# The Builder

## The Doings at Alnwick Castle.

IT is now nearly five years since Professor Donaldson read, to a meeting of the Royal Institute of British Architects, an account of the proposed external restorations and internal decorations of Alnwick Castle. From that time to this the sounds of the chisel and the hammer have not ceased to reverberate on the banks of the Alne, for upwards of 300 men have been constantly at work upon the structure. Their united industry, at the close of the past year, had advanced the completion of the edifice so far as enabled his Grace the Duke of Northumberland to order a banquet to be prepared, in the new kitchens, for 650 work-people, employed on the building and estate. Then was the mighty baron of beef roasted for eight hours

before two tons of coal; and then did a hundred geese and turkeys blend their appetising flavours with the spicy odours of countless plum-puddings. Those who were there to see affirm that the spectacle of the mighty haron, borne on a huge dish by four stalwart men, and preceded by his grace's piper, playing the wild weird notes of "Chevy Chase," was as truly a Medieval sight as the fourteenth century could have afforded. And when the 650 Northumbrian retainers rose as one man, and gave three loud cheers, solitary shepherds out on Cheviot side thought they heard vibrations in the air, as of horses' hoofs and border cries, and went home basily. And when the wreek of the noble haron was removed, and the slighter fragments of the feast disposed of, and the Constable of the Castle proposed the health of Algernon Percy, Duke of Northumberland, then the said shepherds heard more distinctly battle-cries floating on the wind, as it swept over the heather and eddied fitfully round their lowly cots; and again, when the aforesaid Constable proposed the health of her Grace the Duchess of Northumberland, then were the shepherds more and more convinced that the noises they heard in the air were not freaks of the imagination, but were real sounds proceeding from invisible causes; and then did they become more and more convinced of the necessity of strict and punctual attendance at kirk (albeit that modest edifice was seven miles off), if a man wished to keep clear of unceasing folk.

Every mile of Northumbrian ground, radiating from Alnwick Castle, is legend-wreathed with the deeds of the ancient Percies. At Otterbourne was fought the moonlight battle in which the Douglas fell, and Hotspur was made prisoner. On Homildon-hill, that flower of English chivalry routed the Scottish forces in a fierce fight, in which the Earl of Douglas was blinded by wounds, and made a prisoner of war. And (still amid the

Cheviots) at Pipenden, his son, heading a thousand men, met the Earl of Angus in great force, when Sir Richard Percy, and other knights and gentlemen were slain. On Hedgeley-moor, where the worn cross stands to mark the spot, fell Sir Ralph Percy, faithful to the Lancastrian cause, in the wars of the White and Red Roses. Woven in with all these deeds is the legendary ballad of that "woeful hunting," Chevy Chase; and fluttering above them all are the armorial ensigns of the sovereign houses of England, France, Scotland, Leon, and Castile, which the distinguished alliances of the Percies entitle them to bear.

The Percies came into possession of Alnwick Castle, by purchase, in 1309. It was then a Norman fortress, built by the noble on whom William the Conqueror had bestowed the hand of the Saxon heiress, of a previous building, on the same site. Many parts of this Norman castle are still in good preservation, though the greater portion of the structure is the work of the Percy who purchased it, and therefore essentially Edwardian. Of the Norman "bits" the inner gateway of the keep, fretted with zig-zag ornaments (of the same character as those upon that invaluable archaeological treasure, the Priory Church on Holy Island), is the most important; although the Norman work preserved in the lower portions of the curtain-wall is scarcely less so, on account of the certainty it imparts as to the original size of the enclosed space.

The Percy purchaser appears to have enjoyed but five years' possession of the castle before his death; but in that time he managed to strengthen and enlarge the building to the form handed down, through storm, siege, and desertion, to the last century. It was a period of unusual vigour in building operations. The conquest of Wales, and the repression and retaliation of frequent invasion on the Scottish border, occasioned the necessity of strongholds for the various lords and their retainers, on whom devolved the responsibility of maintaining the respective subjugations. Hence all the more important and conveniently situated castles on both these frontiers were enlarged to meet this necessity; and many others were newly built. Caernarvon, Conway, and Harlech, on the Welsh border, present precisely the same characteristic features that are to be found in Alnwick, Dunstanborough, Bamborough, and other northern castles. The peculiar forms of the lancet and shoulder-headed windows, with and without mullions and transoms; the transitional treatment of the doorways and archways, sometimes round, and sometimes pointed-headed, and not unfrequently straight-headed, with the penial corbel or shoulder in the angle of the straight head which prevailed at this period in ecclesiastical as well as castellated edifices (witness the choice specimen at Breckbourn Priory), are to be found in all these buildings. The same skilful scheme of defence, though differently wrought out to suit the site and situation of the various castles, is to be found in them all. The well-defended barbican, which, once gained by the enemy, was but a trap in which he could be assailed from four sides, and the artfully contrived sally-port, are all features they possess in common. On stripping off the plaster-work of the renovations that were made in the last century, the *old Percy's dining-hall*

was found intact, showing all the ancient arrangements, the marks of the dais, a curious piscina, and an amby-like euphoard at the same end, and a perfect staircase leading to chambers above, the fireplace and windows of which remained in the walls, the floors alone having been removed to give height to the modern apartment that occupied the site. We are certain that repairs were made at various periods, and that even additions were not withheld, for we read, among the names of nobles applying to Henry VI. for license to embattle their castles, that of Henry Percy, son of Hotspur; but the great mass of the building remained stone for stone as erected by the first Percy, Lord of Alnwick. The grant of this license to embattle assigns the period of the curious stone figures with which the towers of entrance to the keep are surmounted. These forms represent warriors in the various attitudes of repelling an assault. They are life size, and life-like, and must have done good service in their time, in receiving many an aim meant for the garrison when besieged. We have word, again, of the exact state of the building, in the ample survey, exact plans, and isometrical view made by Clarkson, in the sixteenth century. The keep of the castle (described as "very ancient, large, beautiful, and portlie") is in good "repairious;" but the lodge adjoining the "faire gate house," and divers towers, are "rewynoose and in decaye." And then we come to the restorations in the last century. When we have said that they were in the same style as Fontbill Abbey and Strawberry Hill,—those abused precursors of a genuine revival,—we shall say no more against them, for was not the old Percy dining-hall spared, while, with all our aesthetics and talk about Medieval remains, the present restorations have seen it razed to the ground? And were not our eyes sufficed to see the Falconer's and Armourer's towers, with the length of Norman curtain wall between them, that future archaeologists will seek in vain?

If an Englishman's house is his castle, we are aware how much intrinsically a Percy's castle must be his own. Nevertheless, inasmuch as we are all heirs of Old England's fame, so are we all concerned in the fate of her monuments. Wherefore it does not become us to quietly allow an alienation of one of these to take place; even if the loss be counterbalanced by an importation of half the glories of the Caesars. This observation brings us to an important branch of our present subject,—the Italian decorations of the interior of the castle. With our heads full of the ancient Percies, as Wordsworth said,—with our memories stored with images of "Hot Lord Percy" from Shakespeare's page,—with a resonance of Chevy Chase, more than half made out in the breeze that unfurls the Percy banner, and ruffles the Aln, we enter the ancient house of the Percies, prepared to realize the impressions their spirit-stirring associations have conjured up. But it has been decided otherwise. They must be effaced. "The goldsmith's work, garnished with pearls and stones;" the costly, varied, and rich materials which astonished the historian, who records the right-regal manne in which the Earl of Northumberland received and entertained the king's daughter, when on her road to espouse King James IV. of Scot-

land, no longer possess the power to assert the refinement of rank, or the dignity of wealth. The Field of the Cloth of Gold calls up no reminiscent suggestions of how this utmost gorgeousness might have been attained by historically English means. The remembrance of the Medieval magnificence of Westminster Hall does nothing. The rampant Brahmant lion is nowhere.

We should not have a word to say against the style of internal decorations adopted at Alwicks Castle, if we found them on the banks of the Tiber. We believe them to be as elegant, and as fantastically flowing, as Italian art can be. But we are not reconciled to seeing them pervade the home of the ancient Percys. With this protest we will proceed with our lining. We expressed this opinion strongly before the works were done, and have a right to reiterate it with the result before us.

The keep of Alwicks Castle is surrounded with a curtain wall, which was defended by sixteen towers. Of these, two have been newly levelled to the ground,—we trust not without good reason,—and are being replaced by a new one, which will fill more comfortably, perhaps, into a feature of a new terrace-wall, adjoining the front of the castle that faces the river. At the south-east point of the line of circunvallation are built the new kitchen (which must not be spoken of in other than Tudor phrase,—it is so “marvellously a faire vault”), and the numerous offices; while farther out, a gateway leads to another courtyard, in which are contained the stables and coach-houses. Thus it will be seen, that the keep is reserved expressly for the state and private apartments of the noble owners and their guests. The peculiarity of the arrangement of the covered corridor, by which they are approached from the inner courtyard, induced we assume by his grace's desire to preserve the ancient draw-well, is as successful a feature as any in the restorations. The new Prudhoe Tower breaks the hitherto uniform height of the long sky-line, by rising 20 feet above the cluster of towers of which the keep is composed, and forms a fine bold feature that must materially enrich the landscape. The south-west front of this tower is ornamented with an *alto rilievo* of the Hotspur banquet, immediately over a deeply-recessed and treble-corbelled window.

The military character of this tower strongly contrasts with the peculiar mannerism of the adjoining chapel, which building would have the appearance of a huge oriel window, but for the unusually high-pitched leaden roof bearing a cross at the apex of the apsidal west end, which at once proclaims its purpose. In the Tudor survey, “one faire chapel” is described as being “neighe ye said curting wall,” the foundations of which are buried beneath 12 feet of rubbish, on the spot depicted on the ancient drawings. We can, however, by view favourably a selection of a site which does not entail upon visitors and the several members of the household, young and old, diurnal exposure to the weather. The chapel is lighted by long lancet windows, and has a stone vaulted roof with foliated bosses and corbels. So far all is well. But the classicists are to be gratified here too. Marbles and mosaics are being imported from Rome, to render this north country fine as much like an ancient Roman basilica as its size and adjuncts will permit.

On entering the keep, we perceive a broad staircase, wrought in the white freestone of the country, which conducts the visitor to a vestibule, by which the state apartments are gained. These are nearly completed, according to the arrangements proposed by the late Commandatore Canina in his interesting specification, published in this journal, and carried into effect by his coadjutor Signor Montiroli. The fixing of the magnificent ceilings was a problem which required consideration. With an English treatment, the great main girders, which form part of the construction of the floors above, would have been brought into the composition; but Italian art did not so adapt itself; and, in the case of the library ceiling, 3 feet in height were lost to avoid them. The plan finally adopted was a framework suspended to the beams and girders, to which the coffered panels,

mitred, nailed, blocked, and glued together, were separately screwed up one by one. There is so much repetition in the ornament, that it has been ascertained there are positively miles of the egg-and-tongue pattern adorning the ceilings; but the workmanship has not suffered; it merits all the praise that has been bestowed upon it. We are informed that each of the carved walnut panels of the doors has occupied a man four months, and that a whole year's labour has been skillfully applied to each separate shutter panel. Looking upon the inlaid woods of the dados; the pure white marble of the mantel-pieces, the figures supporting which are copies, by Nucci, of the slaves on the arch of Constantine and the Greek Caneplora; the warm, ripe colouring of Mantovani's friezes; and the exquisite carving of Bulletti, and his studio, we have but one regret,—and that is, that such objects, beautiful though they be, should occupy the place that ought to represent the heronial magnificence of a family so eminent in the annals of English chivalry; in other words, that travellers should find on the banks of the Aln nothing more distinctive in the way of style than a faithful rendering of the Roman art the Cæsars fostered and the Cinque-Centists reproduced. Let copies of such things be conserved in our Art Museums, as these are in the Departure of Art at Brompton; let the best knowledge of the style possible be obtained for the advantage of new buildings; but leave us our national and poetical associations undisturbed by their introduction of Italian decorations into our Medieval buildings.

Our acquaintanceship with the public is now of too long standing for us to need any fresh introduction on the occurrence of a new year. Nevertheless, we cannot let the event pass altogether unnoticed, but will, in a dozen lines, express acknowledgments and hopes. During the past and previous years we have sought to discuss for our readers, promptly and in a fair and liberal spirit, every occurrence and proposition likely to interest the numerous classes to whom our pages are addressed, and to illustrate effectively and correctly the most important new buildings and designs, at home and abroad. A glance at our present Number will, it is hoped, suffice to show that there will be no falling off in energy and determination rightly to do the duty that is before us, and to render this journal more and more nearly all that may be desired. We have in preparation engravings of a number of important works; and we invite, frankly and warmly, the co-operation of all who desire to advance the interests of the arts that adorn and serve.

#### A VISIT TO WELSH TIN PLATE WORKS.

THERE are few of the metals possessed of the same interesting relations as the one we have now before us. The archeology of tin is more than usually attractive, and in the very dawn of history it is mentioned by the great Hebrew lawgiver as one of the metals to be purified by fire. The early inhabitants of Etruria and Central Italy were skilled in the applications of tin; the nations of the Levant were likewise accustomed to its use; but the most interesting point to us in the history of this metal resides in the memorable traffic which the Tyrian mariners pursued with the natives of the British Islands. Perhaps the whole catalogue of Phœnician commerce, so eloquently denounced by the prophet Ezekiel, could yield no article of superior value to this Cornish metal; indeed, it ceases of Lebanon or the gold of Ophir. There was at that period an enormous consumption of bronze by contemporary nations in all their instruments of art and war; and tin,—a metal of rare occurrence and limited distribution,—is the most essential constituent of bronze, as we learn from Pliny. If we recollect, too, that the Phœnicians possessed a monopoly of this commerce, we shall then be able to conceive the inestimable value to its discoverers of this prolific tin country. So fully, indeed, was this importance recognized, that those astute merchants anxiously concealed from their rivals and contemporaries the geographical situation of these “tin islands.” But the secret at length transpired. Puffius, a Roman pro-consul in Spain, after several unsuccessful

efforts, opened to his countrymen the treasures of this undiscovered Dorado; and, all through the long period of history which has since elapsed, Cornwall has continued to furnish an inexhaustible supply of the metal.

After the Norman Conquest, Cornwall was settled by Act of Parliament on the eldest sons of the kings of England, who thus became earls, and, finally, dukes of Cornwall. Tin, of course, constituted an important item of the royal revenue. The celebrated Edmund, Earl of Cornwall, was the first to levy a stated impost on the produce of the mines, which, curious to say, was only recently abolished; and it was also that prince who framed the celebrated Statutory laws, which to this day render Cornwall an exception to all the rules of mining jurisprudence. During the reign of Queen Elizabeth, scientific mining was introduced upon the German models. During the Civil Wars the mines were utterly neglected; but early in the last century they were recommenced with a degree of vigour, and an application of skill which has never since suffered interruption.

Our limits will not permit us to enter minutely upon the subject of Cornish mining. We may state, however, that few departments in the wide domains of mechanical science are so profusely enriched with the triumphs of genius or the rewards of enterprise. The great tin-mines of Cornwall are grouped upon that ridge of mineral veins, so well known to geologists, which traverses the district in an easterly direction, and terminates in the Dartmouth hills in Devonshire. Besides the produce of these mines, tin is found disseminated in enormous quantities throughout the alluvial deposits of the valleys. And not only has the miner pursued the deceitful *lode* above or beneath the surface of the land, but he has in some cases actually carried his explorations under the bed of the ocean. Some of these submarine tin mines—which, on account of their perilous state, have been long abandoned—were calculated to excite the highest emotions of terror. The miners, in certain places, had only left between their workings and the sea a partition so frail that the roar of the waves was distinctly heard overhead; while the water penetrated the chinks and crevices of the intervening rocks.

The tin ore of commerce consists exclusively of the native peroxide, that is, one equivalent of the metal united to three of oxygen. It is met with in primary rocks, chiefly in veins traversing granite, gneis, and mica slate, where it occurs associated with copper and iron pyrites, albite, topaz, and other silicious minerals. It is important to know, says Dr. Gregory, that lithionian, a very rare mineral but easily distinguished by its blow-pipe tests, has hitherto only been found associated with albite and topaz in tin districts. Its occurrence thus associated may therefore be looked upon as a certain indication of the existence of tin; to which scientific truth we shall add that, in the universal scramble for gold which distinguishes the period, if some unfortunate gold-digger should perchance alight on a tin-field, it would eventually turn out the most valuable discovery of the two. The principal localities of tin are Cornwall, Bohemia, and Saxony, in Europe; Malacca, Peru, and Banca, in Asia. Cornwall, notwithstanding its prodigious and long continued drain, is still the most prolific tin district in the world. It has been calculated, by Mr. Porter and others, that Cornwall yields annually upwards of 50,000 tons of the metal, the value of which varies from 400,000, to 500,000.

The Dutch possession of Banca, in the Indian Archipelago, is next to Cornwall, the most remarkable tin district. The ore is found there, in the alluvial deposits, in precisely similar conditions to that of the stream-tin of Cornwall. Beds, exceeding 25 feet in depth, are found to exist between the red iron-stone, with which the island abounds, and the superincumbent elevations of granite. This “oriental tin” is now largely imported into the European markets; and 3,000,000 lbs., in addition, are annually exported from the island to China and Hindoostan. “It is a popular mistake,” says Balli, “into which many authors have fallen, that these Banca mines were only discovered so recently as 1720. We have undoubted evidence to show that, so far back as the ninth century, the Arabs exported the metal to China.”

The metallurgical operation of smelting the tin ores is highly interesting. After repeated processes of stamping and washing, the ores are first calcined, in order to get rid of the sulphur and arsenic which they invariably contain; and, secondly, having been mixed with certain proportions of anthracite (carbon) and lime or fluor spar (used as flux), they are transferred to a rever-

beratory furnace. A strong heat is then applied, until the fluid metal is at length run from an orifice into an outer basin, whence it is ladled into iron moulds. The metal so obtained, however, is still contaminated by other substances. Iron, arsenic, copper, and sulphur, together with some unreduced oxide, are still retained in combination, and to effect a separation of these impurities the crude metal is next subjected to a process of refining. About five tons of the fluid metal are collected in the basin, into which billets of green wood are thrust; and it is thus, from the rapid formation of gas, kept in a state of violent ebullition. This last, we were expressly told, is a most philosophical process; a process, in fact, of "de-oxidation by means of carbon"—the oxygen leaving the metal to unite with the metalloïd, and form carbonic acid, which is driven off, leaving the tin pure. This pure tin is laded into rectangular iron moulds, in which form it constitutes the "block-tin" of commerce. At one time it was customary to distinguish these blocks of tin with an impression of the duchy seal; but they are now simply marked with the somewhat fantastic insignia of the manufacturer, together with the name of the Cornish town wherein they are produced. They usually weigh about 3 cwt. each; and their market price ranges from 80*l.* to 120*l.* per ton. The most invaluable property of tin resides in its well-known anti-poisonous qualities. In this it stands alone among the common metals; and hence the important function it performs as a coating to the surface of iron, copper, lead, and such metals whose reaction is poisonous.

We must now ask the reader to accompany us in a visit to the works. It was a delightful day in the month of October when we arrived at one of those beautiful convergent valleys, for which South Wales is so remarkable; and found a neatly-constructed manufactory, almost destitute of the nuisance of smoke, and not surrounded with debris of any description. It lay as quietly on the landscape as a Dutch mill in one of Berghem's pictures. The waterfall of a picturesque rivulet turning peacefully a large water-wheel, furnished the motive-power for the innumerable processes of rolling which belong to the manufacture. The men and women, too, seemed so unmistakably drawn from the commonest order of Welsh rustics, that we were astonished to find the high degree of dexterity and precision to which they had advanced in their several departments.

After a good deal of observation and inquiry, we ascertained that the different processes of the manufacture of tin plate may be described most properly in seven distinct stages. The first begins with the bars of iron which form the plates; the last terminates with an account of the process of tinning their surface. The description is somewhat technical; but a glance at the following heads will enable the reader to comprehend the whole process.

1. *Rolling*.—The first and most important point requisite to the production of good tin plates is the preparation of the *latten*, or plates of iron, previous to the operation of tinning them. For this purpose the finest quality of charcoal iron is invariably employed, which, in its commercial state, generally consists of long flat bars. These are cut into small squares, averaging half an inch in thickness, which are heated repeatedly in a furnace, and as repeatedly passed through iron rollers. A convenient degree of thinness having been attained, the now extended plates are "doubled up," heated, rolled, opened out, heated and rolled again, until at length the standard thickness of the plate has been reached.

2. *Shearing*.—A pair of massive shears, worked by machinery, is now applied to the rugged edges of this lamellar formation of iron plate. It is cut into oblong squares, 14 inches by 10, and presents the appearance of a single plate of iron, beautifully smooth on its surface. A juvenile with a knife soon destroys the appearance, however, and eight plates are produced from the slightly coherent mass.

3. *Scaling*.—This process consists in freeing the iron surface from its oxide and scorie. In the old method this was effected by first immersing the plates in diluted acid, and then, by exposing them separately, bent in the shape of a drain-tile, to the heat of a flame; but this process, alike tedious and expensive, has long been superseded. After an application of sulphuric acid, a number of plates, to the extent, we shall say, of six or eight hundred, are packed in a cast-iron box, a number of which are then exposed for some hours to the heat of a furnace. On being opened out after this, the plates are found to have acquired

a bright blue steel tint, and, in addition, to be absolutely free from surface impurities.

4. *Cold Rolling*.—It is impossible that the plates could pass through the last fiery ordeal without becoming disfigured. The cold-rolling process corrects this. Each plate is separately passed through a pair of hard polished rollers, screwed tightly together. Not only do the plates acquire from this operation a high degree of smoothness and regularity, but they likewise acquire the peculiar elasticity of hammered metal. One man will cold-roll 225,000 plates in a week, and each of them, in the average, three times passed through the rollers.

5. *Annealing*.—This process is also a moderate improvement on the manufacture. Six hundred plates are again packed into cast-iron boxes and exposed to the furnace. There is this difference in the present process from that of *scaling*: that the boxes must be preserved air-tight, otherwise the contained plates would inevitably weld together and produce a solid mass. The infinitesimal portion of confined air effectually prevents this.

6. *Pickling*.—The plates are again consigned to a bath of diluted acid, till the surface becomes uniformly bright and clean. Some nice manipulation belongs to this process. Each plate is, on its removal from the acid, subjected to a rigid scrutiny by women—their eyes, we presume, are the sharpest,—whose vocation it is to detect any remaining impurity, and scour it from the surface. These multifarious and torturing operations, it will be seen, are all preliminary to the last, and the most important of all—that of tinning. Theoretically simple, this process is practically difficult; and to do it full justice would carry us beyond our limits. We shall, however, mention the principal features.

7. *Tinning*.—A rectangular cast-iron bath, heated from below, and calculated to contain 200 or 300 sheets, and about a ton of pure block tin, is now put in request. A stratum of pneumatic fat floats up on its surface. Close to the side of this tin-pot, stands another receptacle, which is filled with melted grease, and contains the prepared plates. On the other side is an empty pot, with a grating; and last of all there is yet another pot, containing a small stratum of melted tin. Let us follow the progress of a single plate.

A functionary, known as the "Washerman," armed with tongs and a hempen brush, withdraws the plate from the bath of tin wherein it has been soaking; and, with a degree of dexterity only to be acquired by long practice, sweeps one side of the plate clean, and then reversing it, repeats the operation. In an instant it is again submerged in the liquid tin, and is then as quickly transferred to the liquid grease. The peculiar use of the hot grease consists in the property it possesses of equalizing the distribution of the tin, of retaining the superfluous metal, and of spreading the remainder equally on the surface of the iron. Still there is left on the plate, what we may term a *scavage*; and this is finally removed by the means of the last tin-pot, which just contains the necessary quantity of fluid metal to melt it off—a smart blow being given at the same moment to assist the disengagement. This "list-mark" may be observed upon every tin-plate without exception. We may add here, that an expert washerman will finish 6,000 metallic plates in twelve hours; notwithstanding that each plate is twice washed on both sides, and twice dipped into the melted tin.

After some intermediate operations—for we need not continue the consecutive description—the plates are sent to the final operation of cleaning. For this purpose they are rubbed with bran, and dusted upon tables; after which they present the beautiful silvery appearance so characteristic of the best English tin plate. Last of all they reach an individual called the sorter, who subjects every plate to a strict examination: rejects those which are found to be defective; and sends those which are approved of to be packed—300 at a time—in the rough wooden boxes with the cabalistic signs with which the most of us have been familiar since the days of our adventures in the back shop of the tinsmith.

Such is a brief sketch of the contemporary manufacture of tin plate. It would be an idle task to comment on its importance, or to point out its varied and innumerable applications to the necessities of civilized life. Articles of tin plate may adorn, and, in fact, do adorn, alike "the cabinet of the prince or the cottage of the peasant." Tin plate, moreover, is one of those cheap, useful, and admirable productions of modern science which, more than anything else of its class, has contributed to the domestic comfort of our working population. Vessels of tin, or of tin-plate,

have rarely been found among Greek and Roman antiquities, although there can be no doubt that the art was at least understood by the ancients. The modern process, our guide informed us as we walked home to dinner, was an importation from Saxony; and it was first introduced into this country at Pontypool, in Monmouthshire, early in the last century.

LUNATIC ASYLUMS IN SCOTLAND.

At the end of our last article on Lunatic Asylums and the Treatment of the Insane,\* wherein we chiefly spoke of what had been done in England and Wales by the erection of new buildings, and additions to county and other asylums, we adverted to the Chartered Asylums of Scotland as institutions of the kind needed for the wants of the middle-classes in England; but at the same time referred to the deficiency in the number of the asylums, in North Britain generally. We propose now to give particulars of the existing provision for lunatics in Scotland, and of merits and defects of the buildings, as we are able to gather the information from the several reports of commissioners and the evidence before the parliamentary committees.

In the improved treatment of the insane, Scotland was early in the field; and the services of the late William Stark, architect of asylums at Glasgow and Dundee, and the author of a work published in 1807, entitled "Remarks on the Construction of Public Hospitals for the Cure of Mental Derangement," should be spoken of with approval, though his Glasgow building at least, has not the form of plan which we now deem suited to the lunatic asylum as distinguished from the prison. The Glasgow asylum, however, was called, in 1817, by the writer in the *Edinburgh Review*, the best in Britain at the time of its erection; and such it was. It had the radiating or *panopticon* form of plan; but this form, by Stark himself, it appears was not considered equal to that of the asylum at Dundee, which was planned in the form of the letter H, afterwards exemplified in the asylum for the West Riding of Yorkshire, at Wakefield. The Dundee building, opened in 1820, and now accommodating 208 patients, is spoken of by the reviewer, as of "admirable construction;" and a similar opinion is given in 1841, by Mr. Samuel Tuke, in his "Introductory Observations" prefixed to the translation of Dr. Maximilian Jacobi's work, "On the Construction and Management of Hospitals for the Insane," &c. The Glasgow building, of which Mr. Stark was the architect, has now been converted into the workhouse; whilst a new asylum has been built at Gartnavel. At the date of erection of the earlier building, restraint of one kind or another was considered desirable, even by humane persons; for, it was not till 1837, that "the non-restraint system" was introduced in the asylum at Lincoln, and that mechanical contrivances for restraint were declared by Mr. Hill, to be "never necessary, never justifiable, and always injurious." The new asylum for the district of Glasgow was designed, as announced, for the system which eschews all appliances of restraint. A modification of the radiating form of plan was adopted at a recent date, by Mr. Charles Fowler, in the Devon Asylum, as described by him in his paper at the Institute of British Architects, and shown with other arrangements in our volume for 1846. Mr. Fowler certainly got rid of some of the defects of the Glasgow arrangement, and imported some advantages; the value of his plan, however, in the present treatment of insanity, as compared with the H form, or more especially (for asylums of the advocated small dimensions) the fiscal form, has been much answered. Yet Dr. Backhill, who is the medical superintendent, regards the building as "not a bad working asylum," though later buildings are improved.

The Commissioners in Lunacy for Scotland are appointed under an Act which received the royal assent in August, 1857; and they are required to report to the Secretary for the Home Department at the beginning of each year. Their first report, however, was not printed till late in last year. The number of lunatics in Scotland, exclusive of single patients in private houses, was, on the 1st January, 1858, 5,748,—the female patients being about 300 in excess of the male. From the evidence of Dr. Cox, one of the commissioners, we get the total number of lunatics in Scotland as 7,500, or 7,600; whereof about 1,700 or 1,800 were private patients resident in private houses; and 1,784, besides those in workhouses (about 839) were pauper

\* See page 721, vol. xvii.

patients in private houses. It seems that in two years prior to 1858 the proportion of pauper lunatics to paupers had increased about one per cent. For the purposes of the Act Scotland is divided into eight districts. The statute, however, contains provisions for the alteration of these; and the actual arrangement at the commencement of the year 1859 was into twenty-one districts, unequal in area and population. The arrangement does not seem to have worked well, and several districts are too small to support efficient asylums. After the appointment of the commission, it became a question how far the private asylums and the lunatic wards of workhouses were to be recognized as "existing accommodation," or whether district boards were not even compelled to adopt such accommodation before proceeding to build. These particular doubts were removed by the passing of a short Amendment Act, which empowered the commissioners to grant licenses, during a period of five years, for reception of pauper lunatics into wards of poorhouses; and which set forth that it was expedient, provision should be made till district asylums could be provided. Notwithstanding this, however, we were informed lately that much disinclination was shown by the district boards to perform their duties. The Act is not stringent in requiring the provision of the asylums within a definite time; and further legislation may be needed.

Before looking to what is said by the present commissioners, of the provision existing and that which still is required, we may remind our readers of what was stated in our last article, and is shown in the report of 1857, as to the localities of the public and private asylums and poorhouses receiving lunatics. We said—"Striking a line from Aberdeen to Glasgow through Perth, there was in 1857, absolutely no provision in the northern and north-western counties, except a few cells in the basement of the infirmary at Inverness, and a pauper institution at Elgin for forty-six patients." That is to say, the greater portion of Scotland is to be considered as wholly unprovided with institutions for the care and treatment of the insane. The commissioners feel difficulty in estimating the precise accommodation required; and some of the reasons which they give for this are important, viewed in relation to those on which the commissioners for England and Wales seem to have acted. The Scottish commissioners have asked themselves whether, taking into account that asylums as constituted, do not provide a diversity of accommodation for patients affected with different degrees of mental incapacity, it might not in some cases be more desirable to leave a patient in favourable circumstances, under private care, than to place him in an asylum of the present kind. They observe that there is a growing conviction in England, France, Germany, Belgium, and even Spain, that the constitution of lunatic asylums requires great modification,—an opinion founded chiefly on the diversity of forms of insanity, but also on the difficulty of suitably providing for the always increasing number of the insane. Yet in pursuing the subject, they come to meet the same conclusions as the English commissioners; and in an Appendix they print instructions for the general guidance of architects and district boards, in reference to the site and structure of asylums, which in most respects agree with those issued by the English commission, but which in points involving the nature of the buildings to be provided, are such as they consider afford greater latitude of action.

It has always been a question whether the constant increase in the number of the insane to be provided for, is due to an actual increase of cases, or to an accumulation through prolongation of lives by better care. We have already adverted to the opinion of Lord Shaftesbury, that there is an increase of lunacy; and the Scottish commissioners say it is not unlikely both causes are in operation, though it is probable the increase is in great degree only apparent, arising from attention paid to the subject and discovery of a larger number of cases. The crowding of lunatics always increases the known number of lunatics. Transference to an asylum is beneficial, judging only from the fact that one-half the patients admitted to these institutions are restored to sanity; but information as to the extent to which asylums have contributed to diminish the disorder, and regarding what the result might have been had the treatment been conducted in private houses, is viewed as defective. Again, however, practically, the Scottish commissioners tend to the same conclusion as the English commissioners,—saying that the influence of asylums in restoring to sanity is not to be judged by the

past, that immediate treatment is most important, that the discipline of an asylum exercises a beneficial and curative influence, and that, therefore, the question is mainly, whether, as asylums are at present constituted, they fulfil all the expectations which the expense of their maintenance might warrant. Eventually they arrive at the opinion that adjunct houses, in which patients affected with certain forms of insanity, could be received without the legal formalities at present required, would prove a beneficial modification of our asylums, and would tend to increase recoveries by inducing recourse to treatment before the malady had become confirmed. Dr. Bucknill, in England, advocates provision of what he would call Probationary Asylums.

Looking at the question of provision required, in all its bearings, we cannot but regret that it should be now argued by Lord Kinnaird, that one new asylum in Scotland, for Inverness, Nairn, Ross and Cromarty, and Sutherland, would suffice for the cradle lunatics; whilst the incurables, for the sake of cheapness, would be lodged in places centrally situated, and therefore often at great distance from their friends. Is not this in tendency opposed to medical teaching, as well as to the legislation, which has aimed rather at the multiplication of asylums,—the legislation, for the due protection of the patient; and the other efforts, for the avoidance of the evils of asylums too large for superintendence?

In the "suggestions and instructions" before referred to, we find the following modifications from those of the English commissioners. As to sites, it is pointed out that the land should be capable of profitable cultivation, besides affording a supply of water. The quantity of water, exclusive of rain-water collected in cisterns on the roof, the Scottish commissioners say, should be not less than 40 gallons per patient per diem,—instead of 25 gallons. The principal buildings only are those which are named as to be placed near the northern boundary of the land. The locality, they say, "should be within such distance of a town as to command the introduction of gas, water, &c., and one of sufficient size to afford the means of amusement of aid recreation for the medical staff, the attendants, and such of the patients as might derive benefit from a change in the asylum routine." We doubt whether this village is practicable without perilling other advantages of the required site. Gas, even for a small institution, is to be made economically on the premises. In the suggestions referring to construction and arrangements of buildings, the chief modification is with reference to the buildings in connection with the washhouse and laundry on the female side, or the workshops and farm buildings on the male side,—consisting chiefly of associated day-rooms and dormitories for working patients,—or to other inexpensive provision in detached buildings, for the idiotic patients. The suggestions say that cottages might be erected for a large proportion of these "working and in-offensive patients, who might be placed either under the care of the families of the attendants, or of cottar tenants of the asylum." The cottages would be calculated to accommodate from three to five patients. Regarding this extent of divergence, from what may be called the principle of plan of asylums, we should observe that care would be required, lest the result might be some of the evils now existing, where single patients are assigned to incompetent persons. As to the number of beds in dormitories, whilst the English commissioners say there should not be less than three in number, the Scottish commissioners say the rooms should be designed for not less than six beds, or more than fourteen. To this point we shall return. Directions as to attendants' rooms, and some other matters, such as placing windows not more than 4 feet from the floor, are omitted by the commissioners for Scotland.

The existing accommodation for the insane in public institutions in Scotland, consists of that afforded in seven chartered asylums, in the pauper institution at Elgin, in the lunatic wards of the Inverness Infirmary; for criminals, in a department of the prison at Perth; and in poor-houses, with or without separate wards. The condition of these, and of the private asylums, formed the bulk of the matter in the Report of the Commission of 1857, and the Appendix; the latter of which extends to nearly 800 pages. Whilst the provision in Scotland is seriously defective in amount, and therefore leads to lamentable results, the chartered asylums, as we have already mentioned, have been referred to by those who have given most attention to the subject of the care of the insane, as offering advantages which are aimed at by an inconsiderable number of institutions, called

lunatic hospitals, in England. These chartered asylums admit two classes of patients, or one class at a rate of payment, which may be moderate, in addition to the paupers. They are, "in many respects," say the commissioners who reported in 1857, "in a highly satisfactory state;" and this opinion is corroborated by others. In the year named, out of 833 private patients in asylums, 652 were in those chartered asylums; and the remainder, only 230, were in licensed houses. This is Lord Shaftesbury's statement to the committee of the House of Commons. Mr. G. Bolden, honorary secretary to the Alleged Lunatics' Society, before the same committee, stated the number of private patients as 1,011, and the number 786 as of the patients of this class in public or chartered asylums. It will not fail to be observed that either statement, showing that the chartered asylums accommodate a very large proportion of those who are private patients, is consistent with the fact that there is inadequate provision in the same asylums, or in any others, for the lunatics in England and Wales, out of other hand, whilst in many as 2,748 were in private asylums, and 1,696 in public hospitals, the latter number including 669 patients in Bethlem, St. Luke's, and Gny's Hospitals, and the Institution for Idiots, leaving only about 1,000 provided for as in Scotland. The conclusion is, that patients of the very class most needing protection against the inducements of gain, whether in the proprietors of asylums or their own relations, are least protected, in England and Wales. The remedy would be the increase of the number of institutions like the chartered asylums, or the eleven English "hospitals,"—whereof one at Coton Hill, near Stafford, often referred to in the evidence, was described and illustrated in our volume for the year 1854. We may also here refer to the percentage of cures at St. Luke's Hospital, 68½, as still speaking favourably for that institution, in spite of what has been deemed defects of its urban site. A large proportion of the private patients in the Crichton Institution, near Dumfries, were lately, natives of England. In the chartered asylums, separation of the inmates into classes, as to position in life as well as nature of the malady, however, becomes necessary; and it is doubtful whether the results in diminished facilities for exercise are entirely advantageous. In some cases, it would seem, there is a disadvantage from the appropriation of the single rooms exclusively to the paying or superior class of patients.

At Dumfries, Edinburgh, and Glasgow, many of the objections have been obviated through the erection of a separate building for the paupers, adjacent to the original structure, whilst rooms originally designed for the wealthy classes have been appropriated to those of moderate means. Hence the funds of the institution not only have been benefited; but patients associated together are placed under more favourable circumstances for treatment and prospect of recovery; and it is desirable that a similar system should be adopted elsewhere in asylums having, through the regulations, considerable accommodation to spare,—as in the case of the Royal Asylum at Perth, a building possessing a combination of advantages "equal, if not superior, to any similar establishment in the United Kingdom." The system of separate buildings, instead of as at Perth, Dundee, Montrose, and Aberdeen, where the rich and the poor are under one roof, is preferred by the best authorities.

The chartered asylums were founded, and are in great measure maintained by private individuals; and whatever the deficiency of national institutions in Scotland, it is believed that no country has voluntarily done so much. As an instance of this spirit, may be cited the abandonment of the first-erected Glasgow Asylum, in consequence of the extension of the city; the similar change being made at Montrose; also the increased accommodation just provided in the asylums at Aberdeen and Edinburgh, and contemplated at Dumfries and Inverness. In these chartered asylums, the building and grounds being provided, the institution has become self-supporting.

The chartered asylums are the following:—The Royal Asylum, Aberdeen; the Crichton Institution, Dumfries, including the Southern Counties' Asylum; the Royal Asylum, Dundee; the Royal Asylum, Edinburgh; the Royal Asylum, Glasgow; the Royal Asylum, Montrose; and James Murray's Royal Asylum, Perth. The estimated accommodation in 1857 ranged from 42 private patients at Dundee and Montrose each, and from 106 pauper patients at Perth, up to 171

private patients at Glasgow, and 407 pauper patients at Edinburgh, where the private patients, 60, are unusually few in number. The sites of these asylums, with exception of the old one at Montrose, have been well selected, though the quantity of land is too small. The buildings are well constructed, excepting that stone floors, deficient means of warming and ventilating, and provisions for seclusion in dark rooms are to be found; but family arrangements of plan, as now regarded, are observable. Thus, the asylum at Perth, and the Critchton Institution at Dumfries, have each "a central staircase, with a curiously contrived double wall; and galleries which radiate from the staircase can all be inspected through glazed apertures over the doors;" whilst at Perth, Dumfries, and Morningside (Edinburgh) there are open spaces or external galleries, enclosed by ironwork, which appear to have been designed to afford the patients means of exercise in wet weather. None of these arrangements are now recommended, either on grounds of expense or treatment of the patients; the buildings of a more ordinary character, and more domestic, being preferred. In the latter point of view, spacious galleries of any kind seem to be to a certain extent objectionable; indeed, the English commissioners condemn them; and comfort to the inmates, as well as economy of construction, would be furthered by devoting internal space, as far as practicable, to sleeping accommodation, and to day-rooms from which ready access to the open air could be obtained.

As regards the proportion of single sleeping-rooms, a very marked contrast is observable in several of the asylums. Confining attention to the pauper department; in the Aberdeen asylum, there are single rooms for more than half the number of patients; at Glasgow, for rather less than a fourth; and at Edinburgh, for less than one-fiftieth. Evidence is quoted by the commissioners in favour of one-fifth as absolutely necessary, or of two-fifths as advantageous. The English and the Scotch commissioners, both, in their instructions, say that "the proportion of single rooms throughout the asylum need not exceed one-third." Regarding size of the associated dormitories, a point already referred to as somewhat difficultly agreed as to rooms 11 feet in height, and for each patient 50 feet superficial, we notice that it was found by the commission of 1857, that mortality was generally greater where there were large dormitories than where small sleeping-rooms prevailed. This view would seem to be opposed to the experience at the Somerset Asylum, where the dormitory in the male division contained at the last visit of the English commissioners, seventy-six beds,—the system being spoken of as working satisfactorily;—but it is quite consistent with that of Dr. Conolly, who would on no account have in a dormitory, more than five or six beds. The earlier asylums in Scotland, or those of Montrose, Aberdeen, Perth, and Dundee, have the single rooms and moderate-sized dormitories; whilst the new buildings at Gartnavel and Morningside have large dormitories. The largest dormitory at Gartnavel would contain twenty-four. Towards solution of the difficulty of warming and ventilating, little seems to have been done in the Scotch asylums. In the Dundee asylum, where the results are considered "in some respects" satisfactory, there are open fire-places and Arnott's ventilators; but the sleeping-rooms are too cold in winter; whilst in the Glasgow asylum, where there is a warming apparatus, the principle of it requires that the windows should be kept shut, whereby the atmosphere is apt to become oppressive. One of Dr. Conolly's arguments for the small dormitories is the difficulty of ventilating those of large dimensions. The number of cubic feet of space per patient in the Scotch asylums appears to be, as in the Morningside asylum, in the single rooms about 1,000 feet, but in the galleries, 600 feet; or in some asylums which are crowded, there are two patients in a room of 900 cubic feet. In the Devon asylum there are about 470 feet per patient in the dormitories, says Dr. Bucknill; the commissioners laying down that there ought to be 550 feet.

Notwithstanding what has been stated, several of the asylums are overcrowded—probably by patients from those parts of the country not provided with institutions; and this absence of provision leading to delay, the results are not more favourable to general treatment of the patients previously accommodated and belonging to the districts, than to the others themselves.

Though mechanical restraint is almost wholly disused, "seclusion" is practised, and padded

rooms are used; whilst contrivances are resorted to in beds for a certain class of patients, such as have, we believe, in England, given place generally to increased attention. A chief defect in the Scotch asylums, however, appears to be the smallness of airing-courts, wherever there is minute classification. At Perth and Dumfries, however, the courts are planted and neatly laid out. We have already adverted to the deficiency of land. This is being remedied at Aberdeen and Dundee. Of the private licensed houses, which are chiefly in the neighbourhoods of Edinburgh and Glasgow, it may be sufficient to observe that they may be classed with those of England and Wales. Only one instance is mentioned of a house originally built for the purpose. In Lanarkshire, 800 cubic feet of air per patient have been fixed on by the sheriff, as the required allowance; but as regards private asylums elsewhere, the amount averages 300 cubic feet, and is even less than 200 feet, or not one-third of what is usually considered necessary. The condition of the insane in poorhouses is alike unsatisfactory. Most of the existing wards of these buildings have been opened lately, and their existence arises from the deficiency of asylums. In five or six cases, however, these wards form a distinct structure. Ventilation in the west of Scotland is attended to in some measure. Air is pumped into the wards, having been heated previously by contact with the steam-pipes of the engine.

The main conclusion in the report of 1857 as to the asylums in Scotland was, that these did not fulfil to the extent of which they were capable, their purpose of curative institutions. Large asylums show a smaller proportion of recoveries, and a greater mortality, than those of moderate size; and do not offer any counter-balancing advantages to the ratepayers, but the reverse. District or county asylums, of moderate size, and economic construction, for paupers, and including accommodation for the insane belonging to the labouring classes, not strictly paupers, are most required, as likewise better accommodation for pauper lunatics. And, from the evidence of Dr. Cox before the committee, it appeared that, whilst there are economic advantages in having one management and medical superintendence, really distinct asylums or buildings are necessary for the poor and the rich.

It appeared by the report of 1859, that the pressure for admission to the public asylums continued; though regarding the criminal lunatics these did not on the average exceed thirty for all Scotland, and might be provided for in special wards in one of the district asylums.

Still, whatever the want of provision for the insane in Scotland generally, the overcrowding in several of the asylums, and defects, there is much to be learned from the institutions we have chiefly spoken of, both in reference to the extension of hospitals for the middle classes in England, and in structural points; and we shall probably find some further particulars useful to our readers, of these structural and other features of the asylums which have been named.

#### THE FRESCO IN LINCOLN'S INN HALL.

MR. G. F. WATTS, who distinguished himself in the first Government competition in connection with the proposed decoration of the Houses of Parliament, has completed his self-imposed and, we believe, gratuitous labour in Lincoln's Inn Hall, the north wall of which he has covered with a painting in fresco, presenting the early lawgivers from Moses down to Edward I. Founded to some extent in arrangement on Raffiello's "School of Athens," the figures are grouped on a flight of steps with landings, and form three main lines. The first represents a sculptured group of Religion, Mercy, and Justice, below a window of Perpendicular Gothic, which, although perhaps open to objection in a synchral point of view, connects the work with the hall, and materially increases the effect of space.

Moses looking upwards with the tables of the law is the centre figure of the second line. To his right, if we are correctly informed, the figures ranged in row are intended to represent Lycurgus, Minos, Draco grasping the sword, Solon, Numa, and Servius Tullius. On the left of him are seated Sesostris, or Ramesses, as representative of Egyptian polity; Zoroaster, Pythagoras, Confucius, and Mencius.

The central group of the lower line is made up of Justinian and Theodora, with scribes transcribing at their feet, while a juriconsult and a doctor of the church distribute the paduets to the northern barbarians—Lombard, Goth, and Frank. Midway between Justinian and a Saxon group, including

Ina and Alfred, stands the figure of Charlemagne, leaning on his sword. In the right of the foreground are grouped two of the Barons of Runnymede, with Stephen Langton and the Legate; Mahomet with the Koran above; and alone on the left, in the corner, sits Edward I, in regal ermine and knightly harness. The picture is about 45 feet long, and perhaps 40 feet high in the centre, the upper part following the line of the open roof timbers. When we add, that the figures are of heroic size, and thirty-three in number, it will be seen that this is the largest fresco in this and, perhaps, in any country. It is, moreover, a very noble work, with blots and weaknesses, doubtless, but still a noble and admirable work, of which the members of the Inn may be justly proud. Carpers will point to the collapsed body of the reclining Indian figure on the right of the second line; and to the legs of the barons below it, in the foreground; but those who give it more thought, and unprejudiced consideration, will admit a greatness of scope, variety of expression, and skill in the designing of the figures seldom found. It is in no respect garish, splotchy, or gaudy, but, "born with its frame," is thoroughly harmonious and appropriate. It would be materially improved, by the way, if the oak panelling below it were covered with a curtain: the marble pavement from which the steps rise jars with the wainscoting below.

It is to be hoped that the successful result obtained here may lead corporations and other powerful bodies possessing halls and meeting places to call in the aid of the painter, and make a right use of art as a teacher. The various vestry-halls which have been erected for the metropolitan districts would afford good sites for such works. As we have said elsewhere, "The Government and corporate bodies should aid more vigorously the progress of the fine arts in this country than they have done, and use them more extensively for the general improvement and delight. What is wanted is, that art should have a real life—should be made to provide great moral and intellectual lessons for the masses—not remain simply the minister of caprice and luxury. Painting and sculpture must be brought into conjunction with architecture, if we would have them playing their proper part—if we would produce a really great school of art. We would see the arts appealing to every passer-by—instructing, encouraging, and exalting."

#### SCENERY AND THE STAGE.

WHEN it is remembered that sixteen theatres in the metropolis alone, if not more, display at this moment a pantomime or extravaganza with new scenery, machinery, and elaborate effects; it will be seen how large a body the professors of scenic-painting and stage-decoration must have become. Since we began, now years ago, to draw attention to their works separately, and to point out the merits of many of their productions, they have taken a very much better position in public estimation than they formerly held. The sort of criticism to which they are subject is unfortunately not calculated to help their progress towards excellence: the daily press, speaking generally, show little discrimination, praising in the face of most preposterous errors, and caring nothing for chronological correctness. Most of our scenery wants finish, completeness, and solidity. It is often flimsy and imperfect, even when displaying in some respects great beauties. Reading the accounts of the various Christmas-pieces in the newspapers last week, it might be supposed that the perfection of a pantomime or extravaganza was to be found at each house, and that the artists everywhere had surpassed themselves. This certainly is not true. Several of the pieces are very good of their class, with very charming scenery, but we find nothing better than we have seen before.

At *Drury-lane*, for example, Mr. Beverley is said to have outshone himself; whereas his transformation scene, with its pillars of glittering faeries, piled one over the other, displays less fancy than many of his previous works of this kind, which are, in truth, wonders in their way. His scene for the ballet is much better, and remarkably beautiful. It represents a stalactitic cavern, extending as far as the eye can reach, with water at the bottom, in which are floating faeries; and the lines of these running on to those on the stage produce a remarkable perspective effect. The pantomime, as a whole, is a work of large proportions, and deserves to be seen.

At *Covent Garden*, on the evening of our visit the house was so full that they could find us no seat: we must try again hereafter. Mr. Mellon's

very pleasant opera appears to gain in favour. Several of the airs are exceedingly pretty; for example, Mr. Haigh's ballads—

"For thee I love alone,"

and—  
"The heart that is too lightly won,"  
and the close of the first act, and the cavatina—

"Oh! bright were my visions in those happy days," charmingly sung by Miss Parpa.

"The *Ingamared* pantomime, "Valentine's Day," has a story of less interest than usual at this house; but it is, nevertheless, pleasantly put together, and very elegantly placed on the stage. The scenery of the fairy story is painted by Mr. Frederick Fenton, including a February landscape, the Spring Flower Dell, and Conservatory of Crocuses, and the transformation scene, the Opening of the Fairy Valentine. The latter is a most elaborate piece of mechanical scenery, some of the changes in which are very beautiful. In "The Evil Genie" Mr. Buckstone is as racy as ever as *Tom Ripstone*.

"The *Adelphi* has a spectacular extravaganza in place of a pantomime, called after one of the prettiest German legends, "The Nymph of the Lurlenburg." Some of the scenes are very good, but we would suggest, from good-will, not so fault-finding, that more care in the arrangement of sky pieces and the general fitting-together of the scenery, would be advantageous. In the first scene, Rupert's Dining Hall, the window is very well painted. The View of the Lurlenburg, on the Rhine, is a nice landscape; and, in a scene beneath the river, some effect is produced by the change of a rock of coral into a regular set of newel stairs, reaching nearly to the ceiling, up which the *personæ* go. Miss Woolgar and Mr. Toole bear the brunt of the piece, and bear it bravely.

#### THE LATE MR. JOHN CRAKE, ARCHITECT.

MR. JOHN CRAKE, whose premature death suddenly took place on the 27th ult., was a pupil, with Mr. George Mair and others, in Mr. Decimus Burton's office in 1828. He became a student in the Royal Academy about 1831, and obtained the silver medal in architecture, for the best measured drawings of the facade of the London University, Gower-street (W. Wilkins's building). Mr. Crake was an original member of the Architectural Society, now no more. He went to Italy, and on his return commenced practice. The long terrace, Hyde-park-gardens, was erected from his designs, and under his superintendence: he also was concerned for the Earl of Cardigan, and designed and superintended the entrance to Dean park. Since his marriage, and for the last ten years, having an ample fortune, he had retired from practice, and resided chiefly at Datchet, where he expended a large sum of his own money in restoring the church. He was liberal and kind-hearted, a staunch supporter of the Architects' Benevolent Society, and much beloved by all who knew him.

#### GLEANINGS FROM WESTMINSTER ABBEY.\*

HAVING now gone generally through the fabric, I will next advert briefly to some interesting documentary information from the public records, which has just been communicated to me by Mr. Barrt. Of the kindness of this gentleman I cannot speak too strongly. He has, while my paper has been in hand, given himself infinite trouble in searching for notices of the works, and with very considerable success. I am aware that the details of antiquarian documents are not well suited to a meeting like this, and I will, therefore, only advert to a few important points. The first of them is this. As Westminster Abbey is about the earliest work of its style in this country, and as the building of the first portion of it by Henry III. extended over a space of twenty-four years, i.e. from 1245 to 1269, it becomes important to ascertain how early in this period the style of its architecture can be proved to have been defined. Now, a single entry in the documents has been found for ever settled this point. I have before me that the most advanced part of the work (as to style) is the Chapter-house, as that contained crozier windows of four and five lights in a developed form, the tracery is not confined to circles, but containing great trifoliate, and the heads of the lights being trifoliate, which is not the case in the church. Now, it would be most useful to know the exact date of these windows, for, though Matthew Paris gives 1250 as the year of commencement of the Chapter-house, it may have spread over an indefinite length of time, and, as it would be long to twenty years after that date. Let us look then to this. Here we find in an item of "300 yards 37th Henry III., or 1258, and expressed that the eighth year from the beginning of the work, an item of "400 yards of canvas for the windows of the Chapter-house," followed immediately by items for the purchase of glass, showing that the windows in question were completed in 1258, which I see was the year before the king, in company with St. Louis, visited the Salate Chapelle, at Paris, which was then scarcely completed, and the style of which commences a new mode of advancement. I find, also, that during the same year, the beautiful entrance or vestibule to the Chapter-house was erected.

\* By Mr. G. Scott. Continued from p. 852, vol. xvii.

The church itself was by this time—indeed, as early as 1249—in a state of rapid progression, so that the architecture must, in the main, have been quite settled from the time of its commencement.

The entries found by Mr. Barrt are, for the most part, of a somewhat general character; but it is stated in the Pipe rolls, that further particulars have been sent in to the Treasury. These bills of materials, it is to be observed, been, for the most part, lost; but Mr. Barrt has succeeded in finding one complete one for about half a year (probably 1253), which is of so interesting a character that there is no doubt that it will be published with notes, by architectural antiquaries. It is a perfect bill of quantities of the work done during twenty-five weeks, giving the names and measurements of every moulding and every detail of the work, and will form a very curious and interesting illustration of the architectural nomenclature of the period. Attached to it are two amusing little letters from the quarry-master at Purbeck, promising shipments of marble, and begging for speedy orders on the ground of other pressing business.

The notices I have adverted to in the fabric rolls of the works from Edward I. are time and again also very detailed, and give curious particulars as to the mode of employing men at that time. They appear to have been fed and clothed by the employer, and the clothing would appear to be by no means to be complained of. In one year we have an entry of 15s. (equal to 8*l.* or 10*l.*) for a fur robe for the chief mason; but after year nothing further for his robe, because the independent gentleman "refused to receive it on account of the delay in its delivery."

Going back to the earlier accounts, I may mention that extensive works appear to have been going on at the same time in the palace and its chapel, including a great deal of decorative painting; also that the bellry of the Abbey was being built, which, if it is true, as the accounts seem to be of the church, and of which, I believe, that some remains existed at a somewhat recent date.

The only upon the Abbey during the first fifteen years of the work, which, if it is true, as the accounts seem to be, considerably exceed half a million. I must not, however, follow up these details on the present occasion.

I have dwelt so long upon the time remains for any notice of the internal contents of the church. Indeed, they would be more worthily treated of in a distinct paper. I will content myself with a cursory notice of a few to which I chance to have paid particular attention.

That most remarkable work, the Shrine of the Confessor, has been largely dwelt upon before this Institute, when the subject was brought forward several years back by Professor Donaldson, that it would be superfluous to go again into the minutiae of the investigation, to which I devote a great amount of time, and which was fully followed up by my talented friend Mr. Burgess.

I will content myself with a summary of results. Shortly after my appointment to the Abbey, in 1849, I was led, in going to a visit paid to the shrine by the Rev. Martin with myself and some members of the Ecclesiastical Society, to devote a good deal of attention to ascertaining, so far as possible, the ancient form of the shrine; the result of which I gave in a paper read before a meeting of that Society. I removed the brick wall which then blocked up the west end, and exposed the marks showing where the shrine once stood, and came to the conclusion that the pillars now at that end were formerly detached, and carried lights. Probably they were the "feet" which King Henry III. is said to have given for certain lamps to be burned before the shrine.

The retabulum occupies, as I ascertained, its proper position, excepting that it has advanced 18 inches above its original level, a fact proved by its interference with the space required for the completion both of the ancient and the more modern inscriptions, for neither of which there is now sufficient room.

The front and what is seen of the back of the retabulum, being decorated with mosaic, and the edge left plain, it follows that the latter must have been more or less concealed. I judge, therefore, that the attached pillars must have been placed very close to them.

Mr. Burgess has kindly lent me the sketch of his conjectural restoration, which, on one side, I am in doubt whether there existed more than two or three attached pillars. As his view does not show much of the existing structure, I have given a rough diagram, showing by way of explaining how I probably came to my conclusions.

Extracts have been kindly communicated to me, by Mr. John Gough Nichols from diaries kept during the days of Queen Mary, showing that the body of the Confessor had been removed, and the shrine wholly or in part taken down at the dissolution, but restored in Queen Mary's time, when the present wooden shrine, the cornice, the modern inscription upon the painted decorations were added. I am inclined to think that the marble substructure was only taken down far enough to allow of the removal of the body, as its parts have been displaced in refusing so far down as that, but no further. The altar either had not been removed or was probably re-erected at the same time, and was, I think, not removed again till the great rebellion, being needed at coronations, on which occasions a table has always been substituted under the old name of "the altar of St. Edward." I found at the back of where the altar has stood, a slab, apparently taken from some monument, and containing a Latin inscription, which confirms this idea. There is, in Abbot Lillingthorpe's service book in the library, in the initial of the service for St. Edward's day, a view of the shrine, though I fear an imaginary one, the substructure being shown as it now presents the mosaic work, but the seven arched recesses for pilgrims to kneel under, which really occupy two bays, and which are shown on one side. The shrine itself is shown lower than was usual, and a number of figures of the Confessor is shown on its sloping covering.

I will only add that I opened the ground round the half brick pillars at the west end, and found them to agree in height with those at the east, which they so much exceed in diameter, and that I have been so fortunate as to re-discover the broken parts of one of the eastern pillars, and to re-erect and set in numerous fragments, and to re-erect one new piece of only a few inches in length, so that we have now one perfect pillar.

In connection with the shrine I will allude to a little discovery which I have shown to my I dare say, not present. There is a sarcophagus-shaped slab in the floor, immediately to the east of the shrine which is said to commemorate a son of William de Valence, the eldest young. The cross and inscription are nearly obliterated, but its eastern end is covered by the step to the tomb of King Henry V. A very pains-taking friend and assistant of mine (Mr. Irvine), in examining the point of junction

between the step and the slab, perceived signs of some substance being laid into the latter. I obtained permission to remove a portion of the step, when we found that the slab had been laid with brass and glass mosaic. There was, no doubt, the kindness of the same was in hand.

I am enabled by the kindness of Messrs. Minton to exhibit a tablet of mosaic, which was prepared before the altar, executed by Roman workmen, and with materials brought from Rome by Abbot Ware, about 1267 or 1268; of the curious inscription, a part giving the list of things concerned in the mosaic, is as follows:—"Terminus Henricus aris Odoricus et Abbas." Odoricus being the artist, and "aris" of course, means Rome, as is proved by Ware's own epitaph, which says, when speaking of these stones, "quos licet portavit ex aris."

The tracing I exhibit was made many years ago for the late Mr. Minton, and under my direction, by my then highly talented assistant, and my now distinguished brother architect, Mr. Street.

It is curious that both in the monuments laid with glass mosaic, and in the pavements in which the inlaying material is chiefly purpura, the artists, as in the case of the crosses, adopted as the matrix Purbeck marble, in place of the white marble they were accustomed to use in Italy.

The tomb of King Henry III. is too well known to need description here, but that of some of his children and grandchildren in the south aisle is but little noticed; indeed, its Italian forms so much resemble those of a modern monument that it usually passes for one. I exhibit several drawings of it.

Taking the tombs of the Confessor, of Henry III., and his daughter, and of young de Valence, in connection with the pavement before the high altar, and that of the Confessor's Chapel, I would doubt whether I will not say any church north of the Alps—but, I may almost say, widely, executed by an artist of some Italian school, such as mass of Early Italian decorative art; indeed, the very artists employed appear to have done their utmost to increase the value of the works they were undertaking to us, by giving to the mosaic work the utmost possible variety of pattern.

Another object, which does not receive the attention it deserves, is the retabulum from the high altar, now preserved in the south-eastern aisle, and which, as I have said, is a very wonderful work of art, being most richly decorated with glass, gold, and painting, and probably with precious stones, and of some excellent design. The glass enrichments are of two sorts—in one the glass is coloured, and is decorated on its face with gold diaper; in the other it is white, and laid upon a decorated surface. The great charm, however, of the work, must have been in the paintings. They consist of single figures in niches of our Lord and St. Peter and Paul, and two female figures, the number of which is not stated in the account fully painted. I give some unfinished drawings of this retabulum, in which the paintings have been very beautifully copied for me by Mr. Marks.

The west end of the tomb of the most interesting is that of William de Valence. I am not aware whether any old account of this monument exists, but I suppose we may fairly set it down as a French work, and, probably, executed by an artist from Limoges, though the custom of referring all enamel works to that particular seat of the art is not, I think, borne out by facts; indeed, it would appear from the account of the work, that the shrine of the Confessor were executed here, whether by an artist from Limoges is unknown, though we know that one was employed in England shortly afterwards.

The execution of the tomb is truly exquisite, so much so that it is only by the closest examination that any idea can be formed of the wonderful delicacy of the workmanship. I exhibit a drawing of the shield made by Bertrando, one of the official artists at the time of the church, and a very talented and zealous student and delineator of its antiquities, who has also kindly lent me several other drawings of the work.

The monument was thus described by Keefe in 1663:—"A wainscot chest, covered over with plates of brass, richly enamelled, and thereon the image of de Valence, seated on a throne, with a sword in his right hand, and a cross of mail with a surcoat, all of the same enamelled brass, gilt with gold, and bea with the arms of Valence, &c."

Round about the inner ledge of this chest, and most of the top of the chest, are ancient Saxon letters, and the rest of the chest, covered with brass, wrought in the form of lozenges, each lozenge containing either the letters of the alphabet, or the names of the saints. Round this chest have been thirty little brass images, some of them still remaining, twelve on each side, and three at each end, divided by central arches that serve as niches to enclose them; and on the outward ledge, at the foot of each of these images, is placed a coat of arms in brass enamelled with the colours.

Since this time, the greater part of what is above described has disappeared, showing that the spoliation of the Abbey is not generally chargeable against the rebels, but has gone on in modern times during the contemptuous dominion of Queen Anne.

The tomb of Queen Eleanor, with its exquisitely elegant effigy, is too well known to need any description from me. I have but the privilege, since my connection with the Abbey, of promoting the restoration to it of the beautiful piece of ironwork which overhangs it, and which had been removed in 1522.

The effigy of that of Henry III. was executed by an artist named Torrell, supposed by Sir Richard Westmacott, I think, without evidence, to be an Italian. It is of the style of the effigy in Canterbury.

Were this paper devoted to the monuments alone, I would have attempted a description of the tomb of Edmund, Earl of Lancaster, brother to Edward I., and of Arthur.

These magnificent monuments, viewed as architectural works, seem to be intimately connected with several contemporary works, especially the Eleanor crosses, and the tombs of Archbishop Peckham, at Canterbury, and of Bishop de Luda, at Ely, all executed between 1250 and 1300. One of their special characteristics is the extreme closeness with which the plastic work is carried out, and the carvings, every portion of which is laid directly from some actual plant, with no further conventional treatment than was necessary to adapt it to its position. These works occupy the middle position between the conventional foliage of the earlier and the almost equally conventional foliage of the later divisions of our architecture. It is, in fact, a mistake to call the foliage, even of the later

\* An excellent description of this work is to be found in Sir Charles Eastlake's "Materials for a History of Old Painting."

parts of the decorative style, *natural*. The use of really natural foliage is very seldom found after the end of the thirteenth and the few earliest years of the fourteenth century, and many of the remaining differences between the conventionalism of *approach* to the conventionalism of *departure* from nature; the conventionalism of strength and of weakness, of vigour and of effluence.

But the most remarkable characteristics of the two monuments is the splendour of their decorative colouring. The figure sculpture, though possessing considerable merit, is not so fine, either as in the nearly contemporary monuments of Henry V. and Eleanor, or in the somewhat later one of Aymer de Valence. The effigy of Edmund is, however, a very noble and dignified work.

