brodrick is the only competitor who has systematically neglected compliance with the principal conditions, and his design has been chosen. We must explain. Condition No. 2 says—"The plans to be so arranged that, if necessary, the school of art wing, including the art gallery and the class-rooms, &c., may be erected first, leaving the Mechanics' Institution, library, and reading-room, &c., to be erected afterwards." Mr. Bro-

drick has placed part of the school of art over the library and reading-room, and a tea-room, which was to be on the basement of the school of art, he has placed under the central hall; so that with his plan it is impossible the two sections can be built separately. Condition No. 5 says:—"The total cost of the building is not to exceed 13,000*l.*" &c. The selected plan exceeds that sum, without the lions at the entrance, the pediment over the doorway, or the eurytides. In the table of dimensions given in the instructions, the number required to be accommodated in the lecture-hall is 2,000. Mr. Brodrick states in his description that his hall will only seat 1,600; and, if more space be required, the audience must look through the glass screens or doorways at the back of the hall, standing; or a gallery be erected on the external landing for each lecture requiring sitting room for 2,000.

Now, we do not wish to pass a judgment on the committee of selection, which committee, we suppose, includes the men of taste who are subscribers to the institution; but we will quote to them the 12th condition issued by themselves: "As the only object of these conditions is to secure proper and strict impartiality in the selection, so that the best design may be adopted without improper influence or prejudice, it is hoped that they will be strictly complied with: *any breach of them will certainly exclude the drawings.*"

A short time before the drawings were sent in, a circular was sent to the competitors to say that in case of any difficulty of providing for the school of art rooms, some of them might be placed in the Mechanics Institution wing. This, of course, entirely altered all the previous conditions; but it was sent too late to be of use to the majority of the competitors, who have not been able to alter and improve their plans by the arrangement. Thus we find that in the best plans the original instructions are observed strictly: curiously, however, the permission was used in the selected plan.

We will ask this question in the name of those gentlemen who have adhered to the original conditions. Did the committee authorise the issue of the second circular reversing the first, and was it issued on the representation of the majority of the competitors, or by the request of the author of the selected plan? It is due to those who have spent much valuable time in this competition that good faith should be observed towards them. It is right and just that others besides local men should have a fair chance. Competitional morality on the part of committees is not high. We should be glad to hear a satisfactory explanation of this instance of competition injustice. We do not know personally one of the competitors. But we, in common with other professional organs, have a direct interest in the maintenance of strict integrity in public competitions.

It was stated in one of the local papers that the three selected plans were referred to Mr. Scott, for his opinion. We should be glad to know if the three were submitted to that gentleman, and whether he was aware of the existence of the printed conditions, which the committee had issued.

Our object in this inquiry is to give the unsuccessful competitors an opportunity of gaining fresh confidence in the fairness of competitors; for some of them seem to have that confidence shaken; and, we confess, not entirely without grounds.

ON ACOUSTICS.\*

The next unfavourable agency named was that of obstacles. Sometimes in buildings of some size obstacles in the shape of columns, not only may be tolerated, but will bring beneficial results after them on account of the good they do in breaking up or cutting off vacant spaces. This is particularly the case with the columns in churches, which, obstacles though they may be to direct sight and hearing, often help to prevent reverberation, and always are essential to that system of construction with a nave and side aisles, which is not only emulated by ancient tradition, but also found to suit well with modern requirements.

The most serious obstacle to comfort in hearing is the interference of some one's head between the auditor and the speaker. Where the speaker is not very high up indeed, and the audience occupy a level floor of any great extent, the inconvenience from this cause is much felt, and some partial elevation of the back of such a floor is often attempted.

A method of securing an undisturbed ray of sound and line of sight for each auditor was first

published by Mr. Scott Russell in the "Edinburgh New Philosophic Journal," vol. xxvii., for 1839, and has since been re-described and illustrated by Lachez, though it appears to have been practised more or less perfectly by the Romans. It consists in a system for setting out the height of the seats, by which they fall into a curve, called by Mr. Scott Russell the is-acoustic, or equal-hearing curve. The mode of procedure is as follows:—Having a section of the room, and having determined the position of the speaker and the seats, you proceed to determine the height at which you will place the speaker above the first auditor. This settled, draw a line from the speaker's mouth, and let it touch the point where the top of the head of the first auditor ought to be. This will fall on the line marking the position of the second auditor, and you fix the height for his seat, so that this visual line will come below his eye or ear—for this allowing some average dimension. From the point thus obtained, set up a height which will give the top of the head of this second auditor, and so on.

The dimensions that Lachez advises to be followed are:—

	m.	m.	ft.	in.	ft. in.
Back to back of seats	0.60	to 0.75	1	11	to 2 0
Height of seat	0.45		1	0	
Mean height from top of seat to eye	0.75		2	0	
Mean height from eye to top of head not less than	0.15		0	6	
Better as much as	0.30		0	12	

Mr. Scott Russell recommends for face-room, or the height from the mark for the supposed position of the eye to the top of the head, an allowance of 18 inches.

The nearer to the front seat the object to be seen or person to be heard is placed, and the lower it is, the more steep will be the inclination of the seats.

The farther removed and the higher elevated the object is, the less steep will be the curve which, in such cases, even dips down at the commencement of its course.

The seats in the Handel orchestra at the Crystal Palace will give a good idea of the nature of this is-acoustic curve.

There is a great advantage besides the direct radiation of sound to auditors thus placed, and it is, that they are almost of necessity free from the effects of echo. To make a stepped arrangement of seats perfect, they should be arranged on a sweep on plan, and then every auditor will have his face directed towards the speaker—will have an uninterrupted sight and hearing, and will be free from echo at his back; for if any such echo exists, it must pass over the heads of every one but those in the very back row of all.

The remaining obstacle is unshapeliness and bad proportion.

That a disproportioned room is bad for sound is a fact long since admitted, and holds good whether that room be large or small; but when this has been said, and experience has been appealed to for confirmation of the fact, there is very little that, in the present imperfect state of architectural acoustics, can be added. The subject has been alluded to before, and the most probable explanation of what is an admitted truth was then given, namely—that if all the dimensions are not in proportion to one another, the note of the room will not be good and pure. It is very possible that, in time, we shall know this for certain, and shall know, too, what precise series of numbers are best for dimensions, so that a room may be "voiced" beforehand, like a bell or an organ-pipe, by calculation. But we have not reached such knowledge yet.

In connection with proportion, however, I ought to draw your attention to the great division which seems to obtain between buildings for sound. There are, no doubt, two main divisions of speaking places, in the one (of which an ancient theatre is a type), sound is directly radiated from the speaker to the hearer much as in the open air. These should approach a circular or semi-circular shape, and an equal dimension in every way.

The second sort are those where the form of the building combines with the initial direction of the sound, or imparts such a direction to it, and conducts it onwards in one direction. The majority of large rooms are of this class.

Probably, therefore, one or other set of forms and proportions must prevail. If the building is to be on the radiating principle, it must be constructed so as to avoid reflection of sounds, and may be lofty, but must approach a semicircle or a circle on plan.

If conduction is to assist, then there must be one dimension decidedly predominating over the

others, and that dimension should be the length away from the speaker, and should regulate the width and height; with the proviso, that in these buildings the proportions should be rather long than short, and rather low than high.

With one example of an influence upon sound in galleries and long rooms, which is unquestionably due to the proportions of the room, and will be modified by every modification of those proportions, we shall have done with the topic.

It must have often occurred to persons listening to music in a tolerably long hall or gallery, to notice that there are portions where the sound appears more distinct than in others. This was very noticeable in the Floral Hall at the time concerts were given there, and may, I understand, be detected in St. James's Hall.

This phenomenon coincides with an interesting investigation of Savart, published by him in the *Annales de Chimie*. He invented an apparatus for showing visibly the actual condition of the air in a room during the time that a continuous sound of great intensity was kept up; and I mention this investigation, not as having been pushed so far by him as to lead to any practical result, but rather as showing that methods exist by which we may perhaps be able to arrive at information as to the acoustic condition of the air in rooms to a degree hitherto unattempted.

The sound employed in this investigation was that of a bell fixed in front of an open cylinder of such dimensions as to be suitable to reinforce powerfully the note of the bell; and a sound was obtained by this apparatus of such intensity as to be hardly bearable. The effects of this sound on the air were made visible by a sort of artificial ear, formed of a thin membrane stretched tightly over a small wooden frame, and lightly sprinkled with sand.

This membrane, when near the bell, became excited, so that the sand on its surface was thrown into an agitation, but on moving it to and fro along the room, places were found where the agitation varied; in some parts it became very intense, in others very moderate, and on exploring every part of the room, it was established that the points of greatest intensity formed a spiral line, making several revolutions during the length of the apartment. On opening an end-window, this spiral could be traced as continued into the air beyond a considerable distance. The distance from one turn of this spiral to another was not equal to the length of the undulation proper to the note sounded; it became greater the larger the apartment, and in a long gallery approached the length of the sound-wave.

When the windows in a chamber were opened, the position of this line of loudest sound, which, by-the-by, was distinctly perceptible to the ear, as well as visibly demonstrated by the moving sand, was altered, but moving about the sounding apparatus from one part of the apartment to another did not cause any such alteration, which seems to show that this property of a room, if once decidedly manifested, cannot be altered by moving the position of the speaker, but will only be affected by changes in the room itself.

We have now got together some few materials for the design of an acoustic building. Let us for a little consider how they have been applied, or can be applied to various descriptions of structure, commencing with an inquiry how far the simple consideration of size ought to modify the treatment.

The safe limit of direct radiation can, of course, only be very approximately ascertained, but comparing the results obtained by Saunders's experiments, with the observations of that accomplished philosopher as well as architect, Sir Christopher Wren, we may say approximately, that if we were to enclose a space not exceeding 70 feet in length by a somewhat smaller breadth, we should be quite safe in presuming that the natural radiation of a human voice of ordinary power would reach all the audience with no assistance, when the speaker was placed in the best position for being well heard, provided always we were able to insure that no echo from any part of the walls should interrupt. Should our building be much larger than this size it will become desirable to assist, if practicable, the voice of the speaker. If we apprehend a considerable interference of any obstacle with the sound, this may be too great a dimension to be safe. If, on the other hand, circumstances are all favourable, it may, perhaps, be exceeded.

The conditions under which a single speaker can best address an auditory depending upon direct radiation, have been already referred to. The building should have a circular outline, and be in extent something more than a semicircle. Tho

\* By Mr. T. Roger Smith. See page 815, ante.

seats should rise one above another, and the speaker should be pretty well forward among his auditors; and the remotest auditor should not be beyond the limits of direct radiation.

The most perfect type of these buildings, seems to have been an ancient Greek theatre; especially if we bear in mind that the chorus which occupied the most forward part of the stage, was the most prominent feature in the earlier Greek plays. In modern buildings this form has, unhappily, gone out of fashion, except for scientific lecture theatres; but there is one fine example in the great Handel orchestra at the Crystal Palace, the appearance of which, when full, will convey some idea of what the auditorium of an ancient Greek or Roman theatre must have been when crowded with people. Roman theatres differed from the Greek ones in the auditorium not exceeding a semicircle in extent, and in being constructed even down to a late period, and, when of large size, of wood, the resonance of which material was, as Vitruvius tells us, relied upon to reinforce the sound, consequently the *echéie*, or brazen reinforcing jars introduced into Greek theatres, were not adopted in Rome.

There has been much controversy about these *echéie*, and those who wish to know about them, will do well to consult the "Dictionary of the Architectural Publication Society." It may be sufficient to observe that, though in all probability the resonance from them would not have flexibility enough to reinforce speaking, it would be admirably suited to strengthen the effect of slow-sustained declamation, especially if that declamation were of the character of a musical recitative or chant; and if, as seems probable, the principal parts of a Greek drama partook of this character, we cannot doubt that the vases would be a real assistance.

Among English lecture theatres that of the Royal Institution has always been deemed famous. It resembles Roman theatres in being constructed of wood; its seats are arranged in a curve similar to the is-acoustic curve, and its dimensions are very nearly indeed in the ratio to one another of 2, 3, and 4. Its outline presents a semicircle of 30 feet radius, with the ends prolonged 15 feet, and the ceiling is flat, the wall behind the speaker being flat also. One great advantage in this building is the comparatively small volume of air it contains: the favourable form and proportions help it; but it no doubt draws much of its excellence from the resources of the wood employed in its construction.

Lachôz in his pamphlet gives views of all the principal lecture theatres in Paris, and points out that most of them are defective through having too vast a space above and behind the speaker; and he shows that if we wish greatly to extend the space of such an auditorium, the walls should radiate behind the speaker's head, and the ceiling should also be lower where he is than elsewhere.

All modern theatres for dramatic performances depend mainly, though not exclusively, upon direct radiation. In one of the most celebrated and most frequently quoted examples, however,—that at Parma,—the form was such as to favour conduction as well as radiation, while the resonance of the material, constructed as it was internally of nothing but boards, even to the ceiling, no doubt, helped the sound very much. The Parma theatre is connected with the ducal palace, was built in 1618, and so far back as 1790 was in a state of decay. It must not be confounded with the modern Teatro Ducale at the same city.

The dimensions of this building were considerable; its length from the front of the stage to the back of the gallery above the stage is 130 feet, and the width 102 feet, the general form being an oblong rounded off opposite the stage, and the seats being ranged amphitheatrically in steps. Notwithstanding the great size of this house, a low voice could be heard in every part, even if the speaker was as much as 10 feet back, making the distance from speaker to hearer 140 feet.

Of more modern theatres, perhaps, not one is so famous for acoustic effect as the Opera-house in the Haymarket, which was brought to its present form internally about 1790. Here again we have considerable dimensions, though not at all equal to those at Parma; but we have the entire interior constructed of wood, the ceiling of wood, and the stage brought so far forward that a singer may be almost in the middle of the auditorium, and may be heard by all of them directly. The orchestra of course, is even more among the auditors; the stage is extremely shallow behind the curtain; and the auditorium is a little more than a semicircle prolonged by two almost straight sides, which approach each other as they reach the proscenium. The ceiling is an extremely flat curve

over the pit, brought down above the stage to throw the voice forward, and there is a hollow unoccupied space above it. Altogether the form is undoubtedly favourable to sound in a high degree: the space above, behind, and at the sides of the singer is restricted as much as possible, and gradually swells out in the part where the sound is wanted to expand, while the divisions of the boxes which do not radiate from the stage would prevent any echo from the back wall, and break up any wave of conducted sound. More important, however, than the form, in all probability, is the use of resonant material and resonant cavities, and the entire absence of plastered surfaces.