The adjoining tomb of Aymer de Valence is evidently an imitation of those last described, but does not equal them either in its architecture or its decorations, though far exceeding them in the merits of its sculpture. I have seen no old accounts of this tomb, but I fancy that the sculpture is French, both from a decidedly French character in the architectural carving of the niches which contain the statues, and from the similarity of the statues themselves to some of the same period preserved in the Hotel Clugny at Paris.

These, and the effigy itself, rank among the finest specimens of Medieval sculpture.

The tomb of Queen Philippa stands, perhaps, next to them in beauty and interest. It is undoubtedly a foreign work, as in the account of its cost, still extant. It is said to have been executed by one "Hawkin Liege, from Brabant." Its character seems to me rather French than French, and very possibly the artist may have been from Valenciennes, the seat of her father's court.

The monument, as you will recollect, consists of an arch of tomb of Queen Philippa stands, perhaps, next to them in beauty and interest. It is undoubtedly a foreign work, as in the account of its cost, still extant. It is said to have been executed by one "Hawkin Liege, from Brabant." Its character seems to me rather French than French, and very possibly the artist may have been from Valenciennes, the seat of her father's court.

The monument, as you will recollect, consists of an arch of tomb of Queen Philippa stands, perhaps, next to them in beauty and interest. It is undoubtedly a foreign work, as in the account of its cost, still extant. It is said to have been executed by one "Hawkin Liege, from Brabant." Its character seems to me rather French than French, and very possibly the artist may have been from Valenciennes, the seat of her father's court.

One of the niches and several other portions were afterwards found to be deposited in Mr. Cottingham's museum, and, having been purchased from him, have been refixed in their places.

The very curious feature in the design is a scroll like the crook of a pastoral staff between the niches at the angles of the monument; the architectural details had no decorative colouring, but the foliage was gilt. The arms were, of course, coloured, and the figures had beautiful patterns, chiefly in gold upon the draperies; the hair was gilt, the pupils of the eyes touched in with blue, and the lips with red. The head-dresses of the female figures are beautifully enriched with gold and colour. One of the heads was unfortunately broken off while opening it out, for I should mention that the figures were enclosed in a solid mass of rubble work. This head I had a cast made from, and the decoration exactly copied on it. I had also a cast made of the angel before mentioned, and most fortunate it was that I did so.

I afterwards most carefully replaced them with my own hands, having them gilded and gilded; but though I told no one I had done so, and though they were quite out of sight, I was disgusted to find, the next time I examined the monument, that both of them had been stolen! They were so close together, that this loss of ornament and depreciation could only have been effected by a person well acquainted with what had been discovered, and that with considerable difficulty. It is most deeply humiliating to think that the artist, in appreciating the value and interest attached to such objects should be so utterly lost to all sense of honour and decency as to perpetrate such a deliberate robbery. I would not go so far as to say this wretched being, as would, perhaps, have been done of old, but I should rejoice in the opportunity, according to the figurative expression still extant among our rural population, of witnessing the "tanning of the rascal's hide." If, however, what I have said should chance to meet his eye, let him know that there is still for him a *locus penitentiae*, and that if he will anonymously restore what he has fled, his baseness shall be forgotten.

I should mention that the head is so like that of the queen herself, that it is not improbable that it may have been intended for her, though she does not appear in the imperfect list of statues given in the old histories. The open-work of the niches over the head of the effigy itself has been filled in with blue glass. The magnificence of the entire work may be imagined when it is known that it contained, when perfect, more than seventy statues and statues besides several brass figures on the surrounding railing.

Somewhat parallel to this, both in material and workmanship, was the monument of John of Eltham, brother to Edward III. I shall not enter into any description of this work, however, further than to advert to its beautiful canopy, which is thus described by Keepe—

"A canopy covering the whole with delicate wrought spires and masonry work, everywhere intermixed and adorned with little images and angels, according to the fashion of those times, supported by eight pillars of white stone, in the same manner as the work."

This canopy is shown in *Dart* view of the monument, but it was taken down about eighty years back, on the ground of insecurity.

It is often being stated that portions of it were preserved at Strawberry Hill, but I have never been able to ascertain the truth of this. If any one should know of the existence of such fragments, I should be truly obliged by his informing me of them.

The original stalls of the choir seem to have been retained in a more or less perfect state till late in the last century. They are shown in the view given by *Dart*, and the general appearance of the accounts of the coronation of James II. The canopies are shown supported by single shafts. I observed when the new stallwork was

being put up in 1819, that a closet under the organ was lined with old boards which appeared to have formed a part of the back of the ancient stalls, for I could distinguish, by the discoloration of the wood, the form of a trefoiled arch supported by a shaft with a band at half its height.

At a later period, on looking into this closet, I was glad to see the heading still there; but, on looking into it again while preparing this paper, I found that our careful clerk of the works had caused it to be neatly painted, so that this little memento is lost.

There remains, however, in Henry VII's Chapel, one of the ancient Early English misereres, and a fragment of another has been preserved. They are both good Early English foliage.

There is a great fund of minor subjects, on which a separate paper could be very advantageously written, but I must leave them unnoticed on the present occasion. I have gone over my ground as rapidly as I was able, but have more than doubled the allotted time; but Westminster Abbey is at least worthy of an extra hour, and I will only add that I recommend all students of Gothic architecture to devote to it every extra hour they have at their command. London has been pretty much denuded of its Medieval remains, but like the Sibyl's books—those which remain are worth as much almost as their all, and to live in a city which, amidst its gloomy wilderness of brick and compe, contains so glorious and exquisite a work of original art as this, is a privilege which few other cities could offer us. *Let us make use of it.*"

A WATER-FAMINE IN THE SUBURBS OF THE METROPOLIS.

INSUFFICIENT and ill-managed as are many poor districts in the supply of this necessary of life, it is difficult to imagine the condition of outlying districts before a somewhat regular supply of water was brought to this great population. Yet some idea of the inconveniences attending such conditions might have been formed lately in north Islington, and other suburban districts. During the late short but rather severe frost, whole streets, which were inhabited by large numbers of persons, were without water in their cisterns; some supplies in this way to houses which were closely thronged were exhausted on the second day of the frost, and those of neighbours and the tradesmen was soon in the same condition, owing to their willingness to lend to those who were waterless. After a lapse of time the plugs were set up, and motley crowds rushed with every variety of vessel for water needed for immediate use: pans, kettles, and pithers were filled with much jostling and difficulty; but what could be gathered in this way was quite inadequate for the purposes of general cleanliness: cooking was managed with difficulty; washerwomen were in despair; cow-keepers were in sore distress; closets and drains became stopped; and those who had large families of children were struck with consternation, when they found that means were not at hand to wash them. The washing of families could not be done: the scouring of floors was out of the question in many instances; and for it was often said, water was as precious as gold; and one of the old cries of London, "Who wants water, water?" was for a time revived.

During this time of famine the most ingenious means were resorted to in the houses to thaw the pipes and taps: in a few instances provision was made to prevent the action of the frost by overwrapping with oakum, straw, or what is better, casing them with wood filled with sawdust. The former operations would, under the circumstances, as we will afterwards explain, not have been the means of allowing the water to flow into the cisterns; nor would the latter method have been effective; for the stoppage took place between the dwelling and the main pipe, and this was caused by the pipe leading from the main being too near to the surface.

When the frost departed, even after four or five days of open weather, the greater number of the cisterns were still empty. People were surprised, and could not divine the reason. "Why should Mr. So-and-So's cistern be full, and ours not?" The turncocks were well rated, but they pointed to the water in the main pipes, which was coming from the temporary plugs. The fault did not lie there, evidently; but how was it,

\* Among other things I should have given a description of the Coronation Chair, and of the figures remaining in the panels of the old sedilia, commonly called the tomb of King Sebert. The former is a truly magnificent piece of decoration, but sadly mutilated. The decorations are somewhat broken, the whole seems to have been gilt on a thick coating of gesso, and while still soft, the foliage, &c., to have been traced upon the gold, and indicated merely by pricking the outline and the intervals between the leaves. Of the sedilia, however, the whole seems to be in perfect order. They appear to have been slightly touched up, but are mainly original. They represent, I believe, King Henry III. and King Sebert. The figure of King Edward, the Confessor, on ascending the whole, given by M. Meibom, in his "Londinium Redivivum," can now with great difficulty be distinguished. The painting in the canopy of the tomb of Richard II. ought also to have been noticed. The diapered ground is still very perfect, but the painting of the figures has almost entirely perished.

when the frost had left for so many days, that the small pipes still continued to be frozen?

If, in the first instance, the house-service pipe had not been placed so close to the surface, it would not have been so suddenly acted upon by the frost, and it will be found that those houses which were first supplied, and which were longest in having the water stopped, had the service pipe at a greater depth than others.

Taking into consideration the expense of pipes bursting, and the very great inconvenience of having no water in the house, it is incumbent on those who are arranging the conveniences of houses, particularly in neighbourhoods exposed to the severity of the weather, to adopt precautionary measures, *ab initio*. While our chimneys smoke, our water-pipes freeze, the drains get stopped, and half the heat from the fires is wasted, the science of house-building amongst us must be pronounced in a low condition.

ST. GREGORY'S (R. C.) CHURCH CHELTENHAM.

WE illustrate, in our present number, the porch of the church of St. Gregory, lately erected by the Roman Catholics of Cheltenham, from the designs of Mr. Charles F. Hanson, architect, of Clifton. The foundation-stone of the tower and spire, which were omitted from the first contract, was laid on the 30th of November last, by Geo. Copeland, Esq., M.D. The new work will be of unusual extent, 25 feet square at the base, exclusive of buttresses, and 205 feet in height, thus overtopping by at least 50 feet the spire of the fine old parish church.

In alluding to the parish church, we may express our regret that it has been indefinitely closed, having been pronounced in a dangerous state. An energetic attempt was made, by the incumbent, to have the whole church restored and resaced; but, as his plan contemplated the demolition of the present "sleeping-pews," alias pews, the opposition of their owners proved too strong—at least, that is the reason given to us—and he was compelled to close the church, and resort to the expedient of putting up a temporary iron one, to serve till such time as some better understanding be arrived at.

AMSTERDAM CRYSTAL PALACE.

THE Amsterdam Crystal Palace is to be inaugurated in the spring of 1861, with an exhibition of industry, science, and art, which will be open to all nations. The building, which is now being erected on the site of the Utrecht Gate, from the designs of Mr. C. Oubshorn, architect, of Amsterdam, is to be a permanent structure, and will be a great addition to the architecture of that ancient city. The total length of the building is 412 feet; the general width, 172 feet; and the width at the transept, 22½ feet.

The foundations of the building consist of timber piles, longitudinal and transverse timbers, and planking, on which are built brick piers, capped with stone, for carrying the internal columns, and continuous external walls, also capped with stone, which form a plinth to the superstructure of the building. The top of this stone plinth is about 2 feet above ground level, and is also the general floor level of the building. The level of the timber foundations is about 10 feet 9 inches below ground level, about 8 feet of this being made available over the whole area of the building, as a basement story.

The skeleton of the building is entirely constructed of iron; and externally, woodwork is only employed for the main cornices, the rest being of iron also.

The general plan of the building consists of a nave, 64 feet wide, with side aisles, 19 feet 6 inches wide, a central transept hall, 136 feet by 68 feet, with polygonal ends, and two side halls, each 150 feet by 34 feet, on each side of the nave; the side halls and vestibules at each end of the transept being separated from the nave and transept by close partitions and glazed iron gates.

A gallery, 19 feet 4 inches wide, and 29 feet 6 inches above the floor level, is continued round the whole of the nave and transept, and communicates with saloons over the vestibules at the entrances.

The columns are similar in section to those of the Great Exhibition Building, 1851, and are generally arranged in pairs, about 2 feet from centre to centre, both internally and externally, except at the angles, where groups, consisting of from three to seven columns, are employed. The

first tier of external columns are  $7\frac{1}{4}$  inches in diameter, and the internal columns, first tier, are generally  $10\frac{1}{4}$  inches in diameter, each tier of columns diminishing  $\frac{1}{8}$  of an inch in diameter. The columns at the angles of the transept, supporting the gallery and the dome, present the appearance of clusters of shafts. The whole of the columns have cast-iron foliated capitals, surmounted by an entablature.

The galleries are supported by cast-iron open-work girders, and ornamental corbels.

The roof of the nave consists of wrought-iron arched ribs, and is covered entirely with glass, carried by curved wrought-iron sash-bars, which are prepared to receive double thicknesses of glass, about  $\frac{3}{4}$  of an inch apart, these sash-bars being carried by longitudinal H-iron purlins. The main ribs are in pairs over the coupled columns, and are connected together by a perforated cast-iron running ornament. The total height, from the floor level to the crown of the arched ribs, is 89 feet. The ends of the nave are filled in with highly ornamented semicircular windows, the framework being constructed entirely

of cast iron, and prepared for double thicknesses of glass, about 4 inches apart.

The external walls of the nave are filled in with corrugated iron, and the nave and aisles are thus only lighted from the roof and the ends of the building.

About 2,500 tons of cast iron, and 500 tons of wrought iron, will be used.

The principal feature of the palace will be the dome, which surmounts the intersection of the nave and transept. The plan of the dome is elliptical. This being a novel feature, the effect has been questioned; but, judging from a model of this part of the building, which has been constructed to a scale of one-twentieth full size, it is anticipated by those who have seen it that the effect, when executed, will fully equal the expectations of the architect.

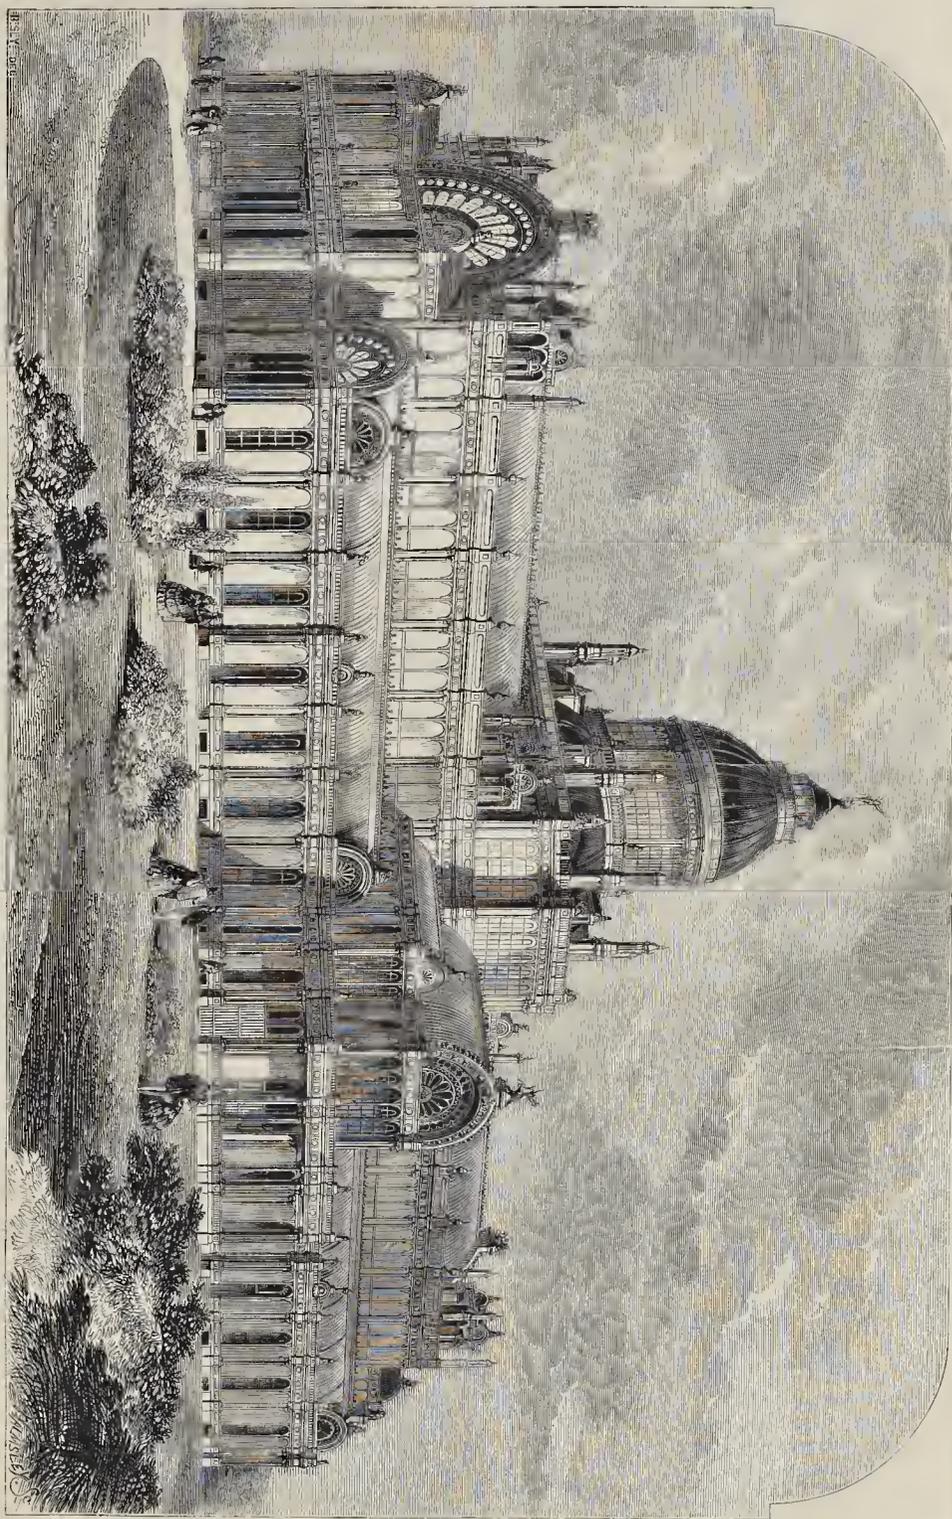

At a height of 95 feet from floor level, open-work quadrant ribs spring from the clustered shafts in the transept, and converge towards the centre of the ellipse which forms the base of the dome, the major and minor axes of which are respectively 70 feet and 42 feet.

On this elliptical base are fixed coupled columns 23 feet high, the spaces between which are filled in with glazed cast-iron framework. These columns support the dome proper, which is constructed of iron, and covered with zinc; the whole being surmounted by a glazed lantern and ball, the total height, from ground level to the top of the hall, being 187 feet.

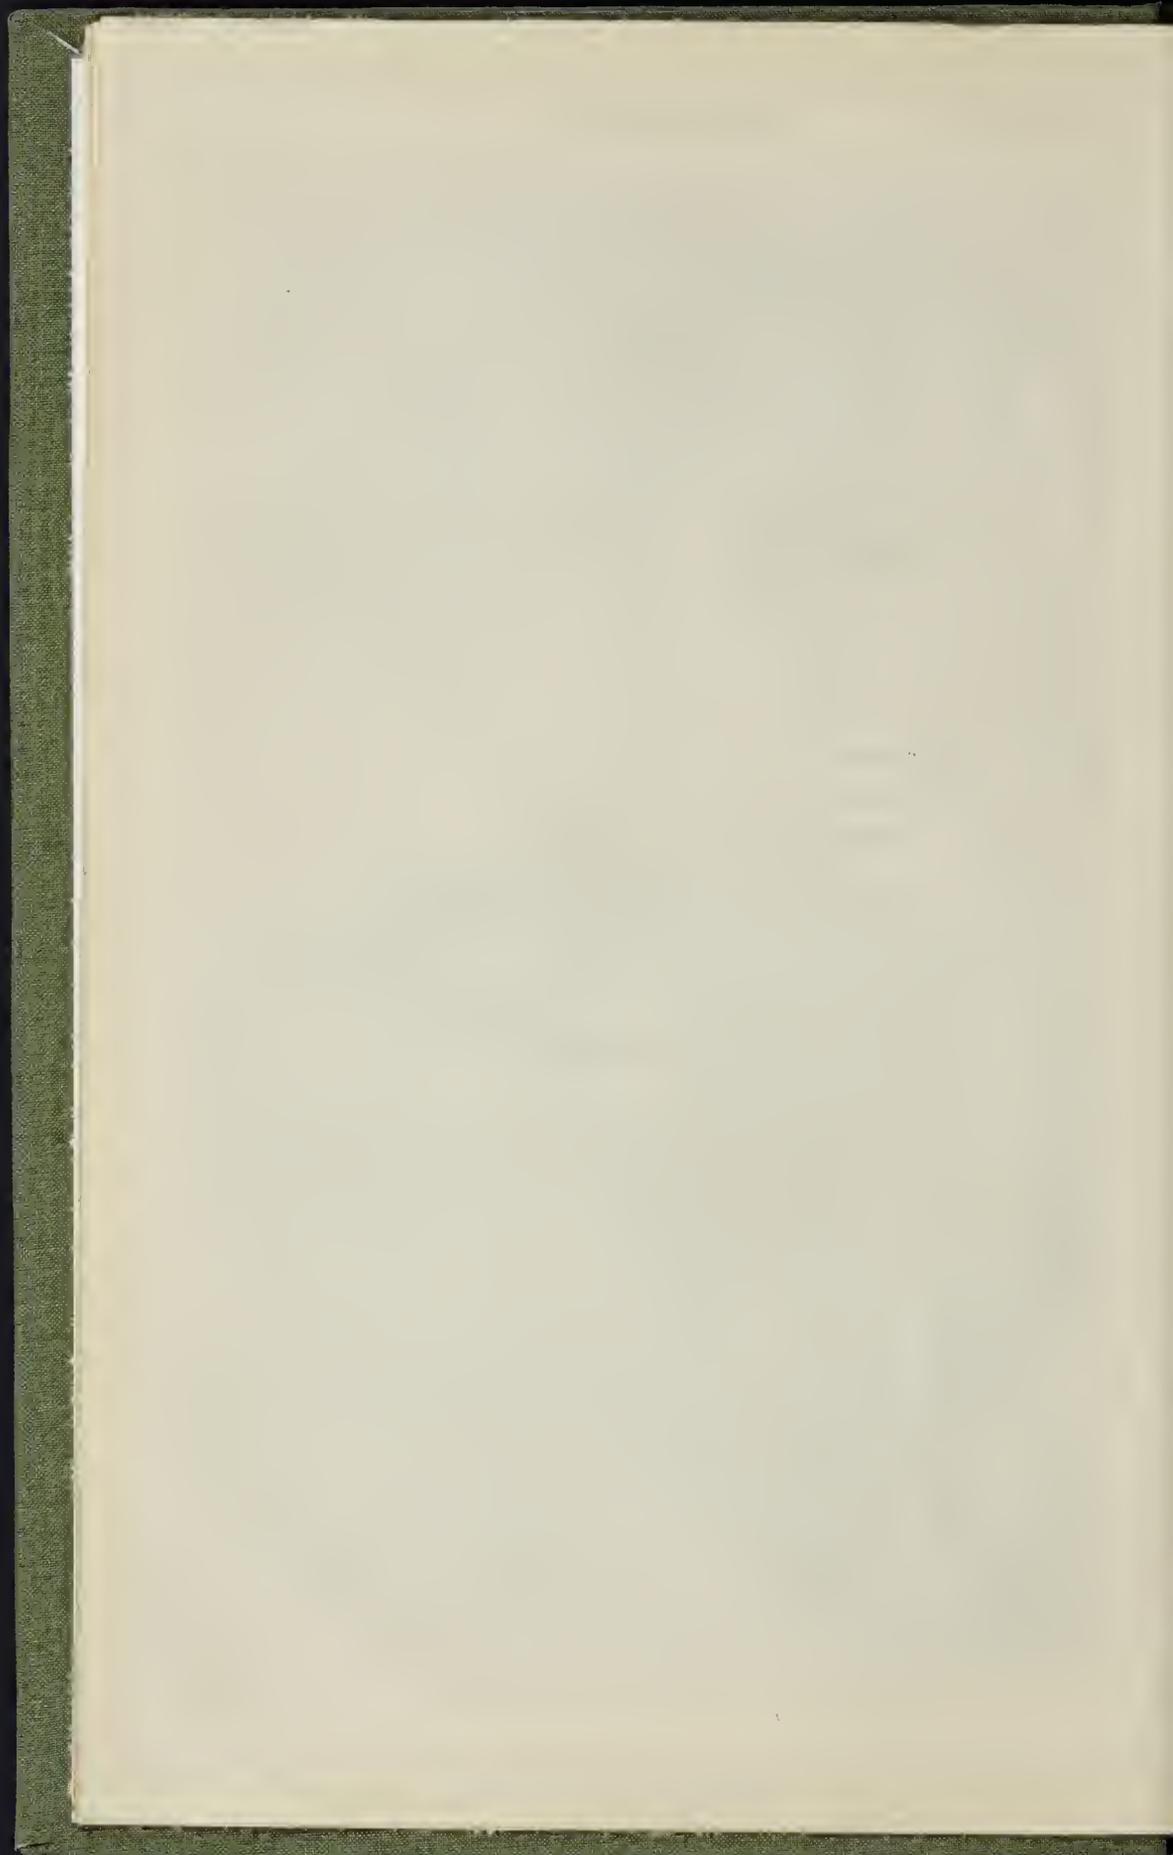

The interior of the building will be of a highly-ornamental character, there being a large amount of decorative ironwork employed. Ornamental painting is also intended to be applied as a decoration, wherever it can be made available, throughout the building.

The total cost of the structure is estimated at 95,000.

The palace, as remarked, was designed by Mr. C. Outhoorn, of Amsterdam; the contractors being Messrs. Van Heel & Holtzman, of Amsterdam; and Messrs. Smith & Son, of Spring-lill Works, Birmingham. The details of construction of the ironwork are entrusted to Mr. R. M. Ordish, of Great George-street, Westminster. The works are progressing.

THE AMSTERDAM CRYSTAL PALACE.—Jr. C. OUDSHOORN, ARCHT.

THE LOUVRE AND THE TUILERIES.

THE LOUVRE, from its association with kings and great men, is one of the first objects of interest in the capital of France. Among the western monarchies there is no other kingdom or empire which more deserves attention. As ancient as the fall of the Roman empire in the East, and formed out of its remains, the kingdom subsisted with glory for more than thirteen ages. Besides, the fertility and the extent of France, the amunity of its climate, the riches that nature and industry produce, the remarkable number of great men of all kinds who have illustrated it, assure for it a pre-eminence which no other nation can have a right to dispute.\* We may say that successively, almost in each part of Europe, all the powers observed a fondness for the art of building, principally in Italy, which seems to have been the first to triumph over the ignorance and fury of the barbarians who had inundated the empire; and at Venice especially, there was not a doge who did not wish to signalise his government by edifices, whether sacred, public, or private; but we easily recognise, in consulting history, that Charlemagne is one of the princes who has the most contributed to the establishment and to the erection of sacred temples.† It was a new era for man, and it was the birth of splendid cathedrals,—of St. Mark's, Venice, and of that of Rheims. Louis le Débonnaire, who succeeded Charlemagne, also caused to be constructed a number of edifices. His illustrious predecessor had covered, as with a zone of beauty and protection, the western empire with churches full of majesty and riches, reflecting the image of the royal founder, and uniting, in a marvellous church at Aix-la-Chapelle, all the inventions of the three Grecian orders with all the forms of the Christian genius; and Louis imitated this peculiar but fascinating taste in sacred piles which he built. Architecture, then employed in the noblest cause, was developed by the co-operation of hard-working monks and wealthy kings until the reign of Philippe-Auguste, 1180.‡ But if we see the happy ages when the sciences and the arts appeared with splendour, experience shows us also, that the splendour is doomed to be soon overcast, and that the duration of the flourishing time is ordinarily included in a short space. The state to which France found itself reduced at the end of the reign of Louis le Débonnaire retarded the progress of architecture throughout the kingdom. Paris attracted the first attention of Philippe-Auguste; he wished to bestow his zeal upon a city on which his throne was set, and which would reward him for the pains. The extent of the capital, since it had extended beyond the limits of its island, named the *Cité*, might be known by the enlargements that this prince gave to it beyond its former compass. Sides exposed to incursions were surrounded by thick walls, flanked by massive towers: the streets were paved (1184),§ and an ordinance issued that they should be cleaned, swept, and kept from dirt which had been allowed to accumulate and infect the air. He established a police, and built a monastery as an asylum for those who wished to quit their bad habits. We recognize in Philippe-Auguste, a genius for fortifications, sieges, and a taste for military machines, for which he nobly recompensed the inventors. The great door and the towers of Notre Dame are the work of his time. He loved buildings. He enclosed Paris with walls. He constructed covered markets, so that the merchandize was protected, and surrounded with cloisters the cemetery of the Innocents, to procure a shelter to those who came to mourn their parents and their friends. He built a palace round the large tower of the Louvre, contributed to the construction of the cathedral already commenced, and to the enlargement of the University. He gave great privileges to learned men devoted to the sciences. He was surnamed Conquerant and Auguste, on account of his victories and his great qualities.¶

The communication with the East accustomed the French to go and seek for themselves the beautiful stuffs and products of India, and the spices that they formerly received from the Venetians and the Genoese. The French have always been celebrated for the textile arts, and have made them a very profitable branch of industry. At this day many combinations of them are still objects of much admiration.

\* Preface to "L'Art de vérifier les Dates." Paris: 1783.  
 † Blondel's (Jacques François) "Architecture Française." Paris: 1782-56; 4to.  
 ‡ "Dictionnaire des Dates." Paris: 1842.  
 § Foot pavement was not laid down in the streets of London to any extent until the fourteenth century.  
 ¶ "Anquetil, "Histoire de France."

In this time heraldry began to become common. Those who returned from the Crusade were not wanting in doing high honour to this expedition; and, to awaken perpetually its remembrance, they placed the banners under which they fought in the most public places of their *châteaux*, as monuments of glory. Families in their alliances with one another commented, to each these signs of illustration, and founded one upon the other. Ladies worked them upon the furniture, upon their clothes, and equipage; the damsels upon those of the knights; soldiers had them painted on their shields; but, as all, they could not hold so many little spaces, they abridged, or condensed, so to speak, the representation of the principal events that should be preserved in memory. We may say that *blazon* has been, in principle, a sort of language which recognizes the rights to public esteem and the alliances.

We owe to the reign of Philippe I. the creation of the most celebrated military orders, which from France have spread throughout all Europe; the Hospitaliers of St. John; the Templars, &c. In the east and in the south of Europe, at Malta, at Cambridge, in London, and in other cities, architecture is indebted to these orders. These orders owe their establishment to Christian charity, and to the desire of being useful to one's kind; whence some others have arisen out of the emulation of piety, and the desire of sanctifying oneself in the exercises of a life more austere than the commonality of Christians, the Chartreux, and other societies of monks.\*

The Freemasons' lodges are as numerous in France as everywhere else. Their famous grand lodge was St. Croix; but I am not aware that they exercise, notwithstanding their principle of humanity, any action of importance upon public opinion.

We shall now mention those kings and those architects who have been concerned in the creation of that interesting palace the Louvre. The Old Louvre—fortress, palace, and prison—was founded in the year 1204 by Philippe-Auguste. The large tower of the Louvre and its precincts, the only constructions that the king erected in this place, were the centre of royal authority. In this tower, known in feudal times, the great servants of the crown humbly came to make their offerings of fidelity and homage.† The king wished to receive there the emperor Charles-Quint, and give, in his lately embellished edifice, a high notion of his power. For a long time the ancient and venerable Louvre was surrounded with *fossés* supplied by the waters of the Seine. Two bridges, constructed upon the boundary of the quay, the only one then existing, admitted into these *fossés* the water which was dammed in by locks. The front elevation of this place, on the side of St. Germain-l'Auxerrois, still preserved its ancient character. It was terminated at two angles by two round towers covered by a roof of a conical form. The principal door was entered by a bridge of arches in stone, and by a bridge raised or lowered as occasion required. The origin of the quays, which now, to a Frenchman, are the pride of the capital, may be traced to the beginning of the fourteenth century epoch, in which Philippe-le-Bel constructed the first quay before the convent of the Augustines, near the tower of Nesle. Near the present site of the Tuileries was under François I., some tile-kilns—called the Sablonnière—like the *céramique* of Athens. From *tuiles* (or tiles) the Tuileries took its name. At that time all the tiles and bricks were ordered to be transferred beyond the walls of the city, near the Tuileries-St.-Honoré, which were upon the Seine, beyond the *fossés* of the chateau of the Louvre. This will give the reader some idea of the circumscribed limits of that quarter in the beginning of the sixteenth century.‡ Constructions in brick at this time were much in use. They were built with little else for a long time, nearly as far as the reign of Louis XIV. The chateau of St. Germain-en-Laye, and many other considerable edifices, were erected with these materials. The roofs of the châteaux were covered with lead, and they, from their size, consumed a great quantity. Plumbing was a good trade. Before François I., architecture consisted only in churches, fortresses, towers, and swing-bridges; but this monarch made all the professions to flourish: with wisdom he sought more the happiness of his people than his personal interest: §

 † Duhaure, "Histoire de Paris."  
 ‡ In the "Atlas Historique," &c., by Lesage, an interesting map of Paris is given, of the gradual and characteristic increase of the French territory from the time of H. Capet to the present day.

foreigners were invited. Cellini and Serlio were working on the royal residences.\* Bramante, architect and painter, who was in the service of François, was, owing to some difference with other artists employed at the court, sent to Rome and other august cities on the continent in the year 1537, with the order to buy and copy antique statues. He cast many beautiful bronzes for the châteaux at Pontainbleau and Saint-Germain. The king could not proceed without having recourse to and aid from the great artists of the day to design and decorate and superintend the two most ancient and the most important palaces of France, and at the same time the immense chateau of Madrid. The artists also threw and made their reputation under his auspices. They came from and were sent to a country where architecture was seen in the greatest perfection, which country was the mother and the ours of literature and of the arts. It is, indeed, a treasury for all things beautiful; and, though Italy is now fallen, its soul once heaved with the noblest impulses. The French architects travelling thither could not but receive from its monuments some advantages, especially on seeing some of a very different character to any in their own country; and when struck with that energy and power so peculiar to the ancient Romans, and so characteristic in their architecture and in every thing they undertook, this influence was not lost. Italy modified France,—France, Spain, long after,—during Napoleon's six years' invasion of that peninsula. The learned curiosity with which all Europe was seized in the sixteenth century turned attention towards these famous countries, whence the arts had departed.† In France, a young Greek nobleman, Lascaris, and some others from Greece, introduced and animated the study of the Greek language and the "Humanities," which later flourished there, as in Italy and Spain.‡ Scholastic theology and the peripatetic philosophy, reigning a long while in the University of Paris, were not less contrary and unfavourable to the progress of letters than clerical intolerance or monastic institutions in other countries.§ François I. effected a great amount of good to his own and succeeding ages by abolishing the Latin, and commanding all the laws and whatever concerned the people to be written in French,—in a language that they could understand. For this he deserves more than many who have acquired the same title,—the name of Restorer and Father of Letters.

Pierre Lescot, abbe of Clagny, commenced the old Louvre in 1528. Schastian Serlio, who was then in Paris, competed for it; but the design of the French architect was preferred, and Serlio had the generous impulse to point out the superiority of his rival's design. Serlio was not the only Italian artist who had failed, and whose designs had been rejected by French adjudicators. Lescot conducted the works with spirit, rapidity, and with success, and the body of the building, named to-day the old Louvre, was, under the reign of Henry II., in 1548, almost entirely terminated, as is proved by a Latin inscription over the door of the Hall of the Caryatides.¶ François I. had been at great expense in the reparations that he executed in this old building; demolishing one part to erect in its place, upon a new plan and after more modern designs, a vast portion intended for residence. The designs, furnished and carried into execution by Lescot, are much admired. It is a monument of the architecture of the sixteenth century. It is to the admirers of the Renaissance what Notre Dame is to the students of the Gothic. One internal order not harmonizing with an external order, the arbitrary proportions of the composition have by some been censured; but if there are slight imperfections, they will not hinder the observer from admiring the effect of the whole. Architects, in the execution of a building of any particular order, are not, in many instances, over scrupulous in following the proportions assigned to them. Even the Greeks regarded the proportions of this art as arbitrary, and we find in the edifices of ancient Rome proportions of all kinds, and which justify all sorts of opinions.¶

Jean Goujon chiselled many of the bas-reliefs of the façade of the court of the Louvre and the fountain of the Innocents, in 1555.\*\* The figures in the court of the Louvre, in the Composite

order, have great relief and great beauty: their subject is boys at play among festoons: they are well accommodated, as these details should be, to the grandeur of the building and the distance of the place for viewing them, as well as by the character of the order in which they are employed. They are sculptured with so much art and with so much poetic feeling, that they are esteemed by connoisseurs among the best pieces of sculpture of the kind that are known.\*

F. LUSI.

## ON STRIKE.

On! my brothers! to me listen,  
Ere the sorrow and the tears  
Cause each smoken eye to glisten  
With the grief of after-years;  
Ere the wretched mothers weeping,  
Sob as though their hearts would break,  
For their infant darlings sleeping,  
And their thoughtless husbands' sake;  
Ere ye tramp on lonely highways,  
Through the village or the town,  
Or in cities' crowded by-ways,  
Sadly wander up and down;  
For employment ever seeking  
Where there's none, alas! to give,  
Till the hunger-glance is speaking  
That ye scarce know how to live.

True, our path is often dreary—  
True, the joy-hopes seldom shine,  
Clearing hearts with labour weary,  
In the factry, field, or mine;—  
True, that sin and shame oppress us,  
In each court, and lane, and street;  
Where but angels few may bless us,  
With their smiles so pure and sweet;—  
True it is, our children dying  
From the poison breath of drain,  
Of with fever'd lips are sighing  
For their daily bread in vain;—  
Whilst we toilers, bow'd with anguish,  
Aged grow before our day;  
And in paper hovels languish  
Till our spirits glide away.

But these ills last not for ever,  
Not all iron is our chain,  
Not all hopeless each endeavour  
To remove the olden stain.  
Round our hearts for ever clinging,  
Filling them with scorn and hate,  
Truth and reason from them flinging,  
Till we murmur at our fate;—  
Murmur at the rich man's treasures,  
At his houses, at his wine,  
At his dearly purchased pleasures,  
At his halls which lighted shine;—  
But, my brothers, murmurs never  
Taught our souls the crown to win;  
Or with lofty courage sever  
Every link of vice and sin.

Not by "striking," or by spurning  
E'ry boon which Science brings;—  
With the aid of Art and Learning,  
Shall we rise to nobler things.  
Honest toil and temperate living,  
Manly educated mind,  
Earnest soul, and heart forgiving,  
Are the means in each enshrined:  
With their aid, each ill degrading  
We may from us swift remove,  
And around us weave un fading  
Wreaths of Joy, of Peace, and Love.  
Now, my brothers, I have euded,  
And my simple strain is o'er;  
If ye deem truth with it blended,  
Go ye forth and "strike" no more.

Kettering. JOHN PLEMMER.

## "STARCH MAKES THE CALICO."

BEAU BRUMMELL'S axiom that "starch makes the man" has been improved upon by the calico manufacturers, as a correspondent of the "Journal of the Society of Arts" (Mr. V. Stones) points out, while making reference to a paper read by Mr. Calvert at the Society's rooms on the subject of Starch. Mr. Stones declares, and we verily believe with unexaggerated truthfulness, that the cotton "fabric, in some cases, appears to be used merely as a vehicle for the starch! being woven extremely coarse or wide, and the interstices filled with starch;" and "of course, with farina at 2d. per lb. it must be very profitable to sell yards of starch at even a much lower price than the lowest cotton

goods could be supplied." In the antislavery world, in which, as some Scriptural commentators tell us, there was no rain, the farinal fabric might have formed a very passable improvement on the fig-leaf; but it is rather too bad that the cotton (?) manufacturers do not try at least to make the starch a little water-proof, especially since the crinolinian mania has suggested to them the idea of rendering it fire-proof; as, for example, by a judicious mixture of borax, which, we dare say, they have already discovered can be sold by the yard at even less than starch. But what will Mr. Stones think of the starch wavers when we tell him that just as starch or flour has been substituted in the place of calico, so and long or the crinolinian era, water-glass had been substituted in the place of starch,—an adulteration of adulterations, which they, doubtless, found they could dispose of at so much a yard even cheaper than borax; reminding one of the grievous complaint of the coffee-drinkers that even the adulterating chickory was itself adulterated, and suggesting, by the way, a similar mode of getting rid of the abominable and rascally imposition of the parasitic starch and all its parasites. At least the manufacturers and adulterators ought to be obliged to sell these woven "ropes of sand"—these "mixed" and heavy fabrics—as recognized, and definite, if not judicious, "mixtures of cotton and starch," or rather of "starch and cotton."

## THE "ART-JOURNAL," OF AGE.

THE *Art-Journal*, after a career of twenty-one years, has begun the new year well, including two of the best engravings it has had for some time, "Lady Constance," by Vernon, after Winterhalter, and "Una," by Lightfoot, after Frost; a clever sketch of Wilson, the landscape painter, by Mr. Thornbury; the commencement of an illustrated paper on "the Hudson," by Benson Lossing; "Rome," by Mr. Dafforne; and the "Companion Guide in South Wales," by Mr. and Mrs. S. C. Hall. The *Art-Journal* is now of full age, and during all its years Mr. Hall has laboured for it with energy, integrity, and ability. It is not often that one person conducts a journal so long and so well, and we sincerely hope that he may be reaping, beyond the rich reward of an accomplished purpose, those personal and worldly advantages which the qualities we have enumerated ought to command.

## LECTURE ON LABOUR.

LATELY in Guernsey, a local advocate, Mr. P. Jereux, delivered a lecture on the "Dignity of Labour." The lecturer, after adverting to the amount of property existing in every community, and pointing out how unequally property was divided, and that, even amongst those into whose hands it falls, how comparatively few are they who can live without labour,—went on to say, "How poor the pittance of the greater number may be readily imagined, when it is ascertained that there are no less than 90,000 persons out of 260,000 bond-holders whose dividend does not exceed 10l. per annum; while 135,000, or 50 per cent. out of the whole, did not exceed 20s. a year, and that, with all our idea of the immense wealth derived from the English Funds, we are struck when we find that the number of persons receiving upwards of 1,000l. is considerably under 2,000,—say 1,719, leaving on the whole an average for each person of 102l. a year." He then spoke about the Funds in France, and continued, "Hence we see the necessity of labour; and its dignity, if measured by utility, will be easily conceived when it is thus found that it is the *numbers* with their small sums, and not the *few* with their large ones, that make up the account required for the common benefit, which constitutes perhaps the greatest proof of mutual dependence. And yet to obtain property is not the greatest desideratum, but to augment it by labour and retain it by frugality. The property and wealth of every community are the storehouse whence all derive their livelihood, and must be fed. Five great sections are continually drawing upon it,—three who produce and consume, two who consume without producing, and which may be divided as follows:—1. The working man. 2. His employer. 3. The capitalist living without employment. 4. They who can labour but who will not, who are numerous, and whose cost of maintenance is far from being the least. 5. They who would labour but cannot. It is the fourth and fifth class that give rise to those great social questions which are constantly agitated respecting taxation, or relative combinations of capital and labour. Strange as it may appear, the great cause of the present discontent

arises from the altered state of the employer and employed from what it formerly was. The rights were no longer all on the side of the master, and the duties all on the side of the servant. They were exactly balanced in the order of nature, which is immutable; and the sense now entertained of them through education is different from that which was formerly entertained. It is to this altered state that all must make up their minds. As to the destiny of the labourer of every grade, it was in his own hands. Property and comfort, however small, were within every man's reach; and, though few could ever attain to opulence, the road was open to all, and it depended very much on the individual exertions of each how his portion of property and comfort would be ultimately allotted to him. The greatest feature of the present turn in the labouring man's condition was the comparative alleviation of his toil wrought through machinery, and his exemption from many of the greatest hardships to which he was formerly subjected."

## PROVINCIAL NEWS.

*Bingham (Notts).*—The schools recently erected in this place by the Wesleyans were opened last week. They comprise school-rooms, 40 feet by 23 feet; class-rooms, 22 feet by 20 feet. They are built in a very substantial manner, in the Italian style, treated freely. The end windows are combined under a tastefully executed head, containing the inscription and surmounted by a bell-turret. There is a neat stone porch leading into the schools. The master's house is unusually large and commodious. The total cost will be about 700l. Messrs. Clifton and Doneaster, of Bingham, are the builders, and Mr. R. C. Sutton, of Nottingham, is the architect.

*Emeth (Wessex).*—The *Cambridge Chronicle* speaks of various indications of external improvement within a short period in this once aristocratic but for many years much neglected parish. To the principal inhabitants much credit is due for many improvements of a parochial and sanitary kind during the last few years; but the improvements to which it chiefly refers began about two years ago, when Mr. Charles Metcalfe, of Wisbech, erected a mansion on the site of the old rectory-ground, to which he has given the name of Inglethorpe Hall. The architect of this mansion was Mr. Dobson, of Newcastle, and the builder Mr. L. Tomson, of Wisbech. In July last the corner-stone of a school-building was laid by the donor of the site, Mr. T. N. Neale, of Emeth Hungate. The building is now approaching completion. The architect is Mr. W. Smith, of London, who prepared the plans for the restoration of Wisbech and Walsoken Churches, and also for the new school at the latter place. In April last, the Ecclesiastical Commissioners began the erection of a new vicarage-house, a few yards behind the site of the old rectory. The architect of this building is Mr. E. Christian, and the contractor Mr. J. Stimpson, of Lynn. The house stands near to the church. The old parish church needs some consideration.

*Nelley.*—The hundreds of masons employed at the Victoria Military Hospital at Nelley have resumed work; they were lately unemployed for about a week on account of the frost. The officers' quarters and the separate barracks have been commenced. The chapel is progressing towards completion, and the scaffolding of the north wing has been taken down, so that the ornamental masonry of that portion of the building can now be seen.

## STAINED GLASS.

*Church of Mottram-in-Longdendale (Cheshire).* Messrs. M. & A. O'Connor, of London, have just finished a stained-glass window, which has been placed in the parish church of Mottram, to the memory of Captain George Kershaw Sidebottom, late of Harewood Lodge, Mottram. The window is in three compartments, the principal figure in the centre division being a representation of our Saviour rising from the tomb, with the watch asleep on the ground. On the left-hand division there is a group, with Christ blessing little children. The right-hand compartment is a representation of Peter baptizing Cornelius. Below these are three smaller subjects, showing episodes in our Saviour's life: on the left, Jesus is walking on the waters; in the centre part, he is asleep in the vessel, and his disciples waking him with fear; in the remaining division, Jesus is rebuking the waves, commanding them to be still.

*Behington Church.*—A window has been put up by Messrs. Harrington, in Behington parish

\* To be continued.

church, to the memory of the late John Deane Case, J.P., and of Mrs. Case, by their son, Mr. J. B. Case, a magistrate for Cheshire. The subjects are, "The Raising of Lazarus," and "The History of the good Samaritan."

**Heaton Norris Chapel (Stockport).**—Some glass paintings have lately been fixed in Heaton Chapel. They form an altarpiece, of which the central and largest opening exhibits a representation of the incredulity of St. Thomas, to whom the church is dedicated. The principal figure in the group is of course our Saviour, who is represented in the act of placing the hand of St. Thomas on his wounded side. There are two other openings, one on each side. The one to the left contains "The Baptism of our Lord;" the corresponding opening contains a representation of "The Last Supper." There are two windows of considerable dimensions filled with armorial bearings. The windows are by Messrs. Edmundson, of Manchester.

**St. John's Church, Leicester.**—A window has just been placed in this church, to the memory of the late Mr. Thomas Miller. The window is the work of Mr. Wailes, of Newcastle. The subjects of the design are "The Betrayal of our Lord by Judas," and "Pilate bringing forth the Saviour to the Multitude," with a crown of thorns and purple robe. Under each of these groups is the type of each. The type of the first is, Joseph's brethren selling him to the Ismaelites; and of the second, a person leading a lamb to the High Priest, who stands ready to receive it. At the apex of the window is an angel with scroll. It is intended that the five windows of the apse shall be a continuous series on the last sufferings and acts of our Lord; and the three centre ones, which are already in, take their place in this projected series.

CHURCH-BUILDING NEWS.

**Potou (Lincolnshire).**—The church of this parish has been re-opened, after undergoing considerable repairs, both to the interior and exterior. The church is an ancient structure of Norman and Early English architecture. The renovation is of a simple character. The work has been conducted by Messrs. Kirk & Parry, of Stamford, at the cost of about 700*l*.

**Acaster.**—The parish church, St. Martin's, has been repaired and altered. The cost of reseating and repairing, according to the *Lincolnshire Chronicle*, has been about 260*l*. The architect employed was Mr. Charles Kirk, of Stamford.

**Iwerne Minster.**—A new church at East Orchard, in this parish, has been consecrated. The edifice has been erected entirely through the exertions of the Rev. Prebendary Huxtable, and is the sixth that has been erected in consequence of his efforts. It is a simple structure in the first Pointed style of English architecture, and consists of a nave, 42 feet by 21 feet 6 inches; a chancel, 16 feet by 12 feet 6 inches; a south porch, and a vestry, on north side of chancel. The nave is lighted by five acutely-pointed windows, with Early cusping on north side; four of the same description on south side; a triplet with cusped heads at east end of chancel, and a quintuplet of acutely-pointed lancet windows at the west end. The roofs of nave and chancel are framed with braced principals, and are open to the rafters. There is a bell-turret at the west end, surmounted by an ornamented wrought-iron cross. All the fittings are of the simplest character of stained deal. The site and the sum of 100*l*. were given by Sir R. P. Glyn, bart.

**Belper (Derbyshire).**—The cemetery here has just been completed. The buildings consist of two chapels, 38 feet by 22 feet, with robing-rooms and cloisters, connected by a central archway, which is of sufficient size to admit a hearse, and is surmounted by a tower and spire, 100 feet high. The frontage exceeds 100 feet. There is a five-light window in each gable, with tracery heads of varied design. The roofs are open timbered, and covered with slating of two colours, in patterns. Four kinds of stone have been used in the exterior, with good effect. There is a residence for the sexton, with a registrar's office. These, with a detached horse-house, boundary fences, and wrought-iron ornamental entrance-gates, complete the buildings, which have been erected at a cost something under 3,000*l*. The style is Late Decorated. The architect was Mr. E. Holmes; the builder, Mr. William Freeman, of Belper.

**Standish.**—The old parish church of Standish has recently been renovated. The old galleries and pews have been removed, and the edifice cleaned and repaired. The long-backed pews have been removed, and replaced by benches. The chancel has been extended as far as the turrets,

The organ is now placed in the north aisle, beside the chancel, and near it are the stalls for the choristers and the officiating priests. The lectern stands in front of the chancel, and the carved pulpit has been restored, fixed on a pedestal, and placed on the north side of the chancel, in front of the organ. The removal of the west gallery discloses an old arch, formerly hidden, and opens a view of the full length of the edifice. The walls have been cleaned, and all the plaster which disfigured them removed, so that the cut pillars and arches are shown.

**Higher Bebbington.**—Christ Church, the foundation-stone of which was laid on Lammas-day, 1857, was consecrated on Saturday last, by the Lord Bishop of the diocese. The edifice is in the Early English style, and consists of a nave, north and south aisles, chancel, organ, north porch, and sacristy. The total length of the nave is 84 feet 7 inches, and of the chancel 28 feet,—in all, 112 feet 7 inches. Width of nave, including aisles, 57 feet. There is a lofty clerestory to the nave, with seven three-light windows to each side. The roofs are of open timber framing, covered with boarding beneath the slates, which are stained and varnished. The nave is separated from the aisle, each side, by an arcade of six bays. The west window has six lights and is of great size, and the east or chancel window, the gift of Mr. J. Spence, of Rock Ferry, is of stained glass, by Edmundson & Co., of Manchester. The stained windows of the aisles are by an artist of Bristol. The height of nave from floor to top of the roof is 47 feet, and that of the chancel 36 feet. All the stone, both externally and internally, is from the Stourton quarries. It is intended to add a tower and spire at a future period. The cost of the church, exclusive of the stone, was nearly 3,000*l*. Amongst the features of the church are the absence of benches in the aisles, and of plaster and paint, all the walls of the interior being of rubbed stone, and the woodwork varnished. The church will at present accommodate 500 persons, but when pews are placed in the aisles there will be accommodation for about 700. Mr. Walter Scott, of Birkenhead, was the architect. The builder was Mr. James Routledge, of Tranmere.

THE DRINKING-FOUNTAIN MOVEMENT.

A new fountain has recently been erected at the Elephant and Castle, the gift, as recorded by an inscription, of one of the inhabitants of the parish. The structure is about 12 feet in height, and occupies a clear space of about 10 square feet, in the centre of the various junction roads leading to this great centre of traffic in South London; at each corner a large ornamental lamp has been placed. The water gushes from a marble couch, placed on a slab of red polished granite, a buttress of which projects on a level with the capitals of the two front columns. On the opposite side or back there is a small reservoir cut into the stone between two columns, for the benefit of horses or other animals. The structure is coped in the form of a flattened spire, with a projecting cornice, surmounted with a bell-shaped ornamental vase.—Mr. Bryson, town surveyor of Newcastle, according to the *Township Observer*, has presented a report to the Gateshead Improvement Committee, in which he says of the Newcastle fountains,—“Some additional public drinking-fountains have been erected during the last year, at the Leazes, Earl Grey's Monument, Neville-street, and the Parade-ground; the first two of which are supplied with spring water, the others from the Whittle Dean. The expenses of the three latter fountains are to be defrayed by Messrs. Dunn & Co., of this town. A well also has been sunk, and a pump erected, at Albert-street, Shieldfield. Drinking cups for the accommodation of the public have been fixed to all the public wells, pumps, and fountains throughout the borough. Another offer of a fountain has been made by a lady, to be erected at the Baths, Gallowgate. The erection will shortly be proceeded with.” Another fountain is in progress in St. Nicholas square, in front of the new Town-hall, on which a large and brilliant lamp is to be fixed by the Gas Company.”—At the quarterly meeting of the Bath Licensed Victuallers' Association held last week at Amery's Hotel, the tender of Mr. Treasure, marble mason, was accepted for the public drinking-fountain which it is proposed to erect in Fountain-buildings jointly by the Licensed Victuallers' Association and the Society for the Prevention of Cruelty to Animals. The fountain will be completed by the 1st of March, from the designs of Mr. C. J. Phipps, architect. It will afford accommodation

for cattle and dogs as well as for the public. The design is Early Gothic, built of Bath stone, with basins, pillar, &c., of marble; and Minton's tiles are used for inscriptions. The height is about 11 feet, surmounted by an ornamental wrought-iron finial.

THE MAUSOLEUM AT HALICARNASSUS.

In replying to Mr. Pullan's letter, which appeared in the last number of the *Builder*, with reference to my proposed restoration of the Mausoleum at Halicarnassus, I can only express my regret that he is unable to see what is so perfectly obvious to every one else.

Mr. Newton has no hesitation in recognizing both the 9-inch and the 6-inch stones, as roofing-stones.

The authorities at the British Museum are equally decided about the first, as they have brought it out of the court-yard and built it up with and upon the other roofing-stones in the corridor under the portico.

As far as my own eyes serve me, I can see both the "groove and the ridge" in the 9-inch stone. Though, as I admitted in my letter, the ridge is absent from the other, still its dimensions, the weathering, and the position of the clamps, besides other characteristics, make out a strong case in its favour. But its testimony is not needed. The existence of one roofing-stone, of a different dimension from those originally found, is sufficient to demonstrate that the pyramid was not straight-lined.

As far as I, individually, can judge of the facts of the case, even this corroboration was not wanted.

The words of Pliny, and the exigencies of the construction as disclosed by the excavations, seem to me to demand imperatively a curvilinear form of roof as the only possible solution of the problem, though it is probable that without the existence of these stones it might have been difficult to make this as clear to others as it is apparent to myself. Now that they are found, I cannot understand how any one should doubt it.

If, however, Mr. Pullan is determined not to see these facts and to overlook these difficulties, it is to be feared that the work which he is editing for Mr. Newton will be as little creditable to himself as to the trustees of the British Museum, under whose patronage and at whose expense it is about to be published. JAMES FERGUSON.

THAMES MUD.

It is no new subject—the Thames mud. We are going ahead in the right direction, in making the sewers independent of the Thames. Cannot we add to this step that most desirable project, the removal of the accumulation of mud-hanks which abound between the bridges. I believe that the value of the mud would more than pay for the trouble, and carriage down the river. The main cost would be loading and unloading barges; the tide would do the rest. The mud, accumulated at different points below London, would prove a cheap and valuable manure; and, if allowed time to drain, its weight would be much reduced for carting. It is not right that this article should be allowed to remain a tyrant nuisance instead of a useful servant to the public.

PROGRESS.

THE ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

PERHAPS you will allow me to make a few suggestions which I think may be of benefit to the subscribers. Your correspondent, "A Photographer and a Local Honorary Secretary to the Association," makes some very sensible remarks, but I do not quite concur in all that he says. I admit that Mr. Bedford's pictures in the exhibition last year were second to none; but, nevertheless, I would advise that other photographers should be allowed to compete in the matters both of price and excellence.

I think that it might be arranged something in this way:—The committee should invite a number of first-rate photographers to send untouched prints from untouched negatives, as specimens, and also a scale of prices at which they would be willing to take various-sized negatives, equal in execution to the specimens sent, which specimens and prices should be subjected to the criticism of a sub-committee of the subscribers, having, as your correspondent suggests, a "knowledge of practical photography," who would recommend to the committee the acceptance of certain tenders.

With regard to printing the positives, I think

that the Association ought to have it as much as possible in their own hands, for every photographer knows that a good negative operator does not necessarily possess taste and manipulative skill in the printing department; therefore I would strongly recommend the committee to get specimens and prices, in the same way as for negatives, from eminent photographic printers, who should guarantee that every print would be toned with *alkaline chloride of gold* only, and *thoroughly washed*, so as to ensure against fading. Or the committee might, I should think, make some arrangement to get their negatives printed at the Royal Engineer establishment at Woolwich or Southampton at a very low rate. The beauty of the pictures printed by the non-commissioned officers of this corps, and their economy in execution, being evident to every one from the specimens at South Kensington and the list of prices recently issued.

By some such arrangements as these the committee would get perfect negatives from various buildings of their own selection (in this I do not agree with your correspondent, as I think that the diverse tastes of subscribers should in a certain measure be consulted, some preferring Classic, others Gothic subjects, &c.); the sizes of pictures and points of view being also under the direction of the committee. These considerations are very important, as there is many an excellent photographer who has no architectural eye. In addition to these advantages the subscribers would get prints of equal tone and beauty, all the negatives being printed at the same establishment, and I think they would be universally pleased.

AN ARCHITECT, AMATEUR PHOTOGRAPHER,  
AND LOCAL HONORARY SECRETARY TO  
THE ASSOCIATION.

#### SPECULATIVE BUILDINGS.

SIR,—Pray send one of your staff to inspect the houses now in course of erection in, and adjoining the—road, Holloway, the heaps upon heaps of old broken bricks (used up in party walls, &c.), the vile scumpling building of these houses, will even astonish you, who have often tried to warn and protect the public against "run-up houses." For a seven-roomed house, for ninety years, at 57, ground-rent, the price is 2257. You see how heavy a purchase money is demanded for houses to appearance not likely to stand upright (when we see them shored up while still in carcass) for five years unless underpinned. It seems to me such a fraud should not be allowed to exist. Give a thought to the poor widow, who, probably, invests her little all in one of these rotten erections, the almost unceasing outlay for repairs, and the constant complaints of tenants. Again, how unjust it is to the fair-dealing builder who employs skilled workmen and uses new sound materials.

Once more let me urge upon you to expose speculative building frauds: I am sure, you will confer a benefit in many ways.

I have noticed also at Dalston, near Hackney, a large quantity of old building materials.

#### "OLD MATERIALS."

P.S. I shall have my eye on other parts of the suburbs, wherever I see old rotten materials and scumpling unskilled labour, and immediately call your attention to the locality.

#### SAFETY IN SKATING.

HAVING for many years heard of the frequent disasters occurring at this period of the year in the various waters in the parks of your city (and some of very recent date), while enjoying the healthful recreation of skating, I had resolved, from year to year, and as often neglected, suggesting a plan by which I am of opinion nine-tenths of the lives and limbs so sacrificed might have been saved. Along each side of the edge of the water, and opposite each other, I would drive piles, say 6 inches square, flush with the surface of the ground, at about 30 inches apart (or at greater distances by substituting a waling-piece), with a hole bored through each. Between these piles and the cross in shortest way of the water, I would stretch tight with screws a wire rope of copper or galvanized iron, and fill the same in between with strong wire netting, threading the rope through the two edges of the netting (before stretching), to support the same. You would then have a perfect platform below the ice, and a person breaking in could take no harm.

I am not certain as to whether it would not be better to let the netting freeze in with the under surface of the ice, as a means of strengthening

the same. The netting and rope could be easily fixed and removed at the beginning and end of the season.

WILLIAM CROZIER, C.E.,  
County Surveyor, Durlham.

#### ON THE RECLAMATION OF THE GODWIN SANDS.

THE recent lamentable destruction of the *Blerrie Castle*, the countless spires thrashed to atoms on the Godwin Sands, suggest to the pondering mind whether something might not be done. For generations, the waves lashed the Eddystone and the Bellrock; but now, colossal watch-towers shed their beacon-rays afar. See what the Dutch have done to exclude the wild waters of the German Ocean. If it be true, as tradition seems to warrant, that this was once dry land, could not British skill and enterprise rescue it from the watery waste again. I conceive that it might and should be done; and not only this, but that all shoals and sunken rocks, so far as possible, should be reclaimed, or at least buoyed off or lighted, so as to diminish, so far as may be, the perils of the deep.

HENRY McCORMAC, M.D.

#### THE BELL CASE.

MRS. DENISON.  
THIS notable case came before Mr. Lush, Q.C., as assessor of damages, and a special jury, in the Secondaries' Court, on the 30th ult., when Mr. Bovill, Q.C., addressed the court on the part of Mr. Mears, stating the case, and commenting with some severity on Mr. Denison's conduct in the matter.

The charge brought by the defendant against Mr. Mears, he said, was not merely that he made an insufficient casting of the great Westminster bell, but that he knew it was insufficient, and yet allowed it to be placed in the tower at Westminster; that there were holes in the casting, which made the bell crack; that he had fraudulently endeavoured to conceal these holes, by stopping them up with a mineral substance, and then washed the bell over with colouring matter, the better to carry out the deception and to impose on Mr. Denison (the defendant) and Professor Taylor, with whom the approval of the bell lay. That was the nature of the libel published by the defendant in the *Times* newspaper. Mr. Denison had himself made great mistakes and these were probably the true causes which had led to the destruction of the bell. He had for the first time introduced a new proportion of metals, making it 22 of copper to 7 of tin. The effect was to make the metal more brittle. It could, by the addition of tin to it, be made nearly as brittle as glass. Now, Mr. Denison made it part of the contract that the old metal, which had the proportion of 22 parts of copper to 7 of tin, should be taken for the new bell, and that any additional metal which might be required should bear the same proportions. This was contrary to Mr. Mears's advice, who knew that the effect would be to make the metal more brittle than that used in other bells, but Mr. Denison insisted on his theory being carried out. Mr. Denison, notwithstanding repeated warnings, resolved that a mass of solid iron, 7½ cwt. in weight, should be used, not as a clapper, but as a hammer, and be adjusted this so as to have a fall of 13 inches on the sound-bow of the bell. Now, he asked the jury to mark the force with which this hammer would fall. In the manner in which it was adjusted it was equal to a force of 1,000 lbs. weight upon the bell. No such weight had ever before been applied to any bell, but this was the result of Mr. Denison's theoretical knowledge. Though warned by Mr. Mears and by the clerk of the works, Mr. Denison, conscious of his own experimental knowledge, and full of the theories he had propounded in books and otherwise, determined to use this enormous hammer. It was used as he had described: 7½ cwt. of iron, turned by the clerk, and accelerated by a fall of 13 inches, was directed against the bell, and cracked it.

Mr. Knowles, Q.C., for the defendant, asked his lordship whether he did not think that the time had come when this case might be brought to a close and an inquiry be saved, which, if begun, must last for some days? He would not enlarge Mr. Denison's conduct; but he had withdrawn the charges. Money, he was sure, was not Mr. Mears's object. His only object was to stand well with the world, and that object he had fully attained. Ultimately the following terms were agreed to:—

The jury to be discharged from giving a verdict. The defendant retracts all the charges and imputations made upon the plaintiff; the defendant to

pay the plaintiff all the costs, charges, and expenses which he has incurred or been put to in consequence of the libel, including legal expenses as between attorney and client, from the time of the publication of the libel, and the expenses of engineers, scientific witnesses, and others in preparing for the trial, though not usually allowed in taxation, including expenses of models and plans, and the journey of two engineers to Oxford. In case of dispute in carrying out these terms the whole to be decided by Mr. Lush upon the principle of full indemnity to the plaintiff. On the performance of these terms all further proceedings to be stayed.