There is one other group of public buildings which peculiarly require to be treated on the amphitheatrical plan, but which hitherto have always exhibited a sort of unsuccessful compromise in their arrangement. I allude to courts of justice.

It is very desirable that the general public should hear well, and they have therefore usually been ranged on steeply-inclined benches; but this has ordinarily been done in a square and often a cubical room, so that all the disadvantages of the square corners and of undue height above the very persons to whom perfect hearing is essential, are retained. In most old law courts various contrivances for contracting the space above the bench are visible; but it would be a much better construction if the court were from the commencement arranged so that there would be a fair prospect that those who *must* hear would hear perfectly, and that all others present would hear well.

The moderate size of our law courts points to the principle of direct radiation of sound, as the one on which they must be constructed. The basilica, on the other hand, the form anciently employed for the same purpose, introduces us to the consideration of the second great division of buildings, namely, those where the transmission of sound is assisted, and whose peculiarity is that they are *oblong*. These divide themselves naturally into buildings with a nave and aisles, and simple large or small rooms.

It will be perhaps desirable to consider first those buildings with nave and aisles of which the basilica may serve as a type, and afterwards to notice large rooms celled in one span, and small rooms.

In the large cathedral churches of Medieval times,—where the object was not simply to build a church just as large as a single speaker might fill with his voice, but to raise a monumental pile for ceremonies,—it was of no moment that the resonance of the air contained in the building should be great, so long as it did not destroy the effect of music; and these buildings afford accordingly a wonderful illustration of the sonority of a large body of air, but very few of them are easy to fill with a distinct spoken utterance.

In Protestant churches of more moderate dimensions, the main object undoubtedly is, that read and spoken words, delivered from the reading-desk, the pulpit, or the altar, shall be perfectly audible to the congregation. How far does the ordinary arrangement of nave and aisles effect this?

There is no question that the columns inseparable from such an arrangement interfere with direct sight, and partly with direct hearing; but I believe it will be generally admitted that the advantages attending upon their use more than counterbalance this disadvantage. I have stumbled upon a passage on this subject in Mr. Denison's lectures on church building, in which I think you will be able for once to concur with that gentleman.

"It is at last discovered," says he, "that so far from the pillars and aisles and broken throats of Gothic churches, built after the fashion of the old ones, being worse for hearing in, they are generally better than the wide-spread buildings all under one span, like a railway station, which it was the fashion to erect in large towns a few years ago. This fact is noticed in two recent reports of the Church-Building Society; and I had observed the same thing myself in several instances, even in small churches, though without knowing that it was general before I read it there. Certainly some of the worst places for hearing in that I know are buildings all under one roof, and of far less capacity than many churches, both old and new, of the nave and aisle construction, in which a large congregation can hear perfectly well; so that in this, as in many other things, the old Gothic builders knew what they were about a great deal better than we do."

The system of open roofs, of a high pitch, so as to accord somewhat with Gothic character, and

carried from wall to wall in a single span, was some years ago employed a good deal for Dissenting chapels; and many instances have occurred where these places are bad for hearing, in some instances to a serious extent. The English Chapel Building Society, is now employing its efforts to promote the erection of buildings divided into a nave and aisles, even where the size of the place of worship is but small.

The position of the pulpit in churches and chapels, with nave and aisles, is a point of considerable importance. In chapels for Dissenters, it is usually placed in the centre of the end of the building, with the communion-table in front of it.

In churches it is almost necessarily placed at the side, principally that it may not intercept sight of the chancel and hearing of the Communion service. There is, however, another quite as good reason for this position, which is, that a centre aisle is almost essential to the decent arrangement of a church; and it is in the highest degree unpleasant to a speaker to have the empty bareness of the aisle in front of him whenever he lifts his eyes, while it is equally unsatisfactory to the congregation to see their minister as nothing better than a dusky shadow, projected on the light of the east window before which he necessarily is fixed, if his pulpit be central.

Is this position acoustically had for the pulpit? and (whether at the centre or the sides) should the pulpit be far forward or not?

In answer to these inquiries, it seems clear that if the building be thoroughly good to speak in, it will not be so very material where the pulpit stands; but I have no doubt that in doubtful or bad cases, especially where there is echo, the side position of the pulpit is much more likely to prove advantageous than the central one; and on that ground it is to be recommended, even for Dissenting places of worship, for the voice being naturally directed towards the main mass of the congregation, will be sent, not straight against the end wall, but obliquely against a side wall.

It is, I believe, always had to place a pulpit directly against a wall. The practice of Sir Christopher Wren, followed by many good architects, is to put it forward some distance into the nave. Others withdraw it into the chancel, or under the chancel arch.

The choice between these two positions must depend rather upon the shape of the church,—if it be nearly square, so that the hearers can be grouped round the preacher on the direct radiation principle, I would put the pulpit forwards among them, and place it against a column, as is done in the great Continental churches. If the church be long, and the hearers must be reached rather on the speaking-trumpet or conduction principle, the pulpit will probably answer best drawn back under the chancel arch. If there are transepts, and a difficulty is found in making people in the nave hear (and this often happens with transepts) it will be quite worth while to try drawing the pulpit a little back into the chancel—for it generally happens in these cases that the communion service, read from the altar, is better heard down the nave than either the prayers or the sermon, owing to the direction the parallel walls of the chancel impress on the sound.

Wren's churches, it seems to me, may be studied as models of arrangement for church-building in large towns; the more so, because, while classic in style they follow the forms of Gothic churches in plan and section. It is remarkable that, notwithstanding that his unrivalled constructive skill gave him every inducement to erect a wide roof, he has not, so far as I know, left a single church without columns in the interior, except only the very smallest. In almost all cases he has placed the pulpit some way down the nave, and in all, the proportions of the cross section, while they avoid the vice of being cramped, present a certain general impression of lowness when seen on a drawing.

It seems agreed that, except in excess, the timber trusses of open timber roofs are advantageous on account of breaking up echoes-surfaces; but I fancy that, so far as it goes, the sharp angle the two sides of such a roof make at the ridge forms a noisy sort of trench, and that a better effect is obtained where a wooden ceiling is thrown across at the level of the collar or higher. This will partly depend on the proportion of the church.

Galleries, if properly inclined, not had places to hear in; but the spaces under them are, unless the galleries are shallow. This especially applies to side-galleries; an end gallery may safely be deeper. Such a gallery sometimes helps to prevent an echo, or the introduction of one will often check an existing echo.

On church building, finally, we have among old

authorities, not only the practice of Sir Christopher Wren, but his recorded opinions, embodied in a letter, from which, had time permitted, I would have made an extract. The document in question is to be found in "The Parentalia," and expresses Wren's conviction that 2,000 was about the extreme numbers that could be accommodated in one church, which he prescribes ought not to exceed 90 feet long by 60 broad. He observes further—"A moderate voice may be heard 50 feet distant before the preacher, 30 feet on each side, and 20 feet behind; and not this unless the pronunciation be distinct and equal." And from this starting point he seems to have regulated his practice.

As to modern practice, the members of this Institute ought to be able to furnish full information on church building, considering the great activity that has lately prevailed in that branch of practice.

The last topic on which I have to trouble you relates to buildings without any columns internally—in fact, large rooms. The most difficult subjects for the architect to treat would seem to be rectangular rooms—perhaps those of moderate size being worse to encounter than larger or smaller ones. Among these I would include great and small halls, lecture-rooms, and concert-rooms, and also the majority of Dissenting chapels, together with such churches as are not built with a nave and aisles.

A rectangular room of considerable size is the commonest form for apartments destined for great assemblies, and is so simple, and has become so natural, that it will probably never cease to be usual for northern nations; and yet it lies open to nearly all the obstacles which we have described as besetting buildings of one or another class. Its flat floor renders it liable to the obstruction of the direct lines of hearing; its straight ends almost preclude any arrangement of auditors on a semi-circular or segmental curve; its flat sides and square angles are very apt to reverberate; its flat ends, coupled with its considerable dimensions, expose it to echo; the mass of air in its height and at the back wall tends to swallow the speaker's voice; and even its very dimensions allow space for the voice to decay, while it is very possible that its windows or its skylights may afford opportunities for sound to be generated of a disturbing character.

I am not prepared to bring forward a single instance that unites all these disadvantages, though Exeter Hall, before the alterations, might have been instanced as exhibiting a good many of them.

I am, however, better pleased to invite your attention to one or two cases where these obstacles have been all successfully surmounted, and from the consideration of these we shall be able to form some tolerably definite ideas of what a great hall ought to be.

We will first consider the case of the Free Trade Hall at Manchester, the work of Mr. Walters, who has most obligingly furnished full information respecting it. The requirements here, as in most great rooms, embraced fitness for both musical entertainments and public speaking, with accommodation for a very large audience, and good architectural effect. All this has been successfully accomplished.

The dimensions of this hall are very considerable; they are, as measured from the contract plans.—The internal width, 10½ feet; length, 176 feet; height, 70 feet; thus bearing very nearly the simple arithmetical relations to one another of 2, 3, and 5. The plan is a parallelogram, with a semicircular sweep at the end opposite the orchestra. The orchestra is partly in a recess with a roof curved upwards, but advances into the body of the hall. The side walls are low, the ceiling coming down on to them with a cove of unusual height.

The side walls are plain below the gallery, the upper part of them being broken only by engaged pilasters, so that they offer no obstacle to conduction, and what reflecting power they exercise will be favourable; but at the remote end, where conduction along the walls would commence, and at the semicircular end, the surface is broken up so as to dissipate or destroy the conducted wave of sound. Columns here take the place of pilasters. Deep, open recesses, used as private boxes, are formed, and balconies are thrown out on corbels; while the gallery, which at the sides is shallow, becomes here deeper, so as more effectually to check the sound that might reach the back wall, and be echoed. The doors of entrance are here, too, covered with cloth; and lastly, the front of the gallery itself has a section of compound curvature, so that it

cannot echo. These precautions, coupled with the curved end of the room, are successful, and there is no echo.

When full, this hall is very successful, either for music or for speaking; but when empty, the resonance on it amounts to reverberation.

The good result, here, it will be remarked, is mainly due to form and proportions; resonant material is not present in an extraordinary quantity, for the walls are plastered, and so is the ceiling; the floor, however, has a space underneath it, and there is a large space above the ceiling. I believe there is a good deal of woodwork about the orchestra—the most important part,—and there is a large organ there which, I cannot help believing is likely, even when not played upon, to be a slight auxiliary to sound.

Another example of great fame in the north of England is the Philharmonic Hall, in Liverpool. I have lately visited it, but am not in a position to speak of its good qualities from personal experience, or to lay before you any authorized information, except what appeared in the *Builder* at the time the Hall was erected. The architect is Mr. Cunningham; and the dimensions given in the *Builder* are,—extreme length, 135 feet; extreme width, 102 feet; extreme height, 68 feet; open part of hall, clear of boxes, is 106 feet by 68 feet. Calculated accommodation, 2,300 persons.

The appearance of the Hall on entering is most peculiar: two elliptic arches of vast span extend along the two sides, while smaller ones cross the end; and by these the very considerable dimensions of the Hall between the walls are masked, and it is brought to appear a moderate-sized apartment with a domed ceiling, and having four recesses opening out of it. These recesses are occupied—one of them by the orchestra, and the other three by two galleries, one above the other, and receding back.

The orchestra is the only place where resonant material appears to have been employed. It is built of wood, and contains hollow cavities of considerable size. In all other parts the architect seems to have dreaded resonance as much as echo. The surfaces likely to echo are curtained over and divided with great care; the boxes into which the galleries are divided are hung with draperies, and on nights of concerts the floor is covered with a carpet, and all the seats are cushioned.

I have been given to understand that the effect upon music is, that it is heard most distinctly, and quite free from reverberation or echo, but that the room affords no support or assistance to the voice or instruments.

It is perhaps not right to conclude a reference to this building without observing that, in arrangements for ingress and egress for the comfort of its occupants, and so far as one could judge, for ventilation, it is one of the best and most liberally planned structures we have.

Coming nearer home, we may refer to the very large and very successful music hall in the Surrey Gardens, for authentic information respecting which I am indebted to the architect, Mr. Horace Jones.

In this large building as many as 13,000 persons have been assembled to hear music and to hear preaching, and in either case have they done so without difficulty. The general form of this building is well known. It is an elongated octagon, or a parallelogram with octagonal ends, and into which the walls of four octagonal staircases project. At the end opposite the orchestra, and up the two long sides, are built three tiers of galleries, with fronts of curved section, and supported on iron columns. The roof over two of these galleries is horizontal; that over the third one inclined; and that over the central space is very similar to the one at Liverpool, both being domed rather like the bottom of a ship.

The dimensions of this hall are very considerable. The extreme height and extreme width are within a foot the same; the width is 68 feet 6 inches; the height 69 feet 6 inches; the length is 153 feet 6 inches, or two and a quarter times the width,—another instance of simple proportions. The form is well chosen, and the galleries act extremely well to prevent echo and reverberation; while yet they are not so near together but that they can be well reached in every part by the voice. The principal reliance of the architect for musical beauty of tone was, however, placed upon the use of resonant materials. The walls are lined with match-boarding on lathens, and it was at one time intended to form the ceiling of wood. The orchestra is constructed of thin, well-seasoned planks, and there is a sounding-board over it in a slightly inclined position, the

action of which is believed to be very beneficial. This is not only of wood, but it was specially required to be of old materials. That these various precautions have been successful is a matter of notoriety; and, in fact, they have answered so well that this hall has been pointed out to me by a professional musician as one of the best in London, not only relatively to its vast size, but absolutely.

Very many other rooms might be brought forward and analyzed, even of those in London alone. To refer to only two others, we will take the hall-room at Buckingham Palace and St. Martin's Hall. The hall-room was built by Mr. Pennethorne. The dimensions are 110 feet by 60 feet, by 45 feet, hearing to one another very nearly the relations of 3, 4, and 8. The angles of the room are rounded, the ceiling slightly roughened with ornament, and brought on to the walls by a cove. The cornice has very little projection, and the lower part of the building is lined with boarding, covered with silk. There is a recess at the end, opposite the place for the music, broken up with pilasters, &c., so as to dissipate echo. This room is admirable for music.