#### THE DRAINAGE OF BRIGHTON.

SIR,—As you have honoured me with your notice in a leading article of the *Builder* of the 24th instant, relating to the Brighton sewerage, I shall be obliged if you will permit me to inform your readers that there is no "mistake" in my estimate; that the nature of the soil and the inclination of the ground on which Brighton stands afford almost unequalled facilities for cheap and efficient drainage; and that I have been fortunate enough to carry out other similar undertakings on a like scale of expense.

T. HAWKSELEY.

#### LORD PALMERSTON ON LABOURERS' COTTAGES.

LORD PALMERSTON, at Romney "Labourers' Encouragement Association," in the course of the proceedings, said:—

Mr. Dutton and myself have built some very good double cottages for the labourers on our own respective properties, but I have heard it said by many that it is all very well for us to do that, but that these buildings are altogether too expensive, that they do not pay, and that other people could not afford to erect them. Now, in the first place, I hold that observation to be founded on a fundamental error. When I build a cottage for a labourer on a farm I do not expect it to pay in money. When I build a good farm-house for a tenant I do not expect rent for that house separate from the farm. Well, the cottage for the labourer ought to be looked upon as a part of the appurtenances of a farm just as much as the buildings for cattle, or any of those other erections essential to the cultivation of the land. How can the land be well cultivated if the labourers are not well housed? If they are obliged to travel three or four miles in order to get at their work, and the same distance home again? It is manifest that they must be not only exhausted physically, but that their time must be wasted in walking to and from their work, and that the farmer does not get from them his money's worth for the wages he pays. Therefore I consider that in providing a farm with accommodation for the number of labourers to be employed on it you are giving facilities to the tenant to cultivate his farm, and increasing the value of the farm which you let to a good tenant. If you get a shilling a-week from the labourer, it is more to impress upon his mind that he is earning the accommodation you give him rather than from any idea that it is to repay the expense of the erection. Then, as to the expense of these cottages. Now, the cottages which Mr. Dutton and myself have built contain really no more accommodation than a decent family ought to have. They have simply one room to live in, a back kitchen, and, what is of the utmost importance, three sleeping-rooms. No cottage ought to have without three sleeping-places,—one for the man and his wife, another for the girls, and another for the boys. It is not necessary to pull down old cottages to build new ones. A great deal can be done at a moderate expense in improving old ones. All you require is to put a little porch in front of the door, which costs little; to give them a boarded floor instead of bricks; to make the walls air-tight and the roof water-tight; to give three sleeping-rooms, and to put up a sort of shelving at the back, with a little place below for a wood-house. The effect of improving these dwellings is almost marvellous. In the first place, you know that the comfort of a man's house depends upon the tidiness of his wife and the mode in which she tries to make him comfortable; but there is a temper of the human mind which is denominated recklessness. When a thing seems impossible, it is given up in despair. When a cottage is in such a runshackle state that it is impossible for the wife to keep it clean, she becomes a sattern, everything goes to ruin, the man is disgusted, and flies to the beer-shop. If, on the con-

rary, the wife feels that she can, by a little exertion, make the cottage decent and respectable, she does so.

**Books Received.**

*Historical Sketch of the Church or Master of Lyminge.* By ROBERT C. JENKINS, M.A. London: Simpkin & Marshall. 1859.

THIS account of the ancient church of St. Mary and St. Eadbury, in Lyminge, though including less architectural description of the structure than we desire, is a superior guide-book. We wish every parish church in the country had a similarly good historian. The author says,—

"There can be no doubt that Lyminge formed one of the Roman stations between Durovernum (Canterbury), and the Portus Lemnis (Lyminge), the site of the ancient park at Lyminge being about halfway between them. The fact that this was an ancient residence of the Saxon kings, who uniformly (as at Reculver, Canterbury, &c.) Roman bricks and masses of a reddish concrete, identical with that found in the Roman Pharos at Dover, are built into and imbedded in the yellow Saxon mortar of the church, and in such of the walls of the monastery as have been hitherto uncovered, while fragments of the same pottery are dug up frequently on the same site. The Court Lodge-green, adjoining the churchyard, is covered with irregular mounds, either concealing Roman remains, or marking the spots from which the Roman fragments in the church were taken."

**VARIORUM.**

An excellent suggestion is made in a tract, titled "Barrack Canteens, as they were; as they are; and as they ought to be: by Common Sense." It is proposed to place the barrack canteens under a departmental system of management, the establishments to be let by public competition triennially, for the provision of articles of the best description, at current market prices, for behoof of the soldiers; the proceeds to form a fund to be called the Canteen Fund, at the disposal of the Secretary at War, in conjunction with the General Commanding-in-Chief, and to be expended in providing for the soldiers those amusements and recreations, within the barrack boundary, which are not strictly barrack requirements; such as lecture-rooms, theatres, gymnasiums, fencing-rooms, rifle-galleries, bowling-green, skittle-alleys, quoits, &c. It appears that the sum which would probably be realized from such a system of management, is no less than 80,000*l.* per annum. This is well known from past experience as to privilege money, which it is thus proposed to reimpose, but with new objects in view, namely the recreation and general benefit of the soldier.—In a printed "Letter" to the Home Secretary, On the Supply of Gas in the Metropolis (King, Bolt-court, Fleet-street, publisher), Mr. T. G. Barlow, C.E., proposes the formation of one great amalgamated gas company, under certain regulations and restrictions, by Act of Parliament, as to maximum price, and minimum quality of gas, &c., for the supply of the metropolis, exclusive of the suburban companies, who are already under the provisions of the Gas Works Clauses Act, 1847. This project Mr. Barlow works as a solution of difficulties.—The Sixth Annual Report of the Boys' Refuge, Commercial-street, Whitechapel, shows that this useful institution is in a prosperous condition. Of 100 boys in the Refuge, 27 are learning to be carpenters, 28 shoemakers, 27 tailors, 11 wood-choppers, &c. They have an instrumental band, and are taught music and military drill. Good conduct and industrial stripes on the jacket form an object of ambition to the young candidates, and are highly prized when attained.

**Miscellaneous.**

**RENDING OF IRON GIRDERS FROM CONTRACTION BY FROST.**—The huge iron hoops or girders surrounding a large tank, containing gas, in the yard of the Hibernian Gas Works, at Dublin, burst with a loud explosion, owing to the extreme expansion upon them, produced by the continuous severity of the late frost. The thousands of gallons of tar thus liberated flooded the entire yard, extended to where the retort furnaces were at work, immediately ignited, and the gas was set on fire in all the receivers before the fire was got completely under.

\* Since writing the above, my conjectures have been verified by the discovery, at a few feet from the south wall of the church, of about 20 feet of the foundations of a Roman wall, built almost wholly of brick and concrete.

**STAIR-RODS AND SOCKETS.**—A patent, dated 10th June, 1859, has been taken out by Messrs. G. J. Farmer, Birmingham, and G. P. Hardy, Brompton, for "stair-rods and eyes or sockets, also applicable for other purposes." This invention relates to improvements and various different formations of these articles. The several improvements are also applicable for hanging pictures and straining table-covers.

**COMPOSITION FOR SPLITTING ROCK.**—Mr. Detrets, of Marseilles, proposes to employ as a composition for splitting rock a compound of nitrate of soda, spent tan, and powdered sulphur, in the proportion of 52½ parts of the soda, 27½ parts of the tan, and 20 parts of the sulphur. The nitrate of soda is dissolved in a sufficient quantity of water, over a fire, and boiled; the tan is then mixed with the solution, until every portion is impregnated with it, and then the sulphur in the same manner. The whole is then dried, inclosed in bags, and is ready for immediate use.

**THREE-BRIDGES, SUSSEX.—FALL OF A BRIDGE.**—Consequent on the Horsham junction running into Three-Bridges, it is imperatively necessary to double the width of the bridge contiguous to the Fox Inn. The new division was so far completed as to warrant the removal of the centres on the 24th, when, unfortunately, towards the evening, the span over the road came down with a tremendous crash. Fortunately, although several pedestrians and vehicles were passing and repassing, they escaped by a few seconds.

**STEAM HAMMER FOR WOOLWICH ARSENAL.**—A steam hammer, to be used in forging the Armstrong gun, is in course of construction at the works of Messrs. R. Morrison & Co., of Newcastle-on-Tyne. The hammer-bar and face weigh four tons, and the cylinder in which this bar works, with its glands, within a few cwt. of six tons. The cylinder is supported on two frames, each of nine tons, and each of these again rests on a hot plate of the same weight. Through these hot plates projects the anvil, which is a mass of wrought iron, faced with steel, and embedded in an immense block of cast iron, weighing upwards of twenty-one tons. Morrison's hammer can be worked with great diversity of power. In regard to speed of working, also, it possesses capabilities which seem to adapt it to almost every variety of work, for it can either be made to descend like the heavy sledge, "with measured beat and slow," or to deliver from 200 to 300 strokes a minute.

**LEAD PIPE MACHINERY.**—The nature of this invention, by Mr. Robert Wilson, of Patricroft, near Manchester, consists in a combination of hydraulic machinery for forcing lead or other metal through dies in the form of rods, tubes, sheets, or of any other required form or section; also in an improved mode of constructing the metal container employed in such machinery. Another part of the invention consists in the application of a self-acting apparatus to hydraulic machinery, by means whereof the motive power ceases to increase the pressure beyond a given limit; also in applying to hydraulic machinery an apparatus commonly called a "cataract," by means whereof the sudden starting of such machinery is avoided. The *Engineer* of 30th December gives details of the invention, illustrated by engravings.

**BUILDING ACCIDENTS.**—At Worcester Corn Exchange the other day a piece of cornice fell, and severely injured two persons, one of whom has since died. A coroner's jury found a verdict of accidental death, attributing the fall to the recent state of the weather.—At the Deritend Brewery, in Alcester-street and Moseley-street, Birmingham, the company were adding to the brewery an extensive range of building for malting purposes, and the work, which was entrusted to Mr. Hardwick, builder, was nearly finished. In the interior were a number of arches. Fifteen workmen were employed by gas-light in various parts of the building, when the entire range of arches supporting the second floor suddenly fell in. The weight of the material which fell caused a portion of the first floor to yield to the pressure, and the interior of the building now presents the appearance of a complete wreck. Fortunately no lives were lost, although but few of the workmen escaped without some injury. The accident is attributed to the late frost, and the heavy rain which followed.—Three of the cast-iron columns which support a roadway fronting warehouses at St. Katherine's Dock have burst with a loud report. The columns have become partially filled with water, which entered at the top, and there being no outlet, the frost must have caused the explosion while the water was crystallizing into ice, which occupies more space than the water of which it is composed.

**ARTISTS' AND AMATEURS' SOCIETY.**—The meetings of this pleasant Association, at Willis's Rooms, St. James's, are fixed for Thursdays, February 2nd, March 1st, March 29th, and May 3rd. Some of our readers, wishing to have a few inexpensive and agreeable evenings, may be glad to know that H. Candell, esq., of the London and Westminster Bank, Stratford-place, Oxford-street, is the treasurer, and would give any information that might be wished.

**STONE-TRIMMING MACHINE.**—M. Bataille proposes to cut rough stones into the shape required by builders, by means of an apparatus like a great pair of sugar-nippers, fixed to a frame provided with a mechanism enabling the stones to be moved as the process requires. In its present condition this machine is not adapted to work hard stones, but it is possible it might be modified so as to accomplish this task.

**THE SEVERN BRIDGE OF THE WORCESTER AND HEREFORD RAILWAY.**—From its completion to the present day, some three or four months since, this bridge has been available only for coal and goods traffic, by reason of the Board of Trade inspector, Colonel Yolland, refusing to certify that it was in a condition to be used with safety for passenger trains. Mr. Liddell, the chief engineer of the line, has been engaged in some important engineering work abroad for the last twelve months, and at a distance to preclude them from obtaining his counsel and advice as to the course best to be taken in their dilemma. Thus situated, they have had recourse, says the *Worcester Herald*, to the services of Mr. Hawkshaw, civil engineer; and that gentleman, having minutely inspected the bridge, and examined into objections made to it by Colonel Yolland, has, as we understand, reported to the Board his opinion to be that these objections are too well founded. As respects the centre pier, Mr. Hawkshaw, we believe, condemns it altogether, and considers that there is no remedy for its defects and insecurity but its entire removal and re-construction; whilst, as to the ironwork of the arches, he says, increased strength and rigidity must be obtained by means of more struts and braces. The estimated cost of these alterations and re-construction of the pier is 3,000*l.* Whilst in progress, Mr. Hawkshaw has suggested to the Board a plan by which the arches may be supported by timber erections, so that the traffic will not be interrupted, and we believe the works will be commenced with very little delay. We are told, adds our authority, that the contractors for the bridge, Messrs. Brassey & Co., are regarded to be free from any responsibility for it, having strictly followed the engineer's plans, and executed the work throughout according to the stipulations and contracts upon which they undertook it. The tunnels, both at Malvern and Ledbury, are said to be now making satisfactory progress. Hitherto by the works at both places have been carried on by the company's own staff of artificers, but recently they have been let by contract to Mr. Knowles.

**THE STABLES AT THE LOUVRE.**—The *Sport* gives details of the arrangement of the new Imperial stables at the Louvre.—"The buildings have the form of an oblong square, divided into two courts, one called the Cour Caillecourt and the other the Cour Visconti. The two sides run parallel to the river. On the left of the Cour Caillecourt is the first stable, divided into fourteen stalls for saddle-horses. Adjoining is a second, which contains ten boxes and a place for washing. The architectural character and decoration correspond with that of the other parts of the building, and the ornamentation is in the Italian style. From the ceiling are suspended gas lamps, and cocks supply the quantity of water required for use. The gallery into which the visitor enters, after passing the washing-place, is about 300 feet long by 14 feet wide. It has a row of stalls on either side, and accommodates eighty-two horses. When lighted up with gas at night the effect is exceedingly striking. The ground-floor of the two other sides of the parallelogram is fitted up as coach-houses, harness-rooms, and other offices. In the coach-house on the east side, in the Cour Visconti, are twelve ordinary state carriages, and on the west side fifty of different kinds. Over these ground-floors are apartments for the grooms, postillions, and stable-boys, and other persons connected with the department. The new stables, which are to be built on the Quai d'Orsay, facing the Pont d'Alma, will be capable of receiving 300 horses, and will contain those of the Empress, the Prince Imperial, and the reserve of his Majesty. The stables of the Louvre, which were begun by M. Visconti, were completed by M. Lefuel."

**SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.**—The opening soirée for the year 1860 is to take place in the Suffolk-street Gallery, containing Mr. H. Wallis's collection of modern pictures, on Thursday evening, January 26th, on which occasion the Vocal Association will give a performance of madrigals and part-songs.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The sixth meeting of the present session was held on Wednesday night, the 28th ult., in the Royal Institution, Colquhoun-street, Mr. T. D. Barry presiding. After the transaction of some routine business, a paper was read by Mr. G. A. Andsley, on "Colour as applied to Ecclesiastical Decorations, and the History and Practice of that Art."

**LECTURE ARRANGEMENTS AT THE "SOUTH KENSINGTON" MUSEUM.**—Lectures on the Art Collection will be given by Mr. R. H. S. Smith, Mr. Robinson, and by Professor Knikel, on Tuesday evenings, up to the 21th of January. A course of lectures on subjects connected with the Architectural Museum, as arranged by the committee, will be given on alternate Wednesday evenings, up to the 4th of April. These lectures will be delivered by Sir Walter James, Mr. G. Godwin, Mr. W. White, Mr. E. B. Denison, Mr. John Bell, and Mr. J. H. S. Smith. Dr. Lankester will also continue his lectures on Food. A course of lectures is also in preparation on the Science Examinations. These will be delivered by the examiners appointed by the Committee of Council on Education.

**REMEDY FOR THE IRREGULARITIES IN THE FLAME OF GAS STVES.**—Place a piece of silk over the end of the pipe, and screw the burner over it. The silk will last a long time, can be easily replaced, and answers the same purpose as the regulating burners so much in use.—*Bristol Mirror.*

**WINDMORHILL SCHOOLS.**—These schools are at length completed. The exterior is faced with red brick, with Bath-stone dressings to the windows, doors, &c. There is a master's house adjoining the schools and facing the road, with the usual accommodation. The roofs are covered with slates, and show open timbers stained, in the interior. There are three school rooms (the style of which is Early Gothic), for boys, girls, and infants respectively, with a class-room to each; also, entrance lobbies for the reception of hats, cloaks, &c., having lavatories. The boys' and girls' schools are separated by a sliding partition, which can be thrown open when required for lectures, &c. The boundary-wall is built of brick, with stone coping and ornamental iron railing; and the part where the gates are situated is circular. The whole has been erected from the designs and under the superintendance of Mr. C. H. Edwards, of London, by Messrs. Peard & Co., of Islington.

**STREET DECORATION.**—In some of the London districts this season, an attempt has been made to exhibit the effigy of "Father Christmas," accompanied by music and lights in the streets. It must be confessed that the arrangements were not managed with much taste. A colossal figure of snowy whiteness, with flowing beard, crowned with ivy and evergreens, was mounted on a car. In front of this effigy was a table, on which were spread a huge piece of pasteboard beef, plum-puddings, and bottles formed of the same materials: a naphtha lamp, such as those used by the costermongers, illuminated the upper part of the figure. Another shone brightly on the table. The whole was drawn by a donkey, surrounded by a noisy crowd, drums beating, and other loud music. Notwithstanding the artistic imperfections of this attempt, we could not but think, with a little more taste, a picturesque affair might be made of a gaudy and artificially devised figure of Christmas, accompanied by pageants, maskers, and better minstrelsy. Such a pageant in the evening time at Christmas, if properly managed, would well repay those who might undertake to carry it out. The people must have amusement, and it should be refined as far as practicable.

**THE ART LIBRARY AT BROMPTON.**—Sir: Doubtless you are aware of the removal of the Art Library into one of the rooms underneath the Turner Collection. The accommodation, both with regard to time and place, is far worse than it has ever been before; and it shows a want of thoughtfulness on the part of the managers, in not studying the convenience of the visitors to the library a little more. I need not say what a boon such a library is to the art student. But what is most extraordinary is, that this library is closed just at the time when the student is at liberty, viz., from four to seven p.m., on account of the entrance to the said library being right through the Museum. Surely this might be remedied.

A STUDENT.

**SOUTH KENSINGTON MUSEUM.**—Christmas week. The visitors on the free days were 17,415; free evenings, 9,332; total, 26,747; from the opening of the Museum, 1,190,915.

**AN EPISCOPALIAN CHURCH FOR LEITH.**—The late Mr. W. Moodie, wine merchant, Leith, left 4,000*l.* towards the erection of an Episcopalian church in Leith; and two members of the Leith congregation have placed a like sum at the disposal of the managers for the erection of the church and parsonage.

**A THREE-ACRE BUILDING.**—A building is in course of erection in Peoria, Illinois, which, when completed, will cover three acres of land, under one roof. It is intended for the manufacture of pottery ware.

**THE SUBMARINE CABLE BETWEEN LIVERPOOL AND BIRKENHEAD.**—The submarine cable has been laid between the south landing-stage and Wood-side slip. The operation was successfully performed under the superintendance of Mr. J. S. Gibbons, electrician of the Mersey Docks and Harbour board.

**PROPOSED MEMORIAL AT SOUTHAMPTON TO DR. ISAAC WATTS.**—The sub-committee, formed to promote the erection of a monument to Dr. I. Watts, in his native town, have provisionally approved of Mr. Lucas's design of a statue and pedestal, 18 feet 6 inches high, of Bilsow stone, at a cost of 450*l.* The subscriptions at present amount to 361*l.* The committee have also suggested that the statue be erected in the West Marlands-park.

**IMPROVEMENTS IN PARIS.**—Workmen have just terminated, in the neighbourhood of the Panorama lately built in the Champs-Élysées, the plantation of the trees and shrubs to complete the transformation into a garden, in the English style, of the left side, near the Palais de l'Industrie. The Panorama opposite the Cirque, which, with its dependencies, covers a surface of 1,750 square yards, is also terminated. The canvas round the interior, and on which artists are engaged in reproducing the principal episodes of the war in the Crimea, has a superficies of 1,680 yards.

**THE SCOTTISH ANTIQUARIAN MUSEUM.**—A *conversazione* of the Scottish Society of Antiquarians was held at Edinburgh for the purpose of inaugurating the National Antiquarian Museum in the building of the Royal Institution. Lord Neaves made a speech, in the course of which he noticed the addition made to the Egyptian antiquities by the valuable relics from Thebes, recently contributed by Mr. Rhind, and which were dug out under his personal superintendance during a residence of two winters in the country.

**OPENING OF THE HAMSTEAD JUNCTION RAILWAY.**—This new line, which will bring the healthy and picturesque districts of Hampstead Heath and Finchley within half-an-hour's ride or so of the City and the north and east end of London, is now open for passenger traffic. The line, which is six miles in length, commences by a junction with the North London Railway near the Camden-town station, and terminates by a junction with the New and Acton Railway at Willsons. The principal work on the line is a tunnel three-quarters of a mile in length, perfectly straight, which passes under a portion of Hampstead-heath. There are four stations, viz. Kentish-town, Hampstead-heath, Finchley-road, and Edgware. Twenty-three trains are announced to run to and from Fenchurch-street each way in the course of the day.

**THE ASTRONOMY OF THE ANCIENTS.**—Professor Mitchell, in his lectures on astronomy, stated that he had not long since met, in the city of St. Louis, Missouri, a man of great scientific attainments who, for forty years, had been engaged in Egypt deciphering the hieroglyphics of the ancients. This gentleman had stated to him that he had lately unravelled the inscriptions upon the coffin of a mummy, now in the British Museum, and that, by the aid of previous observation, he had discovered the key to all the astronomical knowledge of the Egyptians. The zodiac, with the exact position of the planets, was delineated on the coffin, and the date to which they pointed was the autumnal equinox in the year 1722 before Christ, or nearly 3,600 years ago. Professor Mitchell employed his assistants to ascertain the exact position of the heavenly bodies belonging to our solar system on the equinox of that year (1722 B.C.), and send him a correct diagram of them, without having communicated his object in doing so. In compliance with this the calculations were made; and, to his astonishment, on comparing the result with the statements of his scientific friend already referred to, it was found that, on the 7th of October, 1722, B.C., the moon and planets had occupied the exact positions in the heavens marked upon the coffin in the British Museum.

**THAMES TUNNEL.**—The Christmas visitors to the tunnel have been numerous. During the week ending 31st December, 23,339 passengers have passed through, and paid 97*l.* 4*s.* 11*d.* in tolls.

**ROYAL INSTITUTE OF BRITISH ARCHITECTS.**—At the next ordinary general meeting to be held on the 9th of January, the following papers will be read:—"Sixty Years Since, or Improvements in Building Materials and Construction during the present Century," by Mr. G. R. Burnett; and "On the Use of Zinc in Roofs, and the Causes of Failure therein," by Mr. James Edmeston. A special general meeting of members only will be held on Monday evening, January 16th, to elect a president in the place of the Earl de Grey, deceased. Also, to consider the reply from the Royal Academy of Arts, London, and to take such steps thereon as may appear necessary.

**THE MECHANICAL DRAUGHTSMEN.**—Of mere copyists there are hundreds too many. Although mechanical drawing may be an art by itself, and without an eminent draughtsman may be always sure of employment, the demand for mere drawing is limited, and really excellent draughtsmen have always been scarce. The gentlemanly nature of the employment is attractive, no doubt, and it is to this circumstance that we must attribute the brisk trade of the drawing-instrument and water-colour dealers. Perseverance will do much; but if mere adventurers in drawing, who would be draughtsmen because they would like an easy, irresponsible employment, were to examine a portfolio of really first-class drawings—such as those of the Great Eastern in Mr. Scott Russell's office,—they might conclude they were missing their vocation, and determine upon looking up something else in which the probabilities of success would be more in their favour. A young man with only sufficient capacity to become a third-rate draughtsman should have very moderate wishes, for he can never command either the respect or salary which would satisfy a gentleman. But if there is more in him than a faculty for mere ink marking and colour daubing, let him develop himself by all means. Above all, let him devote himself to the design of mechanism in its simplest forms. The rough machinery and appliances of railway drainage and building contractors often require more real skill and accurate knowledge of mechanical forces and proportion than would serve in designing machinery in which a surplus of material may cover up serious blunders. A passable knowledge of dynamics, a habit of estimating strains, weights, and quantities, a little tact in ascertaining the prices of work, together with moderate powers of observation and a fair judgment, would enable many a plodding draughtsman to become a successful engineer.—*The Engineer.*

# The Builder.

VOL. XVIII.—No. 884.

## The Repairs of the "Hanging Ruins" at Lindisfarne.

IF E counties of Northumberland and North Durham, so often pillaged, and ravaged by fire and sword, are, as may be supposed, pre-eminently rich in ruins. These are not confined to any particular period. There are the deserted and silent camps of the ancient Britons,—bleak places out on hill tops with sweeping command over miles of the neighbouring country; buried Roman cities; the great solemn Roman wall; border castles, Norman and Edwardian; peel towers; and religious edifices of various descriptions. In the foreground of

these, in point of consequence and interest, stand the remains of Lindisfarne Priory, to which attention has been recently drawn in our pages. This sombre and massive pile is built on a semi-island, which is twice a-day cut off from the shore by three miles of ocean-billows; and twice a day left in communication with it across three miles of sea-weed dotted sands. About six miles southwards are the Farne Islands, looking in the distance like so many black-backed monsters of the deep sunning themselves on the surface of the waters. These islands in old times were the scene of many a straightened page in hermit life; and in modern days are more luminous still with the memory of the bright example and heroic bravery of Grace Darling. On the margin of the shore, towering upon a huge basaltic rock, stands Bamborough Castle, the residence, in the days of the Saxon heptarchy, of the kings of Northumbria. The proximity and consequent military protection afforded by this regal fortress are supposed to have influenced Aidan, the first bishop of Lindisfarne, in his choice of this very secluded site; and the great facilities afforded by its frequently inaccessible position for those essentials of monastic life, retirement and contemplation, have also been assigned as reasons for the selection.

King Oswald, the founder of the see of Lindisfarne, is mentioned in terms of the warmest commendation by Venerable Bede. During his reign the land flourished in peace and plenty; and after his death his good influence was enjoyed by his subjects, for he was canonized, and many cures were effected at his tomb. The monks on the island pursued the same pious and actively benevolent career. Their renown speedily became so great, that Ceolwulfus, a successor of King Oswald, resigned his crown to become a monk of Lindisfarne. This prince bestowed so many kingly treasures upon the monastery, and endowed it with such large possessions, "that he seemed rather to resign his kingdom to the church than to his successor. He was doubtless a welcome man to that monastery," continues a quaint authority of King Charles's time, "for, for his sake, it was granted the monks to drink wine and ale, who before were only to drink milk and water." But the chief fame of Lindisfarne is based on the

memory of St. Cuthbert. For twelve years he bore the dignity of priorship, when, leaving all things in order, and a cathedral church, built of wood and thatched with weeds, in full operation, he retired to a hermitage he made for himself on Farne Island. In this seclusion, with no eye for a witness, he is said to have performed miracle after miracle. He touched the rocks, and water flowed forth (singularly enough, more profane mortals at this day find water on digging up a few spadefuls of earth); and the ground brought forth corn without tillage. His sanctity and austerity won him many admirers; and the holy Tuda sent him a stone coffin; and the Abbess of Tynemouth presented him with a linen winding-sheet. On his death-bed he conjured the monks not to leave his remains to the mercy of the fiery Danes; but, in case of invasion and consequent flight, to carry these with them. It was this singular helms that laid the foundation-stone of the immense fortune of the see of Durham. For when the faithful monks opened the saint's coffin, with the intention of placing his bones with their other relics, his body was found to be uncorrupted; and from that time ensued a series of miracles, that drew, for many centuries, kings, queens, nobles, and foreign potentates to his shrine; all of whom vied with each other in the magnificence of their offerings.

The Danish invasion, prophetically anticipated by the saint, soon came to pass; and the monks, having previously piled all their valuables into his coffin, took refuge in flight. The Danes landed: they found nothing but a deserted monastery and an empty church; which they set fire to and retired. The abounding wild fowl must have been left in possession of the island for many years; the seals must have basked on the limpet crusted rocks, watching the green waves tossing their white manes, for many seasons; and the cornuents have reared many generations of their ugly nestlings, with nothing, save the rumble and splashing fall of the breakers as they lashed the island at every tide, to disturb them; for a century and more elapsed before the community was re-established. The wanderings of the monks with their illustrious burden are minutely given by Bede. Suffice it for us to say, that they turned their steps first to Scotland, then attempted to cross to Ireland, but finally settled down at Chester-le-Street, about the time of King Alfred the Great.

After a long repose of 115 years, the saint intimated to the bishop (who was schoolmaster to Edward the Confessor) that he wished to return northwards. Peace having asserted her reign once more, the monks, in accordance with this desire, prepared to return to Lindisfarne. Arriving, after much fatigue and many adventures, at Durham, one of the brethren received a supernatural communication from the saint, to the effect that he decided to remain there. All intentions of continuing their route were immediately abandoned; and a temporary shrine was made of branches and boughs of trees to receive their burden during the erection of a building more in accordance with his miraculous consequence. This circumstance, taken in connection with the exact correspondence of their respective details, links the dates of Lindisfarne Priory and Durham Cathedral. When finally deposited in a marble sepulchre in the latter edifice, the shrine of St. Cuthbert was rendered the most gorgeous of any in the kingdom. His strong aversion to women was humoured to the full, and a particular line in the pavement of the cathedral indicated the distance they were to keep from his remains. At Lindisfarne this exclusion was carried still farther; and a separate church was built expressly for women. He was not so unrelentingly severe on every score, for Reginald, the monk of Durham, writing about the rebuilding of Lindisfarne at this period, tells us that the tired and thirsty country people, piously conveying the stone in wains and carts from Cheswick beach to the island, were regaled with the contents of a cup which was never once replenished by mortal hand!

From the varied items mentioned in the

annual account rolls the Lindisfarne monks were required to send to Durham, we may picture their simple daily life—how they went fishing and brewing, see how much they gave for a new boat, or how much they expended in repairing the malt-house; and we may even learn the number and names of the missals in their scanty library. For more architectural details, Britton, in his "Antiquities" &c., has given three excellent engravings of the priory. But for more recent representation of the island, showing church, priory, and castle, with the silvery light on the wide wet sands, we must look to Fenton's photographs. The fine old "hanging" Norman arch which spans the tower from angle to angle is faithfully rendered, as is that probable mystification of future enthusiastic, but unlearned tourists,—the late reparation.

It is highly commendable on the part of the Commissioners of Woods and Forests to recognize the right Posterity has to have sight of such interesting remains. If Time's corroding hand should be unstayed, Posterity would certainly lose so much of his inheritance, as the delight the contemplation of the works of such remote ages must ever afford; but because of the intangibility of the charm of these treasures, let especial care be taken. The feeling in favour of the strict preservation of every feature and every stone in these legacies from the past is so strong that directly a ruin is touched everybody makes it his business to keep his eye upon it. Attention has lately been called to the rough landing of Lanercost Priory, and the demolition of ancient towers at Alnwick, and it behoves us to plead in time for the more ancient and precious remains on Holy Island. What has already been done there may be briefly described thus:—The inner segmental arch of the decorated window at the east end,—

"That portion of the pile Rebuilt in a later style,"

which

"Showed where the spoiler's hand had been,"

has been rebuilt. It stands out in bare relief against the sky, without the symmetrical outline of an outer pointed arch, or mullions, or tracery, and appears to be an unlovely attempt to repeat the effect of the celebrated hanging ruins over the tower. The intention might have been to conceal tie-rods by which to bind the two side walls together; but the effect produced is certainly an appearance of thrusting the walls outwards. For the rest, composure has been laid on the tops of the walls to keep the rain and damp out, and stray stones, gathered together, and eked out by bran new ones of joiner-like smoothness of finish, have been rebuilt in their old places,—the new stones presenting a painful contrast to the old masonry fretted to honeycomb by "the sea-breeze keen," which—

"Had worn the pillar's carving quaint, And mould'rd in his niche the saint, And rounded with consuming power The jointed angles of each tower."

The fears of our correspondent, respecting the probable roofing in of the building, must be groundless. Many of the pillars are scarcely above ground; and quite one-half of the church would have to be rebuilt. If, therefore, it has taken, as we have been informed, seven or eight hundred pounds to make the slight repairs just enumerated, the cost of re-roofing would be some thousands, and no counterbalancing advantages would be obtained; for the church built contiguous to the priory for women (who, it will be remembered, were not permitted to approach St. Cuthbert's shrine), is still in existence, and in use, as the parish church for the residents on the island. As additional evidence of the unlikelihood of further accommodation being required by the scanty congregation, we may mention, that although this structure is in bad repair, the high pew-pews rotten, and strewn with straw, farmyard fashion, nothing could have been done for it, owing to the poverty of the population (composed for the most part of men who go down to the sea in ships), had not the rural dean received a grant from the Dean and Chapter. With the sum thus obtained, we

are happy to be able to add, it is about to be put in something like decent order.

From the reports in the local papers we glean that the day, on which the northern antiquaries made their pilgrimage to the island, was miserably wet; that the rain fell in torrents; that the only means of conveyance from the railway station to the ferry, a distance of five miles, was, by an undignified, though laughter-moving, jolting along a most unfrequented road, in an uncovered cart. Hence, we must not be considered uncharitable if we come to the conclusion, that the favourable criticisms passed upon the reparations by various members of the society, must have been due to the *couleur de rose* medium through which they made their investigations when seated before the blazing fire, and the substantial luncheon hospitably provided for them at the castle. The wet aspect of the ruins could hardly have conducted to the complimentary opinions formed of the repairs.

It is desirable, now, to leave the venerable pile alone, as far as additions go; to look occasionally to the cement on the tops of the walls, to see whether it is answering the purpose of keeping out the damp; to prevent the grass from growing over the bases of the ruined pillars and fragments of carved stone still strewn about; and to keep tourists from doing further damage,—either in the way of talking away specimens, or of erasing their initials. The last time we visited the island, we waded through the grass, fast fading into hay, to find the fragments of the Saxon cross with its basket-work and sculptured devices. They are invaluable as a link in our short chain of Saxon antiquities. But the long grass would not disclose its secret.

There are men upon the island, officers of the coast-guard and others, who take a proper pride in

"The castle and its battled walls,  
The ancient monastery's halls  
(A solemn huge and dark red pile  
Placed on the margin of the aisle),  
With massive arches broad and round  
That rose alternate row and row  
On ponderous columns short and low,  
Built ere the art was known  
By pointed aisle and shaggy stalk  
The arcades of an alley'd walk  
To emulate in stone."

But good will and commiserate means do not always go hand-in-hand. If the commissioners would set apart a small annual sum, and appoint a permanent custodian, the ruins would be spared any further devastation, and future generations would be secured one of the most interesting historie and archeological studies in our English land.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ordinary meeting was held on Monday last, at the house in Conduit-street, Mr. George Godwin, V.P., in the chair.

Several contributions to the library were announced, and thanks voted to the donors. Mr. F. P. Cockerell, of Carlton-chambers, Regent-street, and Mr. E. B. Keeling, of 3, Upper-terrace, Kingston, were elected associates.

Mr. C. H. Hayward, referring to the recent question raised before the county justices at the Sture Hall, Norwich, mentioned elsewhere in our present number, as to whether an architect was entitled to regard as his own and retain in his possession the plans and drawings prepared at the request of his client (Mr. Welsby, Q.C., having decided, in a case referred to him touching the county surveyor, that he was not), asked whether it was the intention of the Royal Institute of British Architects to take any steps in the matter?

Mr. A. Asplund observed that in a case in which the question was raised by Sir Morton Peto, the eminent contractor, it was decided that the drawings belonged to the architect.

Professor Donaldson was of opinion that, as an architect could not recover commission on the cost of the building at law, but was obliged to charge for the drawings, the drawings prepared to carry out the design were the property of the client employing the architect.

Mr. Jennings was of opinion that where architects were employed to carry out the works they ought not to make a charge for the drawings.

Mr. Charles Barry said he was forced to dissent from the views held by Professor Donaldson and

Mr. Jennings, as he was of opinion that drawings were in all cases the property of the architect.

The Chairman said that, as two papers were to be read that evening, it might be inconvenient to prolong the discussion. The subject was undoubtedly of great importance as regarded the general body of architects and the public, and it was his intention to move that a committee be appointed to take the subject into consideration. He differed altogether from Professor Donaldson, maintaining that the drawings were simply the architect's tools and remained his property. An architect was paid for designing and superintending a building, not for making drawings.

Mr. Robert Kerr said he wished to call attention to the Manchester Academy of Fine Arts. Many years since an academy had been established in London, and subsequently in Dublin; but the requirements of art had increased to such a degree that similar institutions were needed at Liverpool, Birmingham, and Manchester. It was now proposed to establish an academy at Manchester in connection with the Manchester Royal Institution; and, as architecture was not to be excluded, as it had been at Liverpool and Birmingham, he ventured to hope that, if convenient, gentlemen would contribute drawings to the exhibitions whenever they should be held. He was sure that the academy would be conducted with spirit, and in a proper manner, and he hoped it would succeed.

The Chairman said the meeting was indebted to Mr. Kerr for having brought so interesting a subject under their notice, and he willingly supported his request.

Mr. G. R. Burnell then read a paper, entitled "Sixty Years since; or, Improvements in Building Materials and Construction during the present Century," which we have printed in full.

During the reading of the paper, Mr. Burnell took occasion to refer to the disaster which had happened to the *Royal Charter* in October last, in Moeffe Bay, and stated that he had arrived at the conclusion that the vessel broke in pieces because the iron used in her construction was not of the best material, and that she putted from her anchors because the cables were not made of the requisite metal. Having some years ago been brought into connection with the iron trade, and having had opportunities of examining the quality of iron used ten years ago, he was in a position to state that it was immensely superior to that in ordinary use at present. The question was one which materially affected the character of manufacturers; and, with regard to the safety of ships, it was of such paramount importance to the public, that he considered it to be the duty of some constituted authority to interfere actively in the matter.

At the suggestion of the Chairman, it was agreed that the next paper should be read, and that the discussion should be taken upon the two.

Mr. James Edmeston then read some notes on the use of zinc in roofs, and the cause of failure therein, the pith of which will be found on another page.

Mr. Asplund inquired of Mr. Edmeston whether it was true that many of the public buildings of Paris were covered with zinc. He understood that, at the New Palace of the Louvre, the Rue Rivoli, the Boulevard Sebastopol, and other places, it was extensively used.

Mr. Edmeston said that was so. His examination, however, had rather been directed to old than new buildings. Zinc was used in Paris in preference to any other material for the covering of roofs.

Mr. Burnell said that some twelve or fourteen years ago he had inquired into the subject in France, and found it was the practice to use zinc in preference to any other material for roofs, and it was quite possible that in the atmosphere of France it might be the best thing to use. He differed, however, from Mr. Edmeston with regard to the effect of the sea air upon the metal, as his experience went to show that sea air caused decomposition. With regard to the use of zinc for ships' bottoms, it seemed to him that a more dangerous material could not be used for that purpose, and he believed that ship-builders had given it up, except perhaps those whose only desire was to turn out cheap ships irrespective of the consequences. He thought that architects as a body of constructors ought to be careful before they consented to use zinc to a large extent. The great difficulty in the way of its more general use appeared to be in getting the metal pure, as it was generally found mixed with lead or iron. He had himself seen lead and zinc in a mine where the lodes crossed each other. In an atmosphere such as that of London, where a

great quantity of coal was used, the admixture of lead or iron generally acted upon the zinc as a decomposing agent. He was quite prepared to believe that zinc might answer at Paris or at Munich, but he scarcely thought it could be brought into general use in London. Mr. Edmeston had stated that the chemical action might take place when the metal came in contact with oak or chestnut timber, but he (Mr. Burnell) certainly never saw chestnut wood used, though he was aware that when zinc and oak came in contact decomposition took place. In London dripping eaves or gutters were not so usual as the box or trough gutter, and in forming the right angles of the latter in zinc, the zinc generally cracked, and decomposition ensued. He confessed that on the whole his own experience had not led him to look favourably on the general introduction of zinc into this country.

Mr. Morris called attention to a water-colour drawing of the interior of the Corn Exchange in Mark-lane, which had been designed by him twenty years ago. The corn factors had previously met in an open area, and, when the new Exchange was contemplated, they expressed a desire to be protected from the weather, and to assemble for the future in a building thoroughly well-ventilated, but with a means of escape for the dust blown away from the corn. In order to meet these requirements he suggested a perforated dome, which was found to give entire satisfaction. It was found necessary to make that dome of some light and at the same time permanent material. To insure that object, zinc of 18 ounces to the foot, with gutters of 8 lb. lead, were used, and the roof had remained ever since without alteration, and without repair. A portion of the building was subsequently destroyed by fire, but the dome (which was the work of the late firm of Locke and Nesham) remained intact to the present, and had not to his knowledge been subjected to any repair.

Mr. P'anson bore testimony to the durability of zinc as a covering material, when properly manufactured and carefully laid. He had himself visited the *Vielle Montagne* works, where the manager had got into a violent passion with him, because in England zinc had not been tested under circumstances favourable to the development of its merits. He had been told that the reason zinc failed in England was, that we did not use it of the proper thickness. The manager at the *Vielle Montagne* works assured him that 21-ounce zinc was required, and that when used of that thickness it would be found to oxidize very rapidly, and that the result would be the deposit of a permanent oxide which would coat the zinc at both sides, and thus make the substance harder and more enduring. He (Mr. P'anson) had used it in the most smoky parts of London for the last twenty years, and he was bound to say that he had found it to answer the purpose very well. There was, however, a difficulty in getting the metal pure.

Mr. Edmeston said that the old roof of the Palais de Justice at Paris was laid in zinc, and, as he understood, had never been repaired. With regard to the sheathing of ships with zinc, he was not in a position to speak from personal observation, but he had been informed that zinc sheathing lasted as long as copper (which was far more expensive); but that in certain places where barnacles existed, it had been found that the animals would stick to the zinc and not to the copper. He was aware that it was objected to zinc, that it cracked in the working; but he was persuaded that if the metal was pure it would be found as plastic as lead, which did not crack.

Mr. Austin said that in cases where he had used zinc, near Canterbury, he had never made the price of the material an object, and that notwithstanding he had been furnished with zinc which had failed.

Mr. Jennings observed, with reference to the paper read by Mr. Burnell, as well as to that read by Mr. Edmeston, that it was most desirable that architects should have the means of testing the quality of the materials used. It seemed to him that the new woods to which Mr. Burnell had called attention, and specimens of which he had exhibited, were not very suitable to architectural purposes, although they might do very well in engineering. With respect to zinc, he had tried it with varied effect; for in some cases it had succeeded, while in others it had failed. He agreed with Mr. Edmeston in thinking that the principal reason of its failure in roofs in this country was to the adulteration to which the metal had been subjected in the process of manufacture. For this reason it was most desirable that the sheets should be legibly stamped with the name of the maker.

Saint-Maur-sur-Marne, and commenced the gallery of the Louvre, of which the first stone was placed by Charles IV., 1568; continued by Henry III.; taken up again by Henry IV., upon plans by Androuet DuCerceau: to this prince, 1590-1611, we owe the châteaux of Presles and of Montceaux, in Brie; the embellishments of Saint-Germain and Fontainebleau; the completion of the Pont-Neuf, commenced under Henry III.; the Palais Royal; the Briare Canal; the restoration of the cathedral of Orleans. He bought, also, the Hotel-de-Ville,\* that curious attempt of revolution in the art; and he gave a new face to the capital by the care which he took in repairing and embellishing it; and invited a number of savans and artists, who received many proofs of his liberality. He is not thought or spoken of by the French but with love. Under Henry IV. and Louis XIII., the light and gracious, but very often empirical, style of the Renaissance was gradually lost and became disused, and the classic adopted, but sometimes spoiled by bad treatment; and often showed how the best things become bad by their excess, and become so in proportion to their excellence.

Philibert Delorme and Jean Bullant, celebrated architects, were charged to furnish the plans of the Tuileries by Catherine de Medicis. They presented the design of a building much more vast than is that of to-day, but this project was not entirely executed. They first raised the great pavilion, placed in the centre of the façade. This pavilion was crowned by a vast dome, circular, and covered with slates. Afterwards they changed the form of this dome, which now has a quadrangular form—a form much more suitable—this large central pavilion, and the two lateral buildings, and the pavilions which were erected at their extremities, then composed, and composed for a long time, the chateau of the Tuileries. The different parts of this edifice were and are still covered with a roof in slates of a great height, as it may be seen above the greater part of the edifices of Paris built in the sixteenth and seventeenth centuries. These enormous roofs, which do not accord with the classic orders to which they are made to associate, owe their origin evidently to the roofs of feudal fortresses, and the latter owed them to thatched houses. Both here and in the court of the Tuileries there existed features, such as open galleries and arcades, which are not presented in the now existing façade, but which are composed of three regular stages of windows (*croisées*). In 1572, Catherine de Medicis occupied it, but soon deserted it. The reason seems to be unknown why, after having built the chateau of the Tuileries, and having employed upon it considerable sums, the talents of the most celebrated artists, and all the results and the delights of luxury, she should abandon it in so little a time after the edifice was completed.†

Chambray, in his "Parallèle d'Architecture Ancienne avec la Moderne," gives two examples of the Louis orders of each of those celebrated architects, Delorme and Bullant. He shows that the profile of Bullant is precisely according to Vitruvius: the former, he says, ought not to be imitated, not being conformable either to antiquity or to Vitruvius, or even to common sense; and not having any regularity in the parts of its composition; that there are many mouldings placed without any motive, most of them little and poor, where the frieze is larger than the cornice, and where, in the base, the general proper disposition of mouldings is reversed, where the great size of the torus is excessive, above the smaller scrolls below. The caryatides, first perhaps introduced upon the degeneration of the Ionic order, in which women are represented, whose delicacy does not correspond to the weight of the burthen with which they are charged, gave rise to all sorts of extravagancies.

Chambray deserves attention, and has authority. He was, says Errard, almost the first who, by his works, made known to France that greatness of manner which gives to the principal members of every order few parts, but great and of a bold relief, so that the eye seeing nothing little, the imagination may be more touched with it.

There are some artists of original stamp who look upon rules and precepts, in short, any prescription for art, only as fetters to them. Such they probably are to those who have no mind of their own. It is well known that Delorme was inventive and skilled in the principles and science

of construction, and was, in producing fine designs for sepulchral monuments for kings, as in the chapels of St. Denis, not by any means deficient. He did many excellent things without the assistance of imitation, and was exempt from that impediment, which has always been cast upon the French nation, of loving and adopting the productions of foreign countries to a mania. Delorme contrived, on his own approved system, in most confined and difficult situations, plans for staircases; and his roofs have been adopted more than once, since the sixteenth century, and by living architects in Paris, in more than one edifice: as an instance, we refer to that of the corn market (*halle au blé*).\*

The palace of Luxembourg, under Louis XIII., was built by Jacques de Brosse, from whom we have the front of St. Gervais. There are numerous imitations of it in Paris, and which were erected during the great revolution, called the renaissance, that took place in the fifteenth and sixteenth centuries. Quatremerre says, of De Brosse, that nothing particular is known of his person or of his life: we are ignorant even of the place and the date of his birth, and of his death. However, he has acquired fame by the front of this church, and by the palace of Luxembourg. The front of St. Gervais far surpasses that of St. Paul St. Louis, built in 1634, after the designs and superintendence of Derrand, a Jesuit; but that, however, is considered as one of the most curious and most interesting specimens for the study of the style of this epoch. The style of Luxembourg palace is somewhat borrowed from that seen so often in the palaces of Florence, and in the Pitti palace, to which many persons have thought it bears a striking analogy. The Luxembourg, built at great expense by Marie de Medicis, who had no want of it, and lived in it but a very short time, ought to bear her name; but this queen having left it to Gaston de France, duke of Orleans, her second son, he wished to name it Palais d'Orléans, by which name it went until the epoch of the revolution.† The alliance of the house of Medicis with that of France made more easily known to the Tuscans the affairs of France, and their influence was felt, for the first years of the ministry of Colbert, upon the politics, the government, the language, and manners of the French. The private relations of epistolary correspondence increased and animated it.‡

In the *procis-verbal* which was drawn up in 1636 upon the streets of Paris, we might see what was then its deplorable state; streets not yet paved, or which were not paved but on one side, or only in some parts. We need not enter into detail, but the obstruction, the absence of light, the badly-built houses, the long accumulation of dirt, were very active sources of corruption and of contagious diseases for the inhabitants in the quarter of the Louvre. Paris then, says Dulaure, much resembled a poor but proud man, wearing gilded garments upon linen dirty and full of vermin.§

Before the reign of Louis XIV., when the arts wanted patrons, French architects, perceiving that the occasions for building were rare in France, and that, notwithstanding the nobility of their art, they could with difficulty distinguish themselves from artisans, preferred rather to take another part than to follow a profession in which they could not satisfy the passion that they had for glory. This coldness and this indifference for architecture lasted some time, and did not much reassume its former character till under the glorious dominion of Louis XIV., by whose order monuments arose which presented to the people of his time and to posterity the brilliant evidences of taste which this great prince had for the arts. He showed on more than one occasion that he knew how to join to the capacity of choosing able architects and artists, a generous inclination to reward their merit: he exerted and supported the emulation of artists by the foundation of the academies of France and Italy, where not only the experienced artists could confer together, but where the pupils had the facility of instructing themselves under professors of distinguished merit, in such a manner that it is by the institu-

tion of these illustrious schools that the French architects show that the genius of the nation yields not to that of other people, and that they could succeed in anything that they undertook when they were excited by the protection of so great a monarch. It is, in short, through this emulation that we have seen so many beautiful edifices; whose examination contributes no less to improve and perfect the arts of our days than the works of the Greeks once served to instruct the arts of Italy. We may say, too, that it is edifices of all kinds which attract to our capital the most distant nations, to draw from them the science of architecture, as well as other arts. Nothing has, perhaps, served so much the greatness of Louis XIV. as the superb buildings which he has created.—(Blouet's (*Jacques François*) "Architecture Française," 4 vols. folio.)

The façade of the Louvre was commenced, among other beautiful edifices, in 1663. In 1664 Colbert charged Leveau to terminate and repair the palace of the Tuileries. This architect made many changes in it. The staircase, of matchless construction, but much out of place, was taken down and placed more conveniently. The centre pavilion was removed: it was decorated with two orders, the one Corinthian, and the other composite; and an attic with caryatides. Colbert resolved to distinguish his administration by finishing the Louvre, and wished to carry to perfection what he found imperfect. Not content with what Leveau had done, nor either with his project of continuing it, he invited artists to compete. The decoration of the front elevation by Leveau, which was throughout in pilasters, was much censured: it was judged as wanting nobility, dignity, a mark of royal distinction, and as having too little relief: his door was unanimously found little, and of too small importance to serve as an entrance to such a monument. The king himself found fault with it. Among the projects which were exhibited, together with that of Leveau, was one by Claude Perrault. It was designed with much taste and propriety, and was universally admired. Charles Perrault, brother of Claude, thus writes of this competition in his "Memoirs," &c.:—"Whatever knowledge Colbert had of the capacity of my brother, Claude, in architecture, I perceived that he hesitated to execute his design; and that it seemed strange to prefer the conceptions of a medical man, in a matter of architecture, to the designs of the most celebrated architects. The envy of the professors and masters of art in Paris was not wanting in railing against the resolution, and the making bad jokes, saying, that architecture must be very ill that it had need to be put in the hands of doctors. Leveau, who presented the first design, and Lebrun, the king's painter (who was not ignorant of the principles of architecture), could not approve of the design of Claude Perrault (which was preferred to Leveau's), always saying that it was only beautiful in painting, and that assuredly they would find it bad in execution, on account of the too great depth of peristyle, which was 12 feet, and that the architraves made all look low; but such precaution was taken, that nothing in the world is more solid, nor is there anything either so bold or so beautiful in all the works of antiquity. At the invitation of Colbert, Bernini came from Rome, although he was working at St. Peter's. He admired the hand of Perrault in the colonnade of the Louvre, and remarked of it, that if Paris contained such a gem, and such a rare genius, why should he be called away from Italy?" Colbert, the Mæcenas of all the arts, formed an Academy of Architecture in 1674. Voltaire† remarks upon this: "It is little to have Vitruvius without Augustus to employ them." The principal front of the Louvre, commenced in 1660 from the designs of C. Perrault, was terminated in 1670. This façade was 525 feet in length; in height 85 feet. It underwent changes, and was embellished under the reign of Napoleon I.

The wars that France had waged seemed, and were when they had ceased, favourable to the arts. It was the ambition of many kings,—whose battles were executions of justice,—whose battles after they had won battles, were loaded with spoils, had subdued their enemies, and had brought peace to the hearts and homes of their subjects,—to turn their attention to such enjoyments as accompany the possession of the arts and the culture of the sciences. The Louvre, commenced by François I.,

\* Victor Calliat, in his "Encyclopédie d'Architecture" (Paris, 1851), says that the Church of St. Eustache and the Hotel-de-Ville, are the two most remarkable monuments erected in Paris in the time of François I.

† Dulaure, "Histoire de Paris."

\* Unfortunately it does not exist now. Legend and Molinos, architects, introduced it, and it caused a general admiration, but which was of short duration. Consisting of wood, it took fire in 1822, by the imprudence of a plumber, and in two hours nothing remained of that immense work of carpentry. For description, or plates of it, see V. Calliat's "Encyclopédie," and Kraft's "L'art de Construction."

† "Siècle de Louis XIV."

and continued through a long line of kings, was after war, the main object of their ambition, and they resolved to enrich, to enlarge, or to complete it. More than one inscription on a plate of gold has been placed by royal hands in the foundations of the Louvre, and has risen, Phœnix-like, when the swords have been sheathed and victory proclaimed. This ancient ceremony of laying the stone has always been an important event in the history of the Louvre, which is the history of France. The effect of the recent and final ceremony, under the auspices of Napoleon III., on the occasion of the finishing of this palace, and its union with that of the Tuileries, was long felt and talked of after that memorable day in Paris, the 25th of July, 1852, had witnessed it. On that day of triumph for art, of gratification for the public, and of reward to the workmen who had distinguished themselves on it, M. Casabianca, Secretary of State, laid the first stone of this superb edifice. Visconti was the architect-in-chief.

It is still astonishing the position that France and her capital occupy in Europe as a great centre and school of art, when she has been so incessantly distracted by wars, and when, if we read the history of France, and the wars during the French monarchy, from the time of H. Capet, we shall find that they form the most considerable and the most distinguished portion of her annals. Yet we see, in the lappy times of peace, that she can become, by the fine arts, and by favouring the exercise of them, not less than by war, most prominent among the nations of the earth. They were to her both her ornament and her strength. Arrived at a higher point of excellence than preceding ages had been able to carry them, they were felt and seen to be the most wonderful things that could emanate from human hands. Those who excelled in them were sure of public esteem, and their productions were the means of bringing them before great men and great powers. The most powerful of kings chose the arts as the objects of their special patronage, and they were viewed by discerning observers with as much curiosity, as much emotion, as the war despatches in turbulent times had been devoured by a crowd of listening enthusiasts. The great work which was being erected, and which had long absorbed the energies and the ambition of many crowned heads, and many very accomplished architects, was the Louvre, which, as taste existed more pure and more diffused, on account of the number and variety of beautiful buildings which could be examined and compared one with the other, it had become a lever to raise the arts nearer to perfection than heretofore, and to benefit the country and trader to a greater extent. If we contrast it in its present finished state with what it was under the reign of François I., we shall be astonished at the great and material change that has taken place in it,—a change which had been in course of gradual and increasing accomplishment for many centuries. This noble and venerable residence of kings, increased and approached to its long-anticipated and much-dreaded completion, from age to age. It took many efforts, and many epochs. Slow and tardy in its growth, like other vast and difficult works it required the result of civilization, the application of great experience and great influence, to develop and complete it. The failures or the prejudices that occurred from time to time to check its progress, the frequent alterations that were made, and the many difficulties that had to be overcome, only show that, after all, men are often but the creatures of their time, and can only do that which is practicable in the condition of society in which they live. There were some great and gifted men who cooperated upon it at one and another period, and who possessed all the professional experience then known, but whose manner was meaner and inferior to those who followed them and stood on vantage ground. Time—that silent and unceasing worker of the destinies of men and their projects—it was indebted to this Time. The Louvre, however, was seen in its present finished aspect, united with its royal neighbour the Tuileries, was not as if each successive portion of the pile prepared by the first course of operations facilitated the next, but it was deemed necessary in one age often to pull down and build in a new style that which had been built in a former age. However, we now behold it worthy in its completion, the fact of which gives an idea of the multitude of difficulties brought to a level, worthy in its varied and magnificent designs of the refined men who conceived and spent their lives upon it; worthy of the noble race of kings who

commanded its execution and spared no pains or expense to witness its realization. Many things render it one of the most interesting royal residences of Europe—a palace which tempts foreigners from all parts of the world, and which is a model and a lasting resource of design to students.

F. LUSK.

FACTS RELATING TO THE USE OF ZINC ABROAD.

THE reputation of zinc for roofing is not good in England. Abroad the material appears to be used very largely and successfully. To ascertain the reason for this difference the Vieille Montagne Zinc Mining Company have recently commissioned Mr. James Edmeston to inquire into the matter. His report, which was read at the Institute on Monday evening last, and is about to be published, is now before us. The Vieille Montagne Company is a very extensive undertaking—

"In the seven large smelting establishments in Belgium and Prussia, comprising 230 furnaces, 29,000 tons of spelter are produced, and 20,000 tons of sheet zinc are annually made, besides about 7,000 tons rolled at mills which are not the property of the company. In the three establishments for making oxide of zinc, about 6,000 tons of oxide are annually manufactured. The company is besides a large purchaser of spelter in the market.

It is said that the general consumption of spelter throughout the world is about 57,000 tons per annum, of which about 45,000 tons are made to take the shape of rolled sheets, and these are estimated to be applied as follows, each quantity being somewhat below the truth:—

	Tons.
Roofing and architectural purposes	25,000
Ship sheathing	3,500
Lining packing-cases	2,500
Domestic utensils	12,000
Stamped ornaments	3,500
Miscellaneous	1,500
	44,000

Fifty years ago the quantity used for roofing did not exceed 5,000 tons: none was employed for ship sheathing or lining packing-cases, and the stamped ornaments in zinc date only from 1852."

The process of manufacture is simple: the calcimine (carbonate of zinc) is first calcined, by which it loses about 20 per cent. of its quantity: it is then ground in a mill, and mixed, to the extent of one-third of its bulk with powdered coal, to assist the smelting. The whole being much moistened, this mixture is put into the smelting-pots, and these at six o'clock every morning are placed in the furnaces. At six o'clock in the evening, that is, in twelve hours, the smelting is complete. The metal is drawn out and run into metal moulds: it then goes into the rolling-house, and is again melted and recast in a metal mould to produce ingots of the proper size and weight for the required gauge of sheets to be rolled: this second melting is also desirable to obtain proper purity.

In the first place, purity in the metal to be used for building purposes is important: if there be much impurity no after-care will be of any avail. For ship sheathing—and zinc is now very largely used in this—perfect purity is essential, for it becomes immersed in a down-right galvanic bath; and if iron be present in even a small quantity, or lead, it would quickly destroy itself. This is not so much the case in roofs, but purity is most desirable; and impurity may exist to an extent sufficient to spoil the best-constructed roofs, and in many cases has done so beyond doubt.

Mr. Edmeston made inquiries in England previously to going abroad, and all the replies were condemnatory, with two exceptions.

"Some instances of failure were brought before me, and these were mostly as follows:—  
Crumbling to pieces; black spots appearing, supposed to be the effect of London atmosphere; holes and wearing out of the metal in a short time;—all these would arise from impurity in the metal, or from contact with iron. Then,

"Cracking in places; soldered joints parting; drips or joints falling in pits; tendency to buckle and to have an untidy appearance in consequence, and general unsoundness of the work;—all these would arise from bad construction."

Abroad, amongst the failures, he mentions one:—

"But, even if the zinc contains no iron, the contact of iron, where a little confined damp may exist, will be quite as injurious. I cannot find that this is understood here: and nails are commonly used for boarding under the zinc, and if a nail head is in contact, and there is damp, in three months a hole will be eaten through. Generally speaking, for the best roofs on the Continent, zinc nails are used for the boarding, and all iron work, where necessary, and if used at all, is galvanized. Or where iron nails are used for boarding they have small heads, and are hammered well into the zinc, so as to be buried, and a little cement or stopping is frequently rubbed in over them. Practice has found that the nails thus used rarely do any mischief, and as the zinc nails require certain care and take more time, and are dearer than the iron, I found that in Paris, at all events, the iron were used frequently, but always with the above precautions.

I could not discover that the contact of lead was injurious, but it is considered to be better avoided. Impure zinc being brittle will crack when turned up

against the rolls, or it will break off entirely, and the builder, who saves something in first cost, is quite likely to lose more in the end from waste.

The second set of defects to which I have alluded, and other indications of them, will be referable to ignorant construction: they none of them exist where proper knowledge has been exercised in this respect, and the one object to be kept in view is to permit *perfect freedom to the sheets*, to confine them no where, and to separate lengths of guttering, and any other portions of a roof requiring to be made in long pieces, as much as possible."

"Eaves gutters should be made in short lengths, bent in the direction of the way in which the sheet has been rolled, and soldered; the solder put between the sheets and one sheet lapping over the other: they must not of course be sewed to the rafter's feet—a practice, by the way, which occasions a constant failure in the joints of iron eaves gutters. Wherever a down pipe comes there should be a stopped end in the gutter, and the gutter should never be continued longer than possible in one piece: where it is laid behind a parapet, as in all the new and magnificent buildings in Paris, a separate piece of flashing will disconnect it wholly from the sheeting on the roof. For guttering, the gauge used should be increased in proportion to length, say No. 14 for 10 feet, No. 15 for 20 feet, and so on up to No. 18. There should be a proper substance in all cases. No. 14 is ample for London: in Germany it is customary to use a less thickness."

The choir of the cathedral at Cologne is covered with Silesian zinc. The old lead was defective and was removed, and the zinc substituted by Herr Zwirner, in 1829.

The gutters are zinc: it is laid in the old way without wooden rolls or fillets, as is the custom still in Germany. Herr Zwirner, the architect to the Royal Commission, informs me 'that zinc is now commonly used for roofs in the whole of Germany,' and that all his practice has taught him 'the solidness and closeness of a well-constructed zinc roof.'

Oak boarding will spoil the zinc, and the fir should be dry; the boards laid with an aperture of about half an inch between each: if they are damp, as much oxidation will take place on the underside of the zinc as on the top of it.

A good way of laying flats in some situations is without rolls, but with sunk gutters between the sheets, with, in fact, inverted rolls, which form gutters: for London, however, I would recommend the ordinary mode, as the small gutters are liable to be filled with blacks and soot if neglected. In forming laps care must be taken to prevent the water from ascending, by capillary attraction: there must either be space enough to prevent the drops thus rising, or the end of one sheet must touch altogether, and that of the other be kept well away; and this is found the best mode, and the least open to careless treatment by workmen.

The thicker the zinc the less its expansion and contraction. And I find as follows, in a report made to the Academy of Sciences, by the director of the Conservatoire des Arts et Métiers—a government institution existing in the Rue St. Martin, to inquire into scientific inventions, civil engineering, and all constructive science—

"It appears from actual experiment that the oxidation proceeds for about four years, gradually diminishing after the first three months, and that it then hardens into a protecting coat ('craquelé') of a dark grey colour, preserving the metal beneath from any further deterioration.' And it concludes by saying, 'that it becomes evident that as a sheet of zinc exposed to the atmosphere for a series of years loses little or nothing of its weight or thickness, and as its surface remains hard and polished, like enamel, it may be fairly deduced that the following years are not likely to occasion any alteration, and therefore that zinc will be placed in the same condition as bronze, which is protected by its 'patine' for ages.'"

Amongst new works in Paris, Mr. Edmeston mentions—

"The new markets, constructed of iron, under the direction of M. Baltard, architect, in 1856. These great roofs are covered wholly with zinc, No. 14 gauge, the gutters being No. 16, the whole in perfect order, except in one place, where some undulation has occurred in consequence of the workmen having confused the metal by solder very needlessly, because a little extra labour was necessary to lay the zinc properly: the downpipes are of zinc No. 14.

Also the entire roofs of the magnificent houses forming the Boulevard des Capucines, the new mansions in the Champs Elysees, the new part of the Louvre, in which the flats are of zinc and the curbs only of slate; the roof of the Hotel de Ville; the roof of the Church of St. Clothilde; and, in fact, nearly every roof formed in Paris within the last fifteen years.

He mentions,—

"That while cement does no injury to the zinc, the lime of Paris destroys it, and that when cisterns or other zinc constructions are confined with brickwork, or in mortar, the custom is to fill in round them with earth so as to protect the zinc from the lime."