St. Martin's Hall was mainly designed, so far as its adaptation for acoustic purpose goes, by Mr. Hullah himself. It measured, according to the account published at the time it was opened, 121 feet 6 inches long, by 55 feet 5 inches wide, and was 40 feet high. The dimensions cannot be exactly reduced to any very simple relation, though they are not very far from 2, 3, and 6. The nearest to them are 5, 7, and 15. The height and length, however, are very exactly proportionate, the height being one-third the length. This room had no recess for orchestra or organ, but the orchestra, placed the most perfect one in London, was built up of wood against one wall. There was a gallery rather deep across the end, and shallow at the sides, with the front carefully reduced to the minimum of surface. Facing the orchestra was a recess, partly breaking up the end wall. The windows were all high up, and were slightly recessed.

The distinguishing feature of this room was its great wooden ceiling, flat in the centre (which occupied about half the entire width), and sloped down at the two sides to meet the walls. This was paneled, and there was a hollow space over it, and under the floor.

The room, when full, answered to perfection for music, but it was, when partly filled, subject to reverberation, owing, no doubt, to its extreme resonance.

Among the smaller public rooms there are a great number of examples of a class for the acoustic construction of which I would earnestly bespeak more care than has ordinarily been bestowed upon them. I refer to the small public rooms in suburban villages or country towns, the failure of which is as great a calamity for the community to which they belong as the non-success of the most important structures would be in great cities.

These rooms are perhaps more frequently than not imperfect, and consequently fail of their end, which is to afford the inhabitants of the place where they are built a good meeting-place on public occasions. Ordinarily, I think, the small means disposable lead to the walls being built bare and unbroken, but plastered. The ceiling is often too high for the other dimensions of the room, and if there is any semblance of an open roof, it is so thin and slight as to offer little or no obstacle to reverberation. Very frequently, too, circumstances render it advantageous to light these places from the roof, and skylights that act as sound-traps are formed, or if not, at least the walls are left quite devoid of any breaks. It would be desirable in building such a room to pay regard to good proportion, and where practicable, to light from side windows. If this is not admissible, probably it will be advisable to break the line of the walls by piers and arches of moderate projection; and above all, to form some description of break or recess, or cant or curve, in one or both of the end walls, and to make the ceiling drop down at the ends. It would be wise partially to line the walls with wood, or form a wooden ceiling, and if it is necessary to keep the surfaces plain, not to plaster them internally, also to curve or cant off the angles on plan, and to cove or cant the ceiling in sections.

In existing rooms that are had the best remedy must be usually left to the judgment of the architect, as the circumstances of the case will vary; but the most generally useful and the most inexpensive palliative for reverberation,—the usual vice of these small halls,—is to hang up curtains in various parts. Matting or carpet on the floor might

often be of use, and a sounding-board, or even a sheet of canvas, so stretched as to cut off part of the air above and behind the speaker, might often be advantageous.

The subject is now before you, gentlemen. We have considered the general laws of sound, and the modes of influencing sound in a building, namely reflection, as in a sounding-board, referring especially to the parabolic sounding-board; conduction, as in the speaking-trumpet; and reinforcement by resonance, as in the violin. The subject of impediments next required attention, and we have considered echo, reverberation, obstacles with the aid of acoustic curve as a means of escaping them, and had proportion.

Lastly, we have referred to the application of these general principles to particular cases, dividing them, according to size and shape, into buildings for direct radiation of sound, or square and round buildings, and buildings for conduction of sound, or oblong buildings. Among the former we have noticed theatres ancient and modern, lecture theatres, and courts of justice; among the latter, basilicas and other buildings with nave and aisles, and large rooms.

#### AMERICA.

On the 28th ult., the back wall of a large building in Whitehall-street, New York, erected last year, and used as a storeroom, gave way. The roof bent by its own weight to the floor. According to the American *Architect and Mechanic's Journal*, the building belongs to Mr. J. T. Johnson, for whose arrest a warrant has been issued, under the Unsafe Buildings Act. The damage is estimated at 75,000 dollars.

At Lewiston, Maine, a new cotton-mill has been completed, 642 feet long, 73 feet wide, and 75 feet in height. A continuation of the building, one story high, makes the total length 609 feet. The buildings occupy more than five acres of ground, and have swallowed up nearly five millions of bricks. A bell has been hung in one of the towers, 6 feet 7 inches across the mouth, and 5 feet 1 inch in height. The buildings will cost 200,000 dollars; the machinery, 500,000 dollars.

Dover-street, Boston, is being raised: whole blocks of houses have been lifted from their original foundations to the required level. In some of them the occupants have pursued their daily life indoors without interruption! One block has been moved back 8 feet.

#### THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held on Friday, the 22nd inst., at the House in Conduit Street.

The chair was occupied by Mr. Bashill. Messrs. Clarkson and Crawley were, on ballot, elected members of the Association.

After the transaction of some routine business, Mr. Blomfield, Vice-President, read a paper "On the Arrangement of Old Churches," to which we shall return.

At the conclusion,

The Chairman observed, that an important and interesting point, referred to in Mr. Blomfield's paper, was that which related to the introduction of a new material in construction, in the shape of cast-iron. Iron and glass were, in fact, the distinguishing features in buildings of modern times. He remembered that he had spent a pleasant hour with Professor Cockerell, in looking over the designs for the church at Constantiople, and that they noticed a general omission of iron and glass. The new reading-room at the British Museum was not, however, open to that objection, as iron and glass had been abundantly introduced. The difficulty of the arrangement of columns was serious, especially when the area of the church was large. This, however, might be got rid of by making the nave large and the aisles small. With regard to the pulpit and reading-desk, he feared that if wood were the material used in their construction, there would be a difficulty in making them fixed and permanent.

Mr. Bunker reminded the meeting, in justice to the gentlemen who had competed for the church at Constantiople, that they were told that earthquakes were not unfrequent in that part of the world. It was therefore thought that a solid pier of 2½ feet was more likely to bear a superincumbent weight than a pillar of ten inches in diameter. With regard to reading-desk and pulpit, it was very important that they should be made structural features, but it generally happened that when the Specifications came out higher than was expected, the

pulpit and reading-desk suffered. This was what often led to insignificant-looking pulpits, more like washing-tubs than anything else.

Mr. Blomfield said he had not multiplied examples of stone pulpits, as many existed in Continental churches which some of his readers had no doubt seen. There was, for instance, a very massive one at Perugia, in front of the cathedral, which was intended for occasional preaching. As preaching was an important part of the English church service, in his opinion no architect ought to design a church without keeping that consideration in view. If the pulpit were of wood, it might be put near a pillar, which ought to be decorated, with a view to its reception.

The Chairman remarked that a large transept was open to two objections: it divided the congregation, and it was extremely difficult to hear in other portions of the church. Large transepts were better suited to Roman Catholic churches, where there was more ceremonial and less pulpit instruction.

Mr. R. Spiers said that, in making a design for a Protestant church in France, he selected the octagon shape, in consequence of the client objecting to Gothic, and that when he put up his façade the building looked like a Dissenting church. The shape, however, was appropriate for seeing and hearing.

After some discussion on the discomfort of the present pew system,

The Chairman said that, unless the roof of a church were also built of iron, there would be an objection to the use of iron pillars. The difficulty might, however, be got over by substituting a cluster of four columns for one pillar. In reference to the orthodox material to be used in the construction of communion tables, it was generally held that stone was "Puseyite." In a case which came within his knowledge in Lancashire an incoming clergyman attempted to remove the stone altar, and an outcry was raised that he was a Puseyite.

Mr. A. Allon asked whether Mr. Blomfield had taken into consideration the large congregations of the present day, such as met at the invitation of Mr. Spurgeon and the class of preachers called "popular"? Such congregations could only be accommodated by a great span of roof (as at Exeter Hall), in a circular building, or one in the shape of the ancient Forum.

Mr. Blomfield replied that he had not contemplated any such buildings. Churches capable of holding 2,000 persons were those which Sir Christopher Wren spoke of as the largest for general convenience.

On the motion of Mr. Herring, a vote of thanks was passed to Mr. Blomfield.

#### THE GRANITE EXPORT.—HARBOUR OF ST. SAMPSON, GUERNSEY.

THE Port of St. Sampson is situated on the east side of Guernsey, and extends some distance inland, where there is a wall, called "The Bridge," which divides the parish of the Vale from St. Sampson.\* This wall was built in 1803, to keep the sea from penetrating across the island, as it had done since 1204: 5,000l. were made by this project, and now corn grows and houses stand where the billows of the Atlantic rolled at the commencement of this century. On each side of the harbour are quays. Outwards there is a break-water, and nearer to the harbour is a pier, extending from the Vale Castle: further inwards are the real pier-heads.

The trade of this place and neighbourhood consists in the preparation and exportation of granite, for the north of the island is the situation of the grey granite of commerce: it is worked all round this neighbourhood, and even on the quays. Guernsey granite is of a better quality than that of Dartmoor or Aberdeen: the experiment was tried in the Commercial-road, London. After having been seventeen months laid down in the tramway, these different kinds were taken up, and found to have lost thus:—

Name of Stone.	Sup. Area in feet.	Original Weight.	Loss of Weight by wear.
	Pt.	Cwt. qr. lbs.	lbs.
Guernsey .....	4,734	7 1 12½	41
Peterhead (blue) ..	3,484	4 1 7½	64
Aberdeen (red) ..	5,375	7 2 11½	11½
Dartmoor .....	4,500	6 2 25	123
Aberdeen (blue) ..	4,823	6 2 10	123

This table shows that the Guernsey granite lasts rather more than three times as long as that

\* William Staines, once Lord Mayor of London, worked in this neighbourhood.

of the blue Aberdeen. The granite of Guernsey is remarkable for its resistance of atmospheric influence for a long period. Lettering cut in the arch of a doorway is as clear and sharp in 1860 as when erected. It is also extremely hard and ponderous, thus resisting friction and wear of all kinds, and is generally exported by colliers, who, after bringing coal, return laden with a cargo of stone. The duties of the harbour of St. Sampson realize an amount of about 1,450l. yearly: in 1843 the dues only amounted to about half that sum. The number of tons exported from this harbour average yearly 116,000; in 1842 there were only exported about one-third of that quantity. One penny per ton is the duty on the stone exported: the prices for freights for London vary from 6s. 6d. to 7s. 6d. per ton. E. A. M.

#### TENDERS FOR THE NORTHERN MIDDLE LEVEL SEWER.

METROPOLITAN BOARD OF WORKS.

At a meeting held on the 21st inst., the Board proceeded to open tenders for the completion of the Northern Middle Level Sewer Works, rendered necessary by the abandonment of the contract by Mr. Rowe, who had originally obtained it.

The engineer (Mr. Bazalgette) said, the matter in reference to Mr. Rowe stood thus: Engineer's original estimate for the work, 280,000l.; taken in 1859, by Mr. Rowe, for 264,533l.; work done by Mr. Rowe, 10,739l.; leaving due on the original contract to Mr. Rowe of work unfinished of the value of 253,794l. The following are the amounts of the tenders sent in:—Mr. Moxon, 322,675l.; Messrs. Brassey and Co., 329,800l.; Mr. Durbach, 335,000l.; Mr. Thirst, 345,000l.; Rowland, Brotherhood, and Co., 346,500l.; Mr. W. Hill, 357,000l.; Mr. J. Digges, 363,000l.

On the motion of Mr. Carpmael, seconded by Mr. Doulton, the tender of Messrs. Brassey and Co. was accepted. The present estimate for the unfinished work is 329,800l., showing an excess to be paid on the new contract of 76,166l.

#### THE GARDENS OF THE HORTICULTURAL SOCIETY, SOUTH KENSINGTON.

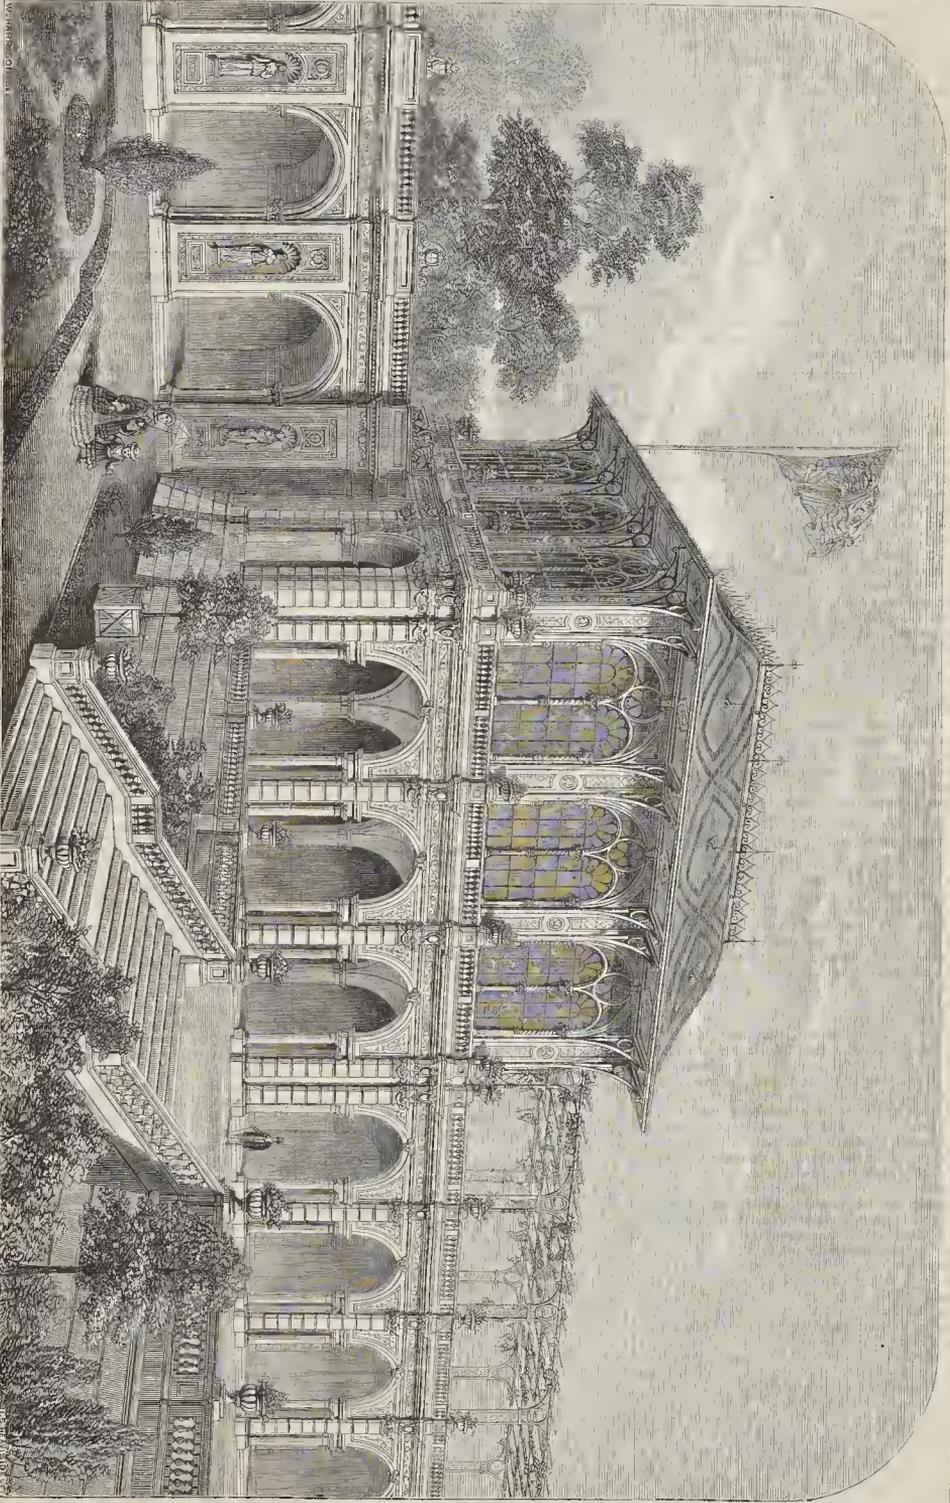

LOITERERS in the fine new roads of Brompton, around and through the land belonging to the Royal Commissioners of 1851, will observe long skeletons of arcades springing into being, and on which, until the occurrence of the present frost, men were busily engaged. When the spring comes, the whole will speedily get into shape. What this will be in one part, the engraving in our present number, representing the upper arcade, with a pavilion as suggested by the architect, Mr. Sydney Smirke, shows. It is but fair towards all parties to say that in the first instance, Mr. Smirke acted only for the Royal Commissioners, and had nothing to do with the works about to be executed by the Horticultural Society. Quite recently, however, the latter body have placed in his hands the architectural portion of the middle arcades connected with Mr. Durbam's Memorial of the 1851 Exhibition now in progress, the fountains, and the terraces. Captain Fowke has the direction of some of the works for the Horticultural Society.

Returning to our engraving, the upper arcades are circular on the plan, and are built of Portland stone and brick, faced with moulded and rubbed red bricks. The frieze, capitals, and spandrels, will be of tessellated work, or glazed terra cotta in colour. The height is 26 feet; the internal width in the clear is 23 feet.

The middle arcades are straight, each 630 feet long; the height to top of cornice is 23 feet; the clear width within 20 feet. The hack walls and roofs of these middle arcades will be temporary. The arcades are of Portland stone and moulded and rubbed red and yellow bricks. The niches, enrichments, and statues, are to be of terra cotta, glazed, and in colours.

The pavilions are intended to be of wrought and cast-iron, partly gilt and partly cased with glazed and coloured terra cotta. The erection, however, of these pavilions will probably be postponed for the present, and may not be carried out at all.

In the lower arcades terra cotta columns are being used. Mr. Nesfield has the entire control over the garden works, and has made some progress. The landscape gardener, however, suffers under the great inconvenience of having to wait for Dame Nature. In whatever pelting haste man may be, Nature teaches us a lesson of deliberate progress. She is slow and sure, whilst man goes blundering on in hot haste, very fast, and some times very wrong.

THE ARCADES AT THE HORTICULTURAL GARDENS, SOUTH KENSINGTON, WITH SUGGESTED PAVILION.—MR. SPINER SAUNDERS, R.A. ARCHITECT.

OF THE RESOURCES OF DESIGN IN THE NATURAL KINGDOM, FOR ARCHITECTURAL DECORATIONS.\*

"Nature,—enchante Nature, in whose form And lineaments divine I trace a hand That errs not, and in its patterns still renew'd,— Is free to all men,—universal prize."—*Comper.*

"Strip'd of her ornaments, her leaves, and flowers, She loses all her influence."—*Comper.*

From time immemorial man has endeavoured to imitate and to convert to useful purposes the beautiful forms presented to us in the vegetable kingdom.

In the buildings of the Assyrians, Egyptians, Greeks, Romans, and the Middle Ages, ideas culled by our ancestors from nature can be traced, either undisguised and self-evident, or being conventional representations founded upon material objects. And this is not surprising for—

"Who can paint, / Can imagination boast, / Amid its gay creation, lines like hers?"—*Comper.*

Some writers object to "copying the forms of nature," and urge that "we have already, in the floral carpets, floral papers, and floral carvings of the present day, sufficient evidence to show that no art can be produced by such means; and that the more closely nature is copied, the further we are removed from producing a work of art." Now these assertions are untrue, and therefore unjust: the floral designs and carvings of the day are insipid and unmeaning, simply on account of the laws of nature having been disregarded in their production: the Gothic architects of the fourteenth century did not merely copy nature, they selected, adapted, designed, and proportioned natural objects upon buildings and works of art, as Nature herself would have arranged them; and therefore the incapacity of modern designers must not be brought to bear against the artists of the fourteenth century, who so successfully followed nature. The fault evidently may be traced to want of skill, and not to the use of natural productions. "The defects," it has been observed,† "arise from various causes, and are of various kinds; but there is one which we notice above all, on comparing the works of these days with those of the thirteenth and fourteenth centuries; namely, the absence of that spirit which is so observable in ancient carving."

It is the practice in the present period to imitate natural leaves upon capitals of columns, and to term the process copying from nature; and how is this accomplished? Not in the manner of the fourteenth century: it is certainly not an easy task to "go back to nature, as the ancients did." The Medieval artists surpassed the sculptors of Greece and Rome in this particular. In Rome, the foliage, fruit, and flowers, were strung in wreaths and festoons, as if fresh gathered, without any further attempt at form or arrangement. Now the Medieval architects worked with nature, id est, they so wrought and distributed the stems, leaves, and flowers in their buildings, that they appeared to grow with greater life and spirit than they ever did in nature: the leaves were not (as they are in our time), sculptured flat, insipid, and spiritless: a vigour was imparted to them that produced a well-balanced and agreeable light and shade.

"Yet so delightful mix'd, with such kind art, / Such beauty and beneficence combined; / Shade, unperceived, so softening into shade, / And all so forming an harmonious whole."—*Thompson.*

The architect should personally select the leaves, flowers, and other natural objects, for his proposed ornaments, as drawings and engravings (however beautifully executed) will not show the form, light, and shade, which exist in the living specimens. The point I wish to urge is, that the laws to be found in nature should be transferred to art, not by literally copying from natural productions, but by forming, disposing, and designing ornament upon natural principles, and, as far as practicable, rendering it symbolical.

By the means of symbols, a sacred character has been given to ecclesiastical buildings, and religious instruction imparted from time immemorial; and it is certainly more interesting and edifying to design ornamental combinations with an intention, than to introduce unsightly and unmeaning decorations. The utility and importance of symbols cannot be doubted, and the extent of their employment may be partly an open question; although they are at the present period seldom used; and when adopted, are often selected without discrimination.

In the ornamentation of our old cathedrals and

churches, appropriate decorations were generally produced: each flower, each leaf, each device, had a significant meaning: "this principle," observes Virgil, "is completely overlooked at present; any design, so long as it is considered to look pretty, is introduced indiscriminately for all seasons, and in all situations."

The ancient sculptors were scrupulously attentive to their discriminative symbols. In the Assyrian sculptures, the pine cone and honey-suckle ornament were frequently used; with the latter the Greeks were evidently acquainted. The leaves and fruit of the vine alternating upon horizontal branches formed an arbour for an Assyrian king and queen. The lily and other flowers were selected for the adornment of Solomon's temple: the palm-tree was carved upon the walls and ceiling; for the capitals of the columns the pomegranate (symbol of sacred things and fertility), was selected; and the olive tree was found serviceable for the cherubim and the doors.

The Egyptians formed columns of clustered stalks of the papyrus, with unopened buds for the capitals; and with these were decorated the Temple of Luxor, Thebes; the Temple of Karnac, the Temple of Philæ, &c. The palm leaf supplied the capitals of the columns of the Temple of Edfou; and in several of the temples built while Egypt was governed by the Ptolemies, the lotus (sacred to Isis) embellished the columns of Dendera.

With the Greeks, the acanthus flourished: it was nurtured and brought to a wonderful perfection. The species supposed to have been employed for the Corinthian capital is *Acanthus mollis*, or *Brank-rose*; but Dr. Sibthorp considers that the *Acanthus spinosus*, still called *acavada* is the one meant. This, however, does not affect our inquiries, and may be left to antiquaries to deal with. The capitals of the columns of the Tower of the Winds, at Athens, have one row of acanthus leaves; and the Choric monument of Lycisates at Athens is also decorated with these leaves. The Greek leaves have been said to have more of the natural character of the acanthus: the Roman acanthus is more artificial. The Greeks chose the lotus for the upper range of leaves on the capitals of the Tower of the Winds at Athens, and the upper leaves of the ornament on the apex of the roof. Leaves of this plant decorate a marble *stèle* (Stuart, vol. v., p. 53): they are also to be seen in the Erectheum. Many capitals at Athens and other parts of Greece are embellished with these leaves. The laurel (dedicated to Apollo) is wrought on the outside of the Choric monument of Lycisates at Athens; laurel wreaths occur on medals. The honey-suckle (which the Greeks borrowed from the Assyrians, and wonderfully perfected) was extensively employed in the Erectheum, at Athens, also on sepulchral marbles and vases, and on a capital from the Temple of Apollo at Branchyda, near Miletus. An *amarantine* wreath was worn at the funeral of Achilles, and often worn at funerals in the early ages of Greece: cultivated, also, on the graves of the ancients were the asphodel (sacred to Pluto), the myrtle, and the mallow. A brazen palm-tree sheltered the golden lamp made by Callimachus, in the Erectheum: the palm was also used for wreaths:—

"With wreaths and palms to bind the victor's brow."—*Virgil.*

In the Pandrosium, over an altar, grew an olive tree (dedicated to Minerva). On medals are sometimes found garlands of olive. In solemnizing the festival of the Dionysia, garlands of ivy (dedicated to Bacchus) and "wreaths of fresh-blown roses" were used. With violets were the Muses sometimes decorated,—

"So wild'd each muse divine, with violets crown'd."

The central acroterion of the Temple of Egina had female figures on each side, holding a pomegranate flower. *Anthemion* is stated to be the Greek name of the plant *Nigella Damascena*, which was given to it for the beauty of its flower. The term *Ἀνθίμων* is derived from the radical word *ἄθος*, a flower: according to Theophrastus it was the name of a plant, and a term applied to artificial floral ornament by Xenophon. The Grecian architects applied the term *anthemion* to antæ, and on the interior wall of the Erectheum portico, as well as to similar ornaments.\* The parsley was also called in to adorn various edifices at Athens;† and the horse-chestnut has been thought to have suggested the "egg-and-tongue" moulding.

The Romans extended, but did not improve, the ornamentation of Greece. The capitals of the

columns of the Temple of Vesta, at Tivoli,—of the Arch of Septimius Severus,—of Jupiter Tonans, Rome,—were decorated with acanthus.\* These leaves were also used in modillions, mouldings, vases, and in architectural and sculptural ornaments generally. The olive supplied the capitals of the columns of the Arch of Titus, the Temple of Jupiter Stator, &c. Olive and oak leaves, rose, &c., occur in the Arch of Titus; also honey-suckles in the cinctum of the same building. The ivy is visible in the festoons on the entablature of the Temple of Vesta, at Tivoli; and in the festoons in the panels at the sides of the entrance of the Pantheon, at Rome, are branches of fruit and flowers of the vine, oak, pomegranate, olive, bay, &c., elegantly arranged, and executed with the appropriate leaves attached to each.

The Medieval sculptors ornamentally combined natural forms in their works with considerable success, and selected, among many other vegetable productions, the strawberry, vine, billy, woodbine, oak, fir, apple, ivy, avens (or herb benet), fern, broom, euphorium, iris, laurel, ranunculus, sunflower, palm, maple, hawthorn, acanthus, common purple iris, myrtle, lily, dog-rose, red anemone, bistle, wood-sorrel, hirony, mallow, mugwort, hazel, elder, margold, hop, kale, cyclamen, and gazelle's horn, almond-tree, &c. These plants were symbolically chosen and expressed: for instance, the billy (symbol of the Resurrection), was sculptured on the sides of a monument in Chichester Cathedral; the vine, symbol of the Saviour; the ivy, immortality; the oak, virtue and majesty; palm, martyrdom; lily, purity; myrtle, peace; yew, was planted generally to the south of the church, to supply green for the decoration of churches at the great festivals; and the branches of yew trees also served anciently for palms in the procession of Palm Sunday.

In comparatively recent times the resources of the natural kingdom have been successfully employed in the adornment of churches. The stalls of the choir of St. Paul's Cathedral have festoons of foliage, flowers, and fruit, beautifully arranged and sculptured, by Grinling Gibbons, in the most artistic manner, and proving the fallacy of the assertion, "that the more closely that nature is copied, the farther we are removed from producing a work of art."

It will thus be seen that architects and artists have, from time immemorial, selected Nature's gifts, and thought them not unworthy ornaments for the adornment of sacred edifices.

In a little work, entitled "Manuals of Gothic Ornaments," it is stated that "perhaps we also, as they (our ancestors) did, mist in the first instance attain like skill to theirs, by the study of the labours of those who have gone before us, recognising, in the past, however, those principles which are always to be found if diligently sought for, and seeking to work in accordance with these principles rather than slavishly imitating style. As with them, therefore, so with us, first the stone remains of older times, then the freshness of nature to give vigour and originality; and, when power and knowledge are thus obtained, then, but not till then, may we attempt new styles; and the time may not be far distant when, instead of the diagrams, scrawled over with figures and arithmetical calculations, the sculptor will take boughs gathered from the tree, and, arranged to suit his construction, will copy them at once with his chisel. But at present our models must be of stone,—these first, and then nature."