A report of a committee, appointed by the Central Society of Architects in Paris, recommends,—

"That zinc, which was at first rejected, but is now so generally used, should be applied with great care, as certain precautions, very simple, but never to be overlooked, are indispensable: thus contact with plaster, which contains a destructive salt, is to be avoided; also contact with iron, which is very injurious, and liable to cause a rapid oxidation; eaves gutters should always be supported by galvanized brackets, and no gutter or sheet zinc should be laid on oak boards."

Mr. Edmeston deduces from these facts and independent inquiries, that it is impossible longer to contend—

"That zinc is other than a valuable and excellent material for building purposes, too important to be overlooked, and worthy of a more extended use, if a better appreciation than it has yet received with us."

DERHAM CATHEDRAL.—The works at the central tower, recently illustrated in our pages, are under the superintendence of Messrs. Walton & Robson.

PROPOSED CAMBRIDGE GUILDHALL—THE ASSEMBLY-ROOM.

## PROPOSED GUILDHALL, CAMBRIDGE.

In our present number we give a view of the design for the Cambridge Guildhall, by Messrs. Peck and Stephens, of Maidstone, to which the first premium was awarded; and also a view of the interior of the Assembly-room, as proposed. In our last volume\* will be found our notices of the drawings at Cambridge, amongst which the present design appeared under the motto "Utility." We refer our readers to the second of the notices, for particulars of this design, as well as to the extract from the report of the professional referee, which we gave subsequently.†

## THE CENTENARY OF HOGARTH.

PROPOSAL TO EXHIBIT THE ARTIST'S WORKS IN THE FOUNDLING HOSPITAL.

ON the 26th of October, 1861, this, in many respects, the most eminent amongst those painters who may be considered as the founders of the English school, will have been dead one hundred years. Since that date his works have increased in money value to a wonderful extent, and his fame has spread not only throughout his own land, but also in many foreign countries.

It is both curious and satisfactory to trace the onward progress of English art since the days of Hogarth, and it should not be forgotten that to him even more than to the exertions of Sir James Thornhill and others, we are indebted for the establishment of the Royal Academy, and for public exhibitions of pictures.

The exhibition of the works of Hogarth, Hayman, and other of his friends, was made in the apartments of the Foundling Hospital, as we noted recently; and so great was the attraction, that crowds thronged to the place.

It has been suggested that the centenary of William Hogarth should not be passed over without celebration, and that nothing would be so

suitable as the exhibition of as many of his works as could be collected together; not only the paintings, but sketches and fine impressions of the engravings which were executed by the artist's hands. A collection of this kind, which would enable us to glance at once at the results of Hogarth's useful and laborious life, would not only have great interest, but would also be the means of enabling many to form a juster estimate of the high position which this artist is entitled to hold. It has been thought that no place would be so suitable as the apartments of the Foundling, in which Hogarth was so frequently a visitor when in life.

## THE ARCHITECTURAL MUSEUM.

ON Wednesday evening last, Sir Walter James delivered the first of the new course of lectures in the theatre of the Museum at Brompton, and was attentively listened to by a good audience. His subject was "The Norman Architecture of Canterbury Cathedral," and he illustrated it with a large number of drawings and plans. First describing a Roman basilica, he mentioned the resemblance to it in early Romanesque churches, and afterwards showed, following the theories of Hope and Whewell, how Pointed architecture had grown out of Romanesque.

Mr. G. G. Scott, in moving a vote of thanks to the lecturer, commented on the advantages resulting from the devotion of time and thought to such subjects by men in the position of Sir Walter James. It would be of no use art-workmen improving themselves, if the public were not also informed and ready to employ them.

Mr. Joseph Clarke announced that the next lecture of the series would be delivered by Mr. Godwin. It would be addressed especially to art workmen and those who might be striving against difficulties.

Cards of admission may be obtained at our office.

## THE PROPOSED DRAINAGE OF RIO.

The following relates to the proposal about to be introduced for the drainage of the city of Rio. It also appears that the guarantee is in the form of a rate (in Brazilian currency) on each house, analogous to that granted to a gas company some years back. There is no city in the world in which drainage is more needed than Rio:—

"29, Threadneedle-street, London, Jan. 7. Sir.—Referring to the notice in your impression of today of the intention of bringing before the public, at an early date, the proposal for draining the city of Rio de Janeiro, and to the effect which it has had upon the Brazilian Railway shares, it is, perhaps, desirable that you should be informed that, although the aggregate of the capital required will be 650,000*l.*, the sum to be paid for the first six months will be under 100,000*l.*, and for the second six months only 65,000*l.*, so that it manifestly would not affect the existing Brazilian securities.

To this we may add that a portion of the capital is already subscribed, and a list of applicants for the remainder is being privately; thus the amount that will be offered to the public will be limited.

HILL, FAWCETT, & HILL, Brokers to the Company."

Our advertisement columns give further particulars of this important and promising undertaking. The concession is for ninety years. The plans have been prepared by Mr. Gotto. The Brazilian Government is bound, by legislative enactment, to pay to the Company 42 milreis per annum, which, at the par of exchange of 27*l.*, amounts to 4*l.* 14*s.* 6*d.* for every house now erected or hereafter built within the three districts during the term of concession, such payment to be made half-yearly for all the houses, whether occupied or not. The number of houses, according to the last returns, amounted in June, 1859, to 13,739; and adding the average number of houses yearly built in the city, there will be, on the completion of the works (within the three districts) at least 14,891 houses (the number provided for in the contract) from which the revenue of the company will arise. The amount to be received upon 14,891 houses will alone produce a gross income to the company of 70,360*l.*

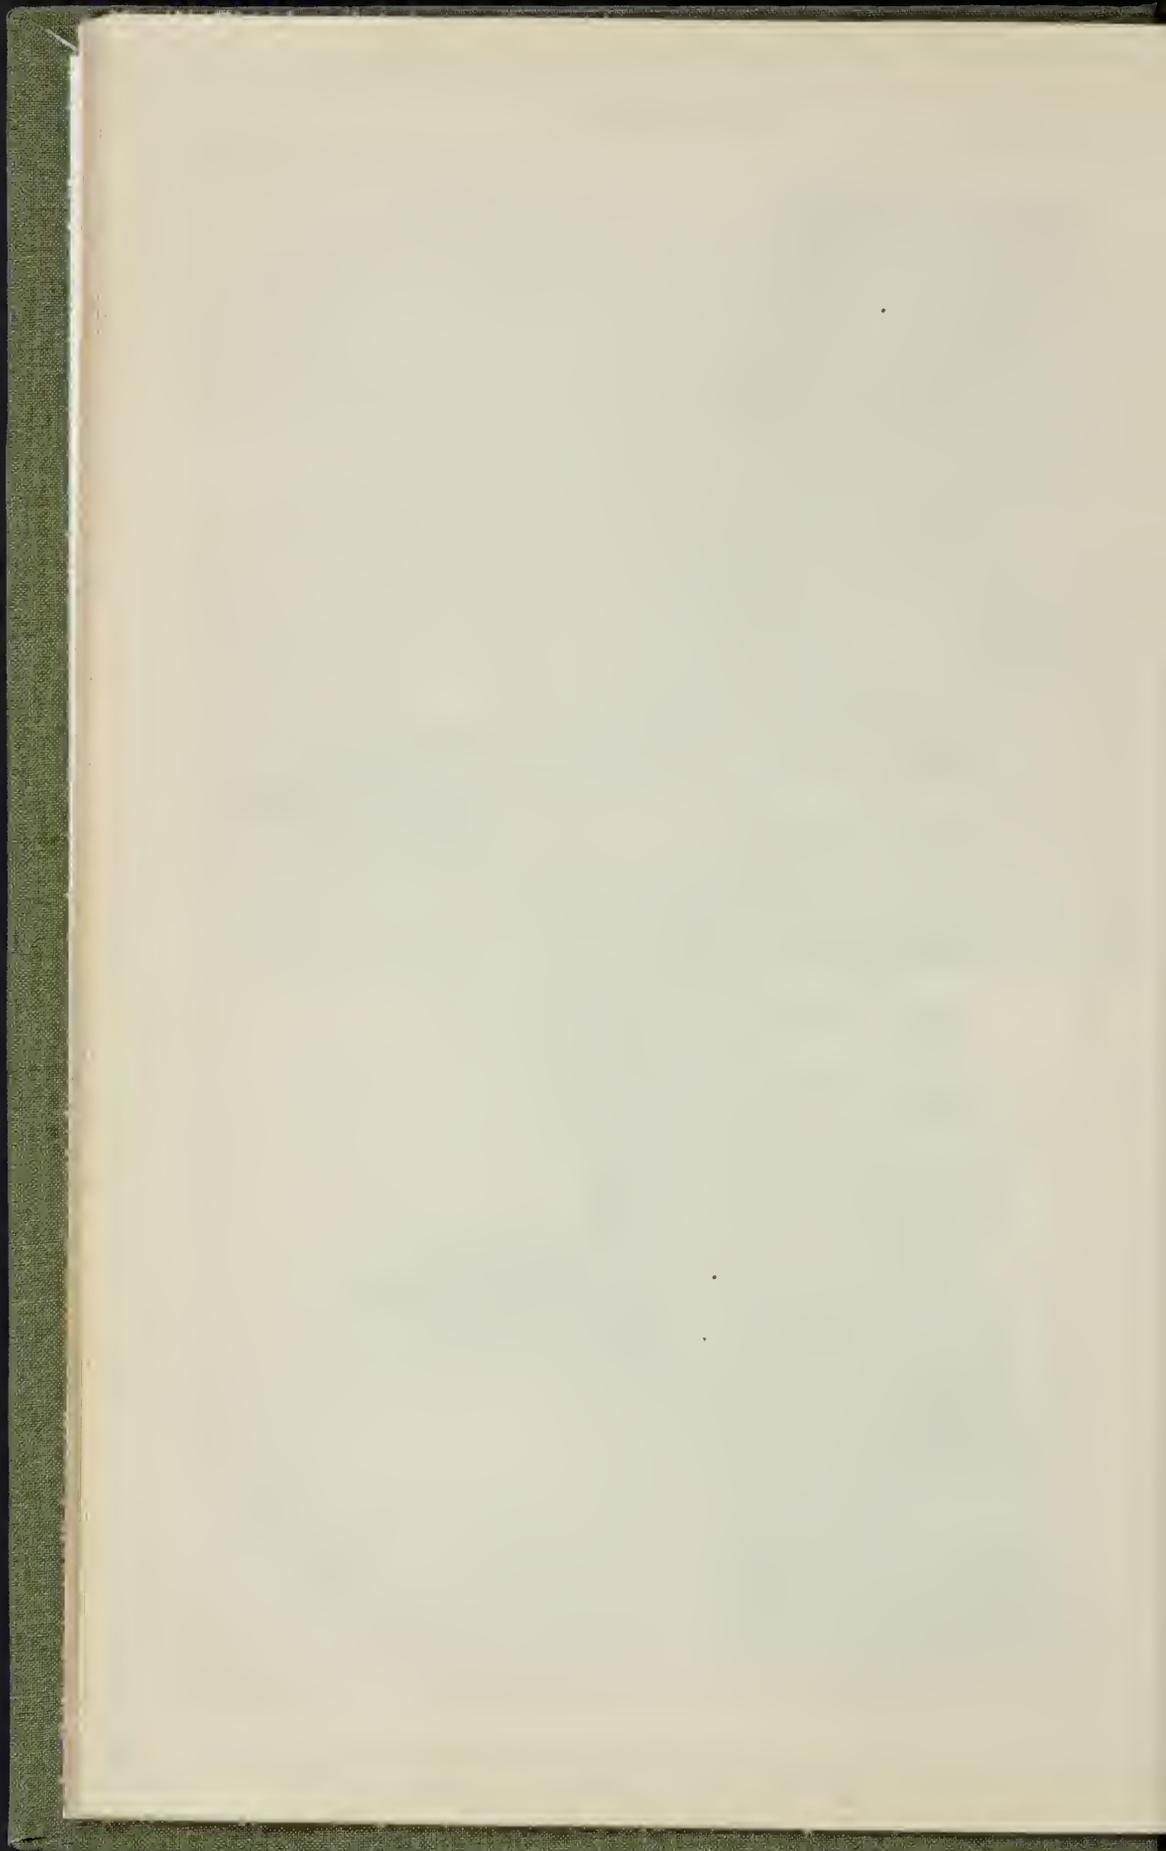

Professor Donaldson is one of the directors.

CAMBRIDGE GUILDHALL: THE SELECTED DESIGN.—MESSRS. PECK & STEPHENS, ARCHITECTS.

BUILDING STONES USED IN  
MANCHESTER.

At the last ordinary meeting of the Manchester Philosophical Society, December 27th, Mr. Wm. Fairbairn, president, in the chair, Mr. Binney read a short communication, entitled "A few Remarks on the Building Stones used in Manchester."

A stranger visiting Manchester, on having his attention directed to the modern buildings in it, will doubtless notice the substantial nature of the bricks of which they are built. Of the stone employed for building, he will most probably be of opinion that it is not of the most enduring character for the climate and atmosphere it is subject to, and the unfair usage by which architects and builders think proper to test it. For, however, well it may be established in theory, that a sedimentary stone in a building ought to lie in the same position as that in which it was originally deposited in the earth, unfortunately in practice architects will persist in attempting to make the stone accommodate itself to their designs of buildings, rather than design their buildings in accordance with the nature of the stones they have to employ. No doubt beds of stone of great thickness and uniform composition are difficult to find, especially in sedimentary rocks, but still that is scarcely an excuse to place it on its end or at right angles to the planes in which it was deposited.

Of late years a considerable number of experiments have been made as to the strength of building stones, just after they have been taken from the quarry, by pressure. This, no doubt, will give an idea of their power of resisting force at the time of the experiment being made, but it will give little evidence of the strength of a building stone after some years of exposure to a climate and atmosphere similar to those which the building stones of Manchester are exposed to, without the stone is of a pure silica, or nearly so. In all stones which are subject to chemical decomposition, these experiments will not surely give us.

Old buildings in country places, remote from the smoke and gases of large towns, are often adduced in evidence of the strength and durability of a stone to be employed in a manufacturing town. However well the dolomite of Bolsover-moor might endure the climate and atmosphere of Southwell, in Nottingham, as it is seen in the Minster there; or the triassic sandstone of Furness might endure, in the abbey of that name, each seven or eight centuries; still, it would be unreasonable to expect that either of these stones could resist the action of the moist climate of Manchester, and the atmosphere of a city in which about forty thousand tons of sulphur are annually burnt in the coal consumed in it, to say nothing of the gases given off by the numerous chemical manufactories, and the exhalations from half a million of human beings.

On examining the buildings of Manchester, we find that the stone employed is chiefly from the middle and lower coal measures; the only instances of triassic or new red sandstones having been used are, as I have been informed, the Portico and St. Peter's Church, from the Oughtrington quarry, near Lymm, and the beautiful church lately built by Mr. Crowther, at Moss-side, which is from Hollington, near Ashbourne.

The cathedral was built from the sandstones of Smedley and Collyhurst, two rocks belonging to the upper part of the middle coal-field. These stones are both soft, and contain a large amount of clay and peroxide of iron. As you proceed farther down into the middle coal-field, you find the sandstones containing less iron in a state of peroxide and considerably smaller proportions of clay; still the stones are not suitable for outside work, as they contain protoxide of iron and sometimes sulphuret of iron, which are scarcely to be seen in the white sandstone when first obtained from the quarry; but, on exposure to the atmosphere, the iron becomes further oxidized, and the stone "bleeds" and becomes discoloured, as well as decomposed. It may be safely concluded that there is no quantity of good building stone, suitable for outside building in a city like Manchester, to be procured from the middle coal-field.

The lower coal-field and the millstone grit yield the only good building stones for Manchester. These strata comprise the beds lying under the Arley or Royley seam of coal and the limestone shale; and, from their being generally found on the high land of the district, are known by the name of "High Moor Stone."

As all the lower coal-field and millstone grit beds have most probably been formed of the debris of granite or granitoid rocks, we find in

them the proportions of silica, alumina, potash, iron, lime, and magnesia, generally met with in these rocks. As a general rule, the more pure silica the rock is composed of, the better building stone it is. A mixture of mica or clay causes the rock to be more schistose or flaggy, as well as softer. Two chief beds of flags, besides several smaller ones, occur in this division; namely, the upper flag of Upholland, Catlow, and Holy Fold, lying between the Arley and Royley coals, and the lower flag or Bradshaw and Shawforth, near Rochdale, lying under the rough rock and above the upper millstone grit. These flag beds yield the stone generally used for par point work.

A fine, sharp grained, silicious grit is found sometimes above the gamister coal, as at Ending Common, near Rochdale, which makes a good building stone.

A stone much used in building is the Halliwell, Woodhead-hill, or Lomax-wood rock, lying immediately under the salts or hest coal of New Mills.

The rough rock, generally known as Summit and High Moor stone (the upper millstone of the geological survey), a stone much used in building, is of a coarser grain than the stones previously mentioned. It is composed of grains and rounded pebbles of translucent quartz cemented together with partly decomposed felspar and a little iron and manganese in the state of oxide. It is soft when first quarried, and works pretty freely, hardening when exposed to the air. As a building stone it is preferred, owing to its working much easier than the two millstones. Parbold, Horwich, Holcome-hill, Blackstone-edge, and Werneth Low, are good examples of the stone.

The upper millstone of Holcome, Bank-lane, Todmorden, Saddleworth, and Tintwistle, is a hard and durable sandstone, composed chiefly of silica. It is much better to work than the rough rock, and stands the weather better, but it is not in great use, owing to its being difficult to work.

The lower millstone, as seen at Reocross and Rhodes-wood, Tintwistle, and the lower part of Pendle-hill, contains some excellent building stones, but they are hard to work, and therefore have not been much used; but it is, no doubt, one of the strongest and most durable stones of the series. In the lower parts of it are some beds of fine grained sandstone, freer to work than the upper beds. A most excellent bed of this description is found at Bailey, near Ribchester.

In selecting a durable building stone for a town like Manchester, the more silica it contains the better. Iron or manganese in the state of protoxide, or sulphuret of iron, as well as clay, all damage the stone. The stones composed of silica, cemented with silicates of soda, potash, lime, magnesia, or alumina, are all durable; but, when clay or silts of iron form the cement, the acids in the atmosphere have a very damaging effect on the building stones containing them.

The sandstones from the lower coal-field in the neighbourhood of Halifax and Huddersfield, and generally known by the name of Yorkshire stone, are much used in Manchester, owing to their good colour and free working qualities. Many of our buildings in which these stones have been used show symptoms of decay, especially in the places where long pieces of stone have been required, and in mouldings and ornamental work.

In some cases the sulphuric acid in the atmosphere has acted on the clay in these stones, and an impure sulphate of alumina having been formed, it is washed by rain out of the stone, and the grains of silica in the latter soon crumble away.

In other instances the water percolates down through the beds of the stone placed on its end until it reaches their bases, and then the frost in winter and the heat in summer expand the water, and thus force off laminae of stone, in addition to supplying acids to act on the stone as above-named.

The under ledges of coping stones, although the stone of which they are formed is placed in its proper bedding, often exhibit evidence of decay. This seems to arise from the moisture percolating the stone and finding its way to the lower parts, which, owing to their being shaded from the sun, are nearly always wet, and thus prepared for the action of frost and heat previously alluded to.

It is surprising to find so small a variety of building stones having been used in Manchester as those above noticed, and it is to be desired that the architects and builders of our city should try other descriptions of stone when they can be had at a moderate price. It is difficult to say how the dolomitic limestones of the Permian group in Yorkshire, like those of Anston, would endure our climate and atmosphere; but so far as my experi-

ence goes no instances of them are to be found in our buildings. By the facilities which railways now afford, one might have expected that some of the beautiful syenite of Shap containing large crystals of felspar, or the grey syenite of Bootle and Ravensglap, would have made their appearance in Manchester; but, to my knowledge, none of them have been used. It is possible that they may not be known to our architects, but most probably the reason why the soft freestones of the coal measures are in such general use is that they are cheap and easily worked. My own impression is, that cheapness is more looked at, both by architects and owners of buildings, in selecting stone, than durability of character.

Some years since a good collection of the building stones of Lancashire was got together and placed in the Museum of the Geological Society of Manchester, where they are open to public inspection without charge. This might be increased with stones from the adjoining counties; and then, if the architects and builders of Manchester would associate together and devote a little time to the subject, we might expect to find a greater variety of building stones, and building stones of greater durability, than are at present to be met with in Manchester. In conclusion, the author of these hasty remarks begs to state that it would give him much pleasure to afford such an association all the assistance in his power to discover the most suitable building stone for Manchester.

THE ARCHITECTURAL ASSOCIATION.  
ARCHITECTURE AND SCULPTURE.

The ordinary meeting of members was held on Friday, 6th inst., at the house in Conduit-street; Mr. Roger Smith, vice-president, in the chair.

The minutes of the last meeting having been read and confirmed,

Mr. Hughes, of 8, Dane's-inn, and Mr. Clever, of Dalston, were, on ballot, admitted members of the Association.

Mr. Randall Druce then read the following paper, entitled, "On the Advantage that a Practical Knowledge of Sculpture would be to all Members of the Profession, and the important Means to that End that the formation of a Class of Wood-carving at the Architectural Association might become."

The Lecturer said:—Mr. Chairman and Gentlemen,—When Orgagna was carrying out the tabernacle in the church Or San Michel, at Florence, as the designer and superintending architect of the work, "he employed various masters in sculpture, selected from various countries, to do all the other parts of the work, but devoted all his attention to the figures;" and then, "having finished them all," he turned his attention to the superintendence of the putting together of the various parts executed by the various artists. "He caused the several parts to be most ingeniously and carefully put together without cement, but with fastenings of lead and copper, to the end that no spot or blemish should lessen the beauty of the polished and shining marbles."

What a perfect combination we have here of artistic skill and love of the beautiful, with business-like superintendence and practical knowledge!

Here is an architect, who has designed a beautiful whole, confident that he alone is most capable of executing the most beautiful parts; a sculptor, taking most delight in the execution of the figures; yet, "having finished them all," being equally confident that no one but himself can so well contrive the mechanical mode of joining the fabric together, and fixing these figures in their place.

Now, I think that all of you will agree with me that as far as this is practicable, this is a desirable position for the architect or designer of a building or any other work which depends on the accumulated skill of many,—the only way indeed in which an architectural work can bear the stamp of the master or be the successful realization of his thoughts and intentions in anything like the same manner as a picture or a statue is, that is the entire work of one man.

Now my intention this evening is to endeavour to investigate how this is attainable. You will probably at first think, and would immediately reply to what I have told you above, that Orgagna was an exception—a great man,—and that an inferior man would have become only a Jack-of-all-trades, not attaining even mediocrity in each of the three callings he followed, much less be able to execute the most difficult parts of the practical work of either of them; and to a certain extent

you are right; only the Organza would take up Organza's position, but the least endowed would surely be at least more competent superintendents of the artists employed for being, even in the very slightest degree, practical artists themselves.

Nor do I think that the attainment of this power of practical superintendence (and I think that you will allow that this of Organza's, although largely concerned in the art-part of the work in question, was practical superintendence even independently of the mechanical contrivance) is so difficult as may be imagined, for much of the knowledge of effect, and the best mode of producing it, that would take years of study of the works of art and writings of the best authorities upon art to attain, practical work with the chisel or brush will teach you in a few hours: the secret of the difference between the two systems—that in practice in Organza's time, and that in practice in our own—lies in this;—that then everything was learnt practically,—now theoretically; then the first step in an architect's education was to apprentice him to a goldsmith or some other practical branch of art,—now, to set him to draw the different by-gone styles in Chambers or Pugin.

Many a difficult point in construction was easily understood and modelled by the hand early trained in modelling the chalice he was to work in gold, which now appears incomprehensible, and consequently becomes distasteful to the artist-mind when presented to him in the unattractive shape of a line diagram; and thus the artistic and practical ornament and construction, now so often antagonistic, were learnt at the same time, and went hand-in-hand, because the knowledge sought for and attained in both was practical. And we have seen incidentally that this knowledge was often begun in the goldsmith's shop; so that we may, I think, fairly argue that the key to the more or less complete attainment of the practical power of design, execution, and masterly superintendence possessed by Organza, is the acquirement of the power of manual dexterity in some one practical branch of art-manufacture. Let us, therefore, before entering on the practical application of these principles to the matter in my title, take a few instances of the first entry into professional life of a few eminent artists of Medieval times.

Arnolfo, who designed Santa Maria del Fiore, and the Or San Michele, at Florence, began by learning painting of his father, and then studied the art of design under Cimabue, for the purpose of employing it in sculpture.

Nicola Pisano, who designed the church of San Antonio, at Padua, first worked under Greek sculptors, and then perfected himself as a sculptor, by the study and practical imitation of Classical remains at Pisa.

Giovanni Pisano, who designed the Campo Santo, at Pisa, learnt sculpture from his father. Giotto, we know, began by painting, but was also a sculptor.

Agostino and Agnolo, both architects, began by studying sculpture under Giovanni Pisano. Andrea Pisano began by studying and practising sculpture.

Organza first learnt his father's calling of a goldsmith, and then studied sculpture under Andrea Pisano.

Brunelleschi, the great architect of the dome of Santa Maria del Fiore, was first placed with a goldsmith, and, as we know, beat Donatello, the sculptor, according to his own acknowledgment, in the design and execution of a wooden crucifix.

Michelozzi, the architect, first studied sculpture under Donatello.

Andrea Verocchio, who was an architect, began as a goldsmith, and was a carver in wood.

Bramanti, the architect, was first taught art as a painter.

Sansovino, the architect, studied sculpture with Andrea di Monti Sansovino, who worked principally in metal, and who had learnt his art from Bartolomeo Ghilberti, a goldsmith.

Michelangelo, the great architect of St. Peter's, began his art education as a painter, but afterwards gave himself almost wholly to sculpture.

Singular it may seem to say that most of these masters were distinguished by their skill in construction when they came to employ their talents in architecture, which I am inclined to attribute to the practical nature of their art-studies, as distinguished from the theoretical nature of those studies, in the so-called art-men, in the profession at the present time. As in the studies in the practical form of goldsmith's work, painting, or sculpture, the sculpture, the practical way of looking at work necessary to design construction was exercised at the same time that the artist was learning art: he was also accustomed to executing work complete in itself, without the aid of others, instead of only

making designs on paper for others to execute; so that when he came to direct, he knew well what directions would be necessary to enable others to execute his designs, according to his intentions.

We see, by the above enumeration of some of the most celebrated Italian architects of the middle ages, and of their mode of education for their profession, that they all began by some practical branch of art, mostly sculpture, although often the very first steps were in the goldsmith's shop; and it appears that, when they had carried on sculpture as a profession for many years, and being as it were perfected in the production of what was then esteemed part of a building, they seem then to have had an ambition to have the entire direction and production of the grander whole; and, probably, it was also from the part that painting played as a means of adornment for buildings, that made the painter also,—when, having practised for some time an art which, still, like sculpture, founded and completeness in itself, with all its beauty, and completeness in itself, grand composition of the building it adorned,—have a like ambition to design the building also.

We see, then, that the way that men in that day fitted themselves for designing and carrying out buildings was by perfecting themselves in some one at least of the sister arts contributing to it; and that required manual dexterity. And what was the result? That which I think might have been expected, viz., that the most ordinary details and accessories of the buildings were works of art, and equally good in their way with the statues and bas-reliefs, which, from the same cause, were first-rate, and were of great frequency, and allotted their full importance as means of architectural embellishment: sculpture and painting became architectural adornments, and architecture became the art of properly and most elegantly supporting and combining these valuable aids to its enrichment.

The architect, or the artist, when he turned his attention so thoroughly to sculpture, or to painting, so thoroughly conversant with the almost resources furnished by the sister arts, and by the practical nature of his training, so able to turn these to their best account, and so well know whether the works he entrusted to other hands were well or ill executed, and, in his branch or branches, was so able to take the leading or most delicate parts, or to give the finishing touches, that a work was turned out as completely a perfect work of combined architecture, sculpture, and painting, as a picture or a statue is a complete work of sculpture or painting alone, and the realization of the ideal of the one sculptor or painter, and as completely a realization of the ideal of the artist; but the two principal best things that they learnt were an intense love of all the arts; while surely, at least an architect should, of all the men of all professions and occupations, except painters and sculptors exclusively, be the best acquainted and the most fond of those arts, and have a conviction of their unity, and how capable they were of combination, and how much they gained by that combination.

Now, there are two things that were, till quite of late years, and to a considerable extent even now are very much required to be learnt by architects of the present day. They seem, till quite lately, very much to have neglected the study of the other arts, even to the extent to which they are cultivated by amateurs engaged in other pursuits, and also to have considered their art perfect in itself, without the aid of the other two; and that the knowledge of by-gone architecture alone was all that was necessary, and that principally at periods when least aided by the others, or from buildings from which the sculpture, which once gave the chief life an expression, has been broken or carried away, and on which the paintings which once shone on the walls, and which gave the chief warmth and constituted their greatest glory, have decayed and disappeared,—content with copying the bodies left by their forefathers, beautiful, no doubt, in their form and proportions, but forgetting to give them the life by sculpture, or the warm and gorgeous apparel by the sublime art of painting, which the originals had when they were first opened to the admiring gaze of the assembled multitude. Now, if a sculptor is the designer of a building, you may be sure that the last thing that he will leave out of it is the sculpture; and that as the chief delight of the sculptor is to represent the human figure, he will be sure, if possible, to find fitting places for it; and, as in studying for the accessories of his figure subjects he has to study leaves, flowers, and animals, you may be sure that he will not forget to wreath and place them in his capitals, and this not only because he can do them, but because he loves them. And if a painter designs a building, you may be sure he will not

forget the colour; you may be sure that the building, when first built, will be intolerable to him,—the cold white stone an eye-sore: everything being the same colour will be unnatural and painful to him, and he will be impatient to alter its tones; to break its monotony with colour, and its dulness with storied subjects; and where the positions are not fitted for painting, he will be only too anxious to enrich his building with beautiful forms, and light and shade, by the aid of sculpture,—and that not only because he possesses the power of enriching the building by painting, but because it is his nature, increased by cultivation, to love these things.

So that I have endeavoured to show you that a genius possessed of the power of working as a painter, a sculptor, and a mechanic, like Organza, will be the best possible architect, i.e. designer and practical superintendence of a large work, or one requiring the assistance of many hands; that an ordinary man possessing as much practical knowledge of these arts as attainable under his particular circumstances, will be a much better architect, as to design and superintendence, than he did not possess that knowledge; that the leading and most celebrated architects of the Italian school of later Gothic, and Early Renaissance, acquired their remarkable skill in designing buildings, in which the most perfect figures, sculpture and imitation of nature in the details harmonized with the paintings and coloured mosaic and inlaying on the walls, combined with many remarkable instances of original and daring construction,—acquired that skill, that love of nature, and perfect and fine work, and knowledge of how work would look and combine, with the practical head and hand required to plan and make models for the execution of those daring feats of construction, in the goldsmith's shop, in the atelier of the sculptor, or the studio of the painter,—each having made many valuable works without the aid of any one else, and been entrusted upon their own responsibility with much valuable material, before attempting to be the sole directors of the work of hundreds, and the sole dispensers of the money of their country, in gigantic works, with many first-rate masters working under their orders.

Also, I have endeavoured to show you the practical knowledge and power of executing works in the sister arts will give men a love for, and an appreciation of them that they would not, and cannot, otherwise possess, to the manifest gain of the buildings, and also to the increased employment of artists' of those branches of art.

This knowledge and power of execution will, in fact, at once, and as a matter of course, produce the sort of feeling which made Mr. Hardwick (according to the *Times* of the other day, in an article on the new fresco in Lincoln's Inn Hall) say, that he was so pleased with it, that he should for the future leave all the spaces he could, in his buildings, for frescoes: and if those are his sentiments, may be long live and keep his promise.

Now, let us turn to the best way of applying these principles to ourselves. Most of us are past the time, and would find it difficult even if we were not, to begin our education as these men began it. Then, what is the next best way of acquiring, in proportion to our opportunities and talent, this practical knowledge of art,—this unprejudiced love of all the arts, and been kept for and love of nature,—and this finger knowledge, that will make even an art man a good constructor, because he looks upon it in a practical manner, and does not waste all his time learning it from books, although much can be learnt from them?

With regard to the love of colour in nature, and the consequent love of the use of it in our buildings, and love and proper appreciation of the art of painting, and all that is to be learnt from a practical knowledge of painting, and a power of producing paintings, as it is not my subject tonight, I will dismiss it with the remark that the best way of obtaining them, for those that are either being educated in the usual system or engaged in the office, is painting from nature whenever they have time and opportunity, and also studying paintings in the exhibitions of the year, and not architecture only. But with regard to the love of form and light and shade in nature, and, consequently, of the expression of them by the art of sculpture in our buildings, and the love and proper appreciation of this art, and all that is to be learnt from a practical knowledge of it, and a power of producing works in sculpture, and of modelling and other means whereby we look on forms of architecture, whether artistic or constructional, from a more practical point of view, and obtain a more perfect power of superintending others in works of sculpture

and other necessary works,—this is the principal object of this paper; and, it seems to me, that as the architects of old obtained these powers by the actual practice of some one practical art, so we, in like manner, although already engaged in some other branch of the profession, may at least correct our deficiencies, and obtain some part of these powers by the occasional practice of one practical art.

I have, after some consideration, selected wood carving, as more cleanly than stone, and propose that those who think with me, or at least thinking that there would be no harm in their acquiring some proficiency in the use of the chisel, should form into a class, on the same principles as the class of design, and engage an experienced carver to set us going, at least in the technical knowledge and right use of the tools, and meet fortnightly for the purpose of learning to produce works of sculpture in wood.

I will conclude with an invitation to all who would like to be able properly to superintend the execution of a capital, a crocket, or a finial, in the words of Donatello to Brunelleschi, when Brunelleschi found fault with his crucifix.—“Take wood then, and try and make one thyself.”

At the conclusion,

The Chairman said that he had been much interested in the paper, which he considered contained some points deserving of their attention as architects and students of art. To these he would venture shortly to refer. The system of education among architects, seemed as if it were likely to be made the subject of change in several respects. He quite agreed with the author of the paper just read, respecting the old plan of studying nothing but drawings and engravings, without becoming familiar with the practical details of a building. Happily, however, for the student of architecture, it had become the custom to visit foreign countries, and there study the most remarkable and note-worthy buildings. To this he was disposed to attribute much of our success in Classic architecture, and the success generally which was beginning to attend the study and practice of architecture in this country. The study of foreign buildings, more especially the Classic and Antique, tended to cultivate a taste for sculpture and painting. An illustration of the development of this faculty was presented in the case of Professor Cockerell, whose pediment of St. George's Hall, Liverpool, showed the great advantage of practical artistic knowledge. As regarded the formation of the proposed class, he entirely approved of the suggestion, and hoped it would be followed up. It had, however, occurred to him that perhaps some person might incline rather to modelling in clay than carving in wood, and upon this point it might be desirable if Mr. Druce were to explain his reason for recommending the latter process. It seemed to him (the Chairman) that there was less difficulty in modelling in clay, owing to the plastic nature of the material; at the same time he was willing to admit that it did not impart the same structural knowledge which was to be derived from carving in wood. The value of knowledge superadded to architecture was notably instanced in the case of England's greatest architect, Sir Christopher Wren, who had acquired a practical knowledge of anatomy, and a European reputation for mathematics, before he commenced to practise the profession of an architect.

Mr. B. A. C. Herring suggested that if students of architecture would regard carving in wood, not as a portion of their daily office-toil, but as a recreation, it might be invested with additional attraction. He quite approved of the suggestions thrown out by Mr. Druce, because he had himself known many instances in which architects had to employ sculptors to design figures for them, whereas, if they had had themselves a knowledge of sculpture, they could have told what figures or groups would have suited their buildings best. That the sculptor's art could be readily attained by the architect was perhaps shown by the fact, that many persons who were neither architects nor professional sculptors, were nevertheless good sculptors. He himself had often heard of cases in which clergymen had executed fountains for their own churches, and why should not architects do the same, and design their own foliage or figures?

Mr. C. M. Lewis observed that if architects could execute their own figures, they would probably introduce sculpture more frequently into their buildings than was now the custom.

Mr. Druce said that the reason why he had suggested wood as the medium for carving, was that, in the first place, it was a cleaner process; and secondly, because, if a complete mastery of the chisel could be obtained, it would be very easy

for the carver in wood to become the sculptor in stone also. It did not appear to him that a knowledge of carving was at all difficult of attainment; and as an illustration he might mention that he knew a case in which an architect in the country, failing to obtain a skilled workman, showed an ordinary carpenter, who had never carved anything of the sort in his life, what was wanted, and, in a short time, he succeeded in producing a very creditable ornament on a weather boarding.

The Chairman called attention to the course adopted by mechanical engineers. When they got a pupil they sent him for a couple of years into the drawing-office; he next went into the workshop to file, turn, forge, and learn what a bit of iron was; and finally, he went for two or three years into the modelling-shop, where he learnt how to make in wood the models from which the machinery was subsequently cast. In like manner, it was the practice occasionally to send young architects into a builder's yard, to learn something of carpentry. If to this could be added a practical knowledge and artistic feeling in the treatment of buildings, it would be most desirable.

The Reader of the paper gave notice of his intention to move at the next meeting that a class for wood-carving be formed, and announced that, should the class be so formed, he had been promised some practical aid in the way of assistance from skilled workmen.

The next subject for the class of design will be a town-hall, and at the ensuing ordinary meeting a paper will be read by Mr. J. Johnson on “Coloured Materials, considered principally with reference to their Application to External Design.”

COUNCILS OF CONCILIATION.

On Wednesday evening, at the Marylebone Literary Institution, Mr. Blanchard Jerrold gave a popular reading, descriptive of the relations between master and man in France, and of his recent visit to the Conciliation Hall of Paris, with a view to the formation of similar institutions in England, for settling disputes between the employer and the employed. The reading did not attract an audience so large as the interest of the question would have led us to anticipate. The subject was treated in an able and amusing manner by Mr. Jerrold; and the reading, which we hope will be repeated under more favourable circumstances, was useful as showing the working of the *Conseils de Prud'hommes* at Paris, existing under the special countenance of the present Emperor. For the decision of cases of certain kinds, and towards the cultivation of amicable relations between masters and workmen, the evidence adduced by Mr. Jerrold showed that the Councils of Prudent Men worked most successfully; but it did not throw any further light upon the question of their use in diminishing the number of strikes about wages, than is to be found in the evidence before Mr. Mackinnon's Committee of 1856, to which we gave attention recently. In the wages question it must be recollected the *Conseils* have no power to enforce decisions; and as it is not argued that similar bodies could have any in this country, their operation in diminishing the most fertile cause of strikes would be indirect, though probably in that way such as would well justify their institution. Mr. Jerrold showed that, in 1857, there were 50,000 disputes, of which only 8,000 proceeded from the “Bureau de Conciliation,” or court of first resort, consisting of a master and a workman, to the “Bureau Général,” or court of appeal, which consists of three masters, three workmen, and a president nominated by the Government; and of this number appeals, 6,000 were withdrawn. Much of the particular success of the *Conseils* in France, or in Paris, was attributed by Mr. Jerrold to the high character and feeling of self-respect in the French artisan,—a feeling, which descended to the class of the rag-pickers, and was in great part the national attribute, of paying respect to the able man as such—one absolutely different from that of society in England. Mr. Jerrold declared from his own observation, that habits of intoxication amongst the French artisans were almost entirely absent. The French workman spoke not of his “master,” but of his “patron.” Whether from these national peculiarities, or from the merits of all such institutions, therefore, it appeared, from Mr. Jerrold's inquiries, that the *Conseils* were working well in France, and that (in corroboration of the evidence before the committee) similar institutions might be of a certain value in this country. But the *Conseils* in France could at any time be swept away by a decree of the Govern-

ment, such as that which re-established them; and in Lyons, in 1831, the attention given to the relations of masters and workmen had not prevented excesses of riot, and in Paris, in 1818, the prevalence of some delusions.

THE WORKS OF ART IN HAMPTON COURT PALACE.

The state of the pictures here, and perhaps still more of the tapestries, requires immediate attention, if they are considered to be worth preserving. Mr. Henry Cole has recently addressed to us some observations on the subject, wherein he urges that instead of being treated as a mere storehouse, Hampton-court Palace would be a much more attractive public sight if the rooms were restored as much as possible to their original state of decoration. He divides the pictures into six classes, and goes on to say,—I would suggest that the works of fine art should be brought to the metropolis where they would be much better preserved, where the facilities for making them available for public instruction would be greatly increased, and all classes of the public infinitely more benefited than by leaving them at Hampton-court Palace, which is visited by the great majority of persons as a palace in the country having beautiful gardens, rather than for the study of works of fine art. The public also possesses pictures and works of art which require constant care, at many institutions, such as the National Gallery, the British Museum, the National Portrait Gallery, Greenwich Hospital, and at the South Kensington Museum, &c. I would suggest that a small committee of consultation, consisting of three artists, with one chemist and one amateur, be appointed to determine what measures should be taken for the preservation of all works of art, either belonging to the public or lent by the Crown for public use, and that premises be provided and skilful persons be chosen for the purpose of carrying into effect, under proper superintendence, the recommendations of this committee.

PRINCIPLES OF DESIGN IN ARCHITECTURE.

ARCHITECTURAL INSTITUTE OF SCOTLAND.

At a meeting of this Institute, held in Edinburgh on the 6th, Mr. James Gowans read a paper, illustrating some of the principles of design in architecture. Mr. Lessells presided. Mr. Gowans, after dwelling on internal arrangements, described the style in which the exterior should be constructed, and the mode in which the materials used should be treated; the first step being to meet adequately the requirements of the inmates of the house, and the second to secure a truthful application of the material which the district afforded. The dressings of the building should, he remarked, be executed with light and cheap material, hewn in such a way as to please the eye, without that accuracy of touch necessary in large public buildings. He pointed out how the coloured stone of particular districts did not find fair play in architecture; observing that it was only when the disposition of these coloured stones was not correct and honest that failure in effect resulted. He had heard it said that it was only in such sunny places as Italy that colour in architecture should be used, and where it could produce its true effect; but he held otherwise; and one of his reasons was, that the deficiency of sunshine in this country called for the application of such material as would give our buildings as cheerful an aspect as possible. With reference to the houses of a larger description, Mr. Gowans instanced his newly-erected mansion at Merchiston-park, Morningside, as an example of the correct principles of architectural design. Whatever might be the effect of that house on the spectator, he assured them that his object in so building it was not simply novelty, but he had endeavoured to erect a building which would put to practical test the system of constructing on squares at fixed angles, thus working out every feature on strict geometrical principles. Another object which he desired to realize was the disposition of colour in the building, so as to assist in developing its general structure and particular parts. Mr. Gowans, in passing, commented upon the importance of thoroughly grounding young beginners in architecture in this anatomy of house-building; so that, instead of borrowing from examples, they might strike out new methods of building, and by mature taste secure a design which would please the eye of the closest critic. He advocated the establishment of a chair of architecture in our colleges, on the ground that architecture had far more to do with our moral and social improvement

than most of us imagined. There should be examinations instituted in such university architectural classes, and diplomas given, to show that a student was well versed in the principles and practical knowledge of the art.

Mr. J. Dick Peddie, in the course of a brief address, observed that the Institute had resolved to have no discussion on papers on the same night as their delivery, but on the succeeding night of meeting. Mr. Gowans had given them some excellent information, but he (Mr. Peddie) did not profess to have much faith in the system of geometrical lines which had been explained. He trusted Mr. Gowans at next meeting would give fuller explanations of this system. But whatever the principles were that Mr. Gowans had worked upon in the erection of his mansion at Merchiston, every one would admit that he had produced a house of highly picturesque effect. If very much doubted whether this effect was the result of the geometrical construction, and also whether it might not have been produced by the ordinary system of architecture. Mr. Gowans reiterated the old complaint against architects, that they were but copyists; but if every architect aimed at producing an original design in house building, the result would be all kinds of monstrosities. The true way was to do as nature dictated, and to make small and gradual steps of improvement in architecture, not to produce new styles. As to Mr. Gowans's remarks regarding chairs of architecture, he agreed with them. We ought in all our universities to have a Professor of Architecture, and it seemed to him to be a disgrace that, in a city like Edinburgh, this art should be so much neglected.

ST. PAUL'S CATHEDRAL.

A COLOSSAL statue of the late General Napier, executed in white marble by Mr. George G. Adams, has been set up near the north entrance to St. Paul's. It is elevated upon a plain pedestal of grey marble, on the face of which is the following inscription:—

CHARLES JAMES NAPIER,  
A PRESIDENT GENERAL,  
A BENEFICENT GOVERNOR,  
A JUST MAN.

It is well spoken of, but we have not yet seen it. We attended the special service there on Sunday evening last, but the building was then too dark, and too crowded to examine sculpture. Mr. Parness's arrangements for the services are more complete than they were, and appear to meet the wants well. He must be anxious, we should think, to get a more satisfactory-looking pulpit than the present. The painting of the flat surfaces in the dome is nearly completed, and a considerable amount of gilding has been done there. When anything is done down below, it is to be hoped that we shall get more colour.

The Rev. Daniel Moore was the preacher, and was heard in every part of the vast edifice by attentive thousands. The effect of the singing, though the organ had been taken down, was admirable.

THE ART UNION OF LONDON PRINTS.

As advertisements have told, each subscriber for the current year will receive, besides his chance of a prize (not at all remote), a volume containing "Thirty Pictures by Deceased British Artists," engraved by W. J. Linton, and a line engraving, by Mr. F. Hall, from the picture called "Come Along," by Mr. J. J. Jenkins. The volume contains "The Corn Field," by J. Constable (an exquisite engraving), Northcote's "Burial of the Princes in the Tower," Reynolds's "Banished Lord," Haydon's "Marcus Curtius," Wilkie's "Rabbit on the Wall," "Death's Door," by Blake; Hogarth's "Marriage à la Mode," Liveriesque's "Cobbett's Register," Fuseli's "Witches in Macheth," Martin's "Joshua commanding the Sun to stand still," Hiltou's "Europa," "A Peat Bog in Scotland," by Turner; "The Defeat of the Spanish Armada," by De Louthembourg; Wilson's "Niobe," Barry's "Victors of Olympia," Etty's "Cupid," "Barrington Old Pier," by Copley Fielding; West's "Death of General Wolfe," poor Müller's "Mennon," Collins's "Cromwell," and others.

The volume itself, we have no hesitation in saying, is alone well worth the guinea subscription. It was an excellent idea, and has been exceedingly well carried out. The line engraving, although necessarily simpler than some of the prints issued by the Art Union (the book of engravings being a costly production), bids fair to be extremely popular and much prized. The *Observer* says of it (and in the case of the Art

Union of London we generally prefer, for reasons, to give the opinions of others rather than our own).—

"The beauty of the scene, the gentle hills, and the gurgling streamlet; the beauty of the subject, a handsome woman and a lovely female child, and the beauty and harmony of the accessories, all contribute to render this engraving perhaps the most perfect, and certainly the most attractive, that has ever been published by the Art Union of London for distribution among its subscribers; the beautiful, are marked in every feature of the original work, and are translated in all but colours by the engraver."

A large subscription, and active proceedings on the part of the council this year, may unquestionably be looked for.

COST OF SEWERS AND PIPES IN PRESTON.

THE following extract from the recently published summary of public works executed during the year ending April 30th, 1859, contains some useful information:—

Variety	E. s. d.	s. d.
69 of Brick Sewers, 2ft. 6 in. diameter, at 7s. ....	21	0
538 3ft. by 2 ft., at 17s. 6d. ....	470	14
294 3ft. 6in. by 2ft. 6in., at 25s. ....	412	12
372 3ft. 6in. by 2ft. 6in., at 28s. ....	520	10
250 4ft. 3in. by 2ft. 6in., at 11s. 9d. ....	524	16
50 4ft. 6in. by 3ft., at 7s. 7d. ....	211	13
93 4ft. 6in. diameter, at 9s. 9d. ....	134	9

THE RIGHT OF COUNTY SURVEYORS TO RETAIN THEIR DRAWINGS.

A MATTER of some interest to the architectural profession came before the Norfolk Quarter Sessions on Thursday, the 6th inst. The county surveyor, Mr. Phipson, it appeared, had intimated to one of the committees of the Court that his predecessor in office, Mr. Brown, declined to give up the plans, &c., which he had prepared during the twenty-three years which he had served the county. The ground assigned by Mr. Brown for this proceeding was that, by the usage of his profession, plans were the property of architects, and not of their employers. A correspondence took place in November and December between the clerk of the peace and Mr. Brown's solicitor; but as no amicable solution of the difficulty could be arrived at, the former was instructed to embody the circumstances in a case to be submitted to Mr. Welsby, Q.C. That gentleman, referring to the conditions under which Mr. Brown was appointed, observed that the question was whether the remuneration which he was to receive, and which was to include all charges for plans, estimates, and attendances, meant only all charges for the labour and skill expended in the preparation of plans, or whether the expression included also the value of the plans themselves. The latter, Mr. Welsby expressed his opinion, was the reasonable construction to be put upon the matter; and he believed the plans had become the property of the persons for whom the work to which the plans related was done. The county magistrates, not being a corporation, could not, Mr. Welsby added, bring an action against Mr. Brown; but he thought the Court might make an order for the delivery of the plans, and that in the event of disobedience an application to the Court of Queen's Bench would result in a *mandamus* being granted to enforce compliance. An animated discussion followed, in which the Rev. E. Postle, the Rev. Lord Bayning, Sir Samuel Biggild, Mr. Fellowes, Mr. P., the Hon. and Very Rev. the Dean of Norwich, and other gentlemen took part; and eventually the Dean stated that he was authorized by Mr. Brown to "offer to the magistrates to allow the clerk of the peace, or any person appointed within a reasonable time, to make, for

the use of the present or future county surveyors, copies or tracings of all plans and specifications for all works executed under his superintendence as county surveyor, or to furnish copies upon being remunerated for the same." It was also proposed, on the part of Mr. Brown, that the matter in dispute should be referred to two eminent metropolitan architects, with power to call in a barrister as umpire. The Court finally determined to instruct the committee who had turned their attention to the subject to enforce their claim, but to endeavour, if possible, to effect an amicable arrangement before proceeding to legal extremities.

ARCHITECTURAL COMPETITION, HULL.

In reply to an advertisement put out by Messrs. Jamieson & Son, for re-building their premises, the following architects submitted designs, viz.—Mr. Brodrick, Leeds; Mr. Brown, Hull; Mr. Peteh, Scarborough; and Messrs. Bellamy & Hardy, Lincoln. The design of the last-named gentlemen was selected.

SCENERY AND THE STAGE.

The *Princess's Theatre*.—Although comparison in such a case is difficult, we are obliged, we are very much disposed to say that Mr. Harris has the best pantomime of the season: that is, if we were to examine each under all the hands involved in getting up, dancing, the actors employed, and so on, Mr. Harris's "Jack the Giant Killer" would get most marks. Miss Louise Keeley is a host in herself, and M. Espinosa certainly one of the most extraordinary ballet-actors that has been seen for a long time. The scenery, painted by Messrs. Gray and Gates, especially "The Queen Bee's Haunt" (a remarkably clever work), and the closing scene, is very satisfactory.

*St. James's Theatre*.—It was a bold thing on the part of Mr. Chatterton to attempt the production of a pantomime at this house, where there were no properties, no scenery, scarcely a trap in the stage. But the public had so well supported him in his undertaking up to that time, that he felt bound to carry out the traditions, and so, at the cost of more than a thousand pounds, there is, for the first time, a pantomime at the *St. James's*. Mr. J. Coventry, a name new to us, has produced one or two very pretty scenes, "The Home of the Queen of Mirth," for example, and the whole is very successful.

ART TEACHING AT THE CRYSTAL PALACE.

It is one of the noticeable signs of the present age that the arts of architecture, painting, and sculpture are brought into use in places where formerly they were but little thought of. In taverns curiosities are used as a means of attraction; many have added concert-rooms to their premises, where good music is to be heard; and of late, pictures of good artists have been collected. There is a gallery of pictures by modern painters in one of these concert-rooms that would be worthy of a place in any of the houses of the rich or noble in the land. While this movement is progressing in a satisfactory manner, it is to be regretted that, in some instances, buildings which have been raised for the distinct purpose of advancing the public art and tastes are being turned from their purpose: one of the most important of these is the Crystal Palace at Sydenham. Here have been copied, at an enormous cost, several of the choicest remains of antiquity. There are the temples of Egypt, Greece, and Rome; curiosities of nature, statues, tombs, the effigies of men of eminence of all ages; flowers, both in and out of season; grounds laid out with great skill, and most carefully kept; and from this palace, provided for the people, is one of the sweetest views in England. Yet all these attractions do not seem to be sufficient. Let us hope, however, that this may partly be in consequence of the distance from town at which this rare exhibition is placed, rather than from a want of general appreciation. It certainly sounds strange, in these times, when we pride ourselves on advanced taste and intelligence, when we hear what is going on in the Crystal Palace, a structure in the first instance devoted to the fine arts. At twelve o'clock Mr. Pepper gives an illustrated lecture in the new lecture-hall, but there is at the same time "Punch" in the centre transept. At one o'clock the band performs the "Riflemen's March," and a French clown exhibits his "whimsical performance." At half-past one "The Chantrell Family, show their surprising feats." At two o'clock there is to be seen a troupe of dogs and monkeys,

from Paris, and a celebrated performing elephant. Then come dissolving views, anything but first-rate; afterwards an "imitable" nigger amuses; and at the close there are grotesque shadows on the great screen. How different is this teaching from that which the anguine looked for when this palæo was first raised. Let us hope that those who throng to see these entertainments may at the same time profit by the more intellectual part of the exhibition which is there provided.

TESTIMONIALS TO THE MANCHESTER EXHIBITION COMMITTEE.

A GALLERY OF ART FOR MANCHESTER.

On the 6th inst., a meeting was held in the mayor's parlour, at the Manchester Town-hall, for the presentation of a piece of plate to each of the seven members of the executive committee of the late Art Treasures Exhibition.

The seven testimonials are made from one model, in silver oxidized and partly gilt, each consisting of a decorated shaft, surrounded by figures of Painting, Sculpture, and Industrial Art (with their emblems), and crowned by an infant Genius, holding aloft his torch, and in conflict with an eagle. The shaft is decked with the rose, shamrock, and thistle, and the base with lustral and ivy entwined with ribands, bearing the names of great artists. There are also medallion portraits of Michelangelo, Titian, and Cellini, and on circular shields the exhibition building, the arms of Manchester, and the arms of the gentleman receiving the testimonial. The work has been executed by Messrs. Hunt & Roskell, from designs by their artist, Mr. H. A. Arnstead.

In the course of the proceedings Mr. T. Fairbairn made an address, wherein he urged the inauguration of an institution, to be dedicated to the arts, which shall be worthy of the wealth and importance and enlightenment of that great city. Let the design of such an institution (he said) be simple and comprehensive; let it be central in its situation; let it be a fitting receptacle for the display of the most costly and the most meritorious works of art,—a home where such works can be well seen and conveniently studied; let it be a free-will offering from the well-to-do among us to those whom we wish to see advancing in prosperity and improving in tastes; and, above all, let it be opened absolutely and entirely free to all, for the sake of the good that it would gradually instil into the public mind; and I will answer for it such an institution shall not lack either noble gifts or public appreciation. I, for one, towards the formation and establishment of such a permanent art gallery, will willingly give my time, money, and whatever energies or influence I possess.

We sincerely hope that the proposition will be immediately acted upon. That such a city as Manchester should be without any public collection of works of art is not creditable or wise. As to the propriety of the presentation of the testimonials above mentioned, all we can say is, that to justify it, the committee should enjoy in Manchester a very different reputation from what they have in London!

IRELAND.

The directors of the Newtownmavady Market Company offer a premium of five pounds for plans and estimates for a market-house, to be built near the railway station.

A new Independent church is to be built at Galway, after designs by Mr. Raffles Brown, architect. The Royal Institute in the same town, recently erected, is an important structure, presenting two principal fronts, and arranged internally both for business, scientific, and dwelling purposes, according to plans by Mr. Carson, of Dublin, architect.

The Ecclesiastical Commissioners for Ireland are about having extensive works contracted for in connection with the church of Ardferd, co. Kerry. The War Department has called for tenders to execute certain alterations and additions at Carrickfergus Castle, in the Belfast district.

The millers of Dublin and eminent mercantile firm in the timber trade are still at variance as to "string" or "calliper" measurement. Mr. Challoners, of Liverpool, was appointed to, to decide the question; and his statements in reply serve to show that in yellow pine (St. John's) string measure is from 1 1/4 to 1 1/2 per cent. less than calliper; birch (St. John's, N.B.) averages 20 per cent. less; Quebec yellow pine, 9 1/2 per cent. less; red ditto, from 8 to 14 1/2 per cent. less; Quebec birch averages 10 per cent. less; Quebec oak, 8 1/2 per cent. less; Danzic and Mamel fir, from 7 1/2 to 8 1/2 per cent. less; Rigafir averages 12 per cent. less; and pitch pine,

8 per cent. less. It is difficult to say how the question may end yet.

The new line between Athlone and Roscommon is expected to be opened about the 1st proximo; it is about twenty miles in length.

The estimate of Mr. Hawkesley for the proposed waterworks at Dublin, including the purchase of land and other contingencies, is 218,558. 8s. 5d.

The Board of Public Works are about executing additions and alterations at the Abbey district model national school-house, and seek for estimates.

It is believed that the Conservative Land Society are about effecting improvements in the dwellings of the Irish operatives and peasantry; also introducing the freehold land system into that country.

The design for the memorial about to be erected by Judge Berwick to the late Father Mathew is by Sir John Benson, and comprises a fountain, with basin 24 feet in extreme diameter, with shaft rising therefrom, and supporting two other basins, 34 feet and 5 feet respectively in diameter. Three dolphins with upturned tails sustain a third basin, above which is a jet, throwing water to a considerable height. Cost, about 150*l*.

Dungarvan has been lighted with gas. Mr. Holloway contractor.

It is proposed, pending the arrangements for the permanent pier and breakwater at Galway, to erect a temporary pier from the point at which the Midland Great Western Railway terminates, to run out far as the pool, and to cost 3,000*l*.\*

STAINED GLASS.

St. Giles's Church, Comberwell.—This church, well known as one of the earliest works of Mr. Scott, has recently been adorned with two stained glass windows placed in the chancel, on either side of the great east window. These two new windows represent incidents in the lives of the Apostles, St. Andrew, St. Peter, St. John, and St. James, and have been designed and executed by Messrs. Lavers and Barraud, being paid for by subscription of a few members of the congregation, one of them entirely at the cost of a munificent lady. The committee, who originated this idea, intend, if they are aided by their fellow parishioners, to complete the other four windows in the chancel in the like style, and have already ordered a third to be placed on the south side by Easter next. This window will, in its two lights, represent incidents in the lives of the Apostles, St. Philip and St. Bartholomew.

METROPOLITAN BOARD OF WORKS.

THE SOUTHERN OUTFALL MAIN SEWER.

At the ordinary weekly meeting of the Metropolitan Board of Works, held on Friday, the 6th, in the council-chamber, Guildhall, Mr. J. Thwaites in the chair, tenders were received and opened for the southern outfall sewer, and were as follows:—Messrs. William Delpech, 330,000*l*.; William Hill, 328,000*l*.; Helling & Co., 315,000*l*.; Joseph Diggle, 328,000*l*.; Edward Thnot, 373,000*l*.; William Moxon, 337,000*l*.; W. H. Rowe, 296,000*l*.; George Baker & Son, 294,000*l*.; Rowland Brotherhood, Chippenham, Wilts, 282,550*l*.; Peto & Betts, 337,715*l*. 9s. 1d.; William Treadwell, 384,536*l*. 11s. 9d. The tender of Rowland Brotherhood, Chippenham, Wilts, was accepted.

THE SANITARY CONDITION OF THE DWELLINGS OF THE POOR.

A communication was received from the Whitechapel Board of Works, calling attention to certain premises now in the course of erection at the rear of Nos. 80 and 81, on the north side of High-street, Whitechapel. It was the intention of the persons erecting the premises in question to construct three houses, in which it was probable that not less than seventy-two persons would reside. The site selected was a pent-up *cul de sac*, with a covered entrance to High-street, Whitechapel, only 5 feet wide, decreasing in width to 3 feet 10 inches, and the height only 8 feet 6 inches. The notice went on to state that the Board viewed with the most serious apprehension this system of constructing dwelling-houses for the poor as subversive to the great end to be accomplished in sanitary regulations, and earnestly requested the Board of Works to cause a special inquiry to be instituted into the matter. A somewhat similar instance existed in Inkhorn-court, also on the north side of High-street,

\* With reference to a note in a recent number, as to the fall of a portion of the works at John's-lane distillery, the architect wishes us to state that it was simply a few perches of brickwork which were thrown down by the accidental upsetting of a water-tank.

Whitechapel, the entrance to which was between the houses 89 and 90, to which their especial notice was also solicited.

The matter was referred to the superintending architect to report upon.

THE ORDNANCE SURVEY OF LONDON.

A report was brought up from the Main Drainage Committee on the arrangements entered into by the committee with the Treasury for the settlement of the claim for the Ordnance survey of London. The report stated that the committee had communicated with the War Department, and had arranged with them that all claims against the Board of Works should be settled by the payment of 10,000*l*. The War Department was to take the plates of the maps, and vestries were to be supplied at a cost only equivalent to their cost to the Government—namely, 1s. per sheet. The original claim had been 24,212*l*. 17s. 8d.

THE TRAMWAYS ON WESTMINSTER BRIDGE.

Stn.—As a great public work must necessarily be open to a certain amount of criticism from that portion of the community who are interested in its utility and successful completion, I feel somewhat inclined to think that the following query will arise regarding the system of tramway adopted on the new part of Westminster-bridge (the privilege of inspecting which the public have now an opportunity of enjoying, by a birds-eye view while passing over the west side of the present structure).

It will be observed that there are two trams in the new roadway, for carriages of various construction; and I presume it is intended that the stream of vehicles should travel reversely. Now I would draw attention to the very small space between these trams, and suggest that it would be impossible for many heavily-laden waggons to pass each other when the burthen they contain hangs over their wheels on either side, even an ordinary distance. I would instance the frequent transit of waggons containing the huge sacks of hops. It would be, I need not say, most unfortunate for two such to meet in the centre, as it would entail the necessity of the one or other retreating by a backward movement.

Of course I may be speaking in ignorance of better and more matured arrangements, but I venture to submit my ideas humbly to your notice. H. C.

THE FOUNDLING HOSPITAL AND BRITISH ART.

YOUR account of the Foundling Hospital and of the congenial efforts of Hogarth and others in 1760 to maintain as well as to embellish that asylum is highly interesting and instructive.

If you would pursue the subject a step further, and supply in more detail the catalogue of the men offering to appear in a Foundling uniform at their next "festival," it would be of great value to the illustrators of the art of that interesting but only half-explored period; when, indeed, we may say, art itself was but a deserted haunting making its first step into existence, and struggling into the full light of public favour. That 7th of December, 1760, may be looked back to as the first dawn of hope for native art, which had just made a probationary effort to "exhibit" itself at the room of the Society of Arts in the Strand, and which was the first of a succession of exhibitions leading on to that of the Royal Academy.

As to the list printed in your number, I could point out sundry slight errors; but if you would supply it correctly, as entered, I should have to thank you for myself and many others interested in the inquiry.

Several of the names are to be found in the catalogue of 1760 and the succeeding years. H. M. Spang, for example, was a sculptor by whom I have a statuette in terra-cotta of Hogarth in the act of making a sketch by stealth, but of whom I find no other trace than that of his being an exhibitor by the side of Rouilliac, Wilton, and Hogarth, at that period. J. H. A.

\*\* Our list was printed from that given by Mr. Brownlow. Since the receipt of our correspondent's letter, Mr. Brownlow has kindly enabled us to see a copy in *fac simile*, and we have found one or two inaccuracies: for example, the fifth name on the list, instead of William Chambers, is William Chambers, the architect of Somerset House; and Nathaniel Honey is Nathaniel Hone. T. White and G. Whately, it may be well to mention to save speculation, were the treasurers of the hospital.

Books Received.

*Moral Emblems, with Proverbs of all Nations; from Jacob Cats and Robert Fairlie. With Illustrations by John Leighton, F.S.A. Translated and edited, with additions, by RICHARD PROCT. London: Longman, Green, & Co. 1860.*

THIS is a beautiful specimen of typography, wood-engraving, and bookbinding; founded, with considerable skill and intelligence, on an existing body of world-wisdom. The binding is especially elegant, a design probably of the illustrator, Mr. John Leighton, the results of whose skill as a designer of such matters are well known to the public, though they may attribute them to one "Lake Linmer." Mr. Leighton has always inclined to typification and symbolical representations; and, in setting forth the works of Jacob Cats, as originally illustrated by Jan and Adrian Van de Venne, he has found a labour that was a delight, and has succeeded in consequence: true indeed it is, the labour that we love "physics pain." Written in Dutch and Latin verse, the Moral Emblems and Proverbs of David Cats are almost unknown in England: they form a code of moral instruction, addressed to the youth of both sexes, and applicable to most phases of life. In addition we have pertinent quotations from the ancient authors, the poems of his contemporary, Robert Fairlie, and a collection of proverbs of all nations. Some of the illustrations are remarkable specimens of wood-engraving. We cordially recommend the book, whether to the scholar, the lover of proverbial philosophy, or the young.