The above advice to sculptors is very questionable; as, without calculation, most lamentable failures frequently occur. Prior to sculpturing a statue,‡ cross, finial, or other ornament, it is absolutely necessary that the altitude of its position in the building should be accurately ascertained. Without this knowledge the sculptor often renders his work either too large or too small, and is seldom, if ever, successful, without the calculation. In illustration of this, we all recollect the well-known competition between Alcamenes and Phidias. These sculptors were each employed to make a statue of Minerva, in order that the finest of them might be chosen, and placed on a very high column. When the two statues were finished they were exposed to the view of the public. The Minerva of Alcamenes, when seen near, seemed admirable, and carried all the voices: that of

\* Virgil alludes to the acanthus in the "Æneid," book i. v. 630 and 711; and in the "Georgics," book iv. v. 122 and 123. Ovid notices this plant (Met. xiii. v. 701).

† It is to be regretted that the author of the "Manuals" has omitted to give definite principles for the guidance of the workman.—W. P. G.

‡ It had been objected that the statues in the west front of Wells Cathedral were unaturally tall; but it had been proved that this was intentional, in order to give them a proper effect when viewed from below.—W. P. G.

\* By Mr. W. Pettit Griffith, F.S.A. Read at the Liverpool Architectural Society, on 26th instant.

† Parker's Manual of Gothic Ornament.

\* See chapter on Grecian ornament, in Stuart and Revett's "Athens," vol. v.

† Stuart, vol. v. p. 53.

Phidias, on the contrary, was thought insupportable—a great open mouth, nostrils which seemed drawn in, and something rude and gross throughout the whole visage. Phidias and his statue were ridiculed. "Set them," said he, "where they are to be placed,"—which was accordingly done, alternately. The Minerva of Alcmenes appeared then like nothing, whilst that of Phidias had a wonderful effect from its air of grandeur and majesty, which the people could never sufficiently admire. Phidias received the approbation his rival had before, who retired with shame and confusion, very much repenting that he had not learned the rules of optics.

Although the Greeks may have extensively borrowed their ideas of conventional foliage and ornaments from the Assyrians, yet it cannot be denied that, in the hands of the Grecian sculptors, ornamentation was matured and perfected, and has never been surpassed.

Interesting as the representations of flowers and other natural objects may be, in the works of the Middle Ages; and addressed as they are to our feelings and love of nature, they (in an educational sense) fall considerably short of the intrinsic beauty of Classic floral decorations. I observed, in 1847,\* that "architecture has not yet reached its *sumnum infantium*. Gothic architecture, now the rage and the fashion, will, in the course of very few years, present a different aspect: the far-famed cathedrals and churches of England, so adored and looked up to with wonder, and restored with precision, will be gazed upon as crude specimens of a not very enlightened age: the ugly gargoyles, the representation of monkish confessions, and other vagaries, will have passed away; and a style, based upon all that is beautiful and good, will rear its head, decked with Nature's gifts in a more Christian-like manner, and with more science and art."

Since the foregoing was written, a decided improvement has been effected; the miserably-executed heads of Mediæval kings—cardinals, monks, and wimpled females,—are now seldom produced, and floral ornaments and other sculptures have been more appropriately substituted.

The Romanesque may be regarded altogether as a transitional period, in which the sculptors introduced in their decorations attempted representations of divine and human figures, animals, birds, foliage, &c., with such incongruity, ignorance, and bad taste, that but little advantage can be derived from a study of their works. They tried to imitate Nature, and studied her, but did not make any progress.

In the thirteenth century the artists had not the capacity to imitate nature, and consequently remained contented with a monotonous trefoiled scroll, which pervaded all their works. In some instances great taste and elegance were achieved, and in every respect the labours of the thirteenth century were wonderfully in advance of all the productions of the Norman era.

During the fourteenth century natural types were very successfully employed upon ecclesiastical and secular buildings: the foliage was well distributed, always upon a system, and considerable vigour imparted throughout. The numerous examples of this period are deserving of study and a careful attention.

The fifteenth century produced works of less vigour, and therefore not so worthy of being studied. The foliage was distributed in too mathematical a manner, which created a formality neither artistic nor pleasing.

In studying, therefore, the works of former ages, we are not so devoid of ideas as to literally copy any one example. The most valuable lesson to be culled from our ancestors' productions is not so much what shall be selected for adoption, as that which is to be avoided.

If Mediæval architecture and sculpture were to be divested of incongruities, of which there are very many, much of its sculptured work being caricatures, a more perfect and beautiful style would necessarily be the result. The Greeks *perfected* their art: the Mediævalists have left their works crude and unfinished. Imagine a cathedral adorned with sculptures, illustrating events in Scripture history, the sculptures being rendered with the same care as that bestowed by Phidias on the Pagan temples. No doubt there is much yet to learn, and that in this country art has not yet reached its culminating point.

During the Middle Ages, at home and abroad, natural ornamentation was cultivated with more or less success: the sculptors sought the fields and the hedges, in lieu of the *plaster casts* and the *books*. Nature was embodied in stone and wood,

in all her loveliness,—not literally copied, as supposed to be by some architects, but so arranged and manipulated as to produce a most harmonious effect. By carefully examining the several churches and other buildings of the present day in which natural ornament is adopted, it will be observed that the leaves and flowers are represented dead, flat, insipid,—no petrified life, no light or shade; and what is the consequence or result? Some writers, of course, object to "copying the forms of nature,"—and others to "the want of force and vigour in nearly all, and the absolute vulgarity of many, of the modern works professedly founded on nature." To successfully embody the works of nature in art-products, care must be taken to design in accordance with natural laws.

In teaching, necessity demands the employment of a mechanical process in setting out ornamental combinations, let it be geometrical or otherwise: the geometrical method is the most natural, as it is self-evident and universal in the floral kingdom. The method adopted in setting out the ornaments in most of the buildings of Rome is alluded to by Taylor and Cresy, in their Architectural "Antiquities" vol. i. p. 10: all these methods, be it understood, are valuable only as a means to an end. The spirit to be thrown into the work must be in the *mind* of the artist.

The projection of each flower, the particular curl of each leaf, the relief of each stem, must be left to the sculptor: he must give the life or the spirit to his work. All the mechanical means in the world will not create a genius: genius is a natural gift; but a correct taste is the result of a good education. It should also be borne in mind that although a man of genius may design and create wonderful productions, yet they may be all in bad taste. To appreciate and to understand the best works of the age of Pericles and the Middle Ages requires education. Thus the importance and necessity of obtaining and possessing examples of correct art for educational purposes are self-evident. Works of genius, unless in good taste, are better avoided—at least, as far as the pleasure to be derived from the examination of beautiful objects is concerned.

Deformities in nature are exceptions to the rule: in the Renaissance and Elizabethan styles, distortions form the rule. It is of importance to distinguish good art from art *per se*: it is an art to sculpture monstrosities. They may be spiritedly executed, and with much talent; but to admire or to encourage such productions would exhibit a morbid taste, to the injury of good or perfect art, and consequently dangerous to art-progress. Examples of correct art should be purchased and preserved, and all had art destroyed—at least, not retained for admiration or imitation.

I take this opportunity of again protesting against the use of Gothic architecture for secular purposes. How can we retain a devotional feeling towards the House of God if our theatres, private dwellings, public vestry-halls, and other secular buildings, be decorated with ecclesiastical architecture? In 1847\* I stated that "the Pointed style of architecture, in a religious point of view, is far superior to every other method of building for ecclesiastical purposes; and, with judicious management, may be adapted to accord with propriety in Protestant churches, by divesting it of all those forms which were used for certain ceremonies which we discard, and using only such as are in accordance with our views and suited to our houses, excise offices, mints, post-offices, museums, banks, offices of assurance, &c., &c., are best adapted for a style of architecture based upon the Classic styles, which, as regards light and convenience, are the best fitted."

Classic architecture requires an educated mind to appreciate it: Gothic architecture appeals more particularly to the feelings. The latter is essentially a Christian architecture, not so much on account of its use in ecclesiastical buildings (as Classic architecture has been similarly employed), but it is not possible for any one to examine the minutest detail of that style without perceiving in it the impress of a Christian mind. In Classic churches we have pagan ornaments used as decorations, even in modern times.

Mediæval architecture (or a style based upon it) is peculiarly fitted for churches, parsonage houses, schools, and other buildings under the surveillance of the clergy; and no doubt the laity would always reverence it: it, however, is an act of extreme egotism for any one to dictate the employment of Gothic architecture for edifices of all denominations, to the entire exclusion of the Classic styles.

The styles of architecture which were common to Egypt, Greece, Rome, and the Middle Ages, are, as it were, dead languages: they belong to the past; and, although a knowledge of them is necessary to enable us to understand the history and feelings of former times, they should not be cherished for reproduction, nor their mutilated and useless and decaying remains preserved (except the intelligible parts in national museums) for *picturesque* studies, either for the painter or poet to muse upon, to the detriment of future progress. Until the system of idolizing *ancient* architecture be banished, we shall never be encouraged to think for ourselves. The Decorated style would not have been produced if the preceding, or Early English, style had been religiously cherished and preserved.

The remains of ancient architecture ought to be carefully measured and delineated, and all sculptures and ornamental portions preserved in museums or proper places built for their reception, so as to form studies for reference, contemplation, and instruction; but not for reproduction in new buildings. To preserve old ruins half-defaced, until every discernible feature of form or expression be effaced by exposure to the elements (which can never be ultimately resisted), would be of no service to the architect, and be only encumbering the earth with picturesque ruins, sublimely unintelligible to all except romantic painters and love-sick maidens.

Although it is much to be lamented that the beautiful works of the Mediæval architects, sculptors, and others, have been (independently of the effects of atmospheric influence) wantonly injured; still, it is a great satisfaction to know of the many examples of early art which have been spared for our contemplation and instruction. The extensive system of *white-washing* every object in the sacred edifice, adopted by churchwardens since the Reformation (until recently, has been of eminent service. To this system we are indebted for the preservation of many finely-sculptured ornaments, which have been thus hidden from the gaze of the ignorant destroyer, until the coming of a more enlightened age.

The cultivation of the fine arts in this country is progressing, and the Government schools will no doubt so far improve the education of the people as to teach the latter at least to respect works of art. The great improvement which has taken place with regard to ecclesiastical architecture has been universally acknowledged. I allude more particularly to its being preserved from mutilation and neglect. The extraordinary ignorance of the beauty of our ancient churches, and the ignorance of its strong terms in the early numbers of the *Ecclesiologist*, and not without reason. There is, however, still existing a want of knowledge of the true principles of Mediæval architecture; and, until this has been properly supplied, not only is the money that is expended upon the so-called restoration of our old churches, and the building of new churches, misapplied; but positive injury is done to the former. The stereotyped excuse for bad architecture is the want of funds. This excuse our ancestors never needed, as they knew how to build their churches in accordance with the money to be expended. When a church or a chapel was erected in the Middle Ages, if the means were small, the building was not crippled. It had not a meretricious front, with the sides and back executed in plain work, but a general uniformity of simple detail was imparted throughout the building. It is not, therefore, the money alone that is required for the production of correct ecclesiastical architecture, so much as a knowledge of first principles and experience.

"One thing there is more needed than expense, and something prior *et cetera* to taste—'t is sense."

I have no doubt that when experience has been gained, through the erection, *inprints*, of many premature new churches, that a proper supply of funds will be forthcoming. It was so in former times. "Pericles," says Müller,\* "induced the Athenian people to expend upon the decoration of Athens, by works of architecture and sculpture, a larger part of its ample revenues than was ever applied to this purpose in any other state, either republic or monarchial. This outlay of public money, which at any other time would have been excessive, was then well timed, since the art of sculpture had just reached a pitch of high excellence, after long and toilsome efforts; and persons endowed with its magical powers, such as Phidias, were in close intimacy with Pericles."

The sculptures and ornamental decorations in ancient cathedrals and churches were usually

\* Ancient Gothic Churches.

\* Ancient Gothic Churches, pp. 9, 9.

\* History of the Literature of Ancient Greece, p. 381.

historical and symbolical expressions, and offered Scriptural instruction. Attention has been directed to the importance of historical sculpture, and notice taken of the angel choir at Lincoln, which gives an epitome of the Advent of the Favour; the 308 pieces in the ceiling of Norwich Cathedral (which illustrate the entire history of Revelation); the Virtues and Vices at Salisbury; and many other valuable examples.

A church, being a material edifice, must be properly proportioned and erected. You may call the construction of a building a mechanical process; its decoration, however, is quite a different matter: in this the artist and sculptor have (as it were) to impart vigour and spirit to the whole work, and thereby render it an intelligent and a living monitor. "A work of art," says M. Fould,\* "is not a thing quite inanimate: life exists really in it: it is that sentiment which is found everywhere, and cannot be assigned anywhere. The ancients have excelled in the art of animating their works, only because they possessed that general and complete instruction which sound studies give."

In conclusion, it is to be regretted that no real progress in architectural sculpture has been made. In 1848,† I considered that the advancement of art towards perfection would be hastened by the establishment in this country of a national academy upon liberal principles, in which, *inter alia*, the art of modelling and sculpturing (upon a large scale) natural ornamentation for all purposes ought to be propounded.

I cannot imagine more instructive and beautiful sources for the inspiration of the sculptor's chisel than the scenes in the Old and New Testament,—subjects scarcely touched upon in the adornment of our new churches.

Prior to anything like excellence being attained in such important subjects as those offered by the Scriptures, our sculptors will have to toil long, and must not enter upon the task without feelings of reverence and respect to holy things.

Useful and beautiful as well executed arrangements of foliage and flowers always are in symbolizing Scriptural subjects, still it must be admitted that they are of minor importance compared with historical sculptures. Floral forms address us through the medium of symbolism, but historical sculptures are at once intelligible to the most ordinary understanding.

Great and praiseworthy efforts have been made at the Architectural Museum to direct attention to the vital importance of historical sculpture, but hitherto not with that success which its advocates so anxiously desired. I have no doubt, however, that ere long our churches and public buildings will receive embellishments of a higher order of art, and not only vie with, but eminently surpass, all former efforts at home and abroad.

**THE FREE PUBLIC LIBRARY AND MUSEUMS, LIVERPOOL.**

THE form in which a citizen of Liverpool has chosen to convey a gift to his fellow-townsmen is a very significant proof of our national development. In the old times the same desire to benefit his generation and posterity would have taken the form of a hospital for the sick, almshouses for the aged poor; or, at the utmost, in an educational direction, schools for a limited number of orphan children. The gift of a free library would have been but a mockery in an age when few could read and still fewer could understand what they read; but now, so exceptional is utter ignorance, and so general is a certain amount of intellectual culture among the working classes, that a public library has been considered the most useful and appropriate donation a wealthy merchant could bestow upon his fellow-citizens: We cannot, however, congratulate ourselves that this ripeness of the fruit Lord Brougham and his fellow-workers have cultivated with so much zealous effort, is general. The same week that saw Mr. William Brown present a library building to Liverpool witnessed a community in sea-port Sunderland calling public meetings, and protesting, with the greatest vigour, against a rate being levied for the purpose of establishing a local free library,—an opposition more to be wondered at as a contribution towards the proper contents of such an establishment, 4,000 volumes of philosophical works, has been recently presented to the town by a private individual. All the more honour to Mr. Brown for leading the van in a movement which cannot fail to exercise a most beneficial influence. This was freely accorded by the dense crowds that kept

Liverpool *en fite*, not only on the inauguration day, but on that preceding it, as well as by a large assembly of the working classes, who, in recognition of the generosity that prompted the good deed, publicly presented, for Mr. Brown's acceptance, a silver shield and a clock. The ceremony of the inauguration we have already spoken of, its processions, deputations, and dinner. In contrast to this all will read with pleasure of the simplicity of the veritable opening of the library, which took place on Monday, the 3rd inst., when the clerk of the works reverently asked for the first book, the *Bible*. The usefulness of the library is enhanced by a comprehensiveness in its arrangements that has included reading-rooms, a lecture-room, a museum, a gallery of inventions, lavatories, and a depot for the safe custody of the parcels with which excursionists seldom dispense. The natural history collection presented by the Earl of Derby will be deposited in the museum. The pictures from the old library, works of the old masters, and copies of royal portraits, are already hung in the principal reading-room. The British and Foreign Bible Society have voted the library copies of the Scriptures in the hundred and fifty languages into which they have been translated; and private munificence has made contributions of scarcely less value. Thus much for the design of the liberal donor, and for the manner in which his aim has been accepted and appreciated. We will now proceed to examine the mode in which the fabric expresses his intention.

In these days, when vigorous efforts should be made to grapple with the evils which exist in all our towns, in the insinuating accumulation of narrow and confined thoroughfares; and when bold measures should be proposed to remedy these evils, which should comprehend sweeping away even acres of fever-breeding tenements to enlarge the lungs—the public squares and main streets,—when evidence of the power and might to do this exists in the case of a great railway company at Birmingham, where to obtain an approach to, and the erection of the great central station, a dash and clearance has been made through a mile or more of closely-packed houses,—we have looked with interest upon the progress which the Corporation of Liverpool has made in this direction, in their co-operation with the donor of the Free Library Building. As to the site of it: almost in the centre, in the very heart of the town, is a space which, if the corporation continue as it has commenced, to take advantage of, would become as grand as a forum in ancient Rome. This space is bounded on the east side by the Limestone railway terminus, and any one of the myriads of visitors arriving here would behold in the centre the solemn huge dark pile—St. George's Hall, and new Assize Courts. To the west of this magnificent new building he would find a strange contrast in the gaunt tower and body of St. John's Church,—a building erected in 1784, in the vilest Churchwarden Gothic. The funeral aspect of this church is made more dismal by its contiguity with the leviathan classic building, and with the ghostly appearance of its large graveyard, where almost every gravestone has been laid flat, and the inscriptions are trampled upon and erased. The removal of the church and the proper inclosure of the vest stony church-yard will be as necessary for the completion of this new aspect of this great forum of Liverpool which we are describing, as was the removal of the old infirmary which stood on the site of the Assize Courts, and the Haymarket adjoining. On the south and west sides the Corporation has yet to exercise, together with private individuals, a discretion which should comprise, for the beautifying of this noble site, the removal of the strange medley of hotels and petty shops, and the re-erection of churches, clubhouses, or public institutions in their place, of the extensive character of the Free Library, which is erected upon the north side. On this same north side the Corporation has wisely commenced a scheme on a grand scale, and it deserves all praise for seconding Mr. William Brown in his noble donation of the Free Library Building. In the alterations in the levels in Shaw's Brow, upon which the building is erected, in the construction of extensive foundations to form the platform upon which the building is placed, and in the terraced approach or platform which is regarded as the high-level road over Byrom-street into Dale-street, a sum nearly approaching 100,000*l.* has been expended,—this amount having been furnished in part out of the surplus revenue of the Corporation, and in part out of money raised upon the security of the Museum rates.

The site which the architect for the Free Library building has had to work upon was most advan-

tageous. And although the east end immediately adjacent is now occupied by an uncovered vegetable-market, with its attendant nuisances, and the rear of ugly tenements is visible adjacent, and although the west end is occupied by vulgar buildings, including a yard for the sale of old building-materials, immediately attached to one of the principal entrances of the museum, we disagree at once with the apologies put forth by the local papers. It is asserted that the surface of the site, a hanging level, is very unsuitable to the style used in the building; and that the architect is not responsible either for the site or the style. We hear in mind the result of the famous competition connected with the designs for this building, when prizemen were displaced, and the local corporation surveyor threw down the gauntlet, and undertook to surpass everything that had been done before in the matter.\* By the adoption of a style which has for the centre of the building a deeply recessed hexastyle Corinthian portico—a diminutive copy of the Temple of Jupiter Stator, in Rome—we are reminded that no condition of site was an obstacle to the ancient Romans; the buildings on the Capitol, and in the great Forum, presenting overcomings of every obstacle as to site in hanging, terraced, or any other levels; and that the corporation surveyor at Liverpool enjoyed a great advantage in the site for the display of the building he should adapt to it.

The general aspect of the building now completed, as seen from all the commanding points of view which are available, is that of a reduced copy of our National Gallery in London, without the pepper-boxes, and with the flanks telescopically folded up. The returns of the wings present the hollow sham of plain brickwork, contrasting disadvantageously with the pretentious appearance of the stone front. The portico has an inner row of four columns, two intercolumniations being omitted to gain width in the entrance; the floor of the portico being attained by steps from the footwalks enclosed within screen walls, and landing at each end of the portico, and not in the middle. The principal entrance doorway is of colossal proportion, and contrasts unfavourably with the simplicity of the rest of the building, by its over-enriched and enlarged ornamentation. The remainder of the front is enclosed with a stone balustrade and iron gates; the form of the balustrade to all the parapets of the terrace being very ugly, and top-heavy, and not unlike the usual upholsterer's leg of a dining-room table.

The two wings have each two Corinthian pilasters, irregularly spaced, the two in the centre standing forward about two feet, and intended, if we may believe the published view, to have colossal figures on the parapets, which would utterly destroy the effect of the building. Between them is a niche, with pedimented cornices on carved trusses; above all are small panels and wreaths. The flanks between the central portico and wings have each five windows, with horizontal cornices or trusses, above which are small panels, with large wreaths in them. The roofs are screened from view by lofty attics on parapet walls.

On entering the building the visitor passes into a vestibule, 31 feet by 23 feet, with a flat paneled ceiling; beyond the vestibule is the central hall; the principal architectural feature of the interior; and beyond the hall is the principal staircase. The central hall is divided at each end from the vestibule or staircase by a screen of two Doric columns in antis. It is 60 feet long, 53 feet wide, and 46 feet high. It is divided basilica-wise, into three portions,—a centre or nave, and the side aisles or corridors; the latter are separated from the nave by an arcade, which supports the gallery floor, and the Ionic columns which carry the roof. At each end of the hall the entablature on these columns is continuous, but at the sides it is broken round each column, and from the cornice spring arches, which are groined into vaults over the gallery. Over the centre of the hall or nave the ceiling is flat, eaved down to the cornice with panels, the mouldings of which are enriched. Three of these panels are glazed, but the principal light is derived from seven round arched windows on each side. Between the columns in the gallery is a stone balustrade. On the ground-floor, to the right of the principal entrance, is the door to the free library, which apartment was opened to the public in the 3rd instant. The reading-room, which is 110 feet long and 50 feet wide, is divided into two portions by two Doric columns in antis near the south end, and here are windows looking into Shaw's Brow. The remainder of the

\* It is asserted that the plan adopted is that of the design selected in the competition; but into this question we are not in a position to enter.

\* In *Journal des Debats*.  
† *Ancient Gothic Churches*, pp. 26-31.

room is lighted by two large skylights, and by windows in an attic raised upon panelled segmental arches. The very heavy appearance of the Doric entablature, which is continued all round the room, and the slight effect of the segmental arches, diminish very much the effect of this room. The proportions are sufficiently massive to have admitted of greater height, and ventilation could have been better provided for. The aspect generally of the room is that of a large cabin on board ship, where height was of the greatest consequence. Adjoining the reading-room is the students' reading-room, 40 feet by 28 feet; and running northwards from this parallel to the principal reading-room, and along the eastern end of the building, is the reference library, 75 feet by 27 feet, fitted up with bookcases, in two tiers, the upper accessible from a light iron gallery; the total accommodation provided is estimated at 100,000 volumes. In the basement of this portion of the building are the rooms for the reception of the books, and for the classification and binding.

On the left of the entrance is the museum, which consists of five rooms upon the ground-floor, and also upon the upper floor. They are being fitted up for the reception of the Derby Museum, the handsome mahogany cases, on carved legs, for the reception of the minerals and fossils being manufactured by Messrs. R. Anderson & Sons, of Bold-street. The basement, under three of the rooms of the museum, have been prepared with solid floors for the reception of sculpture, and other heavy articles; the others will be used as work-rooms by the curator.

In the extreme north-east corner of the building, on the ground-floor, are three class-rooms, and a committee-room; above the committee-room is a lecture-room, 23 feet by 25 feet; and over the class-rooms a larger room, also for lectures, which is intended to accommodate nearly 350 persons.

Not the least important part of the building is that designed to accommodate a collection of specimens and inventions, and now called "The Gallery of Science and Inventions." It occupies 83 feet by 50 feet, a space which was intended to be left for future extensions. Mr. Brown, however, considering that in a town like Liverpool, practical science ought to receive more attention than it was likely to have, unless special provision were made for the purpose, thought it was desirable to convert this space to the purpose. The Gallery of Science and Inventions will consist of a floor on the level of the basement story, and of two galleries on the level of the ground floor and upper floor, each gallery 218 feet by 12 feet.

The entire cost of the building, including the fittings, lighting, warming, and ventilating, will be nearly 40,000*l.*, and the whole will be defrayed by Mr. Brown. The buildings were erected under the direction of the Corporation Surveyor, Mr. John Weightman. Messrs. Holme & Nichol are the contractors for the building. The sub-contractors are—for masonry, Mr. Hugh Yates; slating and plastering, Mr. John Bromley; plumbing and painting, Mr. Thomas Holt; glazing, Messrs. Saul, Moss, & Co.; the plate glass being supplied by the London & Manchester Plate Glass Company; iron work, Messrs. Weher & Co.; the fittings for lighting being executed by the Gas Company, and the apparatus for warming and ventilating by Mr. Alderman Beauett. Mr. Jacob Crivis is the clerk of the works.

The area actually covered by the building is 3,770 yards.

The library was thrown open to the public on the 3rd instant, this being the only portion of the building completed. The approach to this library is temporarily up a back way at the east end of it. The result of the first day's experience was duly celebrated by the local press. We are unable to endorse the glowing account that was given, but are quite willing to believe that in a little time the weak parts of the arrangements will be discovered, and that the Public Library of Liverpool will become all that its munificent founder desires it should be.

#### THE LATE MR. GEORGE BAILEY, ARCHITECT.

We record, with regret, the death of Mr. George Bailey, which took place at 13, Lincoln's Inn-fields, on the 17th inst. Mr. Bailey was a favourite assistant of the late Sir John Soane; and, on the death of that gentleman, was appointed, under the will, the first curator of the Soane Museum. Mr. Bailey was a fellow of the Royal Institute of British Architects, and some years ago acted with great zeal as its honorary secretary.

In the formation of the Architectural Publication Society, in 1818, Mr. Bailey took much per-

sonal interest in it, being present at the first meeting of the promoters, and ever after affording all the information he had collected from time to time, or could procure from the valuable library under his control. Thus most of the biographies of the English architects comprised in the "Dictionary of Architecture," now in course of publication, have been rendered more perfect than was hitherto the case. It is hoped that the honorary secretary for the Dictionary may still have permission to refer to Mr. Bailey's note-books for further accessions to that valuable work.

Mr. Bailey was in his 69th year when he died. He was buried at Highgate on Saturday last.

We would express a hope, without meaning the slightest reflection on the course pursued by the late Mr. Bailey (who did what was considered best), that, in appointing his successor, the trustees of the Soane Museum will seek to make such arrangements as will ensure to the public the freest access possible, and render the collections and books more widely useful than they have been. We have long urged this point, and, we hope, not without effect on the minds of some of the trustees.

#### PROPOSED EXHIBITION IN DUBLIN.

The Royal Dublin Society, on the recommendation of various lovers and owners of works of art, have determined to hold an "Exhibition of the Fine and Ornamental Arts" during May and the three following months of 1861. The object is to collect the *chefs d'œuvre* of painting and sculpture, and to exhibit them with drawings, engravings, photographs, medals, objects of vertu, elaborately wrought plate, works in precious stones and metals, in porcelain, silk, velvet, lace, tapestry, and works in which art forms a material element. The guarantee fund, to cover the expenses in the event of a deficiency in the receipts, was originally fixed at 5,000*l.*, but has already grown to upwards of 9,000*l.*

#### FOUNDATION OF AN ARCHITECTURAL ASSOCIATION IN MANCHESTER.

A NUMEROUSLY-ATTENDED meeting of gentlemen connected with the architectural profession was held on the evening of Monday, the 17th inst., in order to consider the desirability of establishing an Architectural Association in this city.

Mr. G. Shaw Aitken having been called to the chair, it was proposed by Mr. Alfred Darbyshire, seconded by Mr. R. Walker Aitken, and unanimously carried, "That, in the opinion of this meeting, it is desirable that an Architectural Society be formed in Manchester, to be called the 'Manchester Architectural Association.'"