VARIORUM.

"THE Engineer's, Architect's, and Contractor's Pocket Book, for the Year 1860" (Lockwood & Co., Stationer's Hall-court) contains (for a pocket book) an immense variety of useful matter, such as an epitome of measurement, the memorandum book of Mr. Telford, the engineer, tables and general information as to sewers, carpentry, strength of materials, woods, stone, coal, iron, brass, steel, and copper; hydraulics, water-wheels, and a multiplicity of other matter, besides the usual almanac materials, and lists of the office-bearers and members of the Royal Institute of Architects, and Institution of Civil Engineers. "Who's Who," edited by C. H. Oakes, M.A. (Bailey, Brothers, Cornhill) has established for itself a distinguished position as an index to everybody who has anything like a handle to his name, titular or official. The present volume (for 1860) is the twelfth issue, and is dedicated to her Grace the (truly graceful) Duchess of Sutherland.

TENDERS

For forty cottages to be built in Hereford. Mr. J. H. Ewins, architect:—

Riggleson & Bowers (James).....	£2,419 19 0
Stone & Bowers (James).....	2,178 11 0
Price.....	1,979 0 0
Banister.....	1,887 0 0

For Works to St. Saviour's Church, Southwark, Mr. Edward Habershon, architect. Quantities not supplied. The Tenders were sent in with two amounts, one for the screen-walls in brickwork, and the other in stone:—

If screen-walls in brickwork.	
Myers.....	£1,134 0 0
Rider.....	1,108 0 0
Tarrant.....	1,099 10 0
Carter.....	1,074 0 0
Downs.....	1,068 0 0
If screen-walls in stone.	
Myers.....	£1,134 0 0
Rider.....	1,178 0 0
Tarrant.....	1,158 0 0
Downs.....	1,137 0 0
Carter.....	1,149 0 0

The screen-walls in brickwork were decided upon, and consequently Downs's Tender was accepted.

For dwelling house, Homsey-rise, for Mr. A. Davenes. Mr. T. W. Copps, architect:—

Nash.....	£1,065 0 0
Sergeant.....	1,719 0 0
Fowler.....	1,677 0 0
Town.....	1,350 0 0

For alterations, &c., at Bows Manor, Southgate, for Mr. Alderman Silbey; Mr. E. Woodthorpe, architect. Quantities not supplied:—

Piper.....	£1,995 0 0
Jeffrey.....	1,189 0 0
Williams.....	1,144 0 0
Carter.....	1,087 0 0
Filler.....	659 15 0

For underpinning about 2,000 feet run of brick sewer in Bishop's-road and Washborne-grove, Paddington, Mr. W. Merzy, surveyor:—

Thirst.....	£2,656 0 0
Pearson.....	391 0 0
Batterbury.....	465 0 0
Rowe (accepted).....	437 0 0
Surveyor's estimate.....	450 0 0

For workshops, Adde-hill, E.C., for Mr. McDougall; Mr. W. Hudson, architect:—

Burton.....	£2,650 0 0
Child, Son, & Martin.....	634 0 0
Pritchard & Co.,.....	631 0 0
Brown & Robinson.....	625 0 0
Newman & Mann.....	618 0 0
Jefferies.....	598 0 0

For new school, &c., for the Rev. Mr. Eld, Lower Belgrave-street. Quantities supplied:—

Higgs.....	£1,380 0 0
Jefferies, Brothers.....	1,132 0 0
Fish.....	975 0 0

Miscellaneous.

**OIL FOR PAINTERS.**—Oil extracted from the seeds of grapes is recommended as an excellent medium for painting.

**SOCIETY FOR THE ENCOURAGEMENT OF FINE ARTS.**—At the adjourned annual meeting of this society Mr. II. Otley (the chairman) said that the society intended to give two prizes in painting. One would be a square ivory or wood pallet, the "Reynolds pallet," with a silver handle; and that which would be awarded for landscape, or *genre*, would be a silver pallet. A bronze medal would be given for sculpture, and also for architecture.

**THE PURCHASE OF ASTON HALL.**—This purchase, of late regarded as more than doubtful, is now, it is thought, placed on a surer basis. The shareholders have paid 7,000*l.* towards the purchase, and the remainder—about 25,000*l.*—was to be paid in the course of this year, or the purchase would lapse, and the deposit already paid be forfeited. The owners of the hall have agreed to accept new terms. They stipulate that the Interim Managers shall pay 3,000*l.* at once, and thus raise the paid sum to 10,000*l.*, and that the payment of the rest of the purchase-money shall be spread over ten years, if not closed at an earlier period.

**FALL OF HOUSES IN SALFORD.**—During Sunday last two accidents to dwelling-houses occurred in Salford, but fortunately they were not attended by personal injury. About three o'clock in the morning, the front wall of a two-story house in Cross-street, Bury-street, fell with an alarming crash, and rendered the place a ruin. The second accident occurred in Queen-street, soon after two o'clock on Sunday afternoon. A labouring man, named Jones, was about to sit down to dinner with his family in the upper front-room of a cottage house in that street, when there came a loud crack, followed by two others, and a noise "like thunder," as the neighbours declare. The wood-work of the roof had yielded, and the whole mass dropped inward, until it bore upon the top of a four-post bed, in the middle of the room.

**ANNUAL MEETING OF THE EMPLOYED AT POOLE SOUTH-WESTERN POTTERY.**—On the 2nd inst., the whole of the men engaged at Mr. Geo. Jennings's works, together with their wives or friends, according to the annual custom of this establishment, sat down together at the pottery works, to tea. The company were upwards of 200 in number. The tea being concluded, a clearance was effected, and arrangements completed for the evening meeting. At the head of the room a temporary platform was erected, and, arranged on a high table immediately in front of the company, was a collection of electrical apparatus, which in the course of the evening was used for experiments. The meeting was addressed by Mr. J. S. Hudson, the manager of the pottery, and by Mr. G. De Chaville and others, and a lecture on electricity was delivered by Mr. W. Coward.

**INAUGURATION OF THE NEW CORN EXCHANGE AT KIRKALDY.**—The completion of the new Corn Exchange at Kirkaldy has just been celebrated by a public dinner, given in the Exchange, and numerously attended. The site of the new building is in Cowan-street, immediately adjoining the old market, and it is intended to serve for a public hall as well as a corn exchange. The dimensions of the hall are 84 feet by 68. The roof, which rises considerably in the centre, is supported by two rows of pillars placed at regular intervals along the entire length of the hall, at a distance of about 20 feet from the side walls. The height of the hall is about 40 feet in the centre, and 29 feet along the sides. The hall is lighted along the east side, and windows are also placed to the north and south: at the west side there are several doors giving access to side-room accommodation; and any deficiency of light at the west side is compensated by the raised portion of the roof being glazed on both sides. The Exchange will, it is estimated, accommodate about 2,000 people; and it has been erected at a cost of about 2,500*l.*, the architects being Messrs. Hay, of Liverpool.

**NEW APPROACH TO THE TEMPLE CHURCH.**—In a short time a new approach will be made to the Temple Church, from Fleet-street, opposite Chancery-lane. A part of Inner Temple-lane is to be demolished, as also Chureyard-court; and other improvements, it is said, are to be commenced forthwith in that neighbourhood.

**THE LINCOLN FRANKLYN MEMORIAL.**—The sum of 1,500*l.* had been subscribed for a memorial to Sir John Franklin, at Lincoln, and the corporation voted 1,000*l.* to purchase a site in a square in the parish of St. Swithun. To carry out the plan a footpath in the square would have to be diverted: this the parish declined to allow, by a majority of twenty-nine, on a poll, and the money subscribed has consequently been returned to the donors.

**STEEL BELLS.**—Messrs. Naylor & Co., of Sheffield, have lately cast the largest steel bell yet made. The height is 5 feet 3 inches, diameter at the mouth, 6 feet 2 inches, and thickness at the sound bow, 4½ inches. The bell weighs 2 tons 12 cwt., or 5,824 lbs., and is destined for San Francisco, where it is to sound an alarm for fires.

**THE DRINKING-FOUNTAIN MOVEMENT.**—The Metropolitan Free Drinking-fountains Association has received the sum of 100*l.* from the executors of the late James Denington, esq., of Clerkenwell, being a bequest of that gentleman. **MANUFACTURE OF IRON.**—Mr. II. W. Nevill, of Llanelly, has patented an invention which consists in making the molten metal, as it runs from the blast furnace, fall from an elevated position upon a conical surface, which throws it off into the surrounding atmosphere in globules. The globules are puddled, and the hells treated as usual. The granulation of iron direct from the blast surface, and the manufacture of iron by the usual process, from the globules, has long been invented.

**CATHORPE CHURCH STRUCK BY LIGHTNING.**—In a late thunderstorm at Caythorpe, the church was twice struck by the lightning, and damaged to such an extent that it will require some hundreds of pounds, it is said, to make the necessary repairs. The vestry and one of the windows were first struck, with such force that a part of the roof fell in, and of course serious damage was done to the interior by the falling materials. A few minutes afterwards, another vivid flash enveloped the entire building in one mass of flame for several moments; and when the glare had passed away, it was found that about 9 feet of the upper part of the steeple had been knocked off, and had fallen through the roof, some of the pieces of stone weighing several cwt. each. The unfallen portion of the tower was very much shattered, and split almost into quarters. Nearly all the ornamental carving on the steeple was destroyed. Was there a lightning conductor? In all probability there was not—at least a proper one.

**GAS.**—A public meeting of the gas consumers of Pimlico has just been held in support of the delegates from the parish in their application to Parliament to protect the gas consumers against the combination of the gas companies. Sir J. V. Shelley occupied the chair.—At Dingwall, complaint is made of the quality of gas manufactured there. "As we believe," says the *Scott's O'Groat Journal*, "that there is no town in Scotland paying more for gas than Dingwall (13s. 9d. per 1,000 feet), the consumers have a right to expect that the quality be pure. A similar complaint as that referred to may easily be made with reference to Wick. Here the price of gas comes close up to that paid by the inhabitants of Dingwall; while, if their gas is worse than that of Wick, they are to be pitied." The people of Wick and Dingwall ought to agitate in the first place for cheap gas: they may as well have it cheap and had as dear and bad. The companies will then discover that, in order to bring up their profits to the required standard, they must set to work in earnest to occupy the ample field of private dwellings which exists in every ordinarily populous town; and that to secure this field they *must* make their gas purer. The inhabitants will thus have the benefit of gas both good and cheap, in place of bad and dear.—An invention has been patented, which consists in the use of vapours, obtained at a comparatively low temperature, under boiling point, from hydrocarbon liquids of high boiling point, such as coal-oil, or spirit of turpentine, for the impregnation and enrichment of ordinary gas; such vapours having less tendency to condense before combustion. The patentee is Mr. John Amsterdam.

—The directors of the Plymouth and Stonehouse Gas Company have again declared a dividend, for the past six months, of 10 per cent. on the old shares, and 7½ per cent. on the new.—The Hudliffersfield Gas Company have reduced the price of gas from 4s. to 3s. 6d. per 1,000 feet.

# The Builder.

VOL. XVIII.—No. 885.

The Museum of Practical Geology: its Uses to Architects.

WHEN it is said that the value of the mineral produce of the United Kingdom, exclusive of building stones and clays, was, for the year 1855, 31,266,932*l.*, or perhaps half the value of the same kind of produce of all Europe, including the British islands, it will be seen, without reference to the practice of architecture, of what importance is the institution in Jernyn-street; which, under the general designation of the Museum of Practical Geology, comprises, besides the Museum, the offices of the Geological Survey of the United Kingdom, the Government School of Mines, and the Mining Record Office.

But there is no public educational institution, which should be of greater interest to the architect. Besides affording means to the student, of acquiring the essential knowledge of geology as a science; it contains an important collection of samples of building stones, and an extended series of metalliferous and other mineral products, with examples of their application in art. Many years ago, when, as the Museum of Economic Geology, the nucleus of the present collection was located in Craig's-court, and was comparatively little known, we drew to the notice of our readers, and to its capability of aiding in the advancement of architecture and building.\* Subsequently we described the general features of the new structure in Jernyn-street; afterwards,† we gave a view of the interior, an elevation of the entrance as designed (and now perhaps the best work of the kind in the metropolis), and some details of the construction of the iron roof; and more recently, at various times, we have paid attention to the collection, and to different objects of the establishment. We propose to post up our information to the most recent date, and to inquire what points there are in which the value to our profession, of such an institution, may be further developed.

The additional matter, educational and illustrative of the earth's structure, of late put forth, is to be found in the publications of the establishment, rather than in the museum. In the latter, much has to be done to render the collection both instructive to the public, and immediately serviceable as regards the knowledge of elementary geology, and that of the durability and cost of building materials. The maps and sections of the Geological Survey are now completed for Wales and Monmouthshire, and for the counties of Cornwall, Devon, Dorset, Gloucester, Hereford, Salop, Somerset, and Worcester; and those for Wiltshire are about ready. The maps, most of our readers know, are those of the Ordnance Survey, geologically coloured,—those on the scale of 1 inch to a mile. What are called erroneously "the horizontal sections," and which are cross sections along an extended line of country, are drawn to a scale of 6 inches to the mile horizontally and vertically; whilst the "vertical sections" are to a scale of 40 feet to an inch, and illustrate details, such as the thickness of each bed of coal, which it is impossible to give in the "horizontal sections." There is also in

course of publication, an Index Map on the scale of four miles to an inch; and which appears to have extended to parts of certain counties not included in the sheets to the larger scale. For Ireland, maps are published containing the counties of Wicklow, Carlow, Wexford, Waterford, and great part of Cork and Kilkenny. The survey of Scotland is in progress. Specimens for the museum are collected during the several surveys. The collection, however, besides including specimens from foreign countries, extends, as will have been seen, to objects other than the illustration of the nature of rocks, and of remains of organic creation in them. But the main field of the institution is the geology of the British isles, with the commercial value of their mineral products. The complete illustration of geology is supposed to be one of the objects of the British Museum; the Palaeontological collection, in Jernyn-street, however, is very extensive, and is not less interesting than that in the other institution, though not including so many remains of animals of great dimensions. Besides the maps and sections, the publications of the institution in Jernyn-street include "Memoirs of the Geological Survey, and of the Museum of Practical Geology," forming part of which are the annual "Mining Records," or mineral statistics for each year, and papers on the geology of certain districts, such as the Isle of Wight and Cheltenham, and on the iron ores of Great Britain. There are also some earlier publications, including Sir Henry de la Beche's Report on Cornwall, Devon, and West Somerset; a catalogue of the specimens of British pottery and porcelain; and a paper, in the memoirs, on "The Composition of some Building Stones." There are also now published, A Descriptive Guide, and a Catalogue of the Contents of the Mining Record Office, both by Mr. Robert Hunt, the keeper of mining records; and "A Descriptive Catalogue of the Rock Specimens," &c., by Mr. A. C. Ramsay and others. Catalogues, severally, of the Palaeontological collection, the minerals, and the building-stones are in preparation. The "Guide" and the "Descriptive Catalogue" are essential to those who wish to study the collection; they are sold at a very moderate price; and, though we have suggestions to offer, some of which might have been unnecessary with different arrangement in one of these works, both of them are creditable to those by whom they have been prepared.

What the institution mainly requires is, a different arrangement of the specimens in the museum, that is, one more prominently and popularly illustrative of the order of succession of rocks. The present arrangement is intended to illustrate the lithological character, the mineralogical and commercial value, and the organic remains; but these intentions might be better carried into effect. The distribution of the rocks topographically is exhibited by the published plans and sections. The general visitor will neither read through in the museum nor he induced to refer to a volume of 375 pages, like the Catalogue of Rock Specimens; and, for the geologist, or architect, a more lucid arrangement than that which exists at the museum is needed, in order that the formation, or the class of specimens looked for, may be readily found. We do not say that the object we have in view has been disregarded, but only that the arrangement is not sufficiently obvious in the museum, or in the catalogue above named, where it is limited to a list of strata, with cross references to the specimens and to previous pages.

The circumstances under which the collection has been formed seem to have led to preponderant attention to the organic remains as specimens, and to the minerals in their applications in art and manufactures, till the building is now inadequate for that arrangement of the whole contents, or of the specimens of rocks, which would be best both for the popular and educational objects, and for others. To the illustration of the nature of rocks, indeed, considerable attention has been paid by Professor Ramsay, through arrangement of specimens in the second gallery, and by means of his catalogue. In these respects, however, there is room

for improvement, with a view to the objects we have mentioned; and, regarding what is most important to the architect, apparently little has been done at the museum, since the specimens procured by the commission, prior to the building of the Houses of Parliament, were contributed to the museum at Craig's Court. The report of the commission bears date 27th August, 1839. Since that time a considerable amount of experience as to durability has accrued, which should be placed on record; many kinds of stone have newly come into the market in London and the large towns, and questions are suggested as to most of the specimens in the lower hall, to which there is no answer at Jernyn-street. A list, already referred to, of the quarries of the kingdom, with the prices of stone and other information, is understood to have been some time in preparation; and the want of the information of this kind, as well as the desirableness of a stratigraphical illustration in the general collection, are, we may say, admitted. We hope that the catalogue will include the cost of labour and carriage.

The principle to be adopted, as we apprehend, in a geological museum, and *prominently* in arrangement, should be the division of the whole of the specimens, as by the stories of the building, according to the main divisions of strata, primary, secondary, tertiary; by the cantilever galleries, as the subdivisions, lower and upper Palaeozoic, Eocene, and others; by distinctions, say in the cases, as the systems, Cambrian, lower and upper Silurian, Devonian, and so on (the latest in order of time being, as now, in the upper part of the building), whilst the separate strata and their remains would fill the separate shelves. The existing arrangement at Jernyn-street, of the Palaeontological collection, and that of the catalogues, does little to supply this. The space at the top of each case of the collection named, which is given to drawings of restored organic remains, would be better appropriated to drawings of the strata. Such drawings are now confined, nearly, to some sections, and those not very clear, showing the arrangement of the igneous rocks. The visitor to the museum at present sadly wants the means towards a mental synopsis, primarily, of the subject and the collection, other than is supplied by mere names,—though after one visit and elaborate study of the Guide and Catalogue, he would be able to spend a profitable day, and learn much. Ideal vertical and cross sections, as well as the ordinary maps of the British islands, are either wanting; or are not easily to be found. The evil is, that a catalogue is required: yet there is not a catalogue which supplies the key to the knowledge of the strata and the actual arrangement; and the slight differences which will be observed between the grouping of the rocks in Mr. Hunt's Guide (page 282) and Mr. Ramsay's Table of Strata, or in names, will occasion difficulty. One authority uses the term Miocene as that of a group, whilst the other omits it altogether; and the student who happens to go to Ansted for explanation, will find that that author applies the term to the same strata which Professor Ramsay designates "Older Pliocene." The Table of Strata, mentioned, might be improved in other respects; but discrepancies between what emanates from the same department, should, if possible, be avoided. Some of the specimens are marked as of the Quaternary formation; and others, as Post-Pliocene. Either designation (or Pleistocene) would be of advantage, if introduced; but we find them only in the museum, and not in the catalogues. The name Palaeozoic remains over recesses which are filled with remains of recent date. Mistakes on the part of some visitors, and loss of time to others, result. The building, now too small, would have been found well contrived for its purpose, had not the mineralogical and palaeontological departments, from particular and important reasons, absorbed so much space. Light, however, at this time of the year is wanting to the cases in the recesses, though said to be in excess in summer; and we may mention (though it is easier to do so, than always to avoid the inconvenience) that the reflection in the plate glass of the table-cases

\* Vol. III. 1845, p. 87.  
† Vol. VI. 1848, pp. 522, 568, and 530.

interferes much with examination of their contents.

The desirableness of the stratigraphical illustration of the rocks is so far admitted by Mr. Ramsay, that he even intimates that before another edition of his catalogue is issued, it may be well to arrange the rock-specimens on this principle. We would, however, have the arrangement obvious in the whole museum—without omitting the illustration of mineral applications, of the nature of rocks, and of joints and cleavage. In the Scarborough Museum, if not different from what it was some years ago, such an arrangement as we propose is carried out better than in the museum in Jernyn-street; though it is confined mainly to the Yorkshire coast. The stratification of the whole coast is depicted above the cases; and the fossils are laid generally, on shelves inclined to represent the inclination of the strata, in corresponding positions hence.

The catalogue of building-stones will no doubt supply information which cannot be obtained from the specimens in the lower hall. Excepting the specimens of marbles which are worked into pedestals and vases, few of them can be sufficiently examined. The slates are heaped together, almost out of sight. But, besides specimens to be preserved indoors, the architect desires to see others, worked into mouldings, under the action of the weather and exposed in all different positions relatively thereto. No statements of comparative advantages can be satisfactory till tests of this nature are applied, authenticated by a public department. The institution of the commission of 1839 was an excellent measure. Except by the establishment itself of the Museum, and support of its associated undertakings, the Government of this country has hardly at any time seen the value of promotion in a like manner of scientific researches. We regret, therefore, that specimens were not placed some years ago under the test of a London atmosphere. It quite deserves the consideration of the officers of the Museum and the Geological Survey, whether what we speak of should not be attempted now, and Government be moved to provide means for obtaining a site or space for the experiments. Very little space would be needed; but it could hardly be found at the building in Jernyn-street as it exists. The space should be within the populous part of London; whilst for sake of contrast, there should be similar means for placing specimens at some locality in the country. Had something of this kind been done twenty years ago, we should now have possessed knowledge of building-stones suited to London, which would have preserved us from some of the unfortunate failures that have come to light,—allowing that the check often is required over what is sent from a quarry. Experiments might at the same time be made to test effect of preservative processes. A long piece of stone should be worked with mouldings, and then sawn into short lengths (to be marked and registered) in order that the effect might be contrasted, of different processes, and of each with the stone in its ordinary state. The same system of testing by the influence of the weather, could be extended to the different cements, bricks, and terra cottas, and to the metals and their electro-chemical coatings. The "Descriptive Guide" to the Museum says, referring to Keene's cement, that if half a pound of copperas be added to the solution of alim, "the resulting paste has a fine cream colour, and the hardened mass is said to resist the action of the atmosphere." Why should there be left any doubt in the matter? There is need of a good and cheap vehicle for external sculpture.

Though we have shown that the museum in Jernyn-street might be made of greater value, we must repeat that both the collection and the catalogues are very creditable to those whose names are attached. The rock-specimens and the Catalogue by Professor Ramsay, assisted by Mr. H. W. Bristow and others, show "the external characters of such rocks as conglomerate, sandstone, grit, limestone, shale, schist, gneiss, granite, the different kinds of trap, lavas, volcanic tufas or ashes, and, indeed, all

the varieties of stony substances that are of common occurrence;" and the names of the places whence the specimens were obtained are marked upon them. In England and Wales, the general nature of rocks is as follows. The Cainozoic or tertiary stratified rocks, which begin from the south-east portion of the island, and include the neighbourhood of London, are mostly formed of gravel, sand, and clay, with a little soft limestone; and the Mesozoic, or secondary rocks, extending across the island from north-east to south, also circumscribing, as by the chalk, the tertiary rocks, and coming to the surface even in the south-east, as in the case of the Wealden clay of Kent and Sussex, are composed of chalk, clay, soft shale, oolitic and hydraulic limestones, marls, sands, and conglomerates, ending with the New Red Sandstone formation. The Palæozoic, or primary stratified rocks, beginning with the Permian or magnesian limestone system, and including the Carboniferous, Devonian, or Old Red Sandstone, Silurian, and Cambrian systems, include a great variety of mineral substances: in the Carboniferous rocks are shales, ironstones, sandstones, fireclays, coal, and limestones; the Old Red Sandstone has red marl, sandstone, and conglomerate; and the Silurian and Cambrian rocks, the latter much distorted and altered by volcanic action and the rise of the igneous rocks, are in great part of mudstones, grits, and slate, with occasional shales, limestones, and beds of conglomerate, sandstone, and grit. Scarcely any portion of our island presents apparently such difficulties as Wales; yet the arrangement of the strata in Caernarvonshire and Merionethshire, seems to be now as clear as if actual cuttings had been made. To Wales and Shropshire, the "Siluria" of the Director of the Museum is chiefly devoted; but Professor Ramsay has been one of the most recent and useful labourers on the Snowdonian range. There are local peculiarities out of England, in the nature of the contemporary rocks; for example, the secondary limestones of the Alps are often crystalline.

It would be impossible to identify strata by the appearance alone; and it is at this juncture that the value of palæontology is seen. By the organic remains, the uniform succession has been made manifest; and it is shown that however strata may be absent in any locality, the order of succession is otherwise never varied or inverted. When we learn that "it would require 170 years to gather one inch of anthracite coal, and the enormous period of 122,400 years to accumulate 60 feet of the same;" that the formations are measured in thickness by tens of thousands of feet,—the Cambrian rocks in Shropshire having alone been estimated at more than 26,000 feet,—and that, at the base of the vast depth, remains of organic creation are found,—we look with awe at the evidence of the ages over which the work of nature has extended—ages to which the 6,000 years of the existence of man are monuments in comparison. Even should it be proved, as lately supposed, that this existence commenced within the period of the tertiary deposits, we have still the evidence, and in our own island, that ages before that time, the earth and sea teemed with countless forms of animal and vegetable life throughout a succession of changes of climate, and a long series of gradual depositions modified by subterranean forces, and by the action, more recent, of glaciers and floating ice.

One of the cases in the upper gallery illustrates the phenomena of this glacial action, as indicated in North Wales, Lancashire, and other parts of the island, and as now going on in Switzerland. The volcanic action is illustrated by specimens from foreign countries, as well as by specimens from the igneous or altered rocks of Wales and Shropshire. Gneissic rocks and granites are of every geological age. One portion of the collection illustrates the phenomena of alteration and metamorphism of rocks,—by fire, and the intrusion of the igneous rocks among various kinds of strata. From the effects of heat, besides distortion, the new combinations called metamorphic are developed, as mica slate, and all the rocks of the gneissic family. Serpentine is metamorphic rocks. The re-

mainder of the specimens in this department of the museum, illustrate the nature before spoken of, of the substances of which stratified rocks are composed. There are specimens showing the manner in which depositions of carbonate of limo (limestone), as at the present day, from a hi-carbonate of lime in solution, result in calcareous tufas, and stalactites and stalagmites; and others illustrative of formations of beds by chemical action, such as those of gypsum and rock salt. There are many other specimens illustrating the formation of stratified rocks, chemically and mechanically. The manner of chemical deposition has just been adverted to. The mechanical process, which has largely predominated, goes on by the deposition always taking place in the sea, lakes, and estuaries, and the abrasion of the sea-coast. Strata are thus formed, sometimes of sand, mud or clay, or lime, separately or admixed, and sometimes almost exclusively of organic remains. The specimens show the structure of conglomerates, and breccias, grits, sandstones; sands, some shelly or otherwise calcareous; marls, clays, shales, slate, and coal, as well as marls on what was part of the sea-bottom, of ripples and currents, and of the feet of animals. Separate cases are devoted to the siliceous bodies, and concretions and septaria, contained in rocks of various kinds and all ages; and to the limestones of various periods, arranged with reference to their qualities, and the iron-stones.

In the Descriptive Guide, by Mr. Hunt, facts are given respecting the stones and other materials, of which there are specimens in the entrance-hall. The information will be useful; but it does not diminish the argument for something further. The collection on the principal floor is very fully described in the same work. It comprises specimens and models illustrative of the British metalliferous minerals and metallurgy, as of copper, tin, bismuth, cobalt, nickel, arsenic, manganese, uranium, zinc, brass, German silver, antimony, cadmium, silver, gold, lead, mercury, platinum, and iron and steel, and other metals and alloys, and illustrations of mineral lodes, and of processes of mining and smelting. Models of machinery and mines are found on the same floor. The foreign and colonial minerals are classed separately. The specimens include objects of great beauty, as rock-crystal, agates, and precious stones. Iron is shown, both in the ores and as applied in ornamental castings; and the alloys of metals, as copper with zinc, copper with tin, and others, are shown applied to works of decoration and sculpture. The manufacture of gun-barrels and sword-blades is represented in two of the cases; the process of electro-metallurgy in another; and there are Chinese bronzes in a third. Besides this class of works, however, there are on the same floor an extensive series of works of pottery and porcelain, both of ancient and recent date, and other specimens of ancient and modern glass, and of mosaics and enamels. In these departments the materials employed are shown, and information is given as to the manufacture; and of the specimens, many of them are individually interesting historically and as works of art. The composition of several of the specimens, as of those of ancient glass, is given from analyses made at the museum. Bronzes (of the number brought from Assyria by Mr. Layard) which were constructed for some purpose of support, were found on examination to be east with the bronze round a core of iron. There will also be found fragments, from the bed of the sea, of articles of iron, parts of wrecks, showing the cementations incrustation which the metal acquires when in contact with gravel,—a natural process which might be called preservative, and is of great interest to architects and engineers, considering the importance just now of the question, to which on other occasions we have made reference, of the durability of iron in similar situations. In another part of the museum (in the upper gallery) is a specimen showing the rapid decay of the same material when exposed to the alternate action of the air and sea, as by rise and fall of tides from 1811 to 1853. The iron appears to be rapidly destroyed by the

oxidation, ordinarily "leaving a spongy mass of graphite, or impure carbon," but has (as shown in a neighbouring specimen in the same gallery) an "agglutinating power" while undergoing oxidation as in the bed of a river. The subject referred to, however, requires further inquiry. The cramps or straps from the foundations of old Westminster-bridge have been brought up, not greatly altered by oxidation or corrosion.

In illustrations of the structure and products of the earth, and the applications in art and manufactures, and even in the wonderful remains of extinct life, the museum in Jernyn-street, it will be seen, contains much that is of immediate interest and value to the architect. The institution may be made more valuable in points which we have referred to; but by the publications, and the specimens and the geological information continually being obtained, as well as by the lectures and the library, it deserves more attention from our profession, perhaps, than it has gained. The library includes, we may say, upwards of 7,000 volumes, and periodicals, English, American, and Continental, relating to science, as they are published, to which on special application, stating the object in view, access may be obtained. There are also laboratories, metallurgical and chemical; and the College of Chemistry, in Oxford-street, is attached to the Museum.

#### THE NORMAN ARCHITECTURE OF CANTERBURY CATHEDRAL.

The following is the lecture (referred to in our last) which was delivered before the members of the Architectural Museum, in the Lecture Theatre of the South Kensington Museum, by Sir Walter C. James, Bart., the subject being "The Norman Architecture of Canterbury Cathedral." The lecture, as we have already said, was illustrated by many excellent drawings and diagrams.—

It is not possible to add to what such men as Professor Willis, or Mr. Fergusson and Mr. Parker have detailed upon the subject of Canterbury Cathedral, in their various valuable works on Mediæval architecture. It is, perhaps, the province of the lecturer rather to condense what already exists, than to seek too far for original matter, and to give information which, though possibly imperfect, may yet be, as far as it goes, correct, and may, therefore, lead the young inquirer to fresh sources of knowledge, where he may work for himself.

It has been remarked by a modern writer of considerable eminence and talent, that "architectural works enriched by the subordinal arts of sculpture and painting frequently afford the only traces which extinct nations have left upon the earth of their history, their condition, their manners, or their religion." Unquestionably, even in times when the historian has regularly transmitted authentic records of fact, they tend to throw much light upon many transactions otherwise doubtful and obscure.

A description, however, of a single building seldom excites any interest, except in the professional architect or antiquary; and, although there attaches an exceptional interest to Canterbury, on account of the many historical associations with which it really teems, yet, in an architectural lecture, it is perhaps best to make it a type of others, and, as it were, the symbol of a particular age.

For this reason, it may be permitted to look upon Canterbury for the purposes of this lecture as a fair exemplar of our cathedrals up to the beginning of the thirteenth century, when the Pointed or Early English style may be considered to have spread its roots in the soil, and given promise of that rich harvest of architectural excellence which culminated perhaps in the Decorated period.

In considering the state of society which prevailed during the reigns of our Plantagenet kings, we find a clergy united by strong ties of allegiance to Rome as the "mater ecclesiarum." We have a dominant race of conquerors of Norman blood, speaking the French language, and owning the sovereign sway of Norman princes. But we have also, as it were, at the bottom of the scale, an Anglo-Saxon nation gradually rising into importance, and modifying by its own energy the two other elements to which I have alluded.

Thus, it is related that Henry II., on taking leave of the prior of some convent where he had

passed the night, bade adieu to the holy father in the Latin language; while at the same time and place he spoke to his knights and esquires in Norman-French; and to the hegars round the gate, who were asking for alms, in the Anglo-Saxon language.

Indeed, this condition of our English tongue lasted for two centuries at least, after the time to which this lecture must limit its inquiry.

For we find in Chaucer:—

"Let the clerkes endyten in Latin, for they have the property in science and the knowinge in that faculty, and let Frenchmen in their French also endyten their queyt termes, for it is kindly to their mounths, and let us show our fantasies, in such words as we learned in our dames' tongue."

It was not till a century and a half after the building of the Choir at Canterbury, in its present form, that the pleadings of our law courts were required to be in English, and not as heretofore in French, and that all schoolmasters were ordered to teach their scholars in English, and not in French, as they had been used to do.

We should then, arguing *primâ facie* from such a state of society, naturally suppose, that in the architecture of the period to which our attention is directed, we should find a strong but not preponderating Roman element, derived from Christian tradition, and the existing buildings in the great capital of Western Christendom. We should probably have a strong Norman element, intermingled with one of purer French origin; modifying that Romanesque or Romane style which we find in Southern France and the Rhineland, to the exigencies of a northern climate and a northern race. Lastly, we should have our own national forms and English characteristics; our own vernacular developments, stamping, as it were, the impress of the prudent, painstaking English mind upon these grand mediæval churches. Such a statement, it will be found, does not deviate much from the truth. It will be the object of the present lecture to analyse the subject from this point of view, and successively to present to your notice, as far as the limited time at our disposal will permit, an outline of the effects which these different elements have had in bringing to its normal type the English cathedral, of the transitional era, as we find it in the eastern parts of Canterbury, after the introduction of the Pointed arch, both in France and England, but prior to the full development of the Pointed style,—the Cathedral such as it was at the end of the twelfth century.

**Roman Element.**—Rome, as it is the prime fountain whence the stream of modern history issues, so is it the true source of our ideas upon art. To trace these latter to their origin, we may have to go back even to the time of Augustus.

The whole style of Roman architecture, which has been well described as a compromise between the vaulted architecture of Etruria and the trabeated architecture of Greece, was of a transitional character. Grand even in her decay, the imperial city was sowing broadcast over the world fruitful germs of truth, which were doomed to reach perfection under the fostering care of her subject colonies, fated in their turn to become the nursing fathers and mothers of the Christian Church. In the time of Augustus we have forms almost purely Greek. Paganism stamps its genius upon every edifice. In the time of Constantine we have types almost purely Christian.

The temple of the Romans, such as we find it at the dawn of the empire, consisted of an external arrangement of columns without vaults or arches, the cell or internal part devoted to a statue or idol of the heathen god. It was usually darkened, and wholly unsuited to the purposes of the Christian ritual. Towards the end of this period Roman architecture had become an internal architecture, plain in its exterior almost to rudeness. The columns which had adorned the heathen temple were taken, and with "fatal facility" transported or adapted to the interior of the Christian church. A Basilica of the first age after Constantine is almost as well suited now as it was then to the forms and ceremonies of the Christian ritual.

What then were these buildings—basilicas, as we have been accustomed to call them? By the side of the heathen temples (which it may be remarked *passim* never reached the same importance in Rome, that they did in Greece), there were other buildings, courts of justice, halls of commerce (may we not say), providentially well suited to the wants of the young Christian republic.

These buildings seem to have been the outward symbol and expression of much that Rome has bequeathed to us, of real value, her ideas of law, that Christianity which adorns all that she

touches should have taken up her dwelling in such tabernacles as these, is perhaps a theme for thankful praise. For not only do we find everything well suited to the touching rites of the simple primitive ritual, but it seems also (if the phrase may be allowed) that Christianity, by making her home in these scenes of every-day work, declared her great office to be, not so much to debar men from "the world" as to sanctify "the common things," as they are well called, of our daily life by turning them to the highest and noblest of all ends.

The great charm of the buildings to which I refer consists in the unity of idea with which they were invested.

As to the roofs of these buildings—one of their most important features,—six out of seven which we know were covered with timber roofs: the seventh, that of Maxentius, was vaulted.

[The lecturer then described the Christian Basilica. This was seldom, if ever, upon the site of the heathen Court of Justice. Two motives influenced this removal: first, a desire to have buildings *solely* given up to religious uses; secondly, a veneration for the graves of the early martyrs.]

These details have taken up more time than seems fair in an address intended to illustrate Mediæval rather than Primitive Christian architecture, but they connect themselves more readily than might at first be supposed with England and Canterbury.

"When Augustus" (the first Archbishop of Canterbury), says the venerable Bede, "assumed the episcopal throne in that royal city, he recovered therein, by the king's assistance, a church which, as he was told, had been constructed by the original labour of Roman believers. This church he consecrated in the name of the Saviour, our God and Lord Jesus Christ, and there he established an habitation for himself and for all his successors." Now the church so rebuilt by St. Augustine, and subsequently repaired by other bishops, is known to have been copied from the model and immediately upon the plan of that of St. Peter's at Rome. Hence it has been well written, "The Christian architecture of Rome and the Teutonic Romanesque are in the nature of cognate languages; but in each there is a diversity in the inflections—a nationality in the phrase."

The copy is, to a certain extent, a faithful copy; but there is an originality in the touch of the artist.

It is worth noting that Eadmer the Singer, whose account of the building we have, had actually seen St. Peter's, and accompanied Anselm thither about A.D. 1100. He was, therefore, well able to judge of the resemblance, and pronounces it to be good.

[The lecturer then referred to, and explained the plan of St. Peter's, referring particularly to—

1. Its apse at the west—polyandrum and confessionary.
2. Its high altar, under a ciborium or canopy, which rested upon four pillars of porphyry.
3. He then noticed the columns of Parian marble, placed in front, in two rows, ornamented with vine leaves. Tradition states that they came from Solomon's Temple.]

Before quitting the Roman element it may be permitted to ask, first, in what points does the Saxon cathedral coincide with St. Peter's; and, secondly, in what points is the Roman element persistent. What Roman characteristics have been carried forward into the Mediæval cathedral?

1. The position of the crypt extends only under the presbytery and altar end of the church.
2. The entrance into the crypt descends into the confessionary.
3. The position of the matutinal altar is the same.
4. The choir of the singers is extended into the nave—an arrangement quite analogous to that adopted in San Clemente and the other Roman churches.

At the west end was a lady chapel, with an episcopal throne. Professor Willis thinks that this was really the altar end of the church, in imitation of St. Peter's.

In the Church of Lanfranc, to which attention must next be called, we still have, not perhaps all these characters, but—

1. The apses, repeated not only in the presbytery, but in the transepts, and afterwards in the chapels of St. Anselm and St. Andrew. This form is rare in England.
2. The central nave and aisles and clerestory always persistent forms.
3. The wooden roof, the general style in England.
4. Some points of ornamentation.

*Norman and Norman-French Element.*—We may consider the Norman style of architecture to commence with the Conquest. In the account which Gervase gives of the burning and repair of the cathedral, we have a very full account of this church of Lanfranc. The archbishop erected it new from its foundations in seven years. It is upon nearly the same plan as the Abbey of St. Stephen's at Caen, which was built under his direction, begun in 1064, and dedicated in 1077, after his appointment to Canterbury. The present nave, though built in the fourteenth century, is thought with good reason to stand on the foundations of Lanfranc's church. An important part of the building, one of its western towers, was destroyed as late as the year 1834. It is uncertain whether any of the present crypt may be fairly attributed to Lanfranc.

Professor Willis has undertaken the somewhat difficult task of developing three states of the eastern part of the building. First, as left complete by Lanfranc; secondly, as altered and enlarged by Anselm and his Priors; and thirdly, as it came out of the hands of William of Sens and William the Englishman after the fire of 1174.

It is not easy to understand the motives which led to the destruction of Lanfranc's choir so short a time after its completion. It is not impossible that the Archbishop, being intent on the restoration of a stricter discipline in his monastery, and the publication of new statutes to the whole Benedictine order of England, neglected, in some measure, the building of his cathedral in an appropriate style of splendour. Certain it is, that Gervase passes over this somewhat remarkable incident—the destruction of its eastern end—in a mysterious way. We may, perhaps, also find a motive for this change in the vanity of the monks, who wanted more shrine room for the display of their gradually accumulating relics. The simplicity of the earlier Christian ritual was giving way to a more pompous liturgical worship. From the ritual, as has been well said, arises the temple, and the temple again becomes the commentary on the ritual. The form and aspect of the structure appear as evidence of the doctrines taught within its walls.

Of the work of Ernulph and his successor Conrad, considerable portions still exist. From the admirable treatise of Gervase, and the clear explanations which accompany Professor Willis's exact translation, it is easy to trace these parts of the building. The choir itself was long called the "Glorious Choir of Conrad." The murder of Thomas à Becket took place when the cathedral was in the state it was left by Conrad, and it is worth notice how much of the primitive style of architecture, and especially the arrangement of the Presbytery, still remained. The fire took place some years after his death, and appears to have been accidental. It is supposed that when he was murdered he was about to take his seat in the pontifical chair, prior to vespers. Undoubtedly he might, had he chosen, have escaped his pursuers by concealing himself in the crypt, which he was well acquainted.

After the fire, which was the immediate cause of the rebuilding of the cathedral, there would, probably, be no lack of funds for its reconstruction on a splendid scale. The contributions of pilgrims, whether princes or peasants, would furnish these means. French and English artificers, we are told, were summoned to give their opinion on the best plan. Even these differed in opinion. "However, amongst the other workmen, there had come a certain William of Sens, a man active and ready, and a workman, most skilful, both in wood and stone. Him, therefore, the monks retained, on account of his lively genius and good reputation, and dismissed the others, and to him, under the providence of God, the work was committed."

I exhibit a drawing of the cathedral in section, which will give a good idea of what the choir was in the time of Conrad, before the fire, and, as enlarged and beautified by William of Sens—as, in short, it now exists. The whole of the Trinity Chapel, and the crypt underneath it, must be considered the work of English William, and is new from the foundations. Of this, more hereafter. As there remain, however, in the western parts of the choir and transepts some portion of the early work of Ernulph and Conrad, it may not be amiss to mention one or two of the tests by which they may most readily be distinguished.

1. By the style of the masonry. The columns, according to Gervase, were raised 12 feet in height, and exactly at that height a new style of masonry begins.

2. By a different and more elaborate base to the columns.

3. By a nobler and more ornate style of carving.

There are, however, other architectural features introduced by William of Sens in the vaulting and pier arches, and generally in structure, which require some notice, and as it seems conceded by architects and antiquaries, that the Choir and Trinity Chapel are the earliest specimen of the Pointed style which can be authenticated in England, it may be permitted to make a short digression, not upon the subject of the Pointed arch itself, so much as upon the general character which the Round arched architecture of France and England was assuming at the end of the twelfth century. And here, perhaps, I may venture to trouble you with a quotation from the earnest and eloquent pen of the late Mr. Howe.—

"A fortuitous concurrence of circumstances has made many a man invent that which he had not the means to apply, of which he saw not the full use and application. Many a discovery has taken place for the first time at a period when little wanted, it conferred no distinction upon its author, and no benefit upon others, when, like a fire kindled without proper fuel to feed the flame, it again went out, or for many ages smoldered in unperceived obscurity, till, fresh wants and fresh means fanning the latent spark, blew it up into a blaze, when the genius to which it first was owing had already long been forgotten in the darkness of the grave. And thus, for aught we know, it may have fared with the embryo of the arch. If even by some fortuitous meeting of materials, in peculiar relative situations, the embryo of the arch should first have been found in independent Greece; it there remained in a manner dormant and sterile. It received no development. It became not in her edifices a marked feature calculated by its importance to change and remodel the whole face of her architecture."

What has here been said of the Round arch may, with equal truth, be asserted of the Pointed. We find pointed arches in the East, in Sicily, in Greece, in very early times; but it is not till about the middle of the twelfth century that we discern in France examples of what we may fairly term the Pointed style. Thus we arrive at a theory—viz., that it is a great mistake to separate the Pointed from the Round-arched style; and that it is alike more natural and more true to look upon the former merely as the offspring of the latter, perhaps, speaking more correctly, as itself in a more forward state of its development. At St. Denis, the work of the Abbé Suger, whom a modern French theory has stigmatised as the inventor of the Pointed style, we find work of a decidedly Roman or Romanesque character, and yet intermingled with the free use of the Pointed arch.

I exhibit a view of one of the chapels at Noyon, which was built by Bishop Beaudouin, the friend and contemporary of the bishop who built St. Denis. It is notable for a certain general resemblance to Canterbury. I now come to Sens itself, of which I exhibit some details. Their similarity to the architecture at Canterbury will at once be recognized. Of this Mr. G. Gilbert Scott said, in a lecture at the Royal Academy:—"Though a cathedral of the second magnitude, and much injured by subsequent alterations, I know few which have a nobler or more impressive aspect. Even the soaring interior of Amiens, which I embraced to visit a day or two after, did not efface from my mind the sterner grandeur of Sens," and, with the true liberality of thought which marks the English mind, the same architect is reported to have observed to a friend:—"Well! if, as the French say, we may find here the true original of our Pointed style, at least we must admit that we had a noble parentage."

Admitting, then, most fully the interpolation of French work at Canterbury, we must be careful to distinguish,—first:—

That it is not to France as a whole that we concede precedence at this particular epoch, for there are many parts of France where the development to which we allude was specially tardy; but rather to that part immediately round Paris, the domain of her ancient kings. The immense influence gained at this time by the French monastic establishments, and the simultaneous increase of the royal power, brought about the great epoch for building in France.

Secondly, Although this admission with regard to France is just, it should be added that there were in England the same causes at work which were working in France, and which, in all probability, would have led to like results. It would be a narrow view to take, and quite an unnecessary concession, that all other nations followed simply in the wake of the French. The communi-

cations going on through Europe caused each nation to know perfectly well what was passing elsewhere. The tendency to refine and elevate, to substitute grace for sternness, and a sense of beauty for a sense of power, is manifest about this time in all the countries in which the Romanesque architecture prevailed. In all we find the simplicity of its earlier works yielding to that refinement of form, that dignity of elevation, which science and education produce. The barbaric sentiment gives way, and the rude vigour of the early round-arched Gothic is eclipsed by the mechanical skill and the greater taste of the architects of the thirteenth century.

The question remains to be discussed, how did the change take place, and in what parts of the building do we first trace it? To this it may be replied, that the vaulting, as a general rule, may be considered the part in which it first manifested itself.

Up to the middle of the twelfth century timber roofs prevailed in England. At Canterbury we know that the aisles were vaulted, while over the central part a timber roof was used, "excellently painted," as Gervase assures us. But in the south of France, in Provence, and also in Burgundy, vaulted architecture had long been in fashion. The problem seems to have been to combine the advantages of lightness and elegance of form which the timber roof of the north possessed with the greater appearance of substance which the more costly material would naturally afford. Without, then, entering into all the structural details of this question of vaulting, we may ask ourselves what were the great objections to a church in the basilican form, which was then prevalent, in which the semicircular arch was strictly adhered to? Barrel vaults would be those in general use.

1st. There would be a want of light from the clerestory windows. The defect would be generally appreciated, because this mode of lighting, as has been shown, prevailed from very early times; but it would be more than ever felt in the north of Europe, on account of the dark climate and the invention, at that time recent, of painted glass, which is known to have exercised great influence, even on the structural part of churches.

2nd. The enormous weight of barrel vaults, when built over large openings, and their lateral thrust, would cause the question of abutments to be one requiring the most serious consideration of the architect.

3rd. The different forms of the vaults would cause endless perplexity. A semicircular arch is obviously not fitted for a square space of invariable form. The difficulties, therefore, of throwing an arch over a rectangle of variable magnitude were constantly on the increase.

What was wanted was more light, more strength, more height. These three objections were remedied by the pointed arch.

1st. The darkness of the clerestory, by the lighter form of roof, and larger windows.

2nd. The difficulties of abutment, by groined vaults and flying buttresses.

3rd. The structural difficulties connected with the vaulting itself, by using a variable arch to cover a variable space as well as a variable height. Considerably more importance has been attached to the last difficulty by some very able architects than to the two first, and as the vaulting at Canterbury is what is called hexapartite, a word in explanation is permissible.

The hexapartite severy, or ciborium, covers two oblongs. The compartments in the side aisles being square, were vaulted in the usual way by a double cylinder. The question then arose: how to cover the corresponding oblong space in the central aisle? The difficulty was thus met. A square was made out of the two oblongs, but two bays in the side aisles formed only one side of that square. Thus the intermediate pier was brought in, partly as a support, but more perhaps as one of the vaulting ribs, and the difficulty was never met (as Mr. Fergusson says) *satisfactorily*, till the pointed arch came to the rescue. His words are: "This insertion was neither quite a rib nor quite a compartment of a vault, but something between the two, and in spite of all the ingenuity bestowed upon it in England, France, and Germany, in the eleventh and the beginning of the thirteenth centuries, the effect was never quite satisfactory."

The great elevation of the small intervening arches has led some to suppose that in them the pointed arch first appeared: such, however, is not always the case, as in Canterbury, it will be observed from the diagram, they are round, while on the other hand, the large arch spanning the whole central aisle from pier to pier is pointed.

It would be presumptuous in any one in the present day to offer any new theory as to the pointed arch, to the adoption and use of which, as I believe, many causes concurrently gave rise: and yet, in estimating these, perhaps the consideration of what is called the pitch of the roofs has hardly obtained sufficient importance. Pagan architecture in India, in Assyria, in Egypt, in Greece, was essentially, at least in its main features, trabeated—it was the architecture of the lintel; but the transition from the lintel to the gable is easy, and already in Greek architecture we have the pediment,—a form which has been found, curiously enough, by Colonel Vise in the central chambers of the Egyptian pyramids. Again, from the pediment to a rude form of arch the steps are not difficult: the horizontal beam which had been cut in twin to form the gable, cut into three, or five, or seven pieces, gives rise to an arch of which each piece is a voussoir. Thus we arrive at two methods (besides the lintel) of covering a space—the gable and the arch. Now, the pointed arch is a combination of these two methods, and has been well described by a modern writer as an arched or curved gable. Admitting this description to be true, it seems to follow that when we find a vaulted roof in which semicircular arches are used covered with a gable, whether of wood or stone, it is probable that the structural advantages of the pointed arch would be brought to light. Mr. Ferguson, in his excellent "Handbook," cites several churches in the south of France, where, according to M. Felix de Vernheil, a considerable authority, pointed arches were used very early in the eleventh century. No timber roofs were made use of, but the vaults were filled in with rubble: the object of the architect was clear—to avoid loading the arch at its crown to an unreasonable or dangerous extent. The same argument will apply with equal or greater force, where a timber roof is used as a protection. Now, in Italy and Germany, and also in the south of France, the timber roof over a vaulted ceiling gave rise to a very interesting kind of ornamentation—the open arcade. Structurally, perhaps, little can be said of it; but in the eastern ends of churches generally, and especially in their apses, this species of gallery has met with deserved applause. It will easily be recognized, and its adaptation to a southern climate admitted, where little snow falls, and where this kind of double roof would add much to the coolness of the interior. It is not, however, well suited to a northern climate. In Germany we have it travelling up the Rhine as far as Cologne, though generally closed in the north. In France it is confined to the southern provinces. It does not enter into the north of Europe; it shrinks, as it were, from that region which is called the fatherland of the pointed arch. When, therefore, the Northern church builders undertook to alter the Roman or Romanesque style, and suit it to their own taste, this peculiarity would suggest itself as one naturally requiring modification. They found a low, flat roof over a semicircular vault with an intervening gallery. The objections to this form, and the low dark clerestory it involved, have been already stated. To close the gallery and to raise the roof would be the natural course of proceeding, and would, as I contend, very naturally suggest the conversion of the round Southern arch to the Northern pointed.

It would be interesting and possible to show how, in travelling northward out of Italy, every part of the building underwent the same sort of change; to trace the double route, as it were, of the Lombardic architecture into the south of France, on the one hand, and into the centre of Germany on the other; but time does not permit, and will only allow me, in conclusion, to make a few remarks upon our English transition, and the English element, as I have ventured to call it, at Canterbury.

*English Element.*—It is not possible to do so without observing that our Romanesque style is properly called "Norman;" and however justly that nomenclature may be objected to on the Continent, it does not invalidate the claim of that wonderful tribe of Northmen to have founded the English branch of the Romanesque family.

It may, perhaps, be allowed to call our early Norman, "Romanesque, with a strong Gothic tinge," the boldness of the mouldings, and the general sternness of type, indicating a rude energy in the builders. In the choir of Canterbury, as left by William of Sens, we have advanced Norman, with a French, and even a classical tinge upon it, noting our distant connection with Rome and the South, as clearly as the Latin words in our language, or the Latin prayers in our Liturgy.

William the Englishman carried the transition a step farther. In his clerestory, and in other parts of the work, we find the round arches almost superseded. In Becket's crown, the whole of which came from his hand, there is not a single round arch. Of course some difficulty must exist in determining how far his work was his own, and how far he was engaged in carrying out the plans of his predecessor; but the evidence strikes me as in favour of an original mind. He is represented as having been overseer of the masons under William of Sens, and described by old Gervase, "though small in body, yet, in workmanship, acute and honest." I cannot avoid noticing a round base to a clustered shaft, which there is much reason to suppose may have been from a design of English William's, and the two slender shafts in the centre of the crypt, with round abaci, undoubtedly of Early English type. There is nothing at all like them in the work of the Frenchman. To my mind it indicates the birth of that chaste and beautiful phase of the Pointed style, which reached its acme in the lovely spire and perfect proportions of Salisbury.

I shall now only mention one or two more contemporary buildings, of which I exhibit drawings. The choir of Ripon was built by Roger of York, as has been proved by recent research, between 1154 and 1181. The similarity of the clerestory windows to those at Canterbury will be noticed.

Another drawing, for which I am indebted to my friend Mr. G. G. Scott, is that of St. Cross, near Winchester. It was founded by Henry de Blois, brother to King Stephen, who held the church from 1136 to 1171. The mouldings round the windows, which have a peculiar Norman type, are very original.

It is natural to suppose that, in these buildings, English artisans were employed, while at Canterbury, which was the metropolitan cathedral, where no expense was spared, French artists should have had the preference. Looking at the various buildings of this era, in England, it is not a partial verdict to assert, that while they seem to show a knowledge of French development, there is no slavish imitation. On the contrary, there is a freshness of conception, and an originality of design, which is quite captivating. In the Museum here may be seen a doorway from the little interesting church at Barrestron, which will go far to illustrate my meaning.

To sum up the whole. At the beginning of our transition we had a stronger Romanesque character than the French. It had been given us by our Norman conquerors. The keep at Rochester and the nave at Durham exceed, perhaps, in rude sternness, anything we find abroad; but the remarkable converse of this is, that at the close of our transition we had not only thrown off this excess of Romanesque characteristics, but had gone beyond the French in altering those of a less palpable kind. The single column had, in all cases where it was used for a support, become the clustered shaft; the square abacus had given way to the round. Our arch mouldings had become richer and more studied in their profile, composed of distinct and beautiful members. The vertical line in every part of the building had become more pronounced; so that at the end of the period, we had departed much more widely from our Norman type than the French from their Romanesque.

The value of Canterbury as a transitional example, is that its history is well known, and that there is a date for everything, and that we can trace in the work of William of Sens, not what the French would represent as the introduction of the Pointed style, but simply an interpolation of French art, which had its influence, doubtless, on the architecture of the day.

To conclude: If there be, as there perhaps is at Canterbury, a peculiarly foreign type, and if there be French work in the choir, it is also, in many respects, a peculiarly English cathedral: as such it addresses itself very specially to our hearts. It cannot come near the French cathedrals in altitude. Amiens, for example, is, in round figures, double its height. Beauvais, which is a wonderful *tour de force* rather than a work of real art, is even higher than Amiens. But what it loses in this respect of sublimity may perhaps be more than compensated for by the juster proportion of the parts, by its interesting and varied outline, by the pleasing variety of light and shadow, which plays over its double transepts and numerous projections. It is one of the longest of those very long churches—our English cathedrals. It is within 10 or 20 feet the same length as Ely, Winchester, or Westminster, and nearly 100 feet longer than the principal cathedrals of France, Notre Dame de Paris, Chartres, Amiens, and

Rheims. The average is, for the English about 520 feet, and for the French, 420 feet. It is characteristic of England, too, because, whether seen from a distance or close, the masses of its architecture are usually broken by luxuriant foliage. It rises, not like a continental cathedral in the midst of houses, shops, and hovels built up against its sides, but as all buildings look best—almost like a flower from a carpet of green.

It is on the outskirts of the town rather than in its centre, which is also a marked feature of our English cathedrals. The monastic buildings round it are not levelled with the ground, but remain covered with ivy, and here and there a wild rose, full of ruinous beauty. Among them we may remark the Norman staircase, probably of the time of Anselm, which is thought to be a unique specimen, and a building supported upon beautiful Norman pillars, once intended for a tank, which contrary to, even reversing the usual practice, has been converted from a profane to a sacred use, and now forms the baptistery of the cathedral. We may be thankful that these precious relics are no longer desecrated by the hand of Puritanical violence, or left to perish through ignorance or neglect, but tended with all the care of true wisdom which is ever anxious to preserve, and to adapt to present use these noble memorials.

Happy are those who can cherish the traditions and the arts of our ancestors, without sacrificing the many advantages and blessings of modern civilization, who combine with the greatest fitness for a life of business, and the most perfect appreciation of the blessings of liberty in action as in thought, not merely a taste for the refined pursuits of the antiquary, and a love of the picturesque, but a genuine spirit of reverence for whatever may be found of the true, honest, and beautiful in the religion of past times.

SPECIAL MEETING OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE PRESIDENT.

A SPECIAL meeting of the Institute was held at the house in Conduit-street, on Monday evening last, to elect a president in the place of the late Right Honourable Earl de Grey, and to consider a communication received from the Royal Academy in reply to a letter addressed to that body from the Institute.

Mr. George Godwin, vice-president, presided. The meeting was very numerously attended, and included Mr. Cockerell, R.A.; Professor Donaldson, Messrs. Tite, M.P.; Pennethorne, S. Smirke, R.A.; Scott, A.R.A.; H. Ashton, V.P.; Ashpitel, Allason, Baker, C. Barry, J. Billing, Bury, J. Clarke, Ferrey, James Fergusson, Garling, Hakewill, Haywood, PAnson, Jennings, Kerr, Knowles, T. H. Lewis, Mair, Moesta, Mylne, C. C. Nelson, Norton, J. Papworth, Porter, Roumieu, Scoles, Tenlon, Vulliamy, Whitechord, T. H. Wyatt, Digby Wyatt, Edmeston, Hansard, F. R. Wilson, Rickman, and many others.

The chairman having stated the circumstances under which the meeting was held, and read the notice convening it, stated that the Council after deliberating on the subject, and with the view of assisting the meeting in coming to a satisfactory decision of the question, had requested the honorary secretaries to inquire of C. R. Cockerell, esq., whether in the event of his election as president, he was willing to undertake the office; and in the event of the reply being in the negative, to make the same inquiry of Sir Charles Barry. The honorary secretaries had done this, and it was his duty to state that both gentlemen, with strong expressions as to the honour intended to them, had felt it necessary to decline, and had given their reasons for doing so. The matter was in the hands of the meeting, and it was for them to decide on the course to be taken.

Mr. Tite addressed the meeting at considerable length, expressing his gratification at finding that the council were disposed in favour of a professional president, and giving his reasons why, on previous occasions, as then, he had advocated the view. He showed how, shouldered and abowed on all sides, architects had suffered through the president of the Institute not having had architectural knowledge, especially in respect of the Great Exhibition of 1851, and pointed to the Brompton boilers as one actual result of injury to the public. He had no hesitation in saying that Mr. Cockerell was the most learned and accomplished architect in Europe, and he again urged him to accept the position. Failing in that, he moved a resolution to the effect that the selection of a president on the present occasion should be made from the list of Fellows.

Mr. Jennings having seconded this,

Mr. Cockerell, who was loudly cheered, said he viewed the offer made to him as the crowning honour of his life, and yet felt compelled to decline it; firstly, on the ground of his years, which would prevent him from discharging effectively its duties; and, secondly, because he thought it was desirable the president of the Institute should be a nobleman, removed from the possibility of professional jealousy. It was to the House of Lords we must look for a perfect gentleman, and one capable of throwing the oil of gladness on troubled waters.

Mr. C. Barry supported very effectively the proposition that the president should be elected from the professional body.

Mr. G. G. Scott said Mr. Cockerell's was certainly the most illogical speech he had ever listened to. Mr. Cockerell had disproved all his own positions. He had shown by his speech that he could discharge the duties of his office, and he had certainly sketched his own portrait in the individual he had described as dispensing the "oil of gladness." Moreover, if Mr. Cockerell had attained the eminence he possessed in any other profession—the law or arms—he would himself be a peer.

Mr. Pennycuik supported the proposition for an architectural president.

Professor Donaldson differed from that view, and urged that the interests of the Institute would be best served by one who was free from professional predilections, and had access to the throne: he instanced, too, the advantage of such social meetings as Earl de Grey was in the habit of conceiving, and moved an amendment to the effect that the Council should be requested to invite some nobleman or other member of the aristocracy to become the president.

Mr. Mocatta seconded the amendment. Mr. S. Smirke supported it, urging it was desirable to keep to the old course, which had led to most satisfactory results.

Mr. T. H. Wyatt, Mr. Digby Wyatt, and Mr. Asplitt also spoke.

Ultimately, amidst the applause of the meeting, Mr. Cockerell consented to waive his objections; and

The Chairman having put it to the meeting (on the motion of Mr. Tite, seconded by Professor Donaldson), declared him duly elected President of the Royal Institute of British Architects.

In consequence of the lateness of the hour at which the decision was arrived at, Professor Donaldson said he would postpone a motion he had to propose, touching the reply from the Royal Academy, till the General Meeting of the Institute, in May.

We must mention that the discussion was carried on with remarkable skill and kindness.

#### THE PRESIDENT'S ADDRESS AT THE INSTITUTE OF CIVIL ENGINEERS.

On January 10th, the whole of the evening was occupied by the reception of an address from the president, Mr. G. P. Bidder, on taking the chair for the first time since his election. This address has been printed and circulated. Towards the close of it he said:—

As a natural sequence to the preceding subjects, we are led to the consideration of the proceedings which have taken place, with regard to what are termed our Harbours of Refuge,—as it must be obvious that one main object of these works has reference to the operations of our naval forces—and I believe I am justified in observing, from what transpired during a recent discussion at this Institution, that neither mechanically nor financially can they be considered to be in a satisfactory position. According to the present system of conducting such works, it is obvious that the principle of construction employed at Dover and at Alderney must necessarily restrict their adoption to a very limited extent. Whether we look to the time, or to the cost, the results are altogether inadequate to the services required. The protracted time is, to a great extent, owing to the system of voting the funds annually by dribbles,—the result of which is, that neither the Government nor Parliament fairly appreciate, at the commencement of a work, the full extent of the responsibility involved, either as to time or cost. Can it be supposed that Government, or Parliament, when adopting the recommendation of the commission to construct a harbour of refuge at Dover, imagined that the works would involve an actual cash outlay of five or six millions, without interest, or of thirty or forty millions, including interest, and that a hundred years, at least, would elapse before the full efficiency of the works would be secured; or that, after an expenditure of nearly

half a million sterling, and the lapse of upwards of ten years, the constructive resources of Great Britain would be exhibited to the foreigner landing at Dover in the shape of an incomplete jetty, with two inconvenient landing-places? These and other results of a similar character may be fairly attributed to the system adopted, and must not be laid to the charge of any individual or department, and certainly not to the eminent statesmen who guide the helm of the nation for the time being; for in matters of this description they possess no interest, political or otherwise, apart from that of the country at large. No doubt one of the inconveniences of the present system is that of having to apply to Parliament annually for grants—the amounts of which, and the chance of obtaining them, depend upon the financial state of the country and the temper of the House of Commons, even although the period of the session may be selected when the Government has the best command of the attendance in the House. No doubt that, having regard to these circumstances, the original plans of the works have often been conceived on a limited and narrow basis, adapted to the proposed expenditure, but totally inadequate to the objects supposed to be attained; the ultimate result generally being an extension of the design, an enlargement of the estimates, and a final completion of the works in a form or shape which defies investigation to affirm. Thus money is wasted, time is sacrificed, and full efficiency is not attained.