A code of laws was then brought forward and considered; when it was proposed by Mr. Welster, seconded by Mr. Joseph Shaw, and unanimously carried, "That the laws submitted to the meeting be the basis of the Association's constitution."

Office-bearers, and a committee of four, having been elected to serve until the last ordinary meeting in the month of March, the business of the meeting was concluded by a vote of thanks to the chairman.

Mr. R. Knill Freeman is the honorary secretary.

#### SCHOOLS OF ART.

*The Stourbridge School.*—The annual meeting of this school took place in the Corn Exchange, Stourbridge. Lord Lyttelton presided, and there were present in the room some 400 persons. The report of the masters stated that the number of students continued to increase. Since the last council meeting 152 students had attended the classes at the central school, and 622 had received instruction at public and private schools, making a total of 774 under instruction during the year—a larger number, it was said, in proportion to the inhabitants than that furnished by any town in the United Kingdom. Seven medals had been awarded, and sixteen pupils had passed their examination in advanced free-hand drawing, practical geometry, and perspective. Of these eleven had received certificates, and five prizes. Owing to the raising of the standard of excellence, the master recommended that those of the pupils who had remained a certain time in the school should receive prizes and certificates of merit from the Council. The master concluded his report by some remarks upon a letter read by the Duke of Argyll, when addressing a meeting of Associated Mechanics' Institutions in the Free Trade Hall, Manchester, and urged the importance of art to those engaged in the glass trade of the neighbourhood. The fees from pupils during

the year ending the 31st of September last, were 106*l.* 3*s.* 9*d.*; subscriptions, 46*l.* 15*s.*; with sundries, 12*l.* 9*s.* 11*d.*; making a total of 165*l.* 18*s.* 5*d.* The total expenses were 133*l.* 15*s.* 11*d.*, which left an excess of income over expenditure of 32*l.* 2*s.* 7*d.* There is a building debt of 200*l.* The prizes were distributed to the students by Lord Lyttelton.

*The Carlisle School.*—The adjourned annual meeting of subscribers to the Carlisle School was held in the Town Hall. The Mayor presided; but the meeting was exceedingly small, the only other gentlemen present being three, besides the master, the treasurer, and the secretary. The school, however, is now in a somewhat better condition than it has been since its commencement. There are 121 general pupils, 355 pupils taught in public schools, and 84 in private schools. The ordinary receipts during the year were 36*l.* 11*s.* 10*d.*, while the expenditure had been 51*l.* 16*s.* 10*d.*, thus leaving a deficit of 15*l.* 5*s.* The Treasurer stated that hitherto the receipts had been more, but this year an arrear of rent had to be paid. He hoped this deficiency in the revenue account would not be permanent, although they could hardly look to being able to clear their way entirely.—Mr. Lees read a letter which he had received from the Art Union of London, stating that the Council, being anxious to assist in the cultivation of design and the practice of fine art, as applied to manufactures, and especially with reference to the Schools of Art, proposed, with the concurrence of the Department, to set apart the sum of 100*l.* each year, to be offered to the pupils in these schools on certain conditions. There will be five prizes of 10*l.* each, and ten of 5*l.* The subjects of competition suggested are:—Drawings and models of animals or groups of animals from the life; models of clusters of fruit, &c.; a book-case; a sideboard; a bronze candelabrum; clockcase for a mantelshelf; candlestick for ditto; pedestal for reduced bust of Clytie; bust of the Belvedere Apollo; silver prize cup; majolica dish; garden flower vase; tazza, &c. The master said he did not know whether to think of it as a reproach to Carlisle, but they always secured on the point of closing. There appeared to be an apathy as to the school. The public should be made aware that they did not attempt to make artists; they attempted to make useful men. If they got a bricklayer, they wished to make him know the value of his work and make it more ornamental; and the same with carpenters and others. There was no more simple ornament than different colours of bricks; that is a real ornament; and, if they could make a man feel that his work was ornamental and pleasing to the public, they gave an interest to the school which it had not hitherto possessed. He wished they could get the public to feel that they were useful members of society; at present they were only considered ornamental.

#### THE CONDITION OF BRIGHTON.

WITH reference to the recent correspondence on the drains of Brighton, and the remarks in our own pages, a correspondent, "A Resident," says:—

"The most important fact elicited during the discussion on the subject is this—*That there is no medical officer of health in this town.* That is a want which must be deplored on behalf of every locality where the want exists; and, so far as Brighton is concerned, it is to be hoped that the application to the General Board of Health, recently announced, will result in the appointment of a 'sanitary superintendent' for the town. The duties of such a public officer are well described in a paper on 'Public Records of Mortality and Sickness,' read by Mr. H. W. Rumsey, in the Public Health Department of the *Social Science Association*, and printed in the 'Transactions' for 1859.

Much might be done for the improvement of the health of towns by employing the services of a public officer possessing the necessary qualifications for the duties of such an important and responsible post, and entrusted with full powers; much could be done in Brighton, doubtless, as in other places, by enforcing obedience to sanitary laws, which are now neglected because no compulsive agency exists.

The light of sanitary science is beginning to dawn upon men's minds in a degree not contemplated a quarter of a century ago. It is devoutly to be desired that the self-same light may at length penetrate and so far illumine the obscurity in which the deliberations of Town Councils are too generally enveloped; so that the members, individually and collectively, may be enabled to distinguish their true course regarding the vital interests of the several localities over which they preside; and that these bodies—not well esteemed

in general—may, by placing themselves under authoritative direction in matters relating to the sanitary improvement of their respective towns, recover—in one instance, at least—the confidence that they have lost by the mal-administration of municipal affairs with which they are entrusted."

"STAINING WOOD."

OUR correspondents are not unanimous in approval of the recommendation to use the stain before the size, given in a communication signed "G. R. B. Arnott." One of the dissentients, W. H. E., says,

"Timbers stained previously to sizing are of a heavy, dead, blackish tint, instead of the nice varnished light-brown hue produced by the proper treatment [size first, next the stain, then varnish]. Any one using stain and varnish without a size coat, underneath will find any number of coats of varnish entirely thrown away, although the stain will have sunk into the wood as to prevent any amount of scraping from getting it off."

We are disposed to believe that with the best description of stain and the wood the course first recommended is calculated to produce the best and most lasting work. But if common stains be used, or the wood be of unequal texture, the size should be applied before the stain.

WANTED! THE ARCHITECT OF THE EDUCATIONAL BOARD.

SIR,—As the editor of the Builder is supposed to know every thing on every subject, I make bold to ask you to give me some information relative to that mystery, the Education Act, which the Board of Education have just used to call or send to his office in a morning, but, alas! it was a desert. At last, being there at twenty minutes past five, I met with a clerk who had just arrived. Cross-examination soon made clear that the said master were supposed to turn up about two o'clock. Now, as it was then twenty minutes past that hour, and as I have a good deal of business to attend to, I have, therefore, three, I have inclined to believe that it is simply a pleasant fiction of the clerk. We all know how conducive solitude is to the cultivation of the imagination, and I think it is not unfair to attribute his assenting to this cause. The invisible girl, who astonished the good folks of London some few years since, was both amusing and instructive. I am afraid the invisible architect is just the reverse.

ONE OF SOME HUNDREDS WHO WOULD BE GLAD OF THE PLACE, IF TOO HEAVY FOR THE PRESENT OCCUPANT.

THE ADULTERATION OF LINED OIL.

SIR,—The communication from "A Friend to the Unemployed," that appeared on the 1st instant in your valuable journal, has had the effect of causing considerable uneasiness to myself and others interested, who believe your correspondent wrong in remarking that "they (the sellers of lined oil) run no risk and are not responsible for the work spoilt by their rubbish." This statement must assuredly have been made without reflection; and if allowed to pass unrefuted, is, I think, calculated seriously to injure, and not in the least favour, the interests of the unemployed or expectations of the trade.

The Legislature has wisely interposed to prevent the adulteration of food: surely, then, the tradesman, who is bound to uphold his respectability in order to obtain the means of his subsistence, is not to be impoverished and prevented from so doing, or subjected to various ailments, solely upon him, without remedy of some kind. If, however, your correspondent has authority for making his statement, the contrary, then it must be admitted a serious flaw exists in the laws of this country, and all interested should at once petition Parliament to remedy the defect. Unfortunately, there is already abundant proof that the colour merchants generally vend worthless and trashy compounds instead of genuine materials; and this fact being established, it is in my opinion an imperative duty for the painters, as a body, to place themselves in a right position with the public, by proving satisfactory their noncomplicity with the perpetrators of the existing novel yet unprincipled system of fraud. It is idle to argue that the merchant and tradesman are alike victimized by the manufacturer, the former being in a position to ascertain, by reference to his invoice-book, who supplied the adulterated goods; and, failing to institute proceedings to end the nefarious practices of those who have so long and persistently preyed on the honest consumer, I consider the vendor clearly identifies himself with the fraud, and becomes both legally and morally responsible for the loss sustained by his customers. I fully anticipated long since that some eminent and competent authority would have taken the matter in hand; but, assuming the attention of our scientific men to be engrossed by occupations of a more pleasant, though the character, I desire, with your permission, to offer these remarks with the intention of arousing the trade generally to a proper sense of the interests they have at stake, and inducing them to continue a judicious and successful course of investigation, satisfactory mode to all concerned, of submitting samples of the materials supplied during the past twelve months for analysis. It occurs to me, if the necessity of inquiry is more apparent through the medium of the Builder, the proposed movement will at once attain that extent of metropolitan and provincial publicity desirable for the purpose of ensuring active co-operation from all branches of the building trade, and enable the committee, when appointed, to obtain impartial reports from two or more of the most eminent chemists in the kingdom; the only mode, in my belief, calculated to afford satisfaction alike to the employer and employee.

As a case in point, let me instance one among several personal cases of complaint. I ordered from a leading firm one quart of a stock of best quality oil, least standard, paying the highest market price for the articles. With colour prepared from these materials, eight ten-

roomed cup-boarded houses were painted inside and out. Within a fortnight after their completion, I was astounded by the receipt of a note from my employer, stating that he "had lost all confidence in me, and had been compelled to employ a surveyor to go over the work, the tenants having expressed their intention of leaving the houses in their occupation, owing to the smell, appearance, and non-drying properties of the paint used by my men." Feeling from these remarks that my work people had neglected their duty, I immediately visited the place, and cannot find language sufficiently strong to express my feelings of indignation and disgust on discovering the labour well executed, and that the fault lay only with the material. The entire surface was "blotchy and tackey," and, as the only means of saving my reputation, I at once undertook to do the work over again. Fortunately, the surveyor who attended was a gentleman experienced in my business; and, from his favourable representations to the employer, I, after considerable demur, obtained permission to do so. At the present date (nine months after the work has been completed a second time) the light stone fronts present a streaky, dirty, fawn-coloured appearance, and the blotches, after receiving five (and in some cases six) coats, have "sweated out" to such an extent as to render their position too readily describable to the practised eye of a person acquainted with this branch of the building trade. Regardless of time and expense, I made every reparation in my power, for the amoyance occasioned by the colour-merchants supplying me with improper materials; and consequently, as proof of the feeling entertained by employers generally in the matter, I have resolved the morning intelligence that my highly-valued customer has transferred his patronage to another person, who is now actively engaged on work which has for years been entrusted to my care. Having suffered damage to an unascertained extent, I assume I am entitled to recompense from the eminent firm with whom I dealt (who either by complicity or gross neglect, had occasioned me the double loss of money and character); and it is my intention, not to agitate to the utmost, but, whether my brethren join or not in the proposed movement, to submit the question on its merits to the decision of a legal tribunal.

AN INJURED TRADESMAN.

P.S. The secretaries to the Painter Stainers' Company and various metropolitan trade lodges have been written to, and on receipt of their replies a public meeting will be convened, due notice of which will appear in the Builder and daily papers.

Books Received.

The Nuisances Removal and Diseases Prevention Acts of 1855, 18 & 19 Vic., c. 116 and 121. Second Edition. With the Amending Act, 23 & 24 of Vic., c. 77. By W. G. LUMLEY, Barrister-at-Law. London: Knight & Co., 1860.

WE cannot better reply to the correspondents who ask us every week how to get rid of a nuisance than by referring them to Mr. Lumley's edition of these enactments, and by adding, in the words of the appendix,

- 1. Under these Acts any premises in such a state as to be a nuisance, or injurious to health, may be ordered, by two justices in petty sessions, or by a stipendiary magistrate, to be made safe and habitable, to be paved, cleaned, whitewashed, disinfected, or purified; sufficient accommodation, means of drainage and ventilation, may be required to be provided; and while any house or building is unfit for human habitation, in the opinion of the justices, the use of such premises may be prohibited till the causes rendering it unfit for habitation have been removed.
2. Any pool, ditch, gutter, watercourse, privy, urinal, cesspool, or drain, which shall so be a nuisance or injurious to health, may be ordered to be drained, emptied, cleaned, filled up, amended, or removed, and a substitute provided.
3. Any well or cistern kept as to be a nuisance or injurious to health may be ordered to be kept in a cleanly and wholesome state, and, if that be impossible, the animal may be removed.
4. Any accumulation or deposit which is a nuisance or injurious to health may be ordered to be carried away."

Miscellaneous.

ANOTHER COLLIERY EXPLOSION.—A shocking explosion has taken place at Hetton Colliery, near Durham, whereby twenty miners are said to have lost their lives. This colliery is the property of the Hetton Coal Company, and is situated about nine miles south of Sunderland.

DINNER OF ASSOCIATION OF FOREMEN ENGINEERS.—On the 15th inst. the eighth anniversary dinner of the Association of Foremen Engineers took place at their rooms, 35, St. Swinham's-lane, City. About ninety members and friends sat down. In the absence of Mr. H. Grissell, Mr. Joseph Newton, of the Mint, occupied the chair. A report read in connection with the toast of the evening, namely, "Prosperity to the Association of Foremen Engineers," showed that the receipts since establishment in 1852 had been 486*l.* The disbursements were—To unemployed members, 110*l.*; deaths, 40*l.*; incidental, 113*l.* 18*s.* 6*d.* Deducting these disbursements (263*l.* 18*s.* 6*d.*) from 486*l.*, left balance of 222*l.* 2*s.* 6*d.*; with interest, 236*l.* 17*s.* 2*d.* Surely, as we have often before said, there are too many of these societies. If united, the cost of management would be greatly reduced, and the disposable funds would be much larger.