The remedy for this defective state would appear to be, that, antecedent to any application to Parliament, the Government should prepare full and detailed plans of the entire extent of the works intended to be executed, and obtain tenders from competent contractors for the execution, stating the time of completion and the terms and mode of payment. These plans should be deposited, at fixed periods, at the Private Bill Office, for the inspection of all who are interested. Thus, before the vote was taken, there would be ample time for full criticism on all points, and, though additional labour might be thrown upon the public departments in preparing the documents subjected to such investigation, the House of Commons and the members of the State would have the means of coming to the debate fully informed on all points connected with these national works.

In a financial point of view the gain would be considerable, because a work which is executed within a reasonable time is always more economical than one which is extended over an indefinite period; and also for direct financial considerations, which may thus be exemplified. Suppose a work estimated to cost a million is estimated to extend over twenty years, the work being restricted by the annual grant to 50,000*l.* a year. The ultimate cost of this work to the country, supposing the Government to raise the money at 3 per cent., involves an additional annual charge of about 42,000*l.* per annum, whereas, if the work was executed in five years, by annual grants of 200,000*l.* a year, the annual charge to the country would only be 33,000*l.* a year—thus, irrespective of all other advantages, saving 9,000*l.* a year. These observations only apply to works of real utility, and do not apply to undertakings of so useless a character that their execution cannot be too long protracted,—such, for instance, as the pier at St. Catherine's, in Jersey, and others of a similar character.

I cannot but feel assured that, were the principle adopted which I have enunciated, the defects now admitted to exist in the harbours of Holyhead and of Alderney would have been avoided, and the Blue Book mystification at Portland, respecting the expenditure upon the convicts employed upon the breakwater works, would not have occurred, and the nation and Parliament would have had the satisfaction of realizing, on all these works, the full value of the outlay incurred. Ministers, by taking at once from Parliament a grant for the full amount of the expenditure, would avoid the annoyance of the annual appeal and the recurring waste of the public time, in re-discussing all the features of these undertakings.

I have alluded here to certain defects which will always be inherent in the harbours of Holyhead and Alderney; both of which were, doubtless, originally projected on so limited a scale, on account of the difficulty of obtaining parliamentary grants; but, during the progress of the works, their total inadequacy for the objects proposed became so obvious, that it would have been absolutely criminal to have persisted in the original designs; their extension, therefore, became a matter of necessity; but, alas! these extensions could only be carried out in such directions, that

it is now admitted, that, for the same amount of money, the same extent of breakwater might have been constructed, in a form much better calculated to resist the action of the seas, whilst affording more security and nearly twice the amount of accommodation.

Before concluding my address, I cannot avoid contrasting the progress of Government works with those undertaken by private enterprise. There is, within a short distance, an iron bridge, scarcely even partly completed, across the River Thames. There is no doubt that this bridge will be substantially and skilfully constructed; but it cannot be said to involve any feature of mechanical difficulty: it is constructed in London, and thus commands, in respect of labour and materials, the resources of the whole empire. Another iron bridge, spanning the River St. Lawrence in Canada, is entirely completed, and is opened for traffic: this bridge extends nearly a mile and a half across the stream, having a current varying from seven to ten miles an hour; it has resisted the pressure of ice accumulating occasionally to the depth of 30 or 40 feet. The severity of the climate is such as to restrict the actual period of working to a few months in each year: the iron work and the great proportion of the skilled labour were derived from England; and a severe monetary crisis had also to be surmounted, which latter, however comparatively unimportant in Government operations, exercises a formidable influence on private enterprise. Yet this entire work has been executed contemporaneously with the one uncompleted half of Westminster Bridge;—thus evidencing what the civil engineer can do, when impelled by pressure of private enterprise, as contrasted with his exertions when trammelled by the restrictions incidental to the conduct of Government works.

gentlemen, I am well aware that the observations I have made are open to the severest criticism. I have advisedly introduced into my address subjects and opinions of the most controversial character, because it is my design to induce upon them the fullest and freest discussion. I have endeavoured, on the one hand, and I hope with success, to avoid subjects of trivial interest; whilst, on the other, I have attempted to direct my remarks to subjects of national, commercial, and professional importance.

I have now been a member of this Institution for thirty-five years: during that period I have been a careful and anxious observer of its progress, and the result of my observations leads me to believe, that nothing has tended so much to the steady growth of this society as the animated discussions which so frequently occur within these walls. This point may, however, be also a subject of controversy; but, gentlemen, I have only one further remark to make,—upon which I can defy controversy,—that is, that all I have said within these walls, and that my conduct, while occupying this chair, has been and will be inspired by the determination, so far as my humble powers permit, to perpetuate the prosperity of this Institution, and to maintain the reputation of this noble profession of which I am proud to be a member.

The discussion upon Mr. Grantlun's paper, "On Arterial Drainage and Outfalls," was resumed at the next meeting, Tuesday, January 17.

#### MODERN ARCHITECTURE OF GERMANY.

The address delivered by Mr. Tite, M.P., at the opening meeting of the Royal Institute of British Architects, in the new rooms at Conduit-street, fully reported in our pages at the time, has been privately printed in an octavo form, and obligingly presented to each member of the Institute by Mr. Tite.

In an appendix we find the following, under the head "Modern Architecture of Germany":—

"On this subject I applied to my esteemed friend the Hon. Earl Stüler, of Berlin, one of the architects to the King of Prussia, and an honorary corresponding member of the Royal Institute of British Architects. His memoirs are sent to me to introduce the matter into my address, but I gladly take the present opportunity of preserving his valuable and interesting remarks as follows:—

*New Churches and Restorations.*—During the last twenty years about 300 new churches have been erected, among which the chapel of the Royal Palace at Berlin is deserving of special mention.

Among restored buildings the cathedrals at Cologne, Erfurt, Bamberg, and Halberstadt, are deserving of notice; but in all the provinces of the State the restoring of ecclesiastical buildings has been much attended to.

The plans for these churches and restorations have for the most part been made by Stüler and Stüler; but numerous restorations have also been made by Guast and Zwerner.

*Edifices for the Purposes of Instruction and the Study of Art.*—

Stüler.—The new museum, Berlin; the university at Königsberg; buildings for clinical purposes at Königsberg, Halle, and Greifswald.

Gymnasia (high schools) at Magdeburg, Lyck, Trezniez, Bromberg, Inowrazlaw, Posen. — *Rechnhause* at Inowrazlaw, Berlin, Bromberg; Institute for teachers at schools and sundry boarding-schools at Steinau, Munsterberg, Osterburg, Eylau, Pelskretschaw, Ncwuid, Oranienburg. Most of the plans of these edifices are by Zucc.

*Stiller*.—Institutes for the education of clergymen at Wittenberg and Berlin; smaller buildings for schools in great numbers.

*Buss*.—Buildings for purposes connected with the administration of the law; the large edifices for the administration of justice and for imprisonment, at Breslau, Moabit near Berlin, Cologne, Munster, Rathor, Allden, Eisenfeld, Steinau, &c. Smaller buildings of this kind in great numbers. A very considerable number of buildings for the Post-office service, rendered necessary by the increase of communication, and by new railway works.

*Reichinger and Drewitz*.—Numerous barracks and military buildings.

*Huss, Helro, Stutz, Ark, Steadener, Romer*.—Sanitary Buildings.—Great hospitals in most of the large towns. Lunatic asylums at Berlin, J. Schmetz, Ominsk, Commercial Buildings.—Banks in various places; the New Exchange, Berlin.

This activity in architectural matters, on the part of the State, is, if possible, an excessive undertaking, the population having increased in so enormous a degree, that Berlin within the last twenty-five years has doubled her population. The great railway undertakings here have given rise to the most magnificent buildings as termini, and to the activity of engineers; among whom the most prominent are Mellin, Neuhaus, Wiebe, Hentz, Hohmer, Stein, Hartwich, Rosenbaum, and others.

In the principal edifices of Prussia, among whom the most important are MM. Knoblauch and Hetsig, are overwhelmed with commissions; so that the latter for instance has designed and built twenty-seven country-houses and schools, besides many public buildings. In addition to these, the royal architects Stiller, Strass, Schadow, Hesse, Zwiner, Von Arnim, Gotztrux, and others, have been engaged in making numerous plans and designs for private edifices; and have constructed a very considerable number of country and town-houses, besides other buildings.

In reference to the styles in which these buildings have been executed, it must be remarked that they assume an eclectic tendency in Prussia as nearly everywhere else. In the northern provinces, the influence of the Barba school, through the works of Schinkel, renders the tendency to the Greek Antique common; although it is not employed so exclusively and in such purity as it was by Schinkel.

In the western provinces, however, and especially in South Germany, a preference for Medieval architecture, and particularly for Gothic, is to be discovered; and is by many employed to the exclusion of other styles. In Prussia, those who have employed themselves more especially in this direction are MM. Zwiner, Kashiroy, and Stutz of Cologne. Among the most important architects of Northern Germany the following are perhaps the most distinguished:—

*Vienna*.—Forster, Vander Mill, Von Lichtenberg, Hansen, Ferstel, Döderer, Kreuter, Schmidt, &c., having a special tendency to the Medieval style and Renaissance school, first employed with great skill by Martin, for the requirements of the present day.

*Munich*.—Von Klenze, Zuehlund, Lange, and Veit Dürken, whose works are well known.

*Cologne*.—Fulst—see his 'Early Christian Architecture,' and his buildings; Eisenlohr, deceased; see also his publications on architecture.

*Hannover*.—Lubes, Haase, Vogel, Humannus, and others.\*

*Memorial Church of St. James at Gerrard's Cross*.—On this subject Mr. Tito says:—

"In this appendix I may perhaps properly be allowed to say a word for myself on this building, which has been so highly praised, though it did not appear to me to be of sufficient importance to be included in the preceding address. It has been exposed to many remarks and objections, because it is not Gothic. The reasons why it is not at least summed up in the fact that it is a monumental church in the first place, and that, from our earliest associations in architectural history, the character of a tomb is best obtained by a dome being built over it. That opinion is shared by the *Quarterly Review* in the following passage:—'It is remarkable that the dome was first employed in Persia and in India, as in Egypt, for tombs—thus offering a very curious analogy with the sepulchral architecture of the Etruscans, Romans, and early Christians, and suggesting the inference hinted at by Mr. Ferguson, that its use for such purposes was traditional, first among cognate races, and afterwards throughout the whole world.' This led me naturally to the style of architecture which I adopted; and it had also some personal reference to circumstances connected with the history of my gallant deceased friend, but with which the world has nothing to do. I have neither desire nor intention of suggesting that the style I adopted should be imitated or followed. I pleased those for whom I laboured; and, if I may be allowed to say so much, I pleased myself. It has been said it is very costly. I do not think so; but I was not directed to regard the cost. I believe that the total expense of the building has been about 7,000*l.*, which surely becomes a trifle when compared with the lavish though becoming expenditure of the votive-churches of the Arkwrights or the Cubitts; or the still more costly folly of the church in Margaret-street.

If this small example, however, should lead, by the importance which appears to have been given to it, to the propriety at least of considering whether in these days other styles of architecture are worthy of adoption or imitation, I think that I shall 'have done the State some service.'

**OPENING NEW WESTMINSTER-BRIDGE**.—The demolition of Denton's, (late Oliver's) Hotel, the Westminster Hall Hotel, and several of the adjoining houses in Bridge-street, Westminster, has commenced, to form the southern approach to the new bridge at Westminster, which is to be opened for carriage traffic on Wednesday, the 1st of February, foot passengers continuing to pass over the old bridge for a time.

**A THEME FOR THOUGHTFUL ENGLISH WORKMEN:**

OR, OCTAL *versus* DECIMAL.\*

Our fathers, in the ancient times,  
(Tis thus the story goes),  
Did have ten fingers on their hands,  
And on their feet ten toes.

And their fingers oft assisted them  
With numbers upward mounting,  
And thus the number ten became  
The basis of their counting.

They might have counted otherwise  
(So teaches the "Professor"),  
If they had had or twelve, or eight,  
Or other number lessor.

This remnant of the golden age  
Among us moderns lingers,  
The basis of our counting is  
The number of our fingers.

But whether we should use it still,  
Or whether this the season  
To change our mode of numbering,  
Please listen to my reason.

As an integer take the eight,  
Let eight and ten change places,  
You'll have for measure, value, weight,  
A natural, perfect basis.

But should you doubt what I aver,  
And think of disputation,  
I will, with your permission, sir,  
Give you a demonstration.

Thus:—Take at first a little cube,  
Then add a second to it;  
Saying, "One and one are two"  
(A little child may do it).

Add a third, and then a fourth,  
Just behind the other;  
Saying, "Two and two are four;"  
And thus teach one another.

Place four others on the top  
With care, if not with quickness:  
You'll find the eight are twice the first  
In length, and breadth, and thickness.

(And as a child can add them up,  
When once or twice he's tried them,  
So will he learn as easily  
To equally divide them.)

That "Eight of these make one of those,"  
Is true (none can deny it);  
I think, that in arithmetic  
We should be guided by it.

'Tis but a step—but 'tis a step  
(No other step shall differ)  
That leads the mind progressive up,  
Upward and onward ever.

And as it rises, so it spreads,  
Becoming ever greater;  
Embracing all the works of God,  
Our good and wise Creator.

T. G. ATKINS.

**PRIZE DESIGN FOR THE WASHINGTON MONUMENT, PHILADELPHIA.**

THE first premium, of 300 dollars, for a design for a monument offered by the Washington Monument Association of the First School District of Pennsylvania, says the *Ledger*, has been awarded to Mr. George S. Bethel, architect. According to the design of Mr. Bethel, the monument is to be 225 feet high, including a colossal figure of Washington, of about 20 feet. The following strange description is given of it:—Around the base of the shaft will be an octagon-shaped Gothic structure, 80 feet in diameter and 50 feet high, highly ornamented, and to be surmounted on each corner of the octagon by figures representing the patriots of the Revolution. The space between the base of the shaft and the walls of the building is designed as a promenade. Above this structure the shaft has a base of the same shape, in each face of which is a large window, and on the corners figures are to be placed as on the building described. From this base the octagon-shaped shaft rises 72 feet. It is pierced with windows on four sides, and ornamented on the other faces with appropriate devices. The cap or top of the

monument is to be composed of large brackets supporting a cornice with enrichments, and forming a balcony, within which will stand the pedestal to support the figure of Washington. The balcony, from which a magnificent view of the city and surrounding country may be obtained, will be reached by a spiral staircase. It is proposed to build the structure of white Pennsylvania marble, and to use the blue marble for the ornaments.

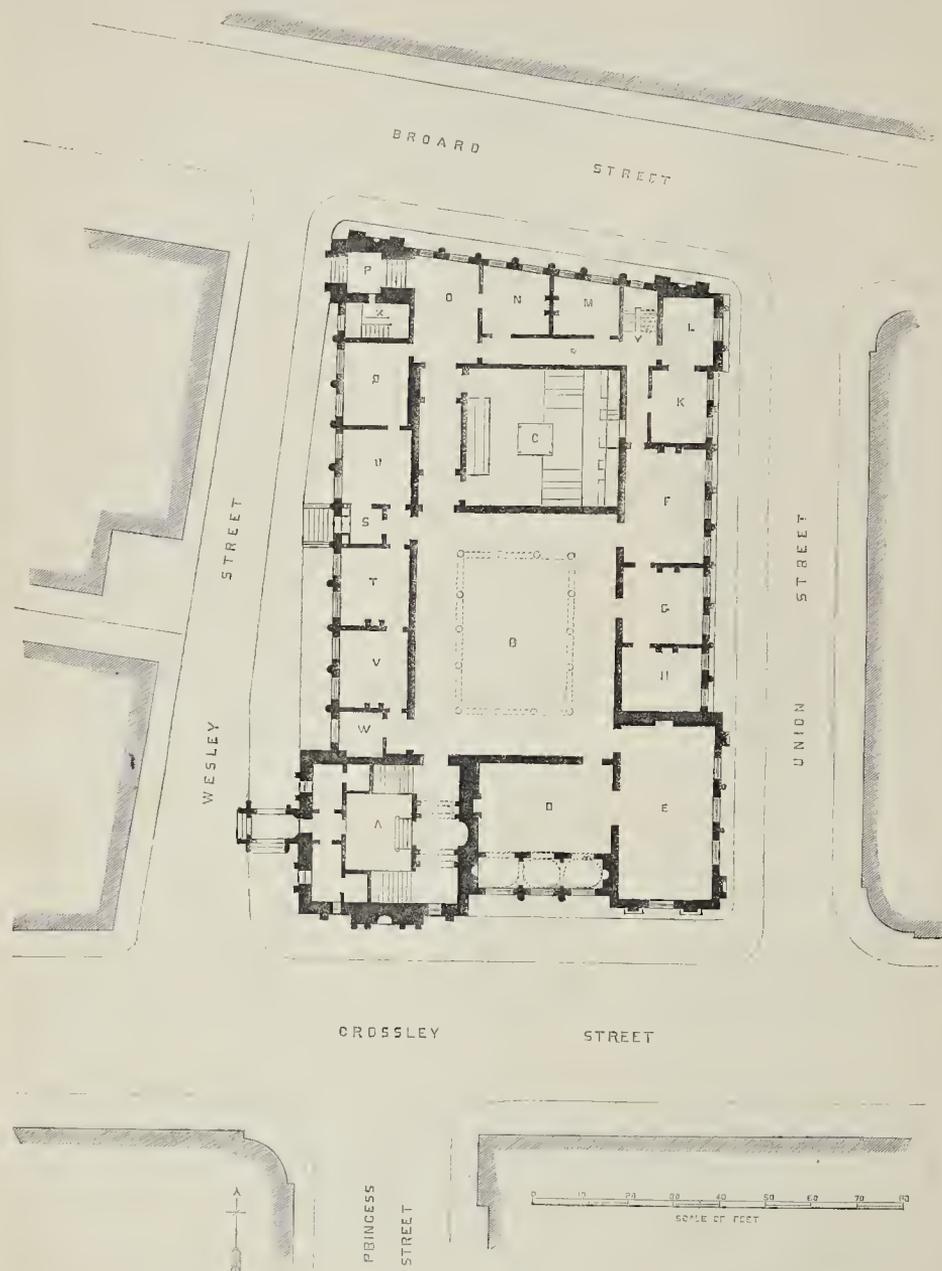

**PROPOSED TOWN-HALL, HALIFAX, YORKSHIRE.**

THE intended Town-hall at Halifax will be placed in the heart of the town, upon property obtained from Mr. Alderman John Crossley, who, when Mayor of Halifax, in the years 1850 and '51, conceived the noble project of removing a considerable portion of the old town, consisting of unsightly and objectionable buildings, and rebuilding that portion of it upon a costly and magnificent scale. With this view he purchased the property in question, and proceeded with the work of demolition and reconstruction, involving, it is understood, an ultimate outlay, on his part, of above 100,000*l.* New and spacious streets have in consequence been since formed on the site of the houses removed, and several public and private buildings adjoining them have already been erected, including a great hotel, a bank, a mechanics' institute, and several costly shops and warehouses. In the midst of these and other proposed edifices of a similar character, is the site for the intended Town-hall, which will be isolated and surrounded by spacious streets and form a conspicuous object at the end of one of the principal new streets, named Princess-street.

After various steps had been taken with reference to drawings for the building, the matter was placed in the hands of Sir Charles Barry, whose design we illustrate in our present number, with a perspective view and a plan of the ground-floor and surrounding streets. The peculiarities of the site, as regards its extent and form, and its position with respect to Princess-street, the great variations in its levels, and the loftiness of the present and proposed buildings, in its immediate vicinity, have suggested the principles of the design. Vertically, it will be obvious, has been striven for. The height of the building, and of the lofty tower and spire, at the south-west angle of it, facing Princess-street, are intended to have the effect of giving importance to the moderate size of the building, whose dimensions will bear no comparison with those of the large and costly edifices recently erected as town-halls in several of the great provincial towns in the North of England; for, unlike those buildings which are generally devoted to festive as well as municipal objects, the new town-hall at Halifax will be exclusively appropriated to the business of the corporation.

The accommodation which the building will afford consists of a large hall, a borough court of justice, with magistrate's room and other appendages, a news-room, a concert-room, three committee-rooms, borough and poor-rate offices, and offices for the town clerk and engineer, the accountant and the market inspector, a mayor's parlour, telegraph-office and waiting-rooms, and residences for a superintendent of police and a house-keeper. All this accommodation is provided in the principal floors of the building. In the basement story, which, on the east side of the building, is almost wholly above the level of the ground, will be the accommodation for the police force of the town, including a parade hall, &c., and cells for prisoners awaiting their trial, also spacious workrooms with engineer's offices and store-rooms attached, required for the gas and water services of the town, which are under the exclusive control and management of the corporation. There are five entrances to the several departments of the building, the principal one being through the great tower, which contains the staircases leading to the upper or principal floor; a chaucer communicating with the terrace flats of the building; accommodation for a clock with four large dials, capable of illumination by night; and a deal of bells. The entire building, with the exception of the lantern-lights over the great hall and borough court, will be covered with a terrace-flat, which, together with the gallery at the summit of the spire, will command extensive views of the town and its suburbs, and afford facilities for occasional public demonstrations by means of flags, illuminations, &c. Tenders have been received for executing the whole of the works for the sum of 23,575*l.*, and the works will be commenced shortly, when the season of the year is more favourable than it is at present for the purpose.

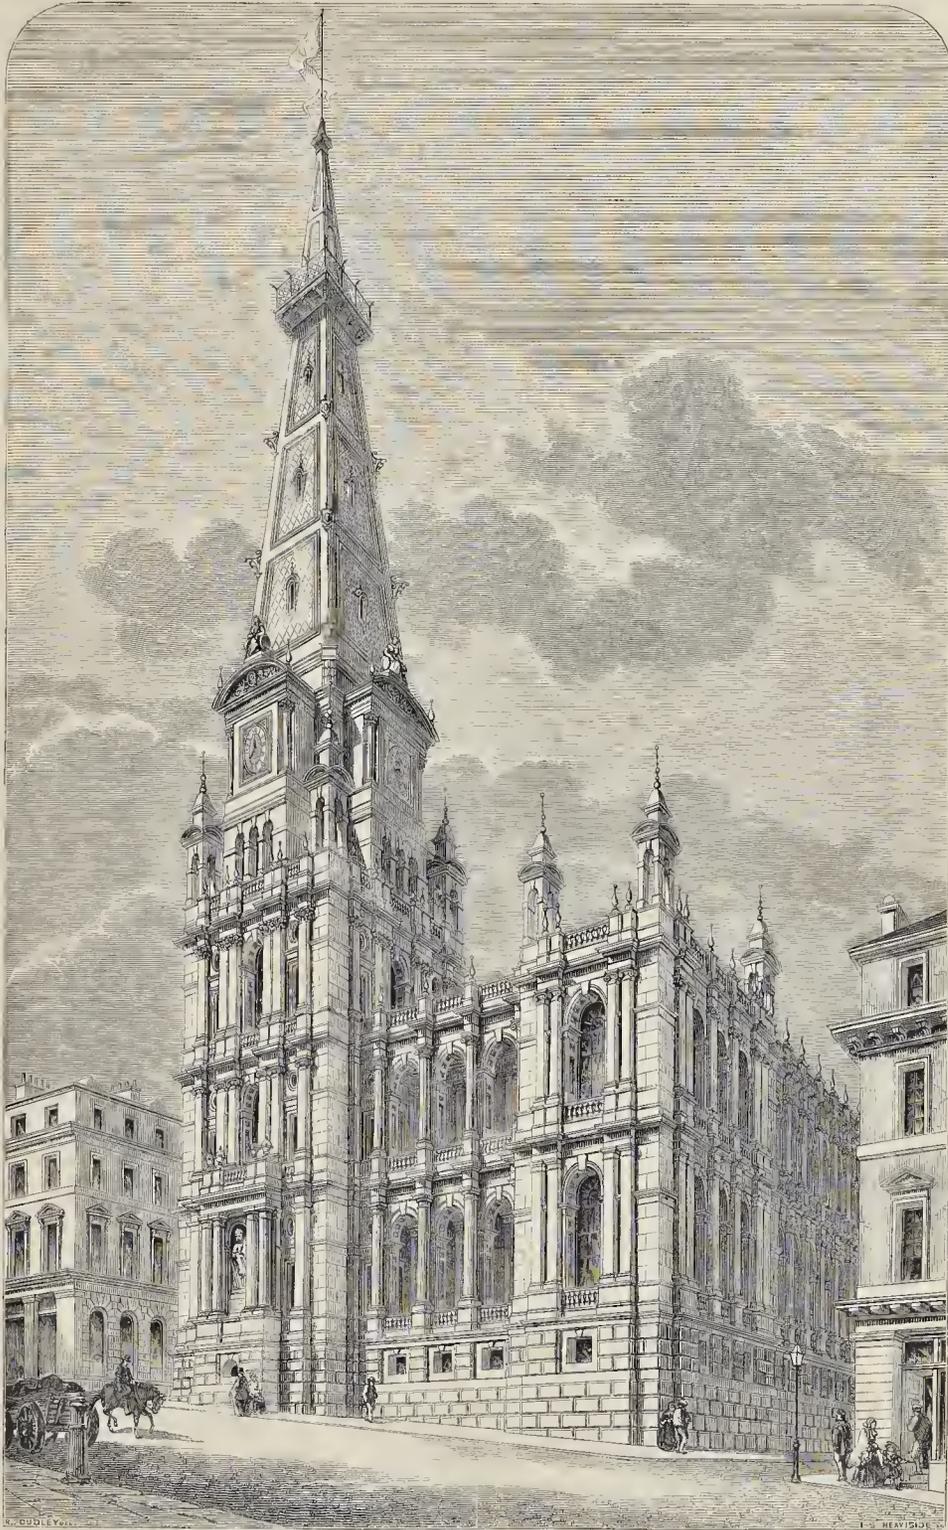

\* We are not to be understood as adopting the opinion set forth.—En.  
† Hennessey.

PROPOSED TOWNHALL, HALIFAX.—*Plan of Ground-floor of Building and the surrounding Streets.*

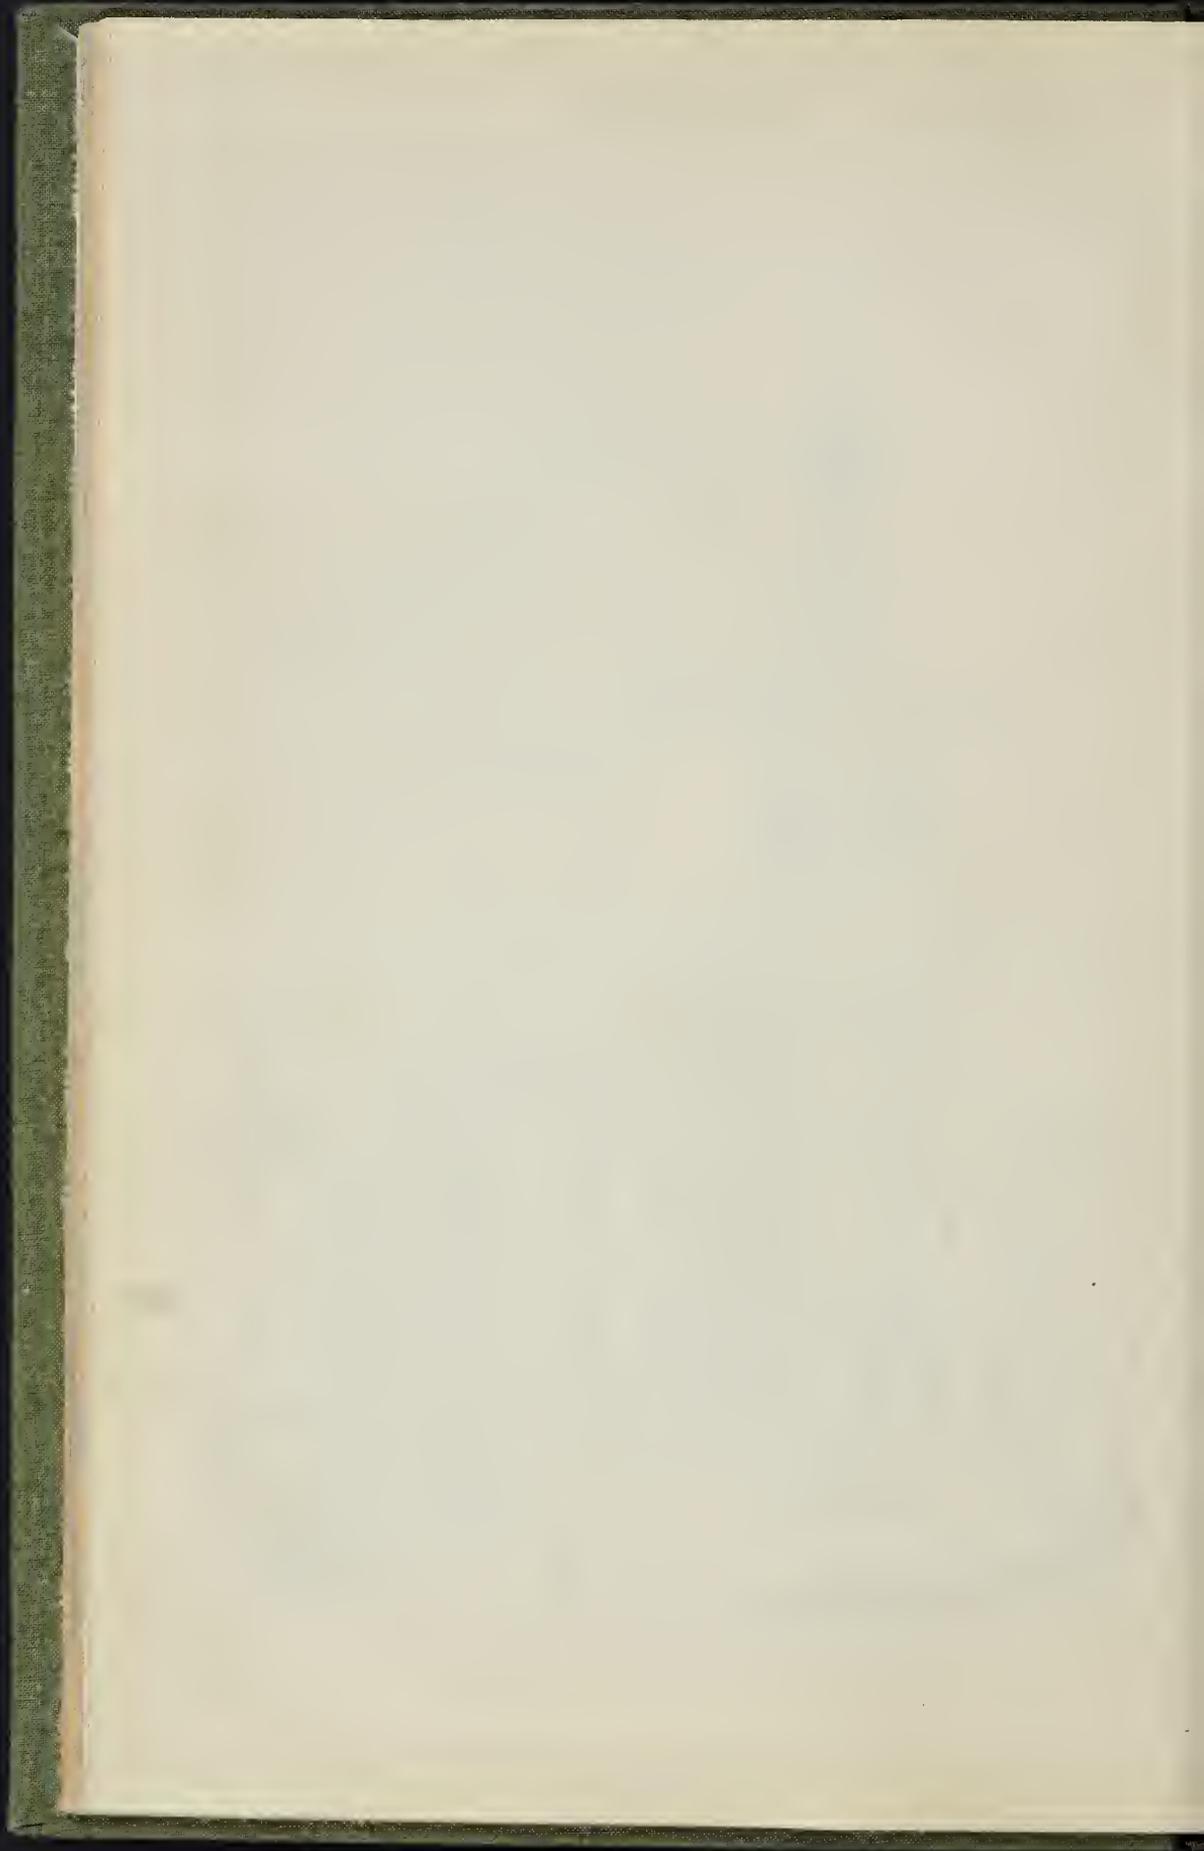

- A. Tower Entrance and Stairs to Council and Committee Rooms.  
 B. The Hall.  
 C. The Borough Court.  
 D. Committee room.  
 E. News-room.  
 F. Magistrates' Room.  
 G. Waiting-room.

- H. Telegraph Office.  
 K. Cloak-room.  
 L. Magistrates' Clerk.  
 M. Police Superintendent.  
 N. Market Inspector.  
 O. The Court Vestibule.  
 P. The Court Entrance.  
 Q. Overseers.

- R. Poor-rate Office.  
 S. Rate-payers' Entrance.  
 T. Borough-rate Office.  
 V. Accountant's Clerks.  
 W. Accountant.  
 X. Housekeeper's Stairs.  
 Y. Police Stairs.

PROPOSED TOWNHALL, HALIFAX, YORKSHIRE — SIR CHARLES BARRY, R.A., ARCHITECT.

**CHELSEA ATHENÆUM CONVERSAZIONE.**

The Chelsea "Athenæum" is a society having for its object, the cultivation of literature and science, especially in the younger members of the community; and a paper is read on some interesting subject by one of the members, every week. Nearly all the members are men who are studying for the various professions. The Athenæum is founded on nearly the same principles as the learned societies of London, and thus differs materially from the "Mechanics' Literary and Scientific Institutions." The subjects are, of course, treated of in a comparatively elementary way. Two or three of the lectures have been printed, and are creditable to the authors of them. The Athenæum has now successfully carried on its operations for a year, and it was thought desirable to commemorate the event by a *conversazione*. This was held last week at the Museum of the Department of Art, at Brompton, by the permission of the authorities. The parts of the Museum occupied, were the rooms containing the Art-Treasures, the Sheepbanks, the Vernon, and the Turner picture galleries; the central hall, and the lecture theatre. At nine, addresses were delivered in the lecture theatre, Mr. Robert Hunt, F.R.S., presiding, by Messrs. Macdonald & Lyon, members of the society. The Rev. J. B. Owen then delivered a suitable concluding address, "On the Usefulness of such Institutions." Votes of thanks were next moved by Mr. Child to Mr. H. Cole, for the facilities he had afforded the committee; and to Mr. P. C. Owen, the deputy superintendent-general, for the way in which the arrangements had been carried out. Mr. Farren (the treasurer) moved a vote of thanks to Professor Hunt, for his conduct in the chair, and the company then dispersed over the various parts of the building. It was altogether a successful gathering.

**ST. LUKE'S HOSPITAL FOR THE INSANE.**

The daily papers a few days ago gave an account of the annual Christmas ball of the patients in St. Luke's. It may be useful to make the position and purpose of this institution better known than they are, and to obtain such improvements in the building as may be possible.

Old-street, and the surrounding neighbourhood of St. Luke's, was in a different condition from what it is now, seventy or eighty years ago when the hospital was raised; then green fields could be seen in all directions; and its projectors, in days when sanitary science was less understood than at present, thought that they had met with a salubrious position. Even in the first instance, however, it could not have been a desirable spot, for the place was little better than a swamp—a continuation of Moorfields—and before this massive building was raised, it was necessary to throw in an immense quantity of bush-wood, and to prepare an artificial foundation: upon this the hospital, designed by Mr. Dance, the architect of Newgate Prison, was placed. It is planned rather in the manner of a prison than an hospital for the cure of one of the most serious ills of humanity.

With thoughts of Hogarth's famous picture of a London Madhouse in our mind, we wandered with painful feelings through the hustling crowd to St. Luke's.

Clanking chains, straight-waistcoats, brutal violence, darkness, filth, and the most terrible neglect were looked upon in his days as the best means of restoring the insane to the world. The architect may therefore be to some extent excused for acting in the spirit of his time; and so came small lights, massive window-frames, which exclude half of the rays of the sunlight, the iron and wire work, and the little care taken for proper ventilation. Modern experience shows that the old terrors of the prison, brutal execrations and violence, and those even worse scenes which were exhibited for a small money payment to the curious, in the madhouses of the metropolis and elsewhere, were errors; and consequently in those buildings which were erected some time ago, it has been necessary to carry out changes, which are made at a large cost. St. Luke's Hospital was reared for about 50,000*l.* during the last six or seven years 15,000*l.* have been spent in alterations, and very much more work remains to be done.

The general plan of this hospital is simple: the frontage extends 493 feet. In the centre is an entrance, with staircase, which divides the building into two equal parts, one of which is formed into apartments for males, and the other for females. The staircase is spacious, but the con-

munication which it has with the cooking operations of the kitchen produces unsatisfactory results. The committee-room, and some of the dwelling-places of the superior officers of the Institution, are situated here, and on each side, the wards for the insane inmates stretch along. Through doors, kept carefully locked, we are admitted into a gallery of great length. The floor is now partly covered with cocoa-nut matting; the other part is painted with a black and white diamond pattern. The walls are neatly papered. At the time Dr. Stephens first became the resident medical officer of this place, these wards had a very different appearance; the brickwork was only imperfectly whitewashed, and a large portion of what is now the principal light of the ward, was blocked up. It is difficult to give an idea of the window-frames. The lower part is fixed; the upper part is moveable. The opening of these windows to the greatest extent, was not a means of ventilating the lower part of the room. When this condition existed,—when there was nothing but the bare boards, and the rough walls, it was necessary to wash the floor frequently. The want of proper ventilation at the right level, allowed the damp and unwholesome moisture to remain long. At this time erysipelas was very fatal in the building, and of common occurrence. Since the matting has been introduced, and the floor painted, which can be cleansed and rapidly dried, this disease has been of very rare occurrence. The wet scouring of floors in hospitals, where large numbers of persons are lodged, is open to objection, for the invisible emanations from the sick are absorbed into the woodwork, which, when wet, gives off unwholesome gases. These have had effects; and experienced hospital physicians and surgeons rightly attribute many bad symptoms, in a measure, to this cause. The painting of the floors of hospitals, and even the rooms of dwelling-houses, is worthy of consideration. If matting or carpets be used, they should be frequently removed to some open place, and carefully dusted.

In those parts where alterations have not been made, there is a comparative gloom. In this curious London picture, which, sad as it is, has its bright side, when we consider the good changes which have been made, we see various neatly-dressed and lady-like young women, singularly different in appearance from the ideas which might be formed of those whose vocation it is to administer to the need of unfortunates of their own sex. A slender chain holds the key of the ward: but for this there is nothing to show their peculiar functions. On the papered walls are some excellent prints, framed, glazed, and mounted by the inmates of the place; and it is a fact worthy of notice that not one of the prints which are ranged round both the male and female wards has been injured. These works of art were the gift of Mr. Graves, the publisher, and will long serve to give pleasure to the inmates. It is an example worthy of imitation. In the light part of the ward a number of females are grouped together, some hazy with needlework, others reading, some carefully wrapped up, lying on couches. Curious eyes peer out at the visitor, and solemnly still the place seems. The song-birds in a large aviary, and a parrot in another part, break the quiet; but the human portions of this scene are peaceable in the extreme. Here is a pianoforte, with some other means of amusement, hooks, a pet cat, but no restraints. "We have not even a straight waistcoat in any part of this house," said the medical attendant. In the darker parts there were figures shrinking, as it were, from the sunlight. The memory of some of these will for long remain. One young girl, with a beautiful face, her long hair flowing behind, led by an attendant, would have been a rare study for a painter. Let us hope the shadow may pass from this fair countenance, for we find that since the establishment of the hospital in 1751 up to the 31st of December, 1858, inclusive, there have been admitted into the hospital 19,463 persons deemed curable on their admission, of whom there have been discharged, cured, 8,667; uncured there have been 6,574; idiots, 1,882; over 500 have been removed by desire of their friends; 1,477 have died. But in the year 1858, of the males, there have been cured at the rate of 65-853 per cent.; of the females there were cured 64-705 per cent.

Proceeding from the main portion of the wards, with the exception of the part which has been thrown open to the light, are various small apartments, some of which are used as bedrooms, bath-rooms, lavatories, &c. There is no over-crowding here at the present time, as the ventilation would not be sufficient, although the alterations just

mentioned have been made. Wirework has been taken away, as have fireplaces, which projected some distance into the ward.

In passing through this and the other female wards where the most quiet of the patients are accommodated, women of different ages are seen, some working without object: one old lady, of pleasant countenance, is nursing a little doll, and pretending at the same time to be stitching; little snatches of song may be heard, and occasionally unmeaning laughter; farther on are heard rougher sounds, which come from the refractory part of the ward, where those who are more violently afflicted are kept. Here there is madness more distinctly shown. At the guard of the fire is a crouching figure: some are expounding in a thrilling manner religious truths; with loud and peculiar voices; language and countenances which to those who are unaccustomed to them are indescribable, are here, but all seem obedient to the management.

In the refractory wards wall papering has been introduced, but here it has been found necessary to panel the wall up to a certain height, with wood. Formerly, before Dr. Stephens undertook the medical superintendence of the hospital, these and the other wards were dingy, and the rough brickwork and heavy window gratings, were most unpleasant to the sight, while owing to the want of proper attendance the inmates camped themselves in parts like companies of wild Arabs.

The sleeping-rooms are arched with brickwork, of great strength, and the windows are most inconvenient. Throughout the entire building the extensive use of bricks is extraordinary; and there is a tradition here that the builder having married the daughter of a brickmaker, received her dowry in bricks, which he was glad to turn to a profitable account. Some of those rooms have been altered: the arches are removed, the lights enlarged, and other improvements made.

In the wards for the males similar improvements to those already mentioned have been made, and the authorities are anxious to remove the prison-like window-frames. To do what is needed, however, would entail a cost of not less than 2,000*l.* In these wards the fireplaces are left unprotected by guards; books and newspapers, bagatelle-tables, and other means of amusement are provided. The furniture here, as well as most of that which is used in other parts of the house, has been made by the inmates. Here, with the exception of the refractory ward, quiet and order reign, and even in the latter, where strong men are violent maniacs, the attendance of the keepers is all the force resorted to.

In this hospital 300 patients might be conveniently admitted, but at present the number is less than that. This, unfortunately, not owing to any decline of the extent of lunacy in the metropolis, but to the ignorance of the public, and even of the medical profession, of the fact that this hospital is for all those who require or have just claims to its use. To those who are really in straitened circumstances this is a perfectly free hospital for the insane. Lately, persons have been admitted whose friends pay partially or wholly for their support, and much good has been done by that means. Owing to the diminished number of inmates, one of the large wards is unoccupied: this has been converted into a ball-room, in which the patients meet once a week, and it very rarely indeed happens that any one has to be removed for rude or improper conduct. The chapel might, at a very small cost, be much improved. Beyond, abutting into the grounds, is a spacious apartment, in which is a capital billiard-table. To add to the means of amusement, a gentleman has presented a complete scenic theatre, which the committee have had fitted up in a suitable building.

In addition to the exercise to be had here, the female attendants take out in rotation four or five patients for a walk in the streets. Many of the male patients have been trusted out on parole without any ill effects having resulted. By the arrangements which have been made more than half of the patients have had an opportunity of visiting the Crystal Palace, the Zoological Gardens, the British and Indian Museums, and the Water Colour Exhibitions.

The basement of the building, for some time past, has not been used for the reception of patients; it was, however, formerly so occupied, and remains since that time in parts unaltered. After passing through the neatly-fitted wards into this dungeon-like place, the contrast is extraordinary. Dimly dark as is this place now, it was worse until a wall, which hindered the light and air from entering, was removed. In these dark-arched and tunnel-like vaults are the kitchens and other

offices, and workshops of various kinds; on part of the ground, a laundry and other offices have been built,—the plan of them is not good.

In glancing at the general arrangements and present condition of this hospital, we cannot but admire the skill and ingenuity displayed by the resident medical officers,—but for the medical officers the condition of the place would have been most unsatisfactory;—and, as we have already stated, still further changes are needed, which will involve considerable expense. It has been properly urged that it is desirable to dispose of this building and site, and erect a new building in the country. We trust that if it is determined to retain this old hospital, vigorous means will be used to raise the sum necessary, to render it more fit for its purpose than it is at present.

#### ON DECORATIVE ART. CONC.

On the 28th ult. Mr. Edward Sheil, the late master of the Cork School of Design, delivered a lecture on "Decorative Art," in the Cork Institution. Mr. Sheil has given up his appointment, in order to visit Rome, and apply himself to painting. In the course of his address, after urging that artists must go to Nature for their highest combinations, he said:—

But Nature's glorious forms, could they be copied literally, are far too perfect and lovely in themselves to be used as secondary things to any work of man. The humblest flower, as the wild geranium, that grows on every bank, would far outshine, for grace, elegance, and marvellous detail, the richest tracery that ever crested a Gothic ceiling. Hence, man, though he must go to Nature for his forms and colours, must adopt a wisdom taught by experience, and be content with only a few of her beauties. The ornamentist is forced to select just as much as may give beauty to his works, and not put them to shame; but, whatever he takes he must hold sacred, and not trifle with; so that, as far as he goes, all who have studied Nature may recognize its truth. This I believe to be the true origin of that treatment of natural forms which is styled conventional, and which is a fundamental principle of all good design, and characterizes beautiful ornaments of all ages;—conventional treatment meaning an arrangement of natural forms, selected and drawn according to certain arbitrary laws. Thus, the cover of the book, which lost its proper character by decorating it with delicately-painted flowers, might have been rendered beautiful in its usefulness by the addition of a few simple lines, leaf-like in their curves, but geometric and unobtrusive. I say geometric, because reducing lines to follow certain laws is merely bringing them within the province of geometry, which establishes such laws with accuracy and truth. This conventional treatment of natural forms has been accounted for in many ways: some derive it from the example of the ancients, others from a horror in the artist of degrading Nature, by applying her forms unchanged to mean and inferior offices. But I fear it is a less noble motive which forces us to strip Nature of some of her glories, and fetter her with geometric forms. I fear it arises more from our secret vanity, which is deeply wounded when we see the hardest work of our hands and brains obscured by the wealth of beauty in any of Nature's works. Now, it might be asserted, with seeming truth, that the copying of any natural form, by man's handiwork, must necessarily be so imperfect as to require no conventional means of degrading it; but admitting that the representation, however perfect, is inferior to nature, yet, because it is man's greatest effort assisted by nature, it must still be far more perfect than man's work unassisted by nature, and therefore unfit to occupy the place of decoration. Having proved, then, the necessity for conventional treatment, and been convinced that the broad field of heaven's work is the great emporium from whence we must draw our knowledge, it is clear that the first step to acquire skill in designing fitly and grandly must be to acquire as intimate and accurate a knowledge of natural forms as our powers permit; and if this is true of all such forms, it applies with greater force to that form which the universal voice of mankind has proclaimed the noblest and most beautiful of all, namely, the human form. The changes that take place from youth to age in a leaf or branch, or even in one of the lower animals, produce no great difference in our ideas of them through all the periods of their existence; but, in the human form, how distinct are our ideas of childhood, manhood, and old age? Innocence and youth, strength and experience, wisdom and infirmity, pass, one by one, across

the lines of the face, which become arched, straight, crooked, or all three combined—as each age and passion thinks fit to impress them. A line in this case is more than a line, it is a short biographical history. It is a mere truisim to say, that the perfect human form is the highest manifestation of God's power upon earth; and as this form is but the external covering of an infinitely complex structure of bones and muscles, which change with every affection of the mind, it is almost impossible by any study thoroughly to understand it. Hence, to draw the human figure well is at once the triumph and the test of an artist's skill. All great schools have founded their knowledge on it.

History proves that it was thus the greatest ornamentists aimed at excellence. The ages which have been most illustrious in great artists were also those that heralded or commenced the best ages of ornamental art—as the ages of Phidias, Paul Veronese, and Raffaele. Hence the proof of my second and third propositions—namely, that art knowledge should be acquired by all classes, and not be confined to one. That this art knowledge must be formed on the study of nature alone, particularly on the human figure. The best practical illustration of the truth of these conclusions consists in the fact, that the schools of design, which were founded on principles contrary to them, failed in realizing the objects for which they were instituted; till at last, under the mastery guidance of the present head of the department, the whole system has been remodelled, to suit all the wants of the nation, and now embraces amongst its students every class in the community,—manufacturers, general art students, and designers; whilst its system of instruction offers almost equal encouragement and honours to every branch of art, decorative or pictorial.

#### SANITARY CONDITION OF LONDON.

##### STATE OF THE CHURCH VAULTS.

In his last report, as medical officer of health for the City of London, Dr. Letheby says:—

"In the corresponding quarter of last year the total number of deaths among the City population was 829, and during the same period of the last ten years the average mortality has been 763; whereas in the thirteen weeks of the last quarter there were but 730 deaths among the inhabitants of the City. This shows an annual saving of 132 lives, or about four per cent. of the whole mortality; and, as I shall presently show, it has been chiefly among adults. As usual, however, the improvement of the death rate, as well as the distribution of deaths in the several unions, has been very unequal. In the western division of the City, for example, with a population of 28,600, there were 190 deaths; in the eastern division, with about 44,600 inhabitants, there were 255 deaths; and in the central, with about 56,000, there were only 255. These are at the annual rate of 26.6 per 1,000 in the first-named union, 25.6 in the second, and only 18 in the third, the mortality of the whole City having been at the annual rate of 22.5 per 1,000. This inequality of the death-rate is sufficiently striking to show that much remains to be done for the sanitary improvement of the City; for although it is not possible to say from physiological data what should be the duration of life, or what the standard of mortality, yet it is manifest from the very inequality of the death-rates that there must have been in some parts of the City an excessive waste of human life. If this is measured by the actual standard of mortality in the whole of England it becomes still more apparent. At this season of the year the mortality in this country is at the annual rate of 21.8 per 1,000 of the population. In the town districts it is 25.2, and in the rural divisions only 18.7; while in many places, scattered over the surface of the country, with every variety of situation, and with a large aggregate population, the mortality is only 15 per 1,000."

Examinations have been made of the vaults under the City churches, seventy-one in number, and it is shown that in some the vaults are even now gorged with corruption, the only partition between the living and the dead being a thin slab of stone and a few inches of earth.

"As far as our investigations have gone," says the officer of health, "we have found about 269 vaults in the City churches, half of which are public; and although it is not possible to obtain accurate information of the number of coffins within them, there is reason for believing that the number is not far short of eleven thousand; besides which there are hundreds of hodies in the graves of the aisles and porches. In most cases the vaults are entered from the general area of the church, the

openings being covered by wooden flaps or by stone flags. The coffins are generally of lead, with an outer covering of wood, and they are often piled up in tiers to the very crown of the vault. When the wood decays, the weight of the upper mass crushes the lead and lets out a filthy liquid of a most disgusting odour. But besides this process of destruction, the lead itself is attacked by the foul gases, and is pierced with numerous holes, as if it were worm-eaten. It then swells up into a spongy mass of porous carbonate, which offers but slight resistance to the passage of putrid vapours, and thus, little by little, the animal part of the body escapes and finds its destination. It is a huge fallacy to suppose that a coffin of lead preserves a corpse indefinitely. The law of nature is that organic matter shall not be idle, it must ever circulate and be in motion."

Years have passed since we set forth the condition of the London vaults in this respect. When we published a view of the vaults beneath a celebrated City church (not one of the worst either), under the title of a Fever-Still, it excited a burst of indignation, and aided in leading to the legislation which has checked, if not stopped the burial of the dead in the midst of the living; but the vaults in many cases appear to have remained in their original abominable state. In consequence "at the night services, or during the winter season, when the air is rarefied by the warmth of the fires, or burning gas, the rank vapours are drawn out in uncontrolled profusion. It is impossible to say what mischief has been done by this, and how many, while worshipping within the sanctuary, have breathed the atmosphere of corruption, and have sickened unto death."

Dr. Letheby appears now to be doing all that is in his power to fill up the vaults, so as to prevent the escape of noxious gases.

#### FOUNDATION OF THE ROYAL ACADEMY.

The *Critic* prints the prospectus originally published on the incorporation of the Academy in 1768. It is dated December 10th, and sets forth that,—

"The principal object of this institution is to be the establishment of well-regulated schools of design, where students in the arts may find that instruction which hath so long been wanted and so long wished for in this country. For this end, therefore, there will be a winter academy of living models of different characters to draw after, and a summer academy of living models of different characters to paint after: there will also be laymen with all sorts of draperies, both ancient and modern, and since casts of all the celebrated antique statues, groups, and basso-reliefs. Nine of the ablest academicians, elected annually from amongst the forty, are to attend these schools by rotation, to set the figures, to examine the performance of the students, to advise and instruct them, and to turn their attention towards that branch of the arts for which they shall seem to have the aptest disposition.

And in order to instruct the students in the principles, to strengthen their judgments, to form their taste of design and colouring, to point out to them the beauties and imperfections of celebrated performances, and the particular excellencies and defects of great masters, to furnish them with an unprejudiced study of books, and to lead them into the readiest and most efficacious paths of study, there are appointed a professor of painting, a professor of architecture, one of anatomy, and one of perspective, who are annually to read a certain number of public lectures in the school, calculated for the purposes above recited.

Furthermore there will be a library of books of architecture, sculpture, painting, and all the sciences relating thereto; also of prints of bas-reliefs, vases, trophies, ornaments, ancient and modern dresses, customs and ceremonies, and instruments of war and arts, utensils of sacrifice, and all other things useful to students in the arts.

The admission to all these establishments will be free to all students properly qualified to reap advantage from such studies as are there cultivated."

Thomas Sandby was professor of architecture, and Sir William Chambers was treasurer. The king had apparently sanctioned the establishment of the Academy in 1767.

#### PRESERVATION OF BUILDINGS FROM WHITE ANTS.

Sir,—I am directed by the Secretary of State for India to transmit herewith a printed paper recently received from India, on the subject of the preservation of buildings from the ravages of white ants, to which you may probably be able to assist in giving publicity. W. T. THORNTON.  
India Office.

#### Memo. by Capt. A. Fraser, Engineers.

In 1856 the flooring and the powder racks in the King's Magazine in Fort Wadia were so far destroyed by white ants, that it was found necessary to renew entirely the former, and nearly the whole of the latter, at a very great expense.

I was then garrison engineer, and, on a suggestion of Major Welser, of the engineers, who had tried the experiment at Ludlow, on his own premises, on a small scale, I adopted the following plan in renewing the floors, &c., of the building:—  
1st. The whole of the old floor was removed, and the

plaster of the walls stripped off to a height of 4 feet above the floor line.

2nd. The earth in the interior was dug out about 1 foot in depth.

3rd. The excavated portion was filled in with concrete, containing a proportion as per note, to yellow arsenic, called in the bazaar "burtal."

In 1856 not only the building, but the whole immediate neighbourhood was swarming with white ants; and in 1859 the Town Major was requested by the Government to make a report as to the effect of the above measures, and annexed is a copy of his reply.

[The reply says, "No traces of white ants have been found either inside or outside the building."]

Memo. by Captain Man. "In 1849 I substituted a planked or a tiled flooring in a room on the ground-floor of my house at Singapore. This was entirely destroyed by white ants in a few months. I laid treble joists and plastered over with the gambier composition, and within two or three days the white ants made their appearance through the crevices between the tiles of the adjoining room, being apparently unable to remain in the vicinity of the protected planking.

I lived in the house for several years afterwards, and the flooring seemed to be in excellent order when I left. I have tried gambier as a preservative against the "teredo navalis" and with equal success, but then I substituted tar or black varnish for dammar oil. I have used it largely on the piles of wooden bridges near the sea, and on the exterior surfaces, and after several years' trial found the timber perfectly free from these destructive animals. I recommended this composition to my successor, Captain McPherson, and he has adopted it with equal success on many occasions.

Gambier Composition. Dissolve three parts of gambier t in twelve of dammar oil over a slow fire, then stir in one part of lime, sprinkling it over the top to prevent its coagulating and settling in a mass at the bottom; it must be well and quickly stirred. It should then be taken out of the cauldron, and ground down like paint on a muller till it is smooth, and afterwards returned to the pot and heated. A little oil should be added to make it tractable, and the composition can then be laid over the material; to be treated with a common brush.

Against the teredo I substituted the same proportion of black varnish on for dammar oil. I of course omitted the grinding down, which would not answer with tar."

From Col. W. Scott, Acting Chief Engineer at the Presidency, dated December 24th, 1858.

"My Lord,—In reply to the second paragraph of the Resolution under Mr. Chief Secretary Young's memorandum, No. 3, 173, of the 14th instant, I have the honor to report that a rule has been in force for some years to eradicate white ants' nests near public buildings. It has, in some cases, been found very effective, but in others white ants abound in places where the nest cannot be discovered, and not unfrequently there are several queens in one nest.

2. Major North used to soak his timber at Belgiam in a solution of sulphate of copper, and the immediate effect was very satisfactory; but Captain De Lisle, from careful experiments with deal, found that the penetration was scarcely appreciable; the effect, therefore, cannot be permanent.

3. When timber is boiled in an antiseptic solution under pressure, the result is very satisfactory, but considerable apparatus is requisite, and the system cannot be economically employed except on a large scale.

4. A mixture of sulphate of copper, or of arsenic, with the lime, in immediate contact with timber, offers, perhaps, the most ready method of preserving it from insects; corrosive sublimate combines with lime, and forms an inert substance (yellow wash of medicine).

5. I have circulated the receipt given below, which is said to answer in the Madras presidency, and requested executive officers to apply it where necessary, taking precautions that it is not applied where it may be accessible, or over any extensive surface:—

Foison for White Ants. Table with 2 columns: lb. and oz. containing ingredients like Arsenic, Aloes, Chunam soap, and Dhobie's mud.

Found the arsenic and aloes, scrape the soap, mix with mud and boil in a large chatty half full of water until it bubbles; let it cool, and when cold, fill up with cold water. The mixture should be boiled for an hour; it is applied as a wash."

VALUE OF LAND IN THE CITY.—At a sale of a portion of the site of the old Rainbow Tavern adjoining the Union Bank, Fleet-street, on Saturday, the 14th instant, the price realized was at the enormous rate of 900,000l. per acre.

\* Two seers (4lbs.) of the yellow arsenic to the 100 cubic feet of concrete.

+ Gutta Gambier is juice extracted from the leaves of a plant of the same name (Uncaria Gambier) growing in Sumatra, and is used in the same manner as Cutch or to cool and harden, and then cut into cakes of different sizes or formed into balls. Chief places of manufacture—Siam, Malacca, and Bintang. It is used by the Malays with the leaves of betel, in the same manner as the Cutch or Cutch in other parts of India. For this purpose the finest and whitest is selected: the red being stronger tasted and rank, is exported to Batavia and China, for the purposes of tanning and dyeing.

THE PROGRESS OF THE ELECTRIC TELEGRAPH.

In various parts of London, high above the busy thoroughfare, numerous workmen are busily employed in passing the electric wires from one situation to another. These will ere long form a curious and striking feature of the streets of the metropolis. Every week this means of communicating information is being more adopted; and, as we have before said, the electric telegraph will prove a means of increasing the power of the police, of spreading the alarm of fire, and important for many purposes of business; it is not unlikely that the laying on of the telegraph, in important establishments, printing offices, &c., will become as necessary as in the case of gaslight and water. Who can say how ultimately this marvellous invention may affect our present post-office system, or to what extent the streets overhead may be covered with wires, like a spider's web? It may be, in business, that the art of working the telegraph may be as necessary as that of writing, and be made a matter of school education; and that tall chimneys and other lofty objects will have a value which is at present not thought of.

GIFTS OF THE LATE MR. MINTON.

I HOPE you will put on record in the pages of the Builder my late friend Mr. Minton's many gifts of beautiful tiles towards the beautifying of God's house of prayer in divers places.

I send you a list as printed.

At the same time commending the introduction of the memorial tile, which I have laid down here (Clyst St. George) to record his gift. It is 12 inches square, and works in well with the other tiles.

The old floor of this church was covered with tomb stones; many of them broken and obliterated. It was my own idea to transfer the names and dates to tiles 12 inches square. Mr. Minton fell in with it, and at once offered to give the pavement for the nave, and these memorial tiles are worked in and form a beautiful design.

We have no right to destroy the records of the dead; as has been ruthlessly done in many churches where tile pavements have been laid down. By introducing these memorial tiles, a beautiful and imperishable record may be substituted.

Besides Mr. Minton's gift, the floor of an aisle has been given, and treated in the same way; and now we have twenty of these memorials, besides the one to Minton's memory.

H. T. ELLACOMBE.

\*\* The list, for which we cannot give space, occupies six octavo pages. It will be found in "Annals of the Diocese of Lichfield, Past and Present."

The memorial tile inserted in the pavement of Mr. Ellacombe's church, Clyst St. George, Devon, takes this shape:—

BUILDING FOR THE PROVINCIAL WELSH INSURANCE COMPANY, WREXHAM.

THERE is but one Welsh Insurance Company, and for this the first stone of a new building in Wrexham was laid on the 3rd instant by Lady Williams Wynn, with some ceremony and great rejoicing. The Welsh Insurance Company was established in April, 1852, for the insurance of property against fire.

The first 10,000 shares of the company were taken up immediately, and the issue of an additional 10,000 shares became necessary to meet the demands of the public. The whole 20,000 were taken up by about 800 persons. A large staff of agents was soon appointed in the United Kingdom and Ireland. A large proportion of the agents from the commencement have been shareholders, so that a vitality was given to the company, at first, which has steadily increased in strength, until up to the present time nearly 20,000 policies have been issued, insuring property to the amount of 7,317,905l. The life assurance business was

commenced in 1854. The site of the new offices is on the south side of High-street, nearly opposite to the office at present occupied by the company, where a block of unsightly dilapidated old buildings has been removed to make room for the new offices, designed by Mr. R. Kyrke Penson, and now in course of erection by Messrs. Lockwood & Farrimond, of Chester. At the entertainment which followed the event reference was made to the energy and ability with which Mr. Dillon, the manager of the company, had conducted its affairs.

WESTMINSTER ABBEY.

SIR W. D'AVENANT'S GRAVE-STONE.

As attention has lately been drawn to Westminster Abbey by the Builder, as well as by the funeral of Lord Macaulay, it has occurred to me that the present is a suitable time to put a question to the dean and chapter or their architect, which I should like to have answered. Some six or seven years ago, strolling in the cloisters, I observed a small slab of stone broken across, with this inscription:— "O Rare Sir William D'Avenant,"

which seemed to identify the stone as having been placed over the grave of the poet of the Restoration.

I do not know where he is buried, so have not been able to ascertain if the slab was ever replaced; perhaps Mr. Scott or some of your correspondents can inform me. J. H.

THE ARCHITECTURAL MUSEUM.

PRIZES FOR WOOD-CARVING.

THE prizes for wood-carving have been awarded as follows:—First prize, 5l. 6s. (offered by the council of the Architectural Museum), to Mr. James Allen, in the employment of Mr. J. B. Philip; an extra prize of 5l. 6s., added by the council, to Mr. William Baylis, of 3, Warwick-place, Bedford-row. Second prize, of 3l. 3s. (offered by Mr. Beresford Hope, the president), to Mr. Charles E. Turner, of 13, Upper North-place, Gray's-inn-road. The prizes will be presented on Wednesday, March 7th. We take the opportunity of adding that the council are soliciting donations in aid of the prize fund for this year. Mr. G. G. Scott, the treasurer, or Mr. Clarke, the honorary secretary, will be happy to receive promises of assistance.

BRIGHTON AND SUSSEX SCHOOL OF ART.