THE BUILDING TRADE AT SOUTHAMPTON.—About 2,000 artisans, mechanics, and labourers, are out of work at Southampton, owing to the slackness of ship and house building. The slackness in the building trade arises chiefly from the high price of bricks, comparatively few having been made this year in consequence of the wet weather.

FATAL ACCIDENT AT CROSTADE.—A St. Petersburg letter states that at Crostade recently a bridge across the entrance to a dry dock suddenly gave way at a moment when thirty persons were passing. As they fell from the height of seventy feet on the granite bottom of the dock twelve were killed on the spot, and the rest so seriously hurt that they are not likely to recover.

STATUE OF SIR WILLIAM PEEL, K.C.B.—Mr. William Theed has executed, in marble, a statue, 7 feet in height, of the late Sir William Peel, K.C.B., of the naval brigade, at the expense of the Right Hon. Frederick Peel, M.P. On the 22nd it was placed in the Painted Hall, Greenwich Hospital.

STREET ROLLING IN PARIS.—Steam rollers have recently been set to work in some of the streets of Paris, forming a great contrast to those unwieldy-looking machines, drawn by eight horses, which every visitor to Paris must have seen at work, crushing down the stones at the Champs Elysees.

THE CO-OPERATIVE MOVEMENT AMONGST THE WORKING CLASSES.—The impetus which has been given to manufacturing co-operative societies by the large dividends that have been declared by the Bacup and Wardle Manufacturing Society, is said to be felt in all directions. There are five co-operative mills in progress according to the Manchester Courier, and a sixth has been projected by the directors of the Callard's Manufacturing Society. This company having an estate of 33 acres, and a river running through its centre, upon which there is already a woollen mill at work, have projected a mill for 20,000 spindles of cotton wool, to be erected on the opposite bank to the woollen mill. The capital now raised is 20,500*l.*, and it is proposed to raise 30,000*l.* more in 5*l.* shares, to be raised in calls of 1*l.*, to be paid in February next, and 1*l.* every six months afterwards, until the whole is paid up. The plan is, however, subject to the approval of the shareholders at their meeting in January next.

MONUMENTAL.—A memorial of the late Mr. Wallace Hall, of Ross, is about to be erected from a design furnished by Mr. G. W. Sadler, of Cheltenham. The design consists of a spiral column, about 30 feet high, wrought in Box-Bath stone, with Forest stone base, having a drinking-fountain attached, with a basin of polished red granite. Messrs. Wingate & Son, of Gloucester, offered to execute the whole for 80*l.*—It has been resolved to erect the Tyndale memorial column on the highest point of Stinchcombe-hill. Sir George Prevost has promised to give the land. The exact shape of the monument has not been decided upon, but it has been resolved that a parabolic reflector should be placed on its summit, as suggested by Earl Ducie.—The Wallace monument executive sub-committee have applied to the town council of Stirling, for liberty to commence the erection of the Wallace monument, the necessary funds being now on hand.—It seems, however, that it is only the main tower which is intended to be erected at present, and which it will take three years to complete. The sum of 1,500*l.*, according to the Falkirk Herald, is still required in order to complete the monument according to Mr. Roched's design.

VALUE OF A "NEW RIVER" SHARE.—Recently, at the Auction Mart, two 36th parts or shares in the king's moiety of the New River Company, being virtually an original half-share, were sold. The auctioneer stated that the undertaking was commenced in 1608 and completed in 1613, and the resources of Sir Hugh Myddelton being exhausted before the work was completed, he applied to the Crown for additional money to carry out the work, and made over half the property in return for half the expenses being paid. In 1636, Charles I. granted his moiety back to Sir Hugh Myddelton on condition of an annual payment of 500*l.* which payment is charged on the king's shares, and distributed over them by the company before paying a dividend. For 18 years after the undertaking was completed there was no dividend paid, and the shares his given away gratis. In 1793, Pennant says his shares sold for 10,000*l.* The lot sold for 8,700*l.*, making the value of a whole share 17,400*l.* This makes the value of the "adventurers'" shares in the property, from not being charged with the payment to the Crown, about 20,000*l.*

ENGINEER OF GREAT WESTERN RAILWAY COMPANY.—Mr. John Fowler, C.E., has been appointed consulting engineer of the Great Western Railway, in the room of the late Mr. Brunel.

THE MANCHESTER OPERATIVE PAINTERS.—A meeting of these operatives has been held to memorialize the masters on the subject of wages. It was suggested in the memorial agreed to that the hour system should be universally adopted, and that payment be at the rate of 6d. per hour. This would be equivalent to an advance of about 10 per cent. in the wages of the men.

CLERKENWELL WORKHOUSES.—For some days past some alarm has prevailed among the inmates of Clerkenwell Workhouse, Cripple-row, in consequence of the subsidence of the front centre wall, which is supposed to have been caused by the excavations carried on along Cripple-hill, for the formation of the Metropolitan Railway. At this point of the line the ground has been excavated to a great depth. Mr. Jay, the contractor, at once adopted measures to prevent any further accident.

RAILWAY WONDERS.—The Times remarks,—"Every year some fresh line is opened which must yield its fresh receipts before fresh revenue can be forthcoming. In 1854, the aggregate of railway capital was, in round numbers, 286,000,000l.; in 1859, it was 331,000,000l.; having increased as nearly as possible to the extent of 50,000,000l. a year. Yet the receipts have not only afforded a dividend on this increased sum, but a better dividend than formerly, and there never was a year more auspicious than the soaking and dreary twelvemonth through which we have just passed."

BURNING OF A SYDNEY THEATRE.—The Australian Mail states that one of the most extensive and disastrous conflagrations that has ever occurred in Sydney broke out on the morning of October 3rd, near the corner of King and Castle-streets, causing the entire destruction of the Prince of Wales theatre and of several adjoining buildings, and resulting in the death of three persons, and in the serious injury of others. One of the adjoining offices was constructed of iron, which was quickly "demoralized," and reduced to wreck, by the intense heat.

EXTENSION OF THE METROPOLITAN UNDERGROUND RAILWAY.—At a meeting of the Paddington representative council, on Tuesday, in last week, the application to be made by the Metropolitan Underground Railway Company, in the ensuing session of Parliament, for an extension of the subterranean line, was brought under consideration. The parish surveyor, Mr. Merry, exhibited plans which had been lodged with the vestry clerk, to ascertain the opinion of the vestry on the proposed extension from Prad-street to Notting-hill-gate, with a branch from Uxbridge-road, under the Broad-walk to Brompton, and with a junction in Hammersmith-road, for the purpose of ultimately extending the same to Hammersmith. The meeting resolved to remain neutral.

THE DRAINAGE AT MALTON.—The drainage works at Malton, noticed in your publication of the 15th inst., are being carried out for the Malton Board of Health, under the superintendance of Mr. John Gilson, architect, Malton, who has prepared a survey of the town to a scale of 10 feet to one statute mile. The drains are laid with glazed stoneware sanitary tubes, socketed at the joints (supplied by Messrs. Barry & Son, of Scarborough), the largest tubes being 18 inches diameter; these are joined with 15 inches diameter, then 12 inches diameter and 9 inches diameter for the trunk drain; branches to blocks of house are 8 inches diameter. In two of the streets the drain will be 12 feet deep for a short distance: the average depth of the drains will be about 6 feet, the estimated expense 1,400l.—J. G.

STRIKE OF THE NAILERS OF SOUTH STAFFORDSHIRE.—A strike has just commenced in the South Staffordshire district, by which some 3,000 men are thrown out of employ. The strike has arisen out of a trades' union dispute. Mr. Walker took on a man not a member of the Horse-nail Makers' Trades' Union. His men thereupon demanded his discharge on an advance of wages. Their demand was not complied with, and the 300 men employed by him left their work. The masters held a meeting a few days ago, and resolved not to give any more work to their men till Mr. Walker's men returned to work. The men upon this throughout the district demanded an advance of 6d. per 1,000 on the nails they make, and thus a general strike has commenced, the masters being determined not to give such a large advance. It is stated a horse-nail makers' wages average 25s. per week.

KILKENNY COUNTY SURVEYORS.—The lord lieutenant, according to the Carlow Sentinel, has appointed Mr. P. Burchall, the county surveyor of Carlow, as successor to the late county surveyor of Kilkenny.

FALL OF A BUILDING.—The barley-chamber of a malt-house, in Newmarket, has suddenly given way; its contents, between 500 and 900 combs of barley, having been precipitated on to the working floor of malt. The beams and joists are said to have clearly indicated that the building was not adapted to sustain the weight of so large a quantity of grain.

PROPOSED CARRIAGE-ROAD ACROSS PRIMROSE-HILL.—At the weekly meeting of the Marylebone vestry, it has been resolved that a memorial be presented to the chief commissioner of public works praying that he would cause a carriage-way to be made from the foot of Barrow-hill, across the eastern side of Primrose-hill, to the junction of the road on the St. Pancras side leading to the Chalk-farm. Mr. Freet, in moving the resolution, stated that the parish of Marylebone had been so built upon that it was a species of *cul de sac*, and some of the districts were blocked up with gates, so that the inhabitants had great difficulty in moving from one place to another. The walks which now existed in what was called Albert-park and once Primrose hill were pleasant enough by day, but at night they were positively dangerous, and scenes of the worst description were taking place there continually.

THE SURVEYOR TO THE BATH CITY ACT COMMITTEE.—A discussion is going on in this committee on a motion that Mr. Parfitt, their surveyor, have six months' notice to quit. The mover and others charge the surveyor with general neglect. The mover, Mr. Cox, stated that he was "not systematic, not methodical, not active, not diligent, and not truthful." Others defended the surveyor, and blamed the surveying committee, who were ever running after him and interfering with his duties. One member said the great difficulty in the case was to know whether the surveying committee had charge of the surveyor, or the surveyor of them. It was not exactly clear; but, at any rate, it seemed that the committee had taken charge of the surveyor. He always had protested against it as an unsound principle. The discussion was adjourned, the understanding apparently being that the surveyor should have time to reply to the charges against him.

ST. BARTHOLOMEW'S HOSPITAL.—On Monday last, a deputation from this famous metropolitan hospital, which was founded upwards of 750 years ago, waited upon the Lord Mayor (Cairns), at the Mansion House, and apprised his lordship that the house committee of the institution had passed an unanimous resolution recommending him to the general Court of Governors as a fit and proper person to fill the office of President of the hospital, which had become vacant by the recent death of Alderman Sir George Carroll. The gentleman composing the deputation were Mr. W. Foster White, the treasurer of the hospital; Mr. Sergeant Payne, Mr. Hooper, Mr. Alexander Jones, Mr. Chas. Hill, F.S.A. Mr. James Bentley, Mr. Daniel Britten, Mr. Win. Gilpin, Mr. Anderson, and Mr. John Morley. The Lord Mayor, while appreciating this mark of confidence and respect, hesitated at first to assume the responsibility of the office; but on the deputation representing to his lordship that the functions incident to the position of president would occupy but little of his time, and that it was simply an honorary distinction they wished to confer on him, he readily and cheerfully consented.—Let us here note that the Lord Mayor's entertainment in honour of Lord Clyde, and at which the Commander-in-Chief, the Duke of Cambridge, attended, passed off in the most admirable manner. The Lord Mayor had a good opportunity and took full advantage of it.

TENDERS

- For six dwelling houses at Saltburn-by-the-Sea, Cleveland; Mr. W. Peachey, architect:—
Robison ..... 4,140 17 4
Allen ..... 1,872 12 8

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and not to the "Publisher."

Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

THE BUYER'S DESIDERATUM.—"The buyer's desideratum is to find an establishment where will be presented to him ample choice of artistic designs, without having forced upon his attention a host of more ingenious ones, and destitute of any other merit, with a tariff of prices adapted to the means of the economic or those to whom price is no object. Such an establishment is that of Mr. J. W. Benson, situate at 33 and 34, Ludgate-hill, whose recent enlargement of his premises has made his show-rooms more conspicuous than any other in the neighbourhood of St. Paul's. His four windows contain such a variety of gold and silver watches as to leave nothing to be desired but the money to buy them with. The high standing of Mr. Benson as a London manufacturer must secure him a large amount of public patronage."—Standard.

Benson's Illustrated Pamphlet, post free for two stamps, is descriptive of every construction of watch now made. Watches safe by post to all parts of the globe.—Advertisement.

ADVERTISEMENTS.

MR. WILLIAM ELLISON, CONSULTING SURVEYOR, 14, STAINSBY ROAD, 13, PENCHURCH-BUILDINGS, PENCHURCH STREET, E.C. Has taken Office as SUPERVISOR ON BREACHES OF CONTRACT, DISPUTED ACCOUNTS, &c.

BOROUGH OF TYNEMOUTH LOCAL BOARD OF HEALTH.—APPOINTMENT OF BOROUGH SURVEYOR.—Notice is hereby given that the Local Board of Health of the Borough of Tynemouth will meet on WEDNESDAY, the 10th day of JANUARY next, to appoint a SURVEYOR for the said Borough. The person to be appointed to this Office must be experienced in surveying, and be able to draw plans, make sections, and to prepare estimates of sewerage works, new streets and roads, and other works which it may be the duty of the Board to carry into effect, and competent to judge of the proper execution of such works. He will be required to examine and report to the Board on all plans of buildings and intended new streets, and to inspect the same during their construction; and to advise the Board when he continues to advise BUILDERS, and tradesmen's accounts, and generally to act under the direction of the Council, and of the several Committees thereof. The person appointed will be permitted to take any professional employment within the limits of the Borough, but may, with the consent of the Public Board of Health, undertake such professional engagements beyond the Borough as will not interfere with the proper discharge of his official duties. The salary is £200 per annum. Parties who desire to be considered for the office should send their names to the Town Clerk's Office, 27, Newcastle-street, North Shields, to whom applications and testimonials are to be sent on or before FRIDAY, the 15th day of JANUARY, 1861, at SEVEN o'clock, addressed to "The Public Health Board, Newcastle." By invitation for the office of Surveyor, THOMAS CARE LETCH, Clerk to the Local Board, Borough of Tynemouth, 20th December, 1860.

MR. W. F. HAMMOND, Auctioneer, Land and Estate Agent, 11, Green-street (opposite the Bank railway, W.C.), and OFFICE in his office for well-educated YOUTH, as a pupil. Premium expected.