The first annual meeting of this school has just been held, in the Townhall, Brighton, the Rev. Mr. Griffith, Principal of Brighton College, in the chair, in the absence of the mayor, from indisposition. The report stated that the entire number of persons taught by the art-master (exclusive of private pupils) during the past year was as follows:—At public schools, 500. At the School of Art,—Day classes: gentlemen's (A), 11; ladies' (B), 31; total, 42. Evening classes: Artisans, &c., (C and D), 112; schoolmasters, 5; schoolmistresses, 4; pupil teachers, 28; other females, 26; total, 175. Making the total in the School of Art, 217; of whom the great majority would have obtained no instruction in elementary art but for the establishment of this school. In point of finances, the result of sixteen months' operations is a balance of 22l. 10s. 1d. in the treasurer's hands. The committee had at no time been in debt. Mr. W. W. Attree, in moving the adoption of the report, said that if they would give a little consideration to what had been the source of progress in all successful schools of art, they would find that it had been patient, steady, "noble correctness" as it had been well called; and one of the deepest thinkers of our country had said, that of all things that he had any idea of in art, the one that struck him most, as a distinctive characteristic of art, was the mechanical portion of it; and that was the particular thing specially pointed out in the report. That "noble correctness" can only be obtained by constant perseverance and the most accurate study; and, so far as he could learn, that had, in all schools, been the necessary foundation upon which success had been built. They all knew the story of the great master of Italian art, who, when asked to give a specimen of his skill, sent a single curve so accurately done that it had passed into a proverb, and when we would express that a thing is excellent and perfect of its kind, we say that it is "Round as Giotto's O." And that was the foundation of a great and noble school of art. This "noble correctness" lay at the bottom of all art:

it was the only superstructure upon which great artists had rested, or ever could rest their hopes of success. The prizes were afterwards distributed in the usual form.

#### NORTHERN ARCHITECTURAL ASSOCIATION.

##### THE ANNUAL MEETING.

The first annual meeting of this association was held on Tuesday, in the Old Castle, Newcastle-upon-Tyne, Mr. Watson, in the chair. Routine business having been transacted, a report was read by the secretary, and afterwards unanimously adopted by the meeting. In this it was said,—

"At the first quarterly meeting, held, by the courtesy of the Society of Antiquaries, in their rooms in the old Castle, Newcastle, the inaugural address was read by the president, John Dobson, esq.; and on the 6th of July the annual excursion meeting was held at Finchall Abbey, attended by a large party of members. During the examination of the ruins several interesting discussions took place, and some valuable sketches and measurements were obtained. The party afterwards visited Lunley Castle, and made a careful inspection of the more valuable features of the edifice, and returned home much gratified with the day's excursion. Your committee wish especially to draw the attention of the members to the advantages obtained by these excursions in connection with the society. The second quarterly meeting was held on the 19th July, when a paper was read by Mr. Anstlin on 'English Architecture of the latter half of the Twelfth Century,' which was illustrated by various diagrams. The third quarterly meeting was held on the 10th of October, when Mr. Dunn read a paper entitled 'Notes on Continental Architecture,' which he illustrated by sketches made on the spot. Not the least gratifying part of the report which the committee have the pleasure of submitting to you is the highly satisfactory statement of its financial condition, which enables them to say that, after having paid the preliminary expenses, the outlay involved in the publication of the papers, and all incidental expenses, there will be a balance in the hands of your treasurer."

The election of officers for the ensuing year was made, as follows:—President—Mr. Dobson. Vice-President—Mr. Wardle. Honorary Treasurer—Mr. Austin. Honorary Secretary—Mr. Oliver. Committee—Mr. Dunn, Mr. Watson, Mr. Greener, Mr. John Lamb, and Mr. Inaswell.

After a conversation, the secretary was instructed to forward, without delay, to the secretary of the Bishop Auckland New Town Hall and Market Company, an extract from the minutes of the resolutions passed relative to a competition for designs, advertised for by the directors of the company, for a Town Hall and Market at Bishop Auckland.

#### THE RHINE BRIDGE.

On Saturday, the 24th December, at seven p.m., the foundations of the fourth and last pier of the celebrated railway bridge over the Rhine were sunk to the required depth of 20 metres. Thus, the four piers are completed. The first was sunk in fifty-three days; the second in thirty-one; the third in twenty-five; the fourth in eighteen days. These are all taken as days of effective labour.

The abutments remain to be constructed. The cube of the foundations of the four piers is 12,000 metres of masonry. The quantity of gravel excavated is 17,000 metres.

The works of the line from Kehl and from the Kintzig bridge advance rapidly. Next September the line will be open throughout, and the journey from Paris to Baden-Baden will be performed in ten hours.

#### THE SOCIETY OF FOREMEN ENGINEERS.

EVERY one is aware of the value of the steam-engine to the inhabitants of the earth. Whether it be employed in the propulsion of vessels, despite the hostile influences of wind and tide, and fro between the most distant regions, and thus facilitating the exchange of the varied products of every country; whether in the form of the locomotive, whisking passengers from one extremity of the kingdom to the other, and "annihilating time and space;" or whether in the stationary form engaged in the execution of works of the most ponderous and the most minute kind, the steam-engine is equally important, valuable, and wonderful. Surely, then, the well-being and progress of the men—for the most part self-raised men—who overlook their construction, the foremen engineers, have a claim on the consideration of all.

It is impossible to watch the construction of any intricate piece of machinery in an engineering establishment without admiring the careful attention given by all concerned in "setting it out," and in practically developing it. And certain it is that no man is ever selected for the post of foreman over the workmen employed in perfecting machinery who is not at once able, steady, and

economical—that is, economical of material. Hence to say that a man is a foreman engineer is to give him a good character. This fact we commend to the attention of all. The Association of Foremen Engineers has its meetings, monthly, at No. 35, St. Swithin's-lane, City, and is, apparently, in a prosperous condition, financially speaking. To quote briefly from the preface to the rules, it may be said that "The Association of Foremen Engineers does not discuss on any occasion the politics of trade. It has no secrets, but waxes rather complete publicity. Its objects are purely and solely philanthropic and instructional. It essays to assist its members in fairly, creditably, and peaceably filling the important posts confided to them; to relieve them under pressure of incidental difficulties; and to afford timely assistance to their sorrowing relatives when the wings of death overshadow them, and make their homes desolate."

This extract gives with sufficient distinctness the aims and objects of the Association; and we feel convinced that in making it better known we are conferring a good upon society. Already, we learn, that nearly 100 members are on its books, and we feel assured that that number will steadily increase, until representatives of every engineering establishment in London are to be found united to it.

One of the rules enacts that no candidate can be accepted who has not held the position of foreman engineer for at least two years prior to his application for the privileges of membership. The entrance-fee is one guinea; the subscription, 2s. 6d. per month. Mr. Joseph Newton, foreman of the coining rooms, Royal Mint, is president; and Mr. John Jones, of Messrs. Grissell's, Wharfedale, City-road, secretary of the Association.

#### SMALL-POX.

THE great increase and continuance of small-pox are causing much anxiety, and in many parishes notices have been issued directing attention to the necessity of vaccination. Knowing something of the feelings of the poor (who suffer most), we may say that in addition to much carelessness in taking the children to be vaccinated, doubts exist respecting the effectiveness of vaccination, and fear lest other and permanent diseases may be generated. These matters are well worthy of immediate consideration, and means should be used to set the public mind at rest on the matter. In several neighbourhoods occupied by the poorest, owing to unwholesome conditions and other causes, the deteriorated condition of a large number of children is deplorable. Scrofula and other complaints affect so many constitutions, that it is not a very easy thing to find, without looking abroad, a sufficient number of healthy children from whom to procure the necessary quantity of good vaccine. The sum allowed to the medical men who attend to the vaccination of districts, is small, and does not induce much care. The present Act, it is said, cannot be properly carried out: it is, in fact, unworkable.

#### TIMBER MEASURING IN IRELAND.

TOWCHING the "string and calliper" was now raging between the Dublin builders and the Messrs. Martin and Son, timber merchants in that city, and in addition to the particulars already given, we find that Mr. Barcroft, timber broker and measurer, in reply to the request of the Association, writes: "In accordance with an experience extending over twenty-five years, I have found a difference in favour of the string of from five to twenty-five per cent., according as timber was squared or wavy, and agree with Mr. Chaloner that it is necessary to have a sworn measurer to act between merchant and purchaser, to prevent frauds being practised by unprincipled parties, especially upon public companies." Mr. Barcroft proposes a deputation of builders, retail timber merchants, and cabinet makers, to wait upon Messrs. Martin, with a view to amicable arrangement. One in the Trade replies to Mr. Chaloner's letter that he, being a Liverpool timber-broker, takes an unselfish (?) interest in the Dublin timber trade, and that having an aversion to a change that would dispense with his services, he leaves the public to judge how far his statements may be biased. Further, that the custom-house officer who measures by "calliper" ought to be protected enough between merchant and trader without the intervention of a second measurer at cost to the latter. Timber is sold by calliper in all the Irish markets and the English ports except Liverpool; and concludes that Mr.

Chaloner is not to be blamed, being only attending to his business in trying to divert the trade to Liverpool.

#### IRISH NEWS.

THE Ennis-killen terminus of the Dundalk and Ennis-killen Railway, recently erected from designs by Mr. William G. Murray, architect to the company, is an important structure, with a platform towards rails extending 300 feet, and a similar frontage towards street. The main building—which is two stories high—comprehends, on ground-floor, a central booking-office, 30 by 17, approached under a covered way or verandah from the exterior, and wings with gentlemen's and ladies' waiting-rooms, left-luggage room, and master's kitchen, respectively, with spacious apartments for the master above likewise; together with one-story wings containing refreshment-room, kitchen, and yard, at one side, approached from platform; and superintendent's office, porter's stores, water-closets, &c., at the other. The expenditure was about 3,500*l.*, and the materials employed, limestone, from Carrickree quarry, hammer-dressed, with Cairnmore quarry sandstone for quoins, window and door-ops, chimneys, bases, &c. The same company have also erected stations at Ballybay (cost 1,700*l.*), Newbliss (ditto), Clones (2,500*l.*), Newtown Butler (1,400*l.*), and Lisnaskea (1,500*l.*). Mr. John Nolan, of Dublin, the builder of all. The above amounts are exclusive of extras.

#### COMPETITION FOR THE HARTLEY INSTITUTION, SOUTHAMPTON.

WE have received several letters directing attention to a preposterous communication addressed to the *Hampshire Independent*, the object of which is set forth in this extract from it:—"I do not object to plans being obtained through public competition, yet I most decidedly think a preference should be given to a local architect, provided his design embodies the requirements as set forth in the scheme issued by the council, and that it will not exceed in cost the sum at their disposal." And he goes on to request the committee without fail to include amongst the designs "selected for their final consideration those sent in by the architects of the town," showing the value he attaches to the fact that the drawings are submitted under mottoes.

We cannot suppose that such a communication will prevent the council from coming to a decision on the merits of the designs alone; but it is as well that the peculiar views which exist on the subject of competition should be known.

#### SCIENTIFIC INSTRUCTION TO THE INDUSTRIAL CLASSES.

EXAMINATIONS of teachers in competency to afford scientific instruction to the industrial classes were held at the "South Kensington" Museum in November and December last. The certificates are of three grades, giving the teacher who obtains them annual payments, whilst teaching, of 10*l.*, 15*l.*, and 20*l.* for each subject. The following is a list of the successful candidates in the first two subjects:—

##### SUBJECT I.

Practical Plane and Descriptive Geometry, Mechanical and Machine Drawing, and Building Construction.

SUBDIVISION I.—Practical Plane and Descriptive Geometry.

Nine candidates, all of whom failed.

SUBDIVISION II.—Mechanical and Machine Drawing.

Second Grade Certificate.—Washington Hudson, Eagle Foundry, Hunt-street, Manchester. Four failed.

SUBDIVISION III.—Building Construction, or Practical Architecture.

Second Grade Certificate.—Washington Hudson, Eagle Foundry, Hunt-street, Manchester.

Third Grade Certificate.—William H. Goolwyn, Marquis of Salisbury's School, Hatfield. Four failed.

##### SUBJECT II.

Physics, Mechanical and Experimental.

SUBDIVISION I.—Mechanical Physics.

Second Grade Certificate.—Isaac Seaman, 18, Cunningham-street, Pentonville; Benjamin Simpson, St. Matthew's School, Bethnal-green.

Third Grade Certificate.—Joseph Haugli, Mechanics' Institute, Leeds; Walter Jeffrey, Blue Coat Hospital, Gloucester; Edward Atkins, St. Martin's School, Leicester; Moses Pilleu, National School, Paiswick, Stroud; Robert J. Nelson, Navigation School, Mercers'-street, Sandwell. Five failed.

SUBDIVISION II.—Experimental Physics.

First Grade Certificate.—Walter Jeffrey, Blue Coat Hospital, Gloucester.

Second Grade Certificate.—Benjamin Simpson, St. Matthew's School, Bethnal-green; George C. T. Bartley, 1, Rectory-place, Stoke Newington.

Third Grade Certificate.—Isaac Kerby, St. Mary's School, Putney; Edward Atkins, St. Martin's School, Leicester. Six failed.

THE STONE USED IN WESTMINSTER ABBEY.

On reading your report of the proceedings at a meeting of the Royal Institute of British Architects, in your edition of the 24th ult., it occurred to me that the stone partly used in the erection of Westminster Abbey, and described by Mr. Scott as "Beer or Bur, and from Stapleton, which he supposed to be near Pontefract," must be the Beer and Silvertown stones, the same as used in building Exeter Cathedral; for, according to the Fabric Rolls of that beautiful work, it appears that it was built of stone from different quarries; the walls, of Beer, near Colyton, Devon; the vaulted roof, from the quarry at Silvertown, in the same county; and the clustered and small pillars, with their capitals (duly supposed to be artificial composition), from the Isle of Purbeck, in Dorsetshire.

I hope these few remarks may be of some value in deciding the exact locality from which the stone used in Westminster Abbey was taken.

THOMAS G. BROWNING.

APPEAL AGAINST CONVICTION OF WORKMEN FOR INTIMIDATION.

At the Surrey Sessions, on the 16th instant, the appeal of Jenkins, Stanley, and Davis, society men, against the conviction of Mr. Elliott, was heard, in the New Court, before Mr. J. E. Johnson and a full bench of magistrates. The appellants in this case belong to the Builders' Society, for the protection of the men on the late strike and lock-out; and on the 9th of November last they were all charged at the Lambeth police-court with using threats and intimidation to John Roy, a bricklayer and a non-society man; and the case having been proved to the satisfaction of Mr. Elliott, the sitting magistrate, he sentenced Stanley and Jenkins to one month each, and Davis to fourteen days. The appeal lasted nearly the whole day.

Mr. Robinson, for the appellants, contended that it would be much better for the Court to let the matter drop by the men entering into their recognizances. The strike was now over (?), and the men saw their folly, and he was sure that a repetition would not occur. The charges against the defendants could not be supported, therefore he now suggested that the appeal should stand over, with the view of its ulterior abandonment.

Mr. Knapp objected to that course. It had been clearly shown to the magistrates that intimidation had been used, and it was necessary that the case should proceed.

The Court was of the same opinion, and the evidence, accordingly, was re-heard. At the close—

The chairman said that the Court was unanimous in their judgment, and confirmed the convictions; and they regretted that a body of men should have been so foolish as to combine for such a purpose, and hoped it would not occur again.

The defendants were then taken into custody. Jenkins and Stanley stand committed for one month, and Davis fourteen days, with hard labour.

ACTION FOR DILAPIDATIONS.

HIS ROYAL HIGHNESS ALBERT EDWARD, PRINCE OF WALES, v. HEATHER.

This was a suit promoted in the Sheriff's Court, on behalf of his Royal Highness the Prince of Wales, as Duke of Cornwall, for dilapidations arising under five leases, comprising thirty-one houses at Kennington, in Surrey. The damages were laid at 1,000*l.* The first count of the declaration recited a lease of 4th March, 1833, between his Majesty King William IV., of the one part, three officers of the Duchy of Cornwall on the second part, and the defendant of the other part; and a demise of fifteen houses in Golden's-place, Chester-street, Kennington, part and parcel of the demesne lands of the manor of Kennington, and part of the ancient possessions of the duchy. There were the usual conditions as to repairs, and the other counts recited at length the demise of the other houses held by the defendant under the duchy. It alleged that the reversion expectant on the determination of the term had become vested in the plaintiff in right of his Duchy of Cornwall; and the breach set forth was that—whilst the plaintiff was so seized of reversion, and whilst the defendant was possessed of the premises, and before suit was commenced—he did not sufficiently repair according to the covenants, and the premises in consequence became ruinous and decayed, &c.

Sir W. J. Alexander and Mr. Garth appeared for the plaintiff, instructed by Messrs. Lyon, Barnes, and Ellis, of Spring-gardens, solicitors to the Duchy. The defendant was not represented, and the only question was as to damages. The evidence was of the usual character as to dilapidations, and the jury assessed the damages at 900*l.*

GLASS.—A steel drill, hardened and used without drawing the temper, will, if the point be kept wet, drill ordinary glass. Window glass offers greater resistance to drilling than glass which is much thicker.

Books Received.

*Practical Remarks on Belfries and Ringers; with an Appendix on Chiming.* With Illustrations. By the Rev. H. T. ELLACOMBE, M.A. &c. Bell & Daldy, 186, Fleet-street, London. 1859.

THE Rev. Mr. Ellacombe is a well-known authority on the subject of bells and bell-ringing, as many of our readers are doubtless aware, even from our own pages. A pastorly desire to reform the moral characters of the "idle and drunken" bell-ringers appears to have actuated the reverend gentleman, no less than his interest in the subject of bells and belfries. The book under notice contains a set of rules for ringers which it would be worth while for others of our many clerical readers to consult, as well as remarks on the formation of belfries useful to our architectural readers. The Appendix gives a full account of an ingenious plan of chiming devised by Mr. Ellacombe.

The meaning of the phrase "a peal" has curiously changed.

"With the half wheels the bells were not raised to a set pull, but rung a little above stock level and kept there a certain time, and then ceased; and so the ringing would be continued, and each time of its repetition was called a peal; and supposing this to be correct, it is more easy to understand the meaning of so many peals in a day."

"The ringing even of a single bell for any length of time would be called a peal, and so it is now termed, particularly in the North, where single bells prevail."

VARIORUM.

"LES Grandes Usines de France," partie Ire: Algar, Clements-lane, London. Under this title it is proposed to describe and illustrate the most important manufactures of France. The first part contains an interesting account of the *Gobelins* manufactory, with several engravings.

The current number of the *Ecclesiologist* contains two interesting views of the Choir of Lichfield Cathedral, as proposed to be fitted under the direction of Mr. Scott, one looking westward, showing screen and stalls, the second looking eastward, showing roscos and throne.

Part 3rd of the new and rewritten issue of "Ure's Dictionary of Arts, Manufactures, and Mines" (Longman & Co.) has been published for January. It extends from "Doring" to "Calomel," and contains an excellent article on "Brick," illustrated by engravings of brick-making machinery. "Brass" and "Cable" also form articles of some importance.—"Lever's Year-book and Railway and Mining Almanac" (Thomsons, Market-street, Manchester), is a useful compendium, for 1860, of facts relating to railways, mines, metals, minerals, bridges, tunnels, breakwaters, &c. with list of railway officials; literary, scientific, and philosophical institutions, and their officers; returns of imports and exports, &c. It contains two horrible caricatures, however, of Brunel and Stephenson, which it would have been much better without, and which, we dare say, most purchasers of any taste will tear out for themselves.—

Amongst a heap we observe two pamphlets on the "Great Ship" great squabble,—one titled "Two Letters to the Shareholders, from L. S. Magnus;" the other, "Minutes of Proceedings" of the meeting of 13th December, with "A Critical Notice," by H. Guedalla. We have no intention, however, to trouble our readers with these unfortunate misunderstandings, and can only express a hope that, now that the directors have resigned, and a committee been appointed by the shareholders, matters will be placed upon a better footing, and the Great Ship principle obtain a fair trial. Mr. Scott Russell, we observe, is not inclined to be altogether silent under the share of opprobrium he has come in for in the squabble, but has published a kind of report of his own on the state and merits of the big ship, which, he says, it was never intended should be completed till after her trial-trip.—A reprint of "Experiments on the Comparative Tensile Strength, &c., of Steel and Wrought Iron, by Messrs. Robert Napier & Sons," from the "Transactions of the Institution of Engineers of Scotland, Vol. II.," and noticed by us on a previous occasion, has been published by Maekenzie, Howard-street, Glasgow.—"Country Trips," by W. J. Pinks (Piekburn, 35, Rosoman-street, Clerkenwell), is the first volume, just issued, of a little work comprising a series of descriptive visits to places of interest in various parts of England. It contains some pleasant reminiscences connected with various, more or less, well-known localities.

Miscellaneous.

ST. DOULOUGH'S CHURCH, CO. DUBLIN.—The preliminary arrangements of the committee for the restoration of this stone-roofed church are stated to be progressing satisfactorily, and the necessary funds will be soon forthcoming. It would seem to be a matter for much congratulation that this ancient relic, perhaps the most perfect in Ireland, should be rescued from ruin; but it would be better if it should be left alone than undergo the process prevalent now-a-days. We trust that, if touched at all, it will be confined to an experienced antiquarian architect.

THE QUEEN'S ROOM AT THE PRINCESS'S THEATRE.—Determined at any rate to *deserve* Royal favour, and to show his desire to obtain it, Mr. Harris has fitted up a handsome and spacious retiring-room in close proximity to the Queen's box. It includes what was formerly Mrs. Charles Kean's dressing-room (the partition has been removed), and is furnished with handsome chairs, looking-glasses, console tables, a table of looking-glass in the centre, and chandeliers. The walls are hung with a light paper with gold spots, formed into panels, with a rich, though somewhat heavy, border of flowers. The whole is creditable as well to Messrs. Rogers & Dean, by whom the work has been done, as to the spirit and enterprise of the lessee.

IRON NAILS IN WOODEN SHIPS.—M. Kuhlman asserts that the use of iron nails in building wooden ships is one of the chief causes of their decay. The rotting or decay of wood is a process of slow combustion or oxidation; and M. Kuhlman considers that the iron nails act as carriers for oxygen, and introduce it into the substance of the timber. By contact with water and air the iron is rapidly converted into a sesquioxide. In this state it yields a portion of its oxygen to the wood, and is reduced to the state of protoxide, which further action of air and moisture converts it to the sesquioxide, and so the process goes on, by a sort of catalysis.

LEEDS TOWN-HALL BELL.—The Victoria bell, cast for the Leeds Town-hall by Messrs. Warner and Sons, of Cripplegate, London, has at last been permanently fixed in the tower, and can now be rung, tolled, or chimed, on special and festive occasions, and applied to denote the hour so soon as the clock shall have been fixed by Mr. Dent. The instruction to Messrs. Warner by the Town-hall Committee, was to provide a bell of 4 tons, and they have produced one of 4 tons 1 cwt. 1 lb. The design for the bell was prepared by Mr. Boswell, the foreman of the establishment, under whose superintendance it was cast. Its composition was 3*l*bs. of cast copper to 1*l*b. of tin. The note produced, B natural, is said to be rich, full, and sonorous. The diameter of the bell is 6 feet 2 inches, height 5 feet, thickness of sound-how 6 inches, and weight of clapper (which is of wrought-iron) 1 cwt. Upon one side of the waist there is a profile of her Majesty, and upon the other the royal coat of arms and Messrs. Warner's patent. The bell, it may be remembered, was brought down to Leeds in the last week of August, and successfully raised, and fixed temporarily for trial, on the 30th of that month. But beyond this and the first trial, little further was done until last week, when the bell was permanently hung upon a wheel, and provided with the apparatus by which it may be rung. The wheel is 10 feet in diameter, or 30 feet in circumference, having two grooves for a couple of ropes, by means of which the bell may be effectually rung, as it has already been. It is believed that the bell will be heard a distance of about six miles when rung; and, when tolled or chimed, three or four miles. It has the advantage, which the more unwieldy bells do not possess, of being perfectly under control. The Great Peter, of York Minster, which, excepting Big Ben of Westminster, is the largest and heaviest in the United Kingdom (weighing 27,000*l*bs., or nearly three times the Victoria bell, and having a diameter of 7 feet 7 inches), is practically rendered almost valueless, owing to its ponderous weight, and can only be tolled, not rung. Great Tom of Oxford was re-hung in 1834, but it was only rung three parts up, when the wheel gave way; and since then the bell has been chained down by order of the church authorities, though occasionally tolled, like the Great Peter, with a hammer. Great Tom of Lincoln, which weighs 12,000*l*bs., and the great bell of St. Paul's, which weighs 11,500*l*bs., and has a diameter of 9 feet and a circumference of 25 feet, are in the same undignified condition, and simply strike the hours. The cost of the Leeds bell and fittings we understand will be about 1,000*l*.

**SOUTH KENSINGTON MUSEUM.**—During the week ending 14th January, the visitors have numbered 12,564.

**ST. PHILIP'S, CLERKENWELL.**—St. Philip's Church has been closed for some time past for the re-arrangement of the interior. The pews and huge erection in front of the altar, the pulpit, prayer desk, and clerk's desk, have been removed, and replaced with open benches, pulpit, choir stalls, &c. The architect is Mr. W. Butterfield. Mr. John J. Austin is the churchwarden. The church will be reopened on the 26th instant.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The seventh meeting of the session of this society took place on Wednesday night, 28th ult., at the Royal Institution, Colquitt-street, Mr. Barry presiding. After the transaction of some routine business, Mr. J. Audsley read the second part of his paper on "Colour, as applied to Ecclesiastical Decorations; and the History and Practice of that Art." Mr. Audsley, in his paper, considered the art principally in its modern application, and illustrated his subject by several drawings.

**INSTITUTION OF NAVAL ARCHITECTS.**—A meeting, principally of shipbuilders and the shipbuilding officers of Her Majesty's dockyards, has been held at the Society of Arts, for the establishment of an Institution of Naval Architects. Sir John Palgrave, the Earls of Ellenborough and Hardwicke, Sir Francis Baring, Sir James Graham, Mr. Sidney Herbert, Lord Clarence Paget, and Mr. H. T. L. Corry have accepted vice-presidencies. With these are also associated, as vice-presidents, several professional and scientific gentlemen; and it has been resolved to offer the presidency to the Duke of Northumberland. The managing council consists exclusively of professional gentlemen, and includes the master shipwrights of all Her Majesty's dockyards and several of their assistants, the principal surveyors of Lloyd's Shipping Register Office, &c. Mr. J. D'Aguiar Samuda, shipbuilder, of Millwall, has been nominated treasurer. With the council are connected Mr. Joseph Maudslay and Mr. J. Macgregor; and to these names have been added those of Sir W. Armstrong, Captain E. P. Halsted, R.N., and Captain Sullivan and Walker, of the Board of Trade, who will be invited to become associates of the council. Mr. E. J. Reed, the naval editor of the *Mechanic's Magazine*, is the secretary.

**THE NEW GOVERNMENT BUILDINGS AT PORT ADELAIDE (SOUTH AUSTRALIA).**—The foundations of the new custom-house, police-station, and the local court at Port Adelaide being completed, the chief stone has been laid. The building has a frontage to the commercial-road of 135 feet, and to St. Vincent-street of 86 feet 6 inches. The centre portion of the frontage to the Commercial-road is occupied by the court-house. The court-room is 36 feet by 28 feet. The height of this part of the building, from the ground to the ridge of the roof, is 26 feet, above which the cupola is raised 20 feet additional. On either side of the court-house are two-story wing buildings, each 34 feet high. That on the right is to be occupied by the custom-house, having on the ground-floor the Long-room, 44 feet 10 inches by 23 feet 10 inches, and other rooms. The fittings are to be of Sydney cedar. On the left side of the court-house is to be the police-station. The whole of the buildings are to be surrounded by an arcade 5 feet wide in the clear, supported by pillars and arches. The front will be executed in rubble stone, with brick cornices, string courses, and dressings. The contractors for the buildings are Messrs. English & Brown. The clerk of the works is Mr. Abbott, of the colonial architect's office.

**THE IRON TRADE.**—There are 125 furnaces in blast, in the iron districts of Scotland, which are computed to have produced 950,000 to 960,000 tons of pig-iron over 1859; and the demand has well nigh kept pace with this produce, which exceeds 1858 by 105,000 tons, and 1857 by 72,000 tons. The price in 1857 was 70s., while the ruling rates of last year have ranged from 47s., the lowest point, to 58s. 9d., the price obtained in the closing week of December. The average number of furnaces in blast, in the South Staffordshire district, during the past year, was 135, which produced 786,240 tons of pig-iron; the average number of furnaces in Shropshire in blast was 25, which produced 145,600 tons; in the Forest of Denby, 4 furnaces in blast, which produced 23,296 tons; 4 furnaces in blast, which produced 23,296 tons; making a total of 955,136 tons of pig-iron produced during the year in these districts; add to this 960,000 tons the produce of Scotland, which gives a total of 1,915,136 tons; exclusive of the produce of South Wales, North Wales, Derbyshire, Yorkshire, North Staffordshire, and the Ulverstone and Cleveland districts.

**ST. SAVOUR'S CHURCH, SOUTHWALK.**—The east window of this church has been filled with stained glass with three subjects, from the life of our Lord, viz.—the Birth, Ascension, and Crucifixion,—and foliage, with dispersed ruby and blue for backgrounds, surrounded by borders. The artist employed was Mr. Charles Gibbs, of 148, Marylebone-road, who was the successful competitor for the same.

**THE GLOUCESTER WATER WORKS AT WITCOMBE.**—A slip occurred, some time ago, at Witcombe, and another has just occurred. "The whole system of operations," says the *Gloucester Chronicle*, "seem to be a gigantic blunder; and a great deal of public indignation is expressed. The highest engineering skill in the kingdom is to be consulted on the matter. A greater portion of the soil of which the embankment is made should have been burnt before it had been put together, for under present circumstances it does not seem likely that it will ever form a tenacious mass."

**THE EFFECT OF THE STRIKE ON THE HEALTH OF WORKMEN'S FAMILIES.**—For some time past the Registrar General has noticed in the weekly bill of health of the metropolis the number of deaths which have occurred weekly in the families of bricklayers, carpenters, masons, painters, and plasterers,—trades which have been sensibly affected by the strike. The number of deaths of wives and children of such workmen in the first week of the new year, was sixty-nine. It is useful to direct attention to such statistics, as showing the effect of certain conditions upon health. It would be, therefore, valuable to give, at the same time with those figures, the average number of deaths amongst the children and wives of those belonging to the trades.

**SOUTH AUSTRALIAN ASSOCIATION OF ARCHITECTS, ENGINEERS, AND SURVEYORS.** At the first monthly meeting of the second year of the above association (the Hon. Major Freeling in the chair), the paper promised by Mr. Goyder for this meeting not having been forwarded by that gentleman, Mr. G. E. Hamilton initiated a discussion respecting the iron ores of the colony, and gave an interesting account of the methods adopted in the preparation of the pig iron of commerce. The drift of his argument was to show that the probability of the iron ores of this colony ever being manufactured was very faint, for reasons that he advanced. He showed that they were of too high a percentage of iron for successful smelting. At the close of his remarks he promised at an early day to introduce the subject in a paper, and to illustrate it by diagrams; also to couple with it his opinions as to the probability of obtaining coal in the colony. It was resolved that the committee consider the proposition of sending to England for books of reference, &c., and to be prepared with a report as to what books they recommended, &c., by the next monthly meeting.

**ST. ANDREW'S CHURCH, DUBLIN, DESTROYED BY FIRE.**—The church of St. Andrew, commonly called the "Round Church," has been destroyed by fire. Smoke was first observed issuing from the roof. The spread of the fire to the roof of the square wing, at the rear of the round building, was prevented by cutting the roof, and thus breaking off the connection, which was done by the firemen. This wing is separated from the body of the church by a stone wall, and contains the belfry and the vestry rooms. In a short time the ruined roofless walls of the round building, together with the burning *débris*, were all that remained of the church. The entire interior of the church, including pews, galleries, and organ, were reduced to a mass of charred ruins. Providentially, the fire did not break out until after all the congregation who attended the Sunday morning service had dispersed. Had it been otherwise, and an alarm of fire been given while the church was full, fearful consequences might have ensued, as the only means of exit was the one large door in the front. The fire is supposed to have originated from a fire in the roof. The Round Church, which no longer exists, was built in 1793, and opened for public worship in 1807, at an expense of 22,000*l.* The design was an imitation of the Church of St. Mary de Rotundo at Rome, and the architect was Mr. Francis Johnston. The building was capable of accommodating 1,200 persons. It was insured until about two years ago. It is but a few weeks since we expressed our fear of hearing more about the church flues ere the winter was over. The worst of it, too, is the imminent risk of fires breaking out during divine service; for, of course it is while the flues are heated for service that the fires break out.

**PHOTOGRAPHIC SOCIETY OF LONDON.**—This society has opened its annual exhibition of photographs in the gallery of the old Water-Colour Society, Pall-mall East. It is a very good collection.

**GAS.**—"The Town Council of this city," says the *Chester Chronicle*, "have decided on adopting the recent Act for the inspection of gas meters. Many complaints are made that gas is reduced in price, yet that the quarterly bills increase in amount. The dry meter is said to be the best and the easiest managed." Various other towns are moving in this matter.—The price of gas at Winchester has been reduced from 6s. 6d. to 6s., and the quality of the gas, it is said, improved, as well as the quantity increased.—The result of the gas agitation at Inverness is now partially realized, the price being reduced to 7s. 6d. per 1,000 feet for the public lights. No reduction, as yet, has been made to the private consumer.

**INCREASE OF RAILWAY EMPLOYMENT.**—The army of "railway men" which, in 1848, numbered 52,688, increased in ten years to 109,329. The guards and brakemen increased from 1,196 to 3,747, and the stationmasters from about 1,150 to 2,673. The secretaries and managers increased from 111 to 241. Of engineers the increase was only from 95 to 115. Gatekeepers increased from 401 to 2,084. There was a falling off in the number of watchmen and policemen from 2,475 to 2,214. Switchmen increased from 1,055 to 3,431. The increase in the number of engine-drivers was from 1,752 to 3,508.

**CAICATRIS.**—It is probable that almost all the popular ideas of prime ministers and leading politicians have been moulded and shaped by the caricaturist. Who does not know the pompos yet kindly Peel, the versatile large-bearded and large-brained Henry Brougham, Russell, or Palmerston, better by Leech's pencil than by any other portrait? When we see the great originals, we are disappointed that they do not come up to the woodcuts; that "Pam" is not so jauntily, nor Brougham so eccentric, as he is drawn. We shape the ideal head to the speech, and measure the action by the dress. The caricaturist has been up earlier than the historian, and has stolen a march on him. He influences popular knowledge, though forgotten; his ink is said, to the end of time, we shall never be quite sure that Palmerston does not carry a perpetual bit of straw in his mouth, or that the nose of Oliver Cromwell was not as real as the lattice of a country roadside inn, so deeply are we tinged with the teachings of the caricaturist.—*The Leader.*

**TENDERS**

For alterations at No. 37, Frederick-place, Hampstead-road, for Mr. J. Hawes. Mr. J. Tanner, architect. Quantities supplied:—  
Turner & Sons ..... £195 12 0  
Butterbury ..... 328 12 0  
Matthews & Co. .... 292 12 0  
R. Lawrence ..... 291 12 0  
Taylor ..... 296 12 0

For alterations and additions at No. 35, Frederick-place, Hampstead-road, for Mr. J. Hawes. Mr. J. Tanner, architect. Quantities supplied:—  
Turner & Sons ..... £197 12 0  
Butterbury ..... 145 12 0  
Matthews & Co. .... 141 13 0  
R. Lawrence ..... 137 12 0  
Taylor ..... 134 4 0

**Tenders for Southern Outfall Sewer.**—We are asked to add, to the list of contractors who tendered for this work, the name of Mr. W. Webster, 367, 700*l.*, and that of Mr. W. Lavers, 315,000*l.* Further, that the amount named by Messrs. Helling & Yeoman, was 425,484*l.*

**Bowes Manor.**—Sir, in justice to the builders whose tenders for works at Alderman Silvey's, Bowes Manor, appeared in your paper of last week, may I beg the insertion of the following remarks:—The lowest tender, which was evidently considerably below the fair value of the work, was not accepted, inasmuch as it was forwarded without the sanction of Mr. Fuller, in whose name it appeared, and the result has been that the next lowest tender, that of Mr. Carter, has been accepted. EDWARD WOODROFF, Architect.

**TO CORRESPONDENTS.**

**Glass and Stone.**—A subscriber asks to be informed what is the best cement for stopping glass in stone work? "The glass is in large squares, and the joints (instead of grooves, as in ordinary work) are in lead work; the stone is Edinwick freestone, and the situation is one of the most exposed, being on a hill. I have tried Portland cement, but it will not adhere to the stone sufficiently, and plaster of Paris will not stand the effects of wet and frost, especially on the sills of the windows where the wet accumulates."

**Anti-Humbug.**—J. G. Oliver Phillips (we have no recollection of the communication referred to.—It varies from 13 to 1 per cent. and is not an unusual charge.—T. W. C.—Mr. G. W. G. (It was *de*, Brunel who swallowed a half-sovereign.—D. A.—G. P.—J. N.—W. P. W. H. B. A.—P. D.—Inquire (apply to Secretary at No. 9, Conduit-street).—T. W. C.—R. C. (we shall be glad to see the drawing).—G. D. B. (we are forced to decline advising in private questions).—Lady L.—W. W.—C. E. A.—J. R.—T. G. A.—Practice.—J. E.—P. E. H. (Buckley). We have already given some account of the southern oil-well; but will use a portion).

# The Builder.

VOL. XVIII.—No. 886.

Saltire.

PUTTING aside the gigantic size of the establishment at Saltire, it exhibits so many other points of interest, that all who go to Bradford, or any other neighbouring town in thriving, far-seeing, hard-fighting Yorkshire, should visit it. The expenditure which was ventured on, to economise labour, to expedite processes, to obtain completeness, and to ensure the comfort of the 3,000 persons who are engaged in the works, will surprise many; but the wisdom of it, even in a financial point of view, soon makes itself evident. Our readers do not require to be told that the title which the mills and rising town here gives us the

name of its enterprising founder, Mr. Titus Salt, M.P., and that of the locality, the beautiful valley of the Aire, in which it is built. It is a joke against the Prince Napoleon, that in an account he gave of the Paris Exhibition of 1855, he pointed out that Mr. Titus had exhibited some magnificent examples of salt! The place which we are speaking is indeed a magnificent exhibition of Salt, and it is to be hoped that he may long live to enjoy the honour it was deservedly gained him. In a previous volume\* we gave a view and plan of the mill, and showed how, with an extension of the Leeds and Bradford Railway in front of it, and the Leeds and Liverpool Canal behind it, the greatest facilities exist for bringing up the raw materials and coal, and sending away the manufactured goods, while plenty of water is obtainable for the steam engines and the processes. Take a few statistics, all in a heap, and get an idea at once of the magnitude of the undertaking. The buildings for the works cover 6½ acres. The main range of buildings—a fine substantial piece of work, fire-proof, and highly creditable to Messrs. Lockwood & Mawson, the architects—extends 550 feet in length and 72 feet in height; and as the top story runs over the central entrance archway, and reaches the whole length of the mill, we get a room 550 feet in length—the longest perhaps in Europe; and, looking from one end to the other, a fine sight it is. The Weaving Shed, however, attached to the mill, eclipses that in area; for here we have in one apartment 2 acres—room to dine comfortably 7,000 persons. In the Combing Shed, of half its area, Mr. Salt did dine 3,500 persons, when the building was first brought into use. Men, women, and children, are at work throughout the building; steam-engines of 1,250 horse-power collectively give motion by 2 miles of shafting to 1,200 power looms; and when we add that the daily produce of these is 30,000 yards, or 5,000 miles annually; in other words, that the length made in a year and a half is more than enough to reach from one side of our globe to the other, if there were a hole through the middle; the skill, energy, and capital, required to carry on such an undertaking, will be strikingly evident. Professional visitors would examine with

interest the mode of construction adopted in the mill proper, to render it fire-proof,—*hollow* brick arches and *wrought* iron girders for the floors; and would, probably, grieve with us that the same precaution was not adopted throughout. They would observe, too, the mode in which fresh air is admitted to each story, and the foul air allowed to escape; and the satisfactory construction of the great chimney. Those interested in machinery would notice the prompt adoption of new inventions: the beautiful combing machine, which is said to have cost Mr. Salt 32,000*l.*; the arrangement for washing the wool, and for drying it,—in one place by centrifugal action, and in another by warm air. In the sorting-room it would occur to them that some arrangement should be made to free the air, or otherwise to preserve the workmen from the dust of the wool; but, generally speaking, they would find little occasion for comment. The care with which all advantages are husbanded is shown in various ways; in this, for example; that the water resulting from the processes, and containing fatty matter, which was formerly allowed to run to waste in the canal, is now collected and strained, and produces 2,000*l.* a-year. The smoke is, for the most part, consumed; the heat from the boilers utilized to the greatest extent.

Leaving the mill, there will be found 450 houses for the people engaged; a large dining-hall for special occasions, at present used as a school-house; and a costly church, with a steeple and semicircular portico of the Corinthian order, at the west end,—the interior being fitted up with handsome plaster-work and scagliola columns, the latter well executed by Dolan, of Manchester.

Returning to the dwellings for an instant, it may be mentioned that for a cottage with three rooms upstairs and two below, the sum of 3*s.* 8*d.* a week is paid, including the rates and water-supply. With the arrangement of the houses no fault can be found excepting this, that the cesspool system is in use, pending the determination of how best to act otherwise. This should be allowed to continue no longer; and then, if careful records were kept, we might expect to find the death-rate in Saltire a low one. It is a noble monument of private enterprise, liberality, and wisdom.

## AN ERMINED ARCHITECT.

We are not about to confute King Solomon's proposition, that there is nothing new under the sun, by an announcement that a member of the architectural profession is about to be raised to the peerage: we simply purpose to pursue a train of thought suggested by a remark made at a recent meeting of the Royal Institute of Architects. One of the members observed, in reference to another, that had he attained the same eminence in the profession of arms, or law, that he had gained in his own, he would have been created a peer long ago. The first question that rises to the surface is—Why so? How far do the services of a soldier, or a lawyer, exceed those of an architect in a national point of view?

We contend that architecture conduces as much to the enduring fame of a nation as military glory; and, in its care for the well-being of the people in their homes, tends as much to the maintenance of public order, as legal instruments do. We are able to realize the grandeur of the Greeks and Romans, as much by the remains of their architecture—their columns of agate, alabaster, and jasper,—as by the relation of warlike deeds and civic virtues in those portions of their literature that are preserved to us; and in the case of the Assyrians and Egyptians infinitely more so. Their soldiers have perished in numbers nearly as countless as the sands of the scorched desert: the papyrus rolls of the lawgivers have been consumed by time; but the works of their architects endure, and the sun still casts the same shadows from the imprishable fabrics on the banks of the Nile that it did 4,000 years ago. We ask how is the greatness of a people visible to foreigners, if not in the extent of their cities and grandeur of their buildings; and how can it be made evident to future generations by any other means? The Danes conquered the country as well as the Romans; but we have formed very different estimates of the two races. Simply because the one

has bequeathed us but a few legends relating to their conquests, and a few names; while the other has left us traces of fifty walled towns, with temples, baths, and other public buildings in each. By the same rule posterity would think but little of us if we handed down a mere territory unenriched with buildings. When the Crusaders arrived at Constantinople, on their road across Europe to the Holy Land, they were overpowered, say the old writers, with the magnificence of the city. The gilded minarets of the mosques, blazing against the opal sky, appeared to them to represent a land of enchantment. A tented plain could not have produced such an effect.

We are next tempted to inquire how far the popular notion of an architect's acquirements represents the varied learned and accomplished skill he should possess. We suspect that few superficial observers take into consideration the fact that in the matter of mathematics, acoustics, the laws of health, and intimate acquaintance with all the branches of the fine arts, architecture is more exacting than either of the professions now contrasted with it. If a knowledge of the dead languages be required for a study of the law, is it not equally so for the study of architecture? Are not all the old monuments written in Latin, and all inscribed stones up to a certain date in the same tongue? Think of the pale tinted chronicles of the old religious houses, perfumed with the scent of departed centuries, and of all the mediæval memorials, whether on stone, on glass, on wood, or on vellum: are they not all written in Latin? Without going so far as Vitruvius, in his well-known treatise, who insisted that the education of an architect should comprise a mastery of the whole circle of sciences, we repeat that his learning must be very comprehensive.

The importance of the use of these varied attainments in the practice of an architect cannot be too highly estimated. The extent of the population is influenced by them; for, if efficient architects were in all cases employed to superintend the erection of dwelling-houses, more especially those of the poor—too often run up by builders in careless defiance of decency and health, a marked difference would be seen in the number of deaths resulting from preventable causes. We do not hesitate to say that our sovereign lady the Queen would be in possession of many a regiment of fine-grown men, whose premature loss, as proved by the returns of the Registrar-General, is consequent upon undrained houses and unventilated apartments. Surely it is as useful to rear soldiers as to command them.

The chance of sudden loss of life in the pursuit of a profession can scarcely be considered to enoble it; but, if it be so estimated, the architect, being scarcely less exposed to it than the soldier, must be proportionally entitled to distinction. Any visitor to a large building, in course of erection, must be struck at the danger to life from carelessness, on every side. A false step on a scaffolding stage, the fall of an unbalanced stone, momentary dizziness or forgetfulness on a ladder, are accidents of too frequent and fatal occurrence. Probably Ely Cathedral is never visited for the first time unassociated with the remembrance of the architect who lost his life there. William de Sens left Canterbury Cathedral with a broken leg. And there are other instances too numerous to mention. We remember that the old Greenwich pensioner who used to show the chapel of the hospital always recounted, with something like martial pride, the narrow escape of the painter's life in the execution of the allegorical decorations of the ceiling.

It seems to us that the lives of her Majesty's subjects are as much in the keeping of architects as they are in that of their other "brave defenders," the army and navy. A church, built without a knowledge of the laws of resistance and pressure, falling upon a large congregation, would do as much havoc, to as many people, as a grand pitched battle. Or insecure foundations for a parliament house might be as fatal in their consequences as an undetected gunpowder plot. And, by way of inverting our examples, proper attention to the philosophy of architecture, as shown in its sanitary arrangements, would be as beneficial to a nation as a long season of peace.

The Lord Chancellor on his woolsack has always been considered, and is, a fine sight; and so is a regiment of horse-guards, their tasselled plumes glittering in the breeze, and their cuirasses glittering in the sunshine as their steeds curve; but they must both give precedence to architecture in point of beauty. Take any one of our cathedrals, with their clustered columns and vaulted roofs, their "tracery of lace," their exquisite proportions and superb details, and point out, if you can,

\* Vol. xii. p. 478.

a more lovely object. Then own that a mind attuned to such soul-filling harmony, and capable of conceiving similar creations, cannot be unworthy of a place among England's gifted sons. We would not be understood to affirm that architecture has been without any recognition: on the contrary, the barren dignity of knighthood has been frequently awarded within the last two centuries; and, in the old times before us, as in the instance of William of Wykeham, honours were heaped upon its promoters, if not professors; but in modern times they have not been so distinguished. Considering how inseparably history is associated with architecture, to what an extent contemporary and posthumous fame depend upon it, and in what measure the population is scathed by the observance of its laws, it can scarcely be denied that the dignity of the profession is not merited to crumble.

#### RUSKIN ON PERSPECTIVE.\*

It has been somewhere said, on the occasion of an allusion to codification of laws, that not less valuable would be a distillation, periodically, of literature,—the essence of books on a given subject being extracted, and codified in a new work, when all the others could with advantage be burnt. There may be some reason in this view. We would have public libraries instituted in far greater number than at present; books should be cheapened, or placed within reach of every one desirous to be instructed, or to be harmlessly amused; but the multiplication of works on the same subject, especially those which are professedly educational, is becoming an evil; and like multitude in an architectural competition, of designs which time will not allow to be examined, operates against the probability of wise selection. More industrious examination and collation of previously published works, on the part of intending writers, is wanted, to direct towards the character of new work that really may be required. Embodying the result, the new publication is justified: otherwise it must to a considerable extent encumber the way of progress, or its leaves have their fitting appropriation only.

"Clothe pipe, line, trunks, or fluttering in a row,  
Beating the falls of Keelam and Sobu."

We have been called upon, late, to notice several works on perspective, and have hinted at the applicability to some of those on the same subject, of a view such as is expressed here-above. It is matter of fact that the majority of architectural students do not learn perspective from books: as we have shown, after becoming acquainted with the orthographic method of representation, or that by plans, elevations, and sections, they get conveyed to them their first lesson, and nearly all that there is in the science, in an hour; and if they falter afterwards, the reason is the having omitted to practise, or the inability to think consecutively, and to know by sight what is wrongly drawn. If books be necessary, for embodiment and preservation of the science,—or if they are useful in tuition under any circumstances,—time certainly is saved by the method common in offices; or the advantages in any other, involve the use of models as means in contradistinction to diagrams.

We have some difficulty in deciding in what category to place the present work by Mr. Ruskin, for we are very doubtful whether he has succeeded in his intention of making the subject clear to pupils in ordinary schools, or whether the demonstrations could be followed at all, without previous familiarity with perspective as commonly learned and practised. This results, of course, not from any want of truth in the mathematics as an adopted form of explanation, and equally, it does not from inability of the author to handle that or another method, or from any stint of labour on the present occasion. There is, however, want of perspicuity in his teaching, in several essentials. He himself refers to the possibility of his "hereafter" bringing the work into "better form;" but without improvement in points other than he mentions, the work cannot be found to "answer its purpose," or enable, as he says, the student "to solve perspective problems of a complexity greater than the ordinary rules will reach;" and in naming Clouet's treatise† and "a series of illustrations of practical perspective now in preparation by Mr. Le Vaugan," he does not rightly pass over some of the recently published English

\* The Elements of Perspective, arranged for the use of Schools, and intended to be read in connection with the first three books of Euclid. By John Ruskin, M.A. 8vo. pp. xii. 144. London: Smith, Elder, & Co. 1859.  
† "Nouveau Traité Élémentaire de Perspective," Bachelier, 1823.

works which have been noticed in our pages. He says:—

"For some time back I have felt the want, among students of drawing, of a written code of accurate perspective law; the modes of construction in common use being various, and, for some problems, insufficient. It would have been desirable to draw up such a code in popular language, so as to do away with the most repulsive difficulties of the subject; but finding this popularization would be impossible, without elaborate figures and long explanations, such as I had no leisure to prepare, I have arranged the necessary rules in a short mathematical form, which any school-boy may read through in a few days, after he has mastered the first three and the sixth books of Euclid."

Now, in "the modes of construction," or "constructions" (to use Mr. Ruskin's peculiar phraseology) with which we are acquainted, we are not aware of insufficiency or difficulty. The present work would leave much of the difficultly which its author hopes to remove, as in some important steps of the demonstration, as in what relates to the practical method of finding the "sight-magnitude" of objects on the "measuring line" and the use of "dividing-points," the want of clearness which we speak of is to be found; and the use of the term "sight-line" in lieu of *horizontal line*, and "station-line" for the line on which would be measured the direct distance of the picture or the object, is of doubtful advantage, considering that the former term would be very liable to be taken for what the author means by the latter, namely, the axis of vision or of the *cone of rays*. The success of the demonstration is further interfered with by want of precision in some of the diagrams, and by omissions of letters of reference. Draughtsmen and engravers are becoming thoroughly careless in these particulars. The opening of the work, and some portion of the Appendix, on the other hand, are clear in style and explanation; but this not being maintained throughout, though we ourselves have perused the work with interest, and can recommend it as a useful mental exercise, we doubt whether it could claim to be more than a vehicle for instruction *différent* in sort from others, and as such, capable of improvement in several respects. In certain points, however, the scheme of demonstration would have great value as compared with any to be found in the catechisms and other works which formerly were used in schools. The actual dimensions of the object, the direct distance, the lateral distance, and the vertical distance, are taken to be the basis of the perspective representation. Thus, as in the case of a drawing of a pillar, the actual object being supposed to be 42 feet in height, and the station-point 70 feet distant from it, and 5 feet from the plane of the picture,— "Then as 5 is to 70 so will the sight-magnitude required be to 42; that is to say, the sight-magnitude of the pillar's height will be 3 feet." Or in another case, taking the plane of the picture distant 2½ feet, the apparent height will be 1½ feet. That is to say, the sight-magnitude of an object is to the real magnitude, as the distance of the plane of the picture from the eye is to the real direct distance, in all cases of parallel perspective at least,—and although the object may be above or below the eye, or at any distance laterally from the direct line, or what the author calls "station-line." Moreover, it is likely that the method of demonstration in the work, could it be more clearly explained, would be of value in sketching; and at present, many of those who have commenced practice of perspective would find of service to them, the instructions on the methods of delineating circles and arches, pyramidal forms, the capitals and base-mouldings of columns, and the lines of gables, and of finding the vanishing-points of lines in the work is rather curious and suggestive, than one which could be put into the hands of architectural students with certainty of its standing them in stead of the instruction which they now derive by ready means; but if codification of the existing information in books be wanted, Mr. Ruskin shows that he could supply that want, and effect something beyond.

#### ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ordinary general meeting was held on Monday last, at the house in Conduit-street; the president, Mr. C. K. Cockerell, R.A., in the chair. The minutes of the last meeting were read and confirmed.

The following gentlemen were, on ballot, elected Fellows of the Institute.—Mr. J. K. Colling, Associate, of 6, Ridgmont-place, Hampstead-road; Mr. Thomas Aiton, Associate, of Barnes, Surrey; Mr. Cuthbert Boddick, of Leeds; Mr.

Edward B. Lamb, of 3, Hyde-street, Manchester square.

Mr. Charles J. Phipps, of 5, Paragon-building, Bath; and Mr. William S. Barber, of Hanover chambers, Buckingham-street, Adelphi, were elected Associates.

The President, in reference to the election of Fellows and Associates by ballot, expressed his hope that in future members would not leave the room without voting.

Mr. Godwin observed upon this subject, that there could be no possible objection to members exercising their privilege of "black-balling," so long as the result of the ballot represented the general opinion of the meeting; but if gentlemen continued the practice of leaving the room before the ballot, a display of personal feeling on the part of two or three gentlemen might at any time exclude a very efficient and desirable member, whereas if the general body remained, the opinion of the great majority might be in his favour.

Mr. T. H. Lewis (honorary secretary) read a list of donations to the library, and called attention to some beautiful specimens of wood-carving by Mr. W. Perry, executed by desire of the Duchess of Sutherland, for a bath-room at Stafford House.

Mr. Wyatt Papworth then read a paper "On the Superintendants of English Building in the Middle Ages," with especial reference to William of Wykeham, to which we shall return. One part of the paper was devoted to showing the reader's reasons for doubting the right of William of Wykeham to be considered the architect of the buildings with which his name was associated.

At the conclusion, The Chairman said that he had heard with great pleasure the instructive and erudite dissertation of Mr. Papworth, upon a subject which to architects was invested with more than ordinary interest. The subject was one of great importance for the profession to pursue, and he was sure there were many gentlemen present who had, more or less, investigated it. He had himself done a little towards vindicating the fame and genius of William of Wykeham, and he was consequently a little disappointed at the estimate formed of him by Mr. Papworth. Born in humble circumstances, William of Wykeham succeeded in raising himself by successive steps to be, not only a high ecclesiastic, but to be the Lord Chancellor of the empire. Feeling strongly as he (the chairman) did upon the merits of William of Wykeham, and his claim to be considered not only a great Medieval architect, but also as the originator of what might be termed a new era in the art, he would like to hear what gentlemen present might have to say in support of his title to those distinctions. It was, at all events, clear that if he did not devise the buildings imputed to him, he was a person of such cultivated taste and accurate judgment as to encourage the art in others, and earn a reputation for himself which time could not destroy. So versatile were his talents, that he appeared to have discharged many public offices of great trust and responsibility. He was made envoy to France, and he was subsequently able, when master of the Cinque Ports, to design a plan for fortifying those places. Such a man appeared to be wanted in the present day. In estimating the character and attainments of William of Wykeham, it was necessary to bear in mind that, at the period in which he lived, ecclesiastics were the only learned men of the day; and that, when they flourished, there were none of those brochures and pamphlets which now teemed from the press, to enlighten the multitude. Mr. Papworth appeared to have applied himself with great diligence to the subject of his paper: he had pursued his researches through seven or eight centuries, and had thrown much additional light upon an interesting and suggestive theme.

The Rev. MacKenzie Walcott warmly defended the claims of William of Wykeham, not only to the credit of works in Winchester Cathedral and Queensbury Castle, but also to be the author of a new style of architecture in this country. He regretted that Mr. Papworth should have called in question, by ingenious and elaborate speculations which he believed to be founded upon an erroneous theory, the fame of a man who had done so much to elevate the profession of the architect. He (Mr. Walcott) knew of no profession which should be so jealous of the reputation of its members as that of the architect, for if they did not set their face against any attempts that might be made to under-estimate their services, there would be no knowing when some speculative theorist might rise up and allocate the merit of their own designs to their pupils' room, or to their master mason. Sad,

indeed, would be the day for their country and their age, when England would become indifferent to the reputation of her sons, or tire of hearing her Aristides called "The Just." Mr. Papworth, in attacking the claims of William of Wykeham, had flown at high game, but he (Mr. Walcott) was persuaded that there were many who would learn with regret that he had ventured to disparage the merits of one who had been to them *in loco parentis*. Mr. Papworth had fallen into many errors in reference to William of Wykeham, and, among others, he said that he was born at Wykeham, in Wilts; whereas he was born at Wykeham, in Hampshire; he also declared that he had not been a Freemason, and quoted in support of his assertion a passage occurring in the reign of Henry VI., whereas Wykeham had been dead some long time before. Mr. Walcott then proceeded to quote the opinions of Professor Willis, of Cambridge; and also of Mr. Cockerell (the chairman), urging that the former had declared that William of Wykeham was essentially a practical man, and one who had been engaged all his life in works of architecture; while the latter had given his opinion that he had never been sufficiently celebrated, and that the restoration of the Cathedral of Winchester proved him to have been a consummate architect and engineer. With regard to his will, he had the expression *novi operis facti per me*, which were to be intrusted to Master William Wynford and other discreet persons versed in their art; thereby showing that he had been the designer of the new works referred to. But to show that William of Wykeham was not the man to arrogate to himself credit which should justly attach to others, it would be found that in the stained glass at Winchester Cathedral were portraits of Thomas the glazier, the carpenter, and the chief mason, who had assisted in building the church.

Mr. Papworth said he had referred to the circumstance mentioned by the reverend gentleman, as it was far from his intention to detract from what he believed to be the merits of William of Wykeham.

The Rev. Mr. Walcott, in continuation, read a number of extracts from ancient records preserved at Oxford and at the British Museum, which the view of showing that a mass of contemporaneous evidence existed to prove that William of Wykeham devoted the greater portion of his life to the study and pursuit of architecture, and that he well deserved the high reputation which he had acquired as the most skilful and original architect of the middle ages. The rev. gentleman said that he was not sanguine enough to believe that he could convince Mr. Papworth, their Cato, but that, if he was successful enough to obtain the verdict of the meeting, he would console himself with the words, *Victrix causa mihi placuit, victor Catoni*.

Mr. Kerr remarked that they were always glad to hear the views of amateurs, and that they were indebted to the rev. gentleman who spoke last for his observations; at the same time it might be desirable to remind the meeting that the object of the paper just read was not simply to clear the biographical question, or to ascertain whether William of Wykeham was or was not what he was represented to be. What was far more important, was to trace the rise and progress of their own profession, and Mr. Papworth had incidentally selected the most prominent amateur architect, to test his merits, and thereby ascertain whether the class of which he was the representative was or was not what it was supposed to be. For his own part, he did not take that lively interest in William of Wykeham which the reverend gentleman near him did, but he had followed Mr. Papworth with great interest; for it was evident that the early history of the architect's profession was hurried in great obscurity. In early times, the church was the only receptacle of learning, and consequently it was not unreasonable to suppose that ecclesiastics were also architects. It seemed to him that the distinctions drawn by Mr. Papworth as to the supervisors of buildings, opened up an extremely useful subject of inquiry, and he hoped that he would follow it up on a future occasion. But that which architects as a body wanted to know was, not whether William of Wykeham was what he was represented to have been, but how it was that the beautiful in art arose in this country out of the mediæval system. At the present time it was fully recognized that there was a profession for the designing of beauty in buildings. What the substitute might have been in the middle ages was a point upon which opinion might differ, but it was, at all events, clear that a condition of progress had developed itself, out of which the architect of the present

day arose, though it could not be said that he was even now full blown. This appeared to him to be the real subject which the paper was intended to elucidate, and with every desire to acknowledge the superior antiquarian lore of Mr. Walcott, he (Mr. Kerr) felt that he could not allow his observations to pass without saying a word in defence of the paper by Mr. Papworth.

Mr. Street said that it was with much diffidence that he rose to oppose a paper so carefully prepared and so instructive as that which Mr. Papworth had submitted, and for which all Gothic architects had reason to be grateful to him. He confessed, however, that in his opinion Mr. Papworth's arguments were inconclusive, and had been answered by the Rev. Mr. Walcott, who had shown that the architects of the Middle Ages had been described at the period by a variety of names, used indiscriminately. In proof of this, it should be remembered that William of Wykeham was himself clerk of the works before he was an architect; but leaving the case of William of Wykeham, he should like to call attention to an older artist, to whom Mr. Papworth had done but scant justice—he meant Elias of Dereham. Mr. Papworth had dismissed him in six words, although Mr. Pugin, on apparently good grounds, had claimed for him the credit of being the architect of Salisbury Cathedral. Elias of Dereham appeared, like other architects of his time, to have been variously named, and to have undertaken a great number of duties, for there were entries that he was to make or enlarge a window in the castle of Winchester, which was to be painted of a green colour, and that he was to give the disposition of it, as also to give directions as to the decorations of one of the king's chambers. He was a canon of Salisbury, and, as he (Mr. Street) believed, the architect of the cathedral. He was present at its consecration; the bishop appeared to have had great confidence in him, and as the king was present at the consecration, it was most probable that the architect was there introduced to him, and that his subsequent employment by the king was to be traced to that circumstance. It seemed to him (Mr. Street) that if Mr. Papworth had not confined his remarks to England, he might have arrived at a truer knowledge of the architects of the Middle Ages. The ordinary title of a Continental architect, from the thirteenth century downwards, was *MAGISTER OPERIS*, as shown by the inscriptions on their tombs at Rheims, Amiens, and in the church of Notre Dame, at Paris. The architects in those days appeared to have arranged the whole of the work; but as time passed away, and the art of construction became better understood, tradesmen were called in to do separate portions of the work, for which it was to be presumed they were held responsible. With reference to the claims of the clergy to be regarded as the chief architects in the Middle Ages, there could be no doubt but that many of them were entitled to that description; but, on the other hand, many churches were erected (Amiens Cathedral, for instance) by laymen. In England, however, the probability was that the majority of architects in the Middle Ages were clergymen. William of Sens and William the Englishman, of Canterbury, were also laymen. William of Sens, when engaged upon Canterbury Cathedral, fell from a scaffold, and being incapacitated from conducting the works, deputed a young monk who had shown great taste and skill in architecture to represent him, and this ecclesiastic continued to discharge his trust until, on the removal of William of Sens to the Continent, for the restoration of his health, he was succeeded by William the Englishman. With regard to the general absence of all trace of the working drawings used in the construction of the cathedrals raised in the thirteenth and subsequent centuries, he wished to state that on examining the roof of the Cathedral of Limoges, he was struck by finding the outlines of the columns and other parts cut on blocks of granite.

Mr. Ferrey expressed his hope that the subject to which Mr. Papworth had called attention would receive further consideration on a future occasion, as it was almost distressing to find the traditions which they were accustomed to regard with so much admiration and veneration so ruthlessly demolished. With regard to William of Wykeham, the bare supposition that he was not the designer of those magnificent works associated with his memory, was distressing to every Englishman, and more especially to those who claimed to be natives of the county in which he was born.

The Chairman said he quite agreed with the last speaker as to the desirability of renewing the discussion on a future occasion, as it was of great importance to them as architects to learn the

history of their ancestors, from whatever source they might have sprung. It was also desirable to collect all the proofs that could be accumulated on so interesting a subject, and he was convinced that their accomplished friend Mr. Papworth would be glad to receive any hints which their collective learning and research might bring to bear with reference to the theme which he had brought under their consideration. The subject was of too great importance to be disposed of in the limited period which could be devoted to one evening's discussion. He hoped, however, that their friend Mr. Asphitel would favour the meeting with his opinion.

Mr. Asphitel said that at so late an hour of the evening little time remained to discuss so large and interesting a topic as that to which Mr. Papworth had invited attention. With reference, however, to the issue raised, and which Mr. Walcott had met with so much vigour, he might say, with that respectable authority in the *Spectator* that "a great deal might be said on both sides." They were, for instance, accustomed to hear that such and such a building had been built by Wolsey, although it was well known that the great cardinal was no architect at all; and, on the other hand, they were taught to believe that certain structures of great beauty had been raised by William of Wykeham, who had devoted his whole life to the study and pursuit of architecture. It did not, however, follow that because no buildings had been constructed by Wolsey the wreath was to be taken from the brow of William of Wykeham. Then with regard to the designation of the architect, it should be remembered that a good deal depended upon the state of civilization at the time in which he flourished. In a low state of civilization the man who built a hut might be described as "Carpentarius;" but, again, in periods at which civilization had attained a high pitch, the architect was found, as in the case of Vitruvius and others of ancient Greece, occupying a position and taking rank with the jurist-consuls of his age. That the title by which the architect was known was not to be considered as derogating from the dignity and importance of his office, was proved even in modern times by the fact that the architect of royalty was called the "clerk of the works," and that until five or six years ago their friend Mr. Banning, who held the office of architect to the corporation of the city of London, was described by the same humble designation.

Mr. Digby Wyatt said that he could supply in his own person a still more modern illustration, as he himself had the honour of being "clerk of the works" to the East-India Company.

Mr. Asphitel, in continuation, observed, that whatever might be the position of the architect in the present day, the fact that William of Wykeham, the son of a poor man, had sprung from the ranks of the lower ecclesiastics to the position which he successively occupied as Bishop of Winchester and Lord Chancellor of the empire was in itself sufficient to show in what high estimation the study of architecture was held in his day, and with what honours the man had been rewarded who had struck out a new style of architecture.

Mr. Digby Wyatt observed, that although some difference of opinion might exist as to the conclusiveness of the arguments raised by Mr. Papworth, they must all acknowledge the labour and research which he had shown by the collection of his facts and historical data. With regard to the actual architects of Mediæval times, they must all admit that the subject was involved in obscurity, and that great credit ought to attach to those who might endeavour to penetrate that gloom, and bring additional light to bear upon the subject. As Mr. Papworth had applied himself to that task he was entitled to their acknowledgments, and he therefore begged to move that the best thanks of the meeting be awarded to him for his able and erudite essay.

Mr. Godwin briefly seconded the motion, which was put from the chair and carried by acclamation.

#### BRIDGE OVER THE ELBE, NEAR HAMBURG.

The gigantic bridge to be constructed over the two arms of the Elbe, between Harburg and Hamburg, will have a total length of 3,300 feet. The left arm is 2,000 feet broad, and is to have six arches each, of 333½ feet span. The superstructure will be 6 feet, and the rails 9 feet, over the highest tide level imaginable, or 18 feet over the ordinary high-water mark. This height is more than sufficient for the river navigation. The second bridge over the right arm will be 1,300 feet long, and consist of five arches of 325 feet each. Each of the bridges is to have a double line

there are persons who cannot appreciate music. For many a man, — for many a woman, — perhaps, in some instances, be revolting to their taste altogether; but that is a defect in themselves, and not the fault of the colour or the music. There is such a thing as "colour" in music, and many curious facts recorded, of persons, who are deficient in the faculty of distinguishing colours. It is said to exist in one male out of twenty. Professor Wilson discovered one case in thirty-seven in the colour of the ovaries. — It is a matter of fact, that literally colour blindness. They doubted about all colours, and on different occasions named the same colours differently. White and black they had no difficulty about.

We know that music and painting are generally appreciated and admired by the public. It is because the mind is consecutively and rapidly engaged with different impressions, from the variety and harmony of the tones or colours presented to the view. I believe that it is wanting in our street architecture, and being compelled to have so much wall space to the fronts of our buildings, that materials of varied colours and tints afford the means of effecting the object.

There are few persons but who admire the effect of an assembly on any festive occasion. The brilliancy and variety in the colours of the dresses, as well as the forms, gives a pleasing result to the spectator. No matter whether in the church, the theatre, the concert-hall, or out in the open air, large concourses of persons give brilliancy, and add greatly to the beauty of the scene. Of course, again, is accidental; but then it proves the universal admiration of variety in colour as well as form.

We see that the two principal things to be considered, in the design of a building, are colour and form. The more important is, undoubtedly, that of form. It is by the many varieties in form that we obtain the pleasing effects in light and shade, which break up all monotony and vulgarity.

We know that the mind, when active, requires to be constantly occupied with fresh thoughts and scenes. We cannot dwell on one subject or form for long together, without the mind being weary of the same. It is, therefore, more important is, undoubtedly, that of form. It is by the many varieties in form that we obtain the pleasing effects in light and shade, which break up all monotony and vulgarity.

"That the endless diversity of men's tastes, and the ever-changing condition of their education and association of ideas, demand for their productions a variety almost as great as the diversity of human colour," but he goes on to say, "Whenever that craving after variety has been gratified irrespective of fitness, novelty has degenerated into frivolity, design into conceit, and style into mannerism and vulgarity."

In all cases variety should be consistent with fitness in the construction.

The same writer says, with regard to form, that it is in nature "an index to all leading attributes,—a clue to recognize the relation of bodies, or their properties, to one another. Thus from form alone to discern at a glance of what materials, and how any particular object examined has been executed."

In Weale's "Rudimentary Treatise on the Principles of Design," the author says that "forms may be divided as regards their inherent or essential expression apart from association) into at least five classes, according to their degrees of contrast and gradation; from the most grand, severe, and forcible, to the most elegant, fanciful, and delicate.

Thus we may arrange—

1. Rectilinear and rectangular forms.
2. Rectilinear and oblique angled forms.
3. Curvilinear forms without contrary flexures.
4. Curvilinear forms with artificial contrary flexures.
5. Curvilinear forms with natural contrary flexures.

It may be taken, then, as a principle in every admiring of form, that variation is so in art, the grander and more forcible varieties in forms should in every case prevail most in the ruling and structural parts of a work, and that the more elegant varieties should find their place chiefly in the details.

In buildings generally all projections and recesses, all variations from straight lines and flat surfaces, constitute that kind of form which gives shade to parts recessed, and beautiful variety, when the architect has space at his command he is enabled to vary the outline of his design, to break up all flat surfaces, to introduce a variety of forms, and by so doing has less difficulty in producing a design that will be generally agreeable and satisfactory to the eye. So far detached buildings, and buildings in which the line of frontage is continually broken, may be arranged generally satisfactory as to external design, but in those cases where the architect has space at his command he is enabled to vary the outline of his design, to break up all flat surfaces, to introduce a variety of forms, and by so doing has less difficulty in producing a design that will be generally agreeable and satisfactory to the eye.

It follows, therefore, that in most modern street architecture, there must of necessity be a great quantity of flat wall surfaces. String courses, architraves to windows, and mouldings, are, therefore, very usefully introduced. Panelling may, perhaps, also be resorted to very advantageously in some situations. These accessories mostly involve considerable extra cost, and, therefore, except in the case of a palace or a very noble residence, are not to be resorted to. If executed in stucco, they are certainly not what they represent. I think they are better left out, if the proper material and construction are such other expedients may not be resorted to. I would sooner see a building without these ornaments altogether than have them stuck on with plaster. If executed in the real material I admire them, and they, doubtless, serve an important purpose in long rows of buildings by breaking up the wall surfaces, by casting shadows over the fronts, and thereby helping materially to destroy the monotony; but, in other cases, they do not break up the surface sufficiently themselves, and some other resource seems necessary to compensate for the loss of variety in forms, and consequent want of light and shade throughout.

If we must sacrifice many of the advantages of form, let us study how we can atone for that sacrifice, by making ourselves well acquainted with the laws and harmony of colour, so that we shall not be afraid to apply it externally as well as internally in the work of such materials as are required for the construction, especially for town houses. Let us get all the variation in outline we can, and then make up for the deficiency by the application of colour in varied surface forms.

I am one of those who believe that our street architecture will eventually be very much improved by the use of coloured materials. It seems to me just what is wanted for our present requirements. The spotty and streaky appearance, complained of by some, wears off by a few years' exposure to the weather, and is not objectionable where the variation is not caused to look great an extent. In time it becomes less marked. The variety in colour is only brought out prominently in those parts we are near to. In the distance the colours become neutralized, and, unless a very great quantity of positive colour be used, do not appear too prominent.

It, therefore, becomes an important question for our consideration, and is a subject which I think should be frequently brought forward and discussed in societies of this kind, in order that many opinions and more general views may be obtained. It is by such means that a proper taste is likely to be cultivated. Errors and follies will be pointed out and avoided, and general observation and experience will lead to a correct appreciation of what is worthy of adoption in all our work. The effect of the atmosphere upon, and the durability of, the various materials is also an important matter for observation. It is by these means—by real practical experience—that we may be enabled to obtain the best results in all our work. We may then hope that the right use of coloured materials in external design will be properly understood, and that further improvements will be made in our artificial manufactures as well as in our natural ones.

I do not think any regular or complete set of rules could be laid down for general guidance, at any rate not at present. We must learn by experience first. It may, perhaps, be of use to give a few errors; but that has been the case with almost everything else. The improvements made in engineering and other sciences have only been arrived at by experience. The great experiments have not been made, but it is from the failures of our own or others that we frequently owe our success.

The great danger which we are liable to in introducing colour to our brick buildings, is in too free use of the primary applied; but it should be used in small quantities, and always be balanced by the use of the secondary and tertiary colours in the larger masses, as recommended by Mr. Green Jones and others. It will rarely fall then to assist in the development of form and light shade.

If due care and attention be paid to the few rules laid down for the use of colour generally, I don't think that any serious errors need be committed. They will be found to apply, and serve to assist us in many instances in arranging colour externally as well as internally.

I should be sorry to see London or any city built entirely with variegated brickwork, although I think that would be a great deal more tolerable than the dull and dingy monotony of yellow or stock brickwork, without any variation in colour, which has accumulated to so great an extent in our streets and principal thoroughfares.

We are never likely, however, to have such a universal application of coloured brick houses. In the larger and more important buildings, stone and other superior materials always have been used, and where the funds will allow, and the importance of the case demand, I should always be in favour of the best materials, both as to appearance and stability, which we have at our command, with coloured brickwork. With different coloured stones or marbles we can get almost any amount of variety. We can obtain light to dark, or by making the colours very forcible and distinct. In the former case this has been done, in my opinion, with most perfect success, in the Crown Life Assurance Office, erected in Broad-street, and in this style. I think there could be no greater improvement in our street architecture. The Venetian Gothic—or secular Gothic—style is, in my opinion, the very suitable one in my opinion, for introducing variety in colour; but I must not enter into the question of style. The mixed colours and tones in the example I have just referred to are of the most subdued description, and afford a beautiful variety, affording all the repose necessary, and yet a total absence of anything glaring, offensive, or vulgar.

I have prepared a few rough sketches to suggest some of the many ways in which variety may be attained by the most simple forms without the aid of colour. Had time permitted, I should have been glad to have worked these out into more finished illustrations. I hope, however, that what I have brought will be sufficient to excite an interest in the subject, and lead to other designs being made by some of the members of the association. I feel sure that brickwork may be arranged with much greater variety in form than many believe, and that too in the most simple manner, and without necessarily increasing the expense, or destroying the bond of the work.

A dozen of the most simple forms in cast bricks, as suggested by the diagrams, would be sufficient to obtain all mouldings necessary. They need only be applied, like strong or positive colours, very sparingly; in such places as labels to windows, above and beneath string-courses, where the projection is sufficient; also in one or two courses at the impost of doorways and window openings, as suggested in sketches; and more freely perhaps in the principal cornice or crowning member of the building. Another necessary variety in form may be obtained by the use of plain and chamfered bricks; and where extreme cheapness is required, cast or moulded bricks may be dispensed with altogether, and the use of the new polychromatic are good examples of what may be done with plain brickwork, by simple arrangements in form, without any varied colouring.

There are many ways in which different forms may be obtained without any projection from the surface of the front. [He then referred to some sketches, which were intended to convey the idea, and showed a variety of outlines by projections or recesses, and then the reverse way, i.e., from the sides or recesses.]

This kind of variety of form is suitable for surface decoration and where colour is to be employed. It is less liable to interfere with the projection and than projections from the face of the work. Strings, and any kind of longitudinal projection, may always be resorted to with safety, proper bearing being all that has to be considered; but any con-

tinuation of vertical joints must destroy the bond of the work, and thereby injure the stability of the construction. For this reason I should never like to employ any vertical projection, beyond the size of a couple of bricks in height, or near to the principal angles, or where there is likely to be much pressure, in case of fracture. I think the representation of quoins stones, as to size, is the good solution. They are generally arranged in three and four courses, forming a series of vertical joints, and destroying the bond where it is most essential. Such construction involves extra thickness in the walls. . . . I see no objection to the employment of strings, projected round the heads of window openings, if those openings be not too near the angles; because here the bond is already broken by the window opening, and the width of a string cannot add much further to the weakness of the work.

It now remains for me to say a few words with regard to the illustrations of the application of colour externally. If any gentleman present should be disposed to look at the sketches after the meeting, I may mention that the numbers to the sectional parts refer to the diagrams on sheet No. 1.

As, for reasons I have before named, we cannot always get sufficient variety in form, to prevent our street architecture having a monotonous and wearisome aspect; and that a multiplicity of small forms appears frivolous, and is almost as offensive and vulgar as gaudy colouring, I contend that we should try to use colour in our street architecture externally, as an assistance to form—which is the way we find it in all the works of nature. It may be applied in many ways, and serve to define a variety of surface forms, which shall harmonize with any solid forms it may be possible to introduce.

Illustrations were given as to how two different colours may be arranged in arches to window openings. This is Mr. Street's work on brick and marble architecture of the Courty. This method of arranging colour according to the course of the bricks, may be applied to cornices and gables. I think with considerable effect. Circles and diamond patterns of different coloured bricks can be introduced in half-brick rings and huses, without materially affecting the bond. A running pattern, as shown on form a light. I think perhaps look very well under a cornice, or elsewhere.

There is an arrangement of colour in the gable ends of the tower to a church in Lambeth, I believe by Mr. Tenon. It consists of a geometrical pattern of three circles filling up the gable. Within the circles are two triangles, placed reversely, intersecting each other, thereby forming a hexagonal figure in the centre of each. The gable is filled with stones, and shown to form a light. It is in my mind a very happy arrangement, and shows one of the many ways in which colour may be applied externally.

The new church and parsonage-house of St. Thomas's, Lambeth, near the Westminster-road, also shows a very great variety in the arrangement of colour and form in brickwork.

According to Monsieur Chervet, 13 and 14 Prop., "colours on white ground appear darker; on black ground, lighter."

Black grounds suffer when opposed to colours which give luminous complexity. It is important always to bear in mind such propositions as these. With proper attention to them black and red bricks may, I think, be used in combination with each other very advantageously.

[Illustrations were given showing the arrangement of black bricks on a red ground, and the reverse.] I think black bricks have been very judiciously introduced in a new building of Messrs. Lee & Lavers, in Edulstreet.

Having thus directed your attention to a few prominent features in this interesting subject, I trust that they may be considered of sufficient importance to elicit a few remarks and suggestions from the members present.

At the conclusion,

Mr. Hewitt said he agreed with Mr. Johnson that the principal obstacle to the introduction of moulded bricks was the difficulty of procuring them, as it did not answer the purpose of manufacturers to keep them. A few years ago, when there was a duty upon bricks, the manufacturers pleaded that circumstance to account for their not making them; but, since the abolition of the duty, there appeared to be no improvement. Perhaps the reason was, that the demand for coloured bricks would not warrant the expense. If the brickmakers would produce samples for coping and gable stones, they might be found to answer. To use colour in the manner suggested by Mr. Johnson required experience, and he did not feel himself justified in offering an opinion upon the subject.

The Chairman said that Mr. Johnson had dwelt at some length upon truth in architecture, for which he (the chairman) had himself been always a stickler. They might read a great deal about these truths, but the simple question was, what was the use of graining or veneering? Was it to render materials more beautiful, or to signify that there had been an expenditure of money? Was it to denote that they had offered to the lamp of Sacrifice or the lamp of Beauty? It then became a question whether the grain of oak was better than that of deal; in this case there would be no harm in graining a deal door, for no one who would use it would consider that it represented a falsehood. He differed from Mr. Johnson in his opinion as to the application of colour to country houses. Mr. Johnson did not approve of colour in the country as much as in town, whereas he (the chairman) thought that colour could not be so successfully applied in town, unless in cases where the architect built the whole of the street. Moreover, it should be remembered the smoke and atmosphere of large towns would speedily deface colour. While referring to this subject, he might be allowed to recommend the study of "Street con-

Italian Architecture," which would be found an excellent guide to any one pursuing this study.

Mr. Hall remarked that the introduction of coloured bricks was a feature in architecture which had not received from the profession the attention it deserved. In some parts of the country, in Cambridgeshire for instance, where bricks only were to be had, coloured bricks were being introduced from forms made from the designs of the architect. The brickmaker lived at Wisleach, and he had produced some Gothic tracery by working simple geometrical patterns. In Belgium many churches were made entirely of brick—millions, tracery, and all. With regard to colour blending, it was quite true that many persons could not distinguish yellow from green or green from red, and he had himself known cases in point; but whether it originated from the formation of the eye, or other causes, he could not tell.

The Chairman said that a friend of his laboured under this infirmity to such an extent that, whenever he wished to produce a very glowing colour, he used purple in his diagrams. With regard to moulded bricks, he had always found that it was difficult, when using them, to preserve a continuous line, or, unless the brick was cut sharp in the first instance, the effect would be unsightly.

Mr. Hewitt said that, to insure sharpness of outline, the quality of the clay must be uniform, and the brick well made and burnt. He admired a coloured building exceedingly, provided the ornamentation was judiciously introduced. A slight variety in the working would be found to produce many pleasing forms.

Mr. Hall deprecated rubbing brickwork to make a continuous line, as a change of colour was usually produced by the process, while the work was more liable to frost.

After some further discussion, a vote of thanks was accorded to Mr. Johnson for his paper, and the proceedings terminated.

It was announced that the next subject for the Class of Design would be a group of allegorical sculpture to celebrate a national event, with pedestal. At the meeting on the 3rd of February a paper will be read by Mr. T. Blashill on "The Application of Ironwork to Architecture."

#### PROVINCIAL NEWS.

**Worcester.**—The annual report of the Local Board of Health on the new drainage and water-supply works shows that the entire length of new sewers is 84,971 feet, and the total amount paid under the contract for their construction, 18,502*l*. The works of water-supply were performed under several contracts, and the entire length of water-pipes laid down is 93,645 feet. The cost of the pipes was 7,518*l*, and in laying them down, 2,810*l* were expended. There has been paid for the erection of the engine-house, filtering-beds, reservoir, &c., 9,789*l*; for the engines, pumps, and machinery, 2,678*l*; hydrants, &c., 859*l*; making a total of about 22,156*l*. This does not include sums paid for purchase of land, legal expenses, engineer-in-chief's commission, and the salaries of the resident engineer, inspectors of works, &c.

**Reduth.**—The new public rooms erected in the town of Reduth have been completed and formally opened. The year in the Pointed style. The chief front facing into Peury-street is composed of a main building and two subordinate wings, the former being slightly set forward. All the gables and window and door dressings are of stone, from the Box-hill quarries, in Wilts. A brick and stone cornice is carried along the eaves and gables, and the vousoirs of the relieving arches on the entire front are of black and red brick alternated. In the north wing is the public doorway which is reached by a flight of granite steps. This room is 55 feet 6 inches long, 36 feet wide, and 22 feet high. The roof timbers of the room show as high as the collar beams. The spaces between the constructive timbers are panelled with boarding, the centre panels being perforated for ventilation. At the north end is a small gallery, projected from the wall on iron brackets, and having a light iron front, painted red, white, and blue, and picked out with gold. The windows, five on each side, afford light. The walls are stuccoed a warm tint, with St. Agnes sand, and the whole of the wood-work is stained in shades and varnished. There are rooms for the Mechanics' or Literary Institution, billiard and chess room, a news-room, the curator's apartments, a room for parochial business, &c. The cost of the building has been 2,000*l*. Mr. W. G. Habershon was the architect; Messrs. Nicholls & Son, of Reduth, and Mr. W. May, of Pool, the general contractors; Mr. J. Trestrail clerk of the works on

behalf of the proprietors; and Mr. S. Knight the representative of Mr. Habershon.

**Nottingham.**—The new Sunday schools, recently erected in connection with Derby-road Chapel, have been opened. The building is in the Geometric style. It is constructed of Balwell stone, with Ancaster dressings. It comes up to the Park Tunnel on one side, and advantage has been taken of the difference in the level to gain on this a dea lower story, containing four class-rooms, the heating apparatus, coppers, &c. The chief entrance is from Victoria-street, and leads into the principal rooms, which are in the form of an L; that intended for the boys' school being 50 feet by 21 feet; that for the girls', 42 feet by 23 feet. They are divided by sliding-doors. A superintendent's room is contrived in the angle, communicating with the schools. This room will also be used as a library. The infants' school is so placed as to be easy of access from the boys' or girls' schools, and is fitted up with a gallery, which can be folded up so that the room may be used for committee meetings, &c. This room is about 20 feet square. A separate entrance from Victoria-street has been made for the boys, and a private entrance to the chapel. The whole of the flues are carried up in a stone chimney-shaft. Mr. Ferguson was the contractor. Messrs. Haden supplied the heating apparatus, and Mr. Wheeler the painter and glazier's work. The total cost will be between 1,200*l* and 1,300*l*. Mr. R. C. Sutton, of Nottingham, is the architect.

**Leith.**—An extensive structure has recently been completed here, at a cost of 25,000*l*. It is called the Leith Flour-mills, which have been built, the machinery and gearing prepared, the engines fitted up and set to work, within the short space of twelve months; it being but eight months since the first pillars were erected. The mill is six stories high, and the granary the same height, but considerably longer than the mill. Mr. Thomas McNeill, of Glasgow, was the architect employed. The engineers and millwrights were Messrs. Emmerson & Murgatroyd, of the Heaton Foundry, Heaton Norris, Stockport. The engines and gearing are calculated to transmit a power of 300 horses indicated. The mill is fitted up, at present, with twenty-four pairs of French Burr-stones, driven by belts from a centre line of uprights, twelve on each side, which uprights are driven by a line of shafting 30 feet in length, and having upon it twelve large mortise-wheeled gearing into the pinions of the uprights. Mr. R. Young, of Glasgow, has furnished the machinery for the various processes connected with the grinding, prior to the material being ready for the market. Mr. Spiden was the contractor for the masonry work, but he only survived the completion by a few days. The joiners' work was completed by Messrs. Henson & Wilson, of Leith; and the boilers, which are fitted with Young's patent for the prevention of the smoke misgiver, were furnished by Messrs. Hawthorn, of Leith.

#### THE ANCIENT ARCHITECTURE OF CEYLON.\*

There is a trace, in extreme antiquity, of a curious connective link of commercial association between the island of Ceylon in the far east, and the island of Great Britain in the far west, which Sir Emerson Tennent has assisted in bringing more clearly into light; and which, in these days—when Britain has not only close and continual relationships, of a similar kind, with this *ultima thule* of the eastern Indies, but is, in fact, her sovereign mistress,—is peculiarly interesting. "A careful perusal of the Scripture narrative," remarks Sir Emerson, "suggests the conclusion that there were two places at least to which the Phœnicians traded, each of which bore the name of Tarshish; one to the north-west, whence they brought tin, iron, and lead; and another to the east, which supplied them with ivory and gold." Now it is obvious that this author has a British—that is, a Cornish—port in view, as the Tarshish of the north-west, it being well known that the ancient Phœnicians obtained their tin from Cornwall, and probably their lead and iron also from Britain. But what Sir E. Tennent more especially directs his attention and that of his readers to is the probability that the eastern Tarshish of the Phœnicians was the port of Galle in Ceylon, which, he remarks, "is by far the most venerable emporium of foreign trade, now existing in the universe: it

\* Ceylon: an Account of the Island, Physical, Historical, and Topographical; with Notices of its Natural History, Antiquities, and Productions. By Sir James Emerson Tennent, K.C.S., &c. &c. Illustrated by Sir James Mays, Plans, and Drawings. Third Edition, thoroughly revised. London: Longman & Co. 1859.

was the resort of merchant ships at the earliest dawn of commerce, and it is destined to be the centre to which will hereafter converge all the rays of navigation, intersecting the Indian Ocean and connecting the races of Europe and Asia."

We cannot follow Sir Emerson in his lucid exposition of the reasons which induce him to urge the identity of the ancient Tarshish of the east with the port of Galle in Ceylon, and Malacca with Ophir,—on the way to which the island of Tarshish lay; our purpose, in the present article, being simply to dig out a few architectural details from a very valuable, miscellaneous, and interesting quarry which he has presented to the public in his work on Ceylon. We may quote a portion, however, of what he says on the subject of the eastern Tarshish:—

"The Ships intended for the voyage were built by Solomon at Ezion-geber on the shores of the Red Sea. The rowers ceased along the shores of Arabia and the Persian Gulf, headed by an east wind. Tarshish, the best situated in an island governed by kings, and carrying on an extensive foreign trade, the voyage occupied three years in going and returning from the Red Sea, and was a very valuable, and precious. Gold could be from Ophir, after spread into plates, which is particularly by Jeremiah, as an export of Tarshish, is one of the substances on which the sacred books of the Scripture are even now incribed; ivory is found in Ceylon, and must have been both abundant and full grown there before the discovery which the Tarshish of the east effected destruction of elephants: opes are indigenous to the island; and peacock are found there in numbers. It is very remarkable, too, that the terms by which these articles are designated in the Hebrew Scriptures are identical with the Tamil names, by which some of them are used in Ceylon to the present day; thus *lutecium*, which is rendered in our version, in one passage, as being recognized in *luhi*, the modern name for these birds, and apes, is the same in both languages; and the Sanskrit *ivory*, is derived with the Tamil *ivory*.

Thus, by geographical positions, by natural productions, and by the fact of its being from this island, the moral resort of merchant ships from Egypt, Arabia, India, the Persian Gulf, and India, Java, and China, on the other, Galle seems to present a combination of every particular essential to determine the problem so long and particularly essential to determine the problem so long and interfering its identity with the Tarshish of the sacred historians, the great Eastern mart so long frequented by the ships of Tyre and Judæa."

The two volumes of the excellent work under notice are plentifully interspersed with architectural details; but the author has also given a general view of Ceylonese or Singhalese architecture, to which we will gladly have recourse, as affording a condensed abstract, more accordant with our limits, and at the same time affording our professional and other readers some idea of the interest of the other portions of the work,—to them in particular, as well as to the general public.

**Architecture.**—In Ceylon, as in Egypt, Assyria, and India, the ruins which survive to attest the character of ancient architecture are exclusively sacred, with the exception of occasional traces of the residences of theocratic royalty; but everything has perished which the ancients afforded an idea of the dwellings and domestic architecture of the people. The cause of this is to be traced in the perishable nature of the sun-dried clay, of which the walls of the latter were composed. Added to this, in Ceylon there were the pride of rank and the pretensions of the priesthood, which, whilst they led to lavish expenditure of the wealth of the kingdom upon palaces and monuments, and the employment of stone in the erection of temples and monasteries, forbade the use of any other material than such as was found in the occupation with their dwellings of the British army of Kandy, after its capture in 1815, that to find the palaces and temples alone constructed of stone, whilst the streets and private houses were formed of mud and thatch.

Though stone is abundant in Ceylon, it was but sparingly used in ancient buildings. It was but very occasionally employed, but large slabs seldom occur, except in the foundations of dagobas. The vast quantity of material required for such structures, the cost of quarrying and carrying, and the want of mechanical aids to substitution of blocks into position, naturally led to the employment of bricks for the upper portion of the super structure.

There is evidence to show that waggons were employed in the transport of blocks in the quarry, and the amount of labour devoted to the preparation of those in which strength, irrespective of ornament, was essential. In the remains of the 1,650 undressed pillars which supported the Braze temple at Anarajapora, and in the 1,000 stone steps, many of them extending 10 feet in length, which led from the base of the mountain to the base of the mountain at Anarajapora, a single piece of granite lies in the shape of a hollowed-out "elephant trough," with ornamental pilasters, which measures 10 feet in length by 6 wide and 2 deep; and amongst the ruins of Pollanara, still more remarkable slab, 25 feet in length, by 6 feet broad and 3 thick, bears an inscription of the twelfth century, which records that it was brought from a distance of more than thirty miles.

The majority of the columns at Anarajapora are of dressed stone, octagonal, and of extreme graceful proportions (fig. 1.). They were used in profusion to form the colonnades around the principal dagobas, and the pillars which still remain, which still remain, are one of the peculiar characteristics of the place, and justify the ex-

\* The "Rajavali" states that these rough pillars were originally covered with copper; p. 222.  
† See page 59 for illustrations.

profession of Knox, when, speaking of similar groups elsewhere, he adds them to be heavy stone pillars.

Allusions in the Mahawanso show that extreme care was taken in the preparation of bricks for the dagobas. Major Skinner, whose official duties as engineer to the Government were connected with all parts of Ceylon, assures me that the bricks in every ruin he has seen, including the dagobas at Anarajapora, Bintenne, and Pollanarua, have been fired with so much skill that even the most delicate tests has but slightly affected their sharpness and consistency.

The sand for mortar was pounded, sifted, and ground on a grinding-stone, the 'cloud-coloured stones,' the Geyser, and the receptacle for the water, and the sacred relic was enclosed, were said to have been imported from India; and the 'nawanita' clay, in which these were imbedded, was believed to have been brought from the mythical Anantika lake in the Himalayas.

Dagobas.—The process of building the Ruwanweli dagoba is thus minutely described in the Mahawanso:—'That the structure might endure for ages, a foundation was excavated to the depth of one hundred cubits, and the round stones were trampled by enormous elephants, whose feet were protected by leather cases. Over this the monarch spread the sacred soil, and on it laid the bricks, and over them a coating of brown stone pillars. Above this a layer of sand stones, and on all a plate of iron. Over this was a large pholita (crystallized stone), then a plate of brass, 8 inches thick, imbedded in the water of the small red cocoa nut.'

The shape of these huge mounds of masonry was originally hemispherical, being that best calculated to prevent the sun's rays from striking on objects so sacred. Dutakamun, according to the Mahawanso, when about to build the Ruwanweli dagoba, consulted a mason as to the most suitable form, who, filling a golden dish with water, and dipping his hand, caused a curved bubble in the form of a coral bead to rise on the surface; and he replied to the king, 'In this form will I construct it.'

The dagobas at Anarajapora, the Alay-narari and Jeyta-wana-rama, still retain their original outline: the Ruwanweli, from age and decay, has partly lost it: the Thupa-ranaya is flattened on the top as if suddenly brought to a close, and the Lanka-ranaya is shaped like a bell.

Monasteries and Wikaras.—... Simplicity and retirement were at all times the characteristics of these retreats, and the most rapid and accurate accounts are only recorded instances of extravagance in this particular was the 'Brazen Palace' at Anarajapora, with its 1,600 columns; an edifice which, though nominally a dwelling, and a thousand domestics, having been built a vast suite of halls for their assemblies and festivals, and a sanctuary for the safe custody of their jewels and treasure.

Altars are occasionally made to other edifices more or less fantastic in their design and structure, such as 'an apartment built on a single pillar,' a 'house of an octagonal form,' built in the twelfth century, and another of an 'oval' shape, erected by Prakrama I.

Palaces.—The royal residences, as they were first constructed, must have consisted of very few chambers, since mention is made in the Mahawanso of the earliest, which contained 'many apartments,' having been built by Pandukabhaya, B.C. 432. But within two centuries afterwards, Dutugamuna conceived the magnificent idea of the Loha Pasada, with its quadrangle 190 cubits square, and a thousand domestics, with ornamental windows. This palace was in its turn surpassed by the castle of Prakrama I. at Pollanarua, which, according to the Mahawanso, was 'seven stories high, consisting of 5,000 rooms, lined with hundreds of stone columns, and outer halls of an oval shape, with large and small gates, staircases, and glittering walls.'

In what now remains of these buildings at Anarajapora, there is no trace to be found of an arch, truly turned and secured by its keystone; but at Pollanarua there are several examples of the false arch, produced by the progressive projection of the layers of brick. The same species of dome, but in the form of a shell, to be seen amongst the ruins of the latter city, where the material is compact and smooth, and the edges sharp and unsworn. The mortar shows the remains of the pearl grey, and the feet of the columns are decorated with which the walls were coated still clings to some of the towers, and retains its angularity and polish.

Of the details of external and internal decoration applicable to the structure of the Dagobas, which attest a perception of taste, however distorted by the exaggerations of Oriental design. 'Guided ties' in their bright and sunny atmosphere, must have had a striking effect, especially when surmounting walls decorated with beaded mouldings, and festooned with 'carvings in imitation of creeping plants and flowers.'

\* The 'cloud-coloured stones' may possibly have been marble, but no traces of marble have been found in the ruins. Diodorius, in describing some of the monuments of Egypt, alludes to a 'party-coloured' stone, λιθον ποικίλον which likewise remains without identification.—Diodorus, l. i. c. lvii.

\* Mahawanso, ch. xxix, p. 169; ch. xxx, p. 178. The same structure is described at Bilsah, in Central India, presents the arrangement here described, the bricks being laid in mud, but externally it is faced with dressed stone.

\* Mahawanso, ch. xxx, p. 175. This legend as to the origin of the semicircular form of the dagoba is at variance with the conjecture of Major Forbes, that these vast structures were merely an advance on the mounds of earth, piled up by the Hindus, which, in the progress of the constructive arts, came to be converted into brickwork.—'Eleven Years in Ceylon,' v. i. p. 222.

\* Mahawanso, ch. xxvii, p. 165. Like the 'nests' of the pyramids of China, and the 'Maya Paya' was originally nine stories in height, and Ferguson, from the analogy of Buddhist buildings in other countries, supposes that these diminished in succession as the mounds rose. His outline, in which he has assumed the form of a pyramid ('Handbook of Architecture,' b. i. ch. iii. p. 41). In this he is undoubtedly correct, and a building still existing, though in ruins, at Polonnaruwa, and known as the 'Seven-stories palace,' probably built by Prakrama, about the year 1170, serves to support his conjecture.

\* Expressions in the Mahawanso, ch. xxvii, p. 164, which are equally as applicable to the Dagobas, and the Sinhalese were acquainted with this beautiful cement, which is susceptible of a polish almost equal to marble.

On the subject of carving, the author offers some curious and interesting remarks, especially as regards 'the beautiful kala hanza' or 'sacred gose,' ever 'eager to set out for the sacred lake,' and reminding one of the Scripps, and ever ready to fly to 'its windows,' and the Egyptian Isis, ever waiting to fly into the adytum of the temple, where its monolithic stone torso stood (as depicted on mummy coffins, with bare feet in front, and the bird looking out), and where it was probably fed with its favourite serpents. The 'watahali' and 'faithful' gose of the Romans was already sacred to Juno, and domesticated in her temple, as Sir Emerson remarks, previous to the saving of the citadel by the ancestral watchers, so that this latter event does not account for even the ancient Roman respect for the gose. It was also sacred among the Egyptians, by whom, as by the Burmese, balance weights were made in the shape of the sacred gose; and even the Christian crusaders adored a gose, which they believed to be filled with the Holy Spirit, as Mill in his history of the Crusades informs us. Gas (spirit?) is the Swedish name of the gose, which latter word itself seems to have had the same etymological origin. It is remarkable, however, that a carved kala hanza in the Sinhalese royal palace of Kandy much more closely resembles the dodo (a giant of the Columbiad order, believed to be now extinct (in New Zealand), but still extant in Thibet, than any known gose.

In his chapter on the 'Ruined Cities,' Sir Emerson gives an account of the rock temple of Damboul. The ascent is by a steep and toilsome path across the lower mass of the rock; and the grand gateway, profusely adorned with carvings in stone, and disclosing within a seated figure of 'The Vanquisher,' of which we give a view (fig. 2), is approached on crossing a courtyard.

Fig. 3 is a representation of the *Sar-Mahal-Prasada*, whose name perpetuates the memory of the 'Seven-storied House.' In front of this extraordinary building lies an enormous carved slab, called the 'Stone-book,' from its resemblance to a Sinhalese volume of law. It is a monolith, 26 feet in length, 4 feet broad, and 2 feet thick, bearing an inscription containing the intimation that 'this engraved stone is the one which the strong man of the King Nissanga brought from the mountain at Anarajapora, a distance of more than eighty miles.' The inscription is said to have been engraved about A.D. 1196.

We will conclude our extracts on the subject of Ceylonese architecture with a few further remarks on—

\* Temples.—The temples of Buddha were at first as unpretending as the residences of the priesthood. No mention is made of them during the infancy of Buddhism in Ceylon; at which period caves and natural grottoes were the only places of devotion. In the sacred books these are spoken of as 'stone houses,' to distinguish them from the 'houses of earth' and other materials used in the construction of the first buildings for the worship of Buddha; such temples having been originally confined to single chambers of the simplest description, and those which it became the custom at a later period to place a statue of the divine teacher, reclining in dim seclusion, the gloom being increased to heighten the scenic effect of the ever-burning lamps by which the chambers are imperfectly lighted.

The construction of both these descriptions of temples was improved in later times, but no examples remain of the ancient style of the Buddhist religion, and those of the rock temples still existing exhibit a very slight advance beyond the rudest attempts at excavation.

Of the modern temples the author says,—

'It was in all probability owing to the growth of these [modern] institutions, and the establishment of colleges in connection with them, that halls were eventually appropriated for the reception of statues; and these apartments so consecrated were devoted to the ceremonies and worship of Buddha. Hence, at a very early period, the dwellings of the priests were identified with the chaityas and sacred edifices, and the name of the Wikara came to designate indifferently both the temple and the monastery.'

But the hall which contains the figures of Buddha, and which constitutes the 'temple' proper, is always detached from the domestic buildings, and is frequently placed on a calanase from which the view is commanding. The interior is painted in the style of Egyptian chambers, and is filled with figures and illustrations of the legends of Gotama, whose statue, with hands uplifted in the attitude of adoration (or with the two fore-fingers extended, as in the Papal act of benediction, as elsewhere remarked), or reclining [with closed eyes, and] in repose, emblematic of the blissful state of Nirvana, is placed in the dimness of the shrine. Here lamps cast a feeble light, and the air is heavy with the perfume of flowers, which are daily renewed by fresh offerings from the worshippers at the shrines.'

As to a peculiar, but heretofore known, mode of lighting the statue in Indian temples, of which the author suspects that one instance, at least, occurred in Ceylon, he says,—

'Allusion has already been made to the identity in certain particulars observable between the Buddhist temples of Ava and those of Ceylon. Amongst the latter, such as Pagamany, or the Iravathi, is a *pyrota* known as the 'Cave of Ananda,' and in it a gilded figure of Buddha, similar in attitude to that in the Jaya-wana-

rama [an immense edifice of brick, in the highest style of ornamented southern Indian architecture' in Ceylon, 'built by Prakrama Bahu I., after the model, it is said, of one erected by Buddha himself at Kapili-vastu, the place of his birth'], stands in a vaulted cell, situated at the further extremity of a darkened aisle. Into the alcove in which it is placed the only light that is admitted streams through an opening so situated as to be unseen by the spectator in front, and thence it is poured like a beam over the head of the glorified object below. (See fig. 4.)

This mode of illuminating an interior is common in the rock-cave basilicas of India, in which 'one undivided volume of light, coming through a single opening over head, falls directly on the altar or other principal object, leaving the rest of the structure in comparative obscurity.' The similarity of position and the identity of attitude between the two statues, in Ava and Ceylon, suggest the conjecture that the figure at Polonnaruwa, like that at Pagan myo, may have been placed in the recess which it occupies, so as to admit of being lighted in a similar manner on an aperture concealed in the roof; and it will be an interesting inquiry, for some future explorer, provided with the necessary facilities, to determine, by a minute examination of the walls, whether they may not have been constructed as to cast a mysterious light on the gilded idol below.

Buddha himself, as Sir Emerson remarks, is not worshipped as a deity, but 'merely revered as a glorified remembrance,' and certainly such a mode of exhibiting his statue, like that of the Thibetan and Indian rituals, in which lights, flashed round the head, suddenly and momentarily reveal the Buddha, or other statue, in the midst of intense darkness, is capable of suggesting just such an idea as that of a 'glorified remembrance,' and reminds one of the curious 'Buddha rays,' which the morning sun in Ceylon sheds round the head of the *Aradon* of the human form projected on the ground.\*

\* The following very curious extract on 'The Illuminated,' from the 'Diyavanshavi,' of India, 'that most mystic of all mystic books' (as a writer in the *Dublin University Magazine* calls it), will here be of interest, as it seems to comprise an endeavour to describe the nature and appearance of a 'thaumaturgic saint,' in the state of 'divine absorption,' or, in fact, just such some 'glorified' being as that represented by the statue of Buddha, when reclining, as in the divine quiescence or entranced repose of 'Nirvana,' or seated, with uplifted palm and fingers, as in the act of exhorting or of blessing the devotees;—whether, in short, as the 'waking God,' or the sleeping man, or the waking man in the 'sleeping God.'

In this passage the 'glorious body' of 'the illumined' is itself compared (with a touch, mayhap, of the Oriental imagery, descending from the divine thaumaturgic perfection, molten [softened] down; to me, beholding, it appears Quiescent saint, personified with limbs,—as a painting of divine bliss,—a sculptured form of the sovereign happiness, or the divine quiescence, or presence of Light that is sitting on yonder seat? Such becomes the body, what time the annular power [in 'contemplative abstraction'] drinks the moon-fluid of immortality, descending from the brain [by a discharge from above,] into 'the mouth of the power' [beneath]. Then, O Friend! Death dreads the shape of the body. This disappears old age! The knots of youth are cut to the pieces, and the last state of childhood reappears. [See *Dublin University Magazine*, April, 1854, on 'The Dream of Ravan.']

The splendour of the illumined and immortalized body thus 'condensed into that of a perfect man,' or man-god, is described in glowing language. He casts his old skin, like the serpent, as well as his teeth and nails. 'The body,' it is said, 'becomes of gold in lustre,'—like the statue of Buddha, which is generally gilded. It is also compared, among many other things, to 'a vase filled with liquid saffron,'—reminiscent of the 'saffron-hued' baschins of the Greeks; and 'like a pillar lit from within,' or 'of the interior,' allusive, doubtless, to 'the lactiform body,' which, Sudaas tells us out of Jadorus, 'still exists, within this terrestrial body of ours, like light within dark lanterns,'—but it is evoked into autotypic exaltation,—as it would here appear, by 'the annular power'—henceforth the great brain,—whatever may be meant by that 'annular power' and its 'middle chambers,'—and these at all acquiescent with that most mysterious of all mysterious anatomical and physiological subjects,—the structure and functions of the brain, great and small, of the annular protuberance, and of the medulla oblongata,—need have little difficulty in perceiving that here there is at least 'a method' in what others may be led to look upon as little else than mystic 'madness.'

This 'annular power' it is said, 'retires [in 'contemplative abstraction'] into the middle chamber: then, with a discharge [as of 'lightning' from above, the reservoir of moon fluid of immortality, contained in the brain, leaning over to one side, communicates with the mouth of the power, thereby the [artery] tubes are filled with the [immortalizing and illuminating] fluid, and it penetrates into all the members.'

But enough of the physiological *modus operandi* of the regeneration and immortalization of the Oriental 'twice born,' or 'deathless brotherhood' of 'two origins,' who, whatever they may once have been, are linked but a 'glorified remembrance,' with but a few real and objective existence, in this 'iron age' of ours. We may here, however, add a very few words more, from the conclusion of the curious description, just quoted, of 'the illumined.' It is said that 'He is called Kuchara, the Sky-goer. This step being attained is a wonder among people in the [natural] body. Behold the Sadakaka—the thaumaturgic Saint,' in his—

'My extremities and illumined sleep. The body's trance—the spirit's seeing.'

Just such a 'glorified' and saintly human being, 'bound in the bundle of life together with his 'Irradiates' or Illuminator, diesthe statue of the Buddha seem to have been intended, of old, to represent, in the belief of the Buddhists, of the human race. Buddhism and Brahminism are closely akin. See articles, in *Builder* of 16th October, 1858, and 15th January, 1859, on 'Symbols,' by John E. Dove.

## SELECTED DESIGN FOR THE NATIONAL WALLACE MONUMENT.

The monument proposed to be built on the Abbey Craig, near Stirling, consists of a lofty and imposing Scottish baronial tower, upwards of 200 feet high, and 36 feet square, having walls 15 feet to 6 feet at the top. The masonry is to be of a strong and enduring description, concreted with thin hot lime. At the east side of the tower is the keeper's house, between which and the monument is an open courtyard, entered by a massive circular-arched gateway, having bold mouldings, characteristic of the Scottish baronial style, above which is placed the heraldic arms of Sir William Wallace. Passing through the gateway into a stone-arched passage, a straight flight of steps, set in the thickness of the wall, leads to an open octagon winding staircase, the walls of

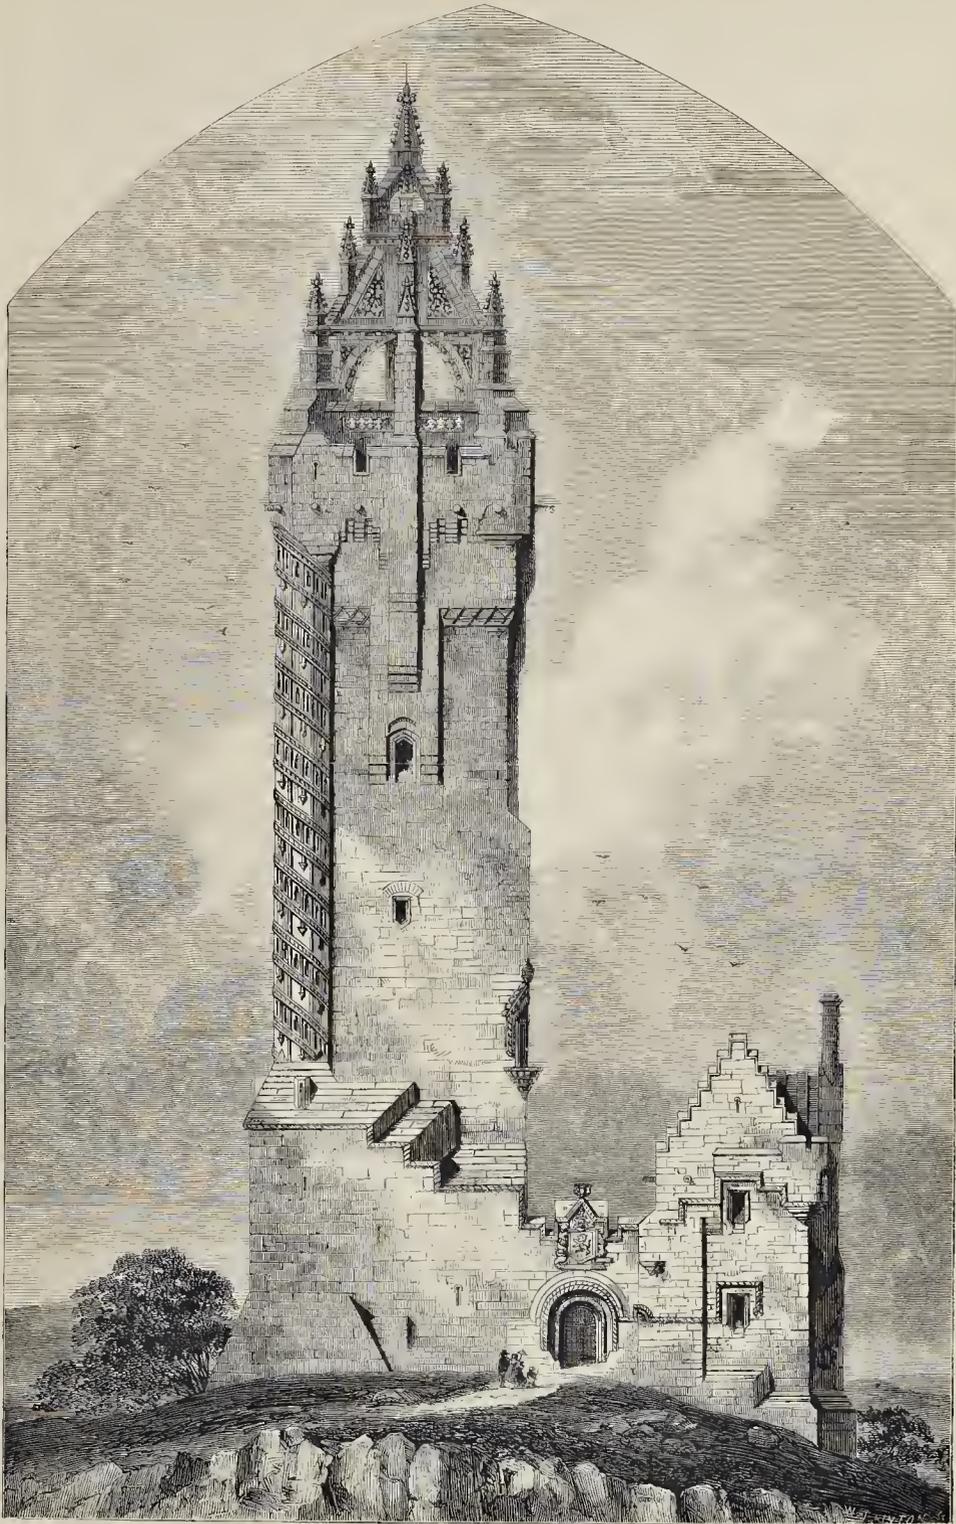

which are of solid ashlar work, projecting from the south-west angle of the tower, and running up nearly its entire height. The walls of the staircase raking with the stair are pierced with arrowlet slits, or lights, continuously in each flight of steps to the summit of the square tower. Externally the walls of the staircase are bound about with imitation rope-work, with bold moulded angles. The handrail is wrought out of the solid newel. This staircase conducts to several spacious and lofty halls, the ceilings and floors of which are fireproof, being arched with brick, having the floors laid with mosaic tiles. It is proposed to set apart these several rooms as visitors' and reliquary rooms, or museums for the reception of old armour and other antiquarian relics illustrative of early Scottish history, and should the funds permit, an appropriate marble statue of Wallace will be placed in the uppermost gallery or hall. The apex of the monument exhibits the

form of an imperial open crown of stone. The whole monument can scarcely fail to present a commanding outline and graceful feature when seen against the open sky. The coronal top or crown is upwards of 50 feet high, and consists of eight arms, from the angles and sides, all converging and abutting on the centre upon an open newel staircase, and forming a series of flying buttresses, broadly ribbed, having the spandrils richly filled in with open tracery; the outer raking flanks of the buttresses are surmounted with massive crocketed pinnacles.

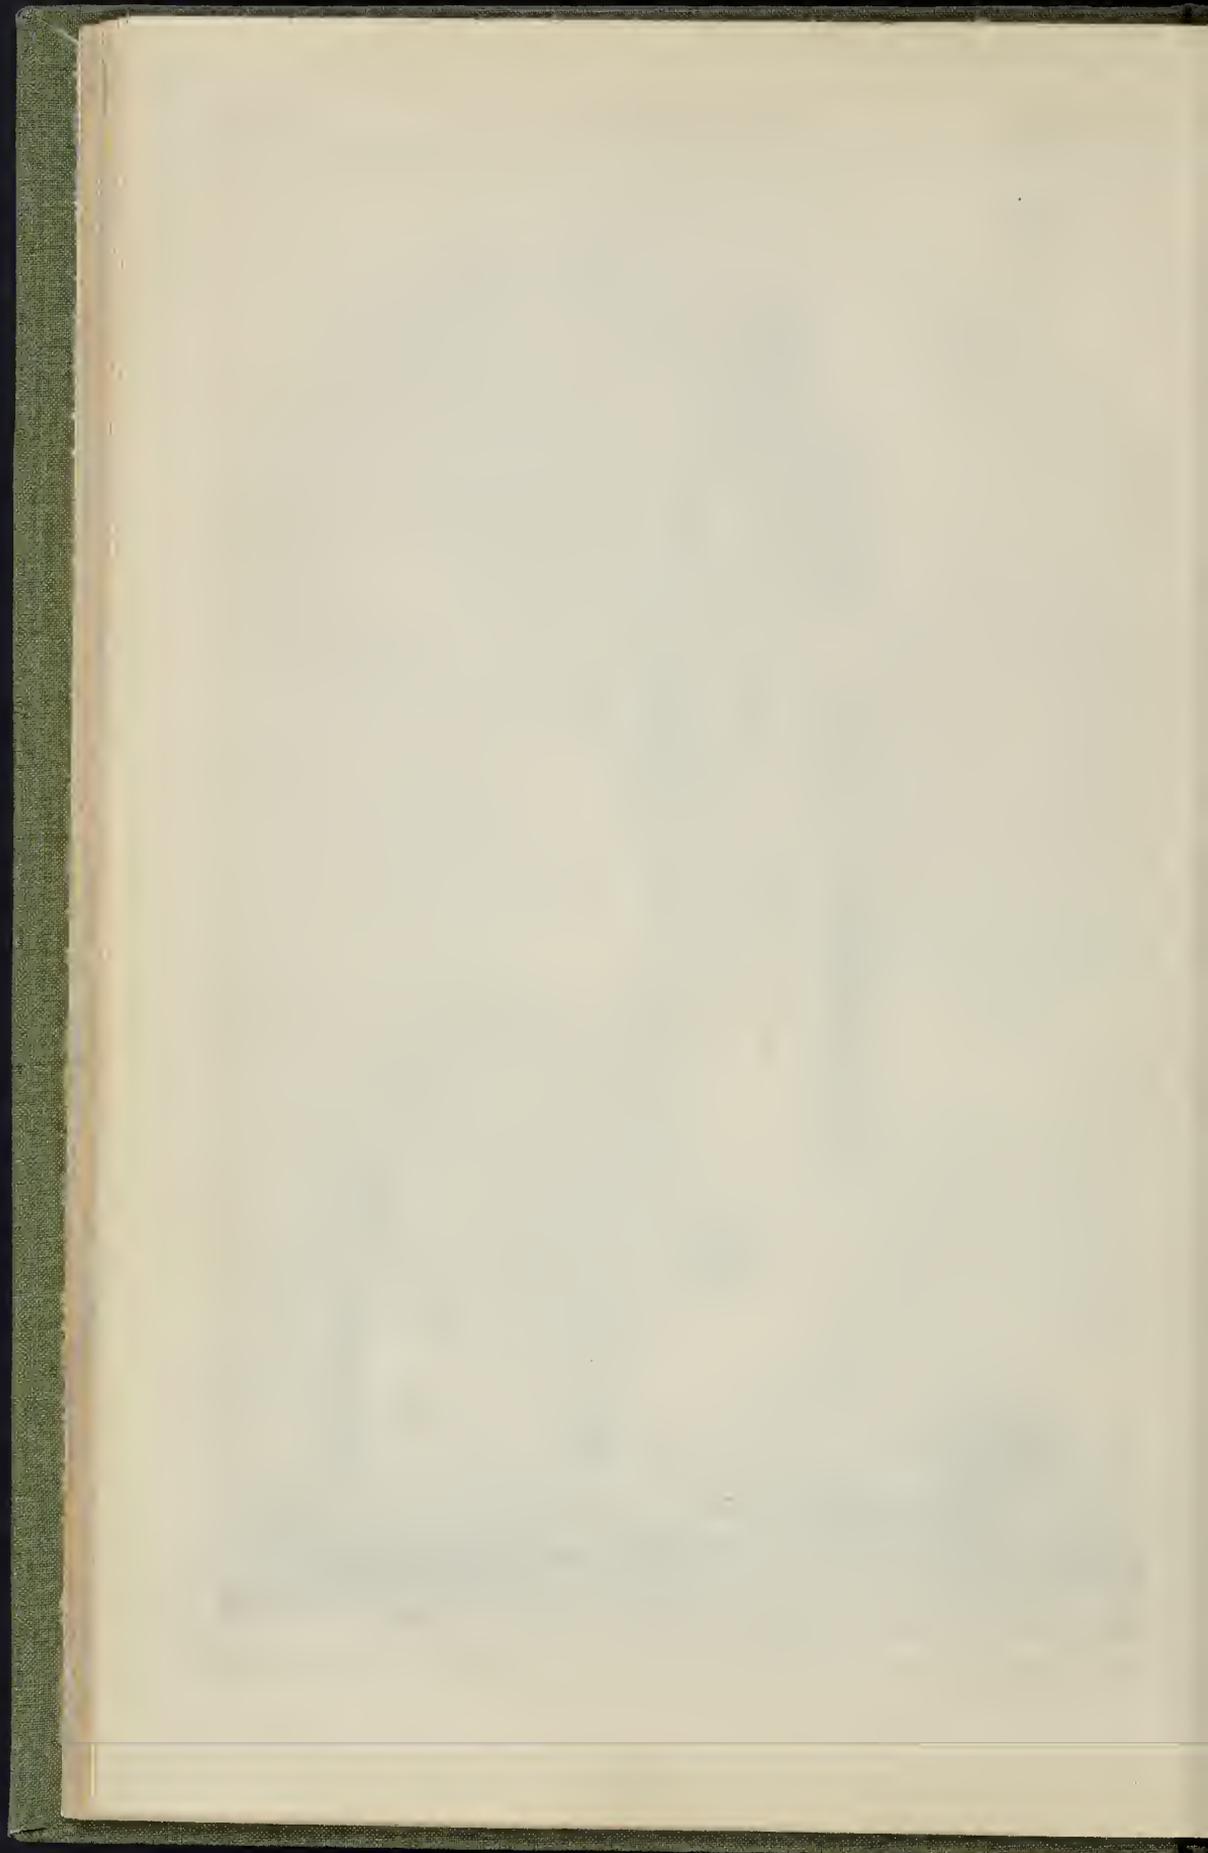

We may add that the site is one of great beauty, and from the monument will be had some magnificent views of a wide and extensive plain of country, overlooking, as it does, the scene of numerous and hard-fought battle-fields.

We understand it is determined to carry out the design. Mr. J. T. Rochard is the architect.

\* See page 54.

SELECTED DESIGN FOR THE WALLACE MONUMENT, STIRLING, SCOTLAND.—MR. J. T. ROCHEAD, ARCHITECT.

THE ARCHITECTURAL MUSEUM.

On Wednesday evening last, Mr. George Godwin delivered a lecture in the Theatre of the South Kensington Museum, under the heading "Memorials of Workmen: the Past to encourage the Present."

There was a very full meeting, including a large number of art-workmen. A. Beresford Hope, esq., presided. On taking the chair for the first time since his election as president, Mr. Hope commented in feeling terms on the loss sustained by the Museum in the death of Earl de Grey, and renewed his own "oath of fealty" to the Institution. In the course of his speech he mentioned an offer received from India to deposit in the Museum some interesting specimens of the architecture of that country, and he then introduced the lecturer.

The lecture was addressed to those who, with abilities and aspirations, doubt their power of overcoming the difficulties that surround them, and treated of those who, in spite of the most adverse circumstances, have worthily developed themselves and benefited others. Bernard Palissy, Quintin Matsys, the men of Nuremberg,—

"Quaint old town of toil and traffic,  
Quaint old town of art and song,  
Memories haunt thy pointed gables,  
Like the rooks that round them throng;"

the weavers, Hargraves, Arkwright, and Crompton; Brindley, the engineer; Watt, and George Stephenson, were passed in review, and such deductions were drawn as seemed valuable. James Tassie, the gem engraver, Wedgwood, Flaxman, Hogarth, Turner, Sir John Soane, John Britton, Chantrey, Thomas Cubitt, and many others followed; and the lecturer concluded with suggesting that it was neither necessary nor to be expected that all should distinguish themselves or take the top place. To do one's work, whatever that may be, so that others will be the better for it, is something; and he pointed out to the workmen of his audience where they might derive advantage, and how easily happiness was to be obtained irrespective of position.

The Chairman, in flattering terms, moved a vote of thanks to the lecturer, and Mr. S. C. Hall, in seconding it, added some interesting anecdotes of John Martin and Allan Cunningham.

BURFORD'S PANORAMA.

The new painting in the well-known building in Leicester-square is not so much "a View of Venice from the Piazzas of St. Mark" as a view of the Cathedral of St. Mark and its surroundings. It does not convey an idea of Venice, but of what it does show a capital picture is made. The cathedral is to a large scale, and the doorways are so cleverly painted that in one point of view they have all the effect of a stereograph. The domes are less deceptive—wanting roundness. At the present moment, when all must feel interested in the miserable condition of Venetia generally, the picture has an extra attractiveness.

PROGRESS OF RAILWAYS ABROAD.

The works of the Limoges and Agen railway are progressing rapidly. The most important portions of the Limoges tunnel have already been arched, and the bridges over the Vienne and Briance rivers have been commenced.

In the spring of this year the new line from St. Gobain to Chaunay will be opened for passenger traffic. Already the produce of the celebrated glass works of the former town has arrived at Chaunay by goods' trains; the reception of the works, by the directors of the factory, having taken place in the first week of last November.

The Western Railway Company of France has demanded three millions for works to be executed in 1860 on the St. Malo branch line. The Government have accepted the proposition. These works will take at least three years to complete them.

On the line from Mans to Angers the works are to commence this month (January).

An order from the prefect of the Jura, issued in conformity with the law of 3rd May, 1811, institutes an *enquête* of eight days' duration for the purchase of land for the Bourg and Besançon railway—a feeder for the Paris, Lyons, and Mediterranean Railway. The *parcelle* plans have been deposited at the *mairies* of the *Communes* of Moncheard, Pagnoz, Aiglepieire, Les Arsures, Montigny, Vilette, Arbois, and Grozon, through which the line passes as far as the Creuse Roadway, in the *arrondissement* of Poligny.

In a month or so the works of the Paris and Granville Railway will be in active progress—that is, as soon as the judiciary formalities are gone through for the purchase of land from refractory landholders, who would not treat à l'amiable with the company.

An important section of the Paris and Soissons Railway is to be shortly opened: it starts from a point on the *Chemin de Fer du Nord*, in the middle of the plains of St. Denis.

A large staff of the *Compagnie du Chemin de Fer du Midi* is at present at Dax busily collecting materials for the construction of the three great structures on the line from Ramous to Dax. These works comprise the bridges over the Adour at Dax, and over the Lay at Oro, and the Habas tunnel.

Surveys are actively being made for a railway from Bayonne to Biarritz, about five miles long, to be open for traffic the next bathing season, according to the *Journal des Actionnaires*.

Biarritz, the "Osborne" of the French monarch, deserves a railway; but, in order to have the works completed within the specified time, and according to contract, &c. &c. he must really call in the assistance of Mr. Robert Houdin, *lunenburg-in-chief*.

At Stockholm the Government has determined to bring forward a railway law, followed up by a loan of twenty-five millions of rixdollars. It is rumoured that many members of the Diet wish the proposed sum increased, in order that the railway resources may be of longer duration.

The preparatory works for the construction of a railway from St. Petersburg to Viborg, in Finland, are terminated. The line is staked out, and the work has only to be commenced, everything being ready for the contractor. It is reported to be of unrivalled facility of construction, the nature of the ground being most favourable, and materials, labour, &c. very cheap.

The Spanish Government has just approved of the concession of the Ciudad-Real and Badajoz Railway granted to Don José Forus, with a subvention of ninety-seven millions reals vellon (about 970,000*l.*) in specie, or in state "obligations" for railways. The concessionist represents four banking houses, besides railway contractors and those for public works.

M. Salamanca, the well-known Spanish capitalist, has obtained the concession for the Albacete and Carthagna line. Before the works commence, the original surveys upon which the concession was based are to be checked by the engineers, and it is said that some important modifications will be introduced into the details.

The line from Seville to Jerez is announced ready for being opened for traffic this month.

It is considered that the Barcelona and Saragossa Railway will be in full working order in the course of the present year. In the first months of the year, 180 kilometres of the line—viz, from Manresa to Llerida—are to be opened. Platelayers are at work on many points of the line, and the necessary buildings, guard-houses, &c. are being run up. The Manresa station is nearly finished, and those of Terrega and Calaf are in a forward state.

The new line from Carthagna to Alicante has been set out by the engineers. It will have stations at Murcia, Oribecla, Callosa, Catral, and Elche.

The concession of the Tarragona and Barcelona railway has been granted to Don Magin de Grau.

The Pamplona and Tafalla line is to be opened next month.

PHOTOGRAPHIC SOCIETY'S EXHIBITION.

We have already said that the Exhibition of Photographs, now open in Pall Mall East, is a good one; but we must go a little into particulars. It consists of 586 frames, some containing several specimens, and is very varied in character. Copies of oil paintings seldom are successful, and we saw no exception to this rule in the present collection. Copies of drawings on the contrary usually are,—witness particularly those by Mr. Thurston Thompson, after Holbein and Raffiello. Mr. Roger Fenton in landscape retains his position: 130, "The Reed Deep, River Ribble," and 140, "Valley of the Ribble," are excellent specimens: Mr. James Mudd (20, "Durham Park"), Mr. Lyndon Smith (67, "View of Knaresborough"), and Mr. F. Bedford, compete worthily with him. "Pagan Rome" (476), "Christian Rome" (473), and "Rome" (484), are three remarkably fine photographs of the Eternal City, made by Mr. Lake Price expressly for the Art-Union of London. "Arcades from

Rome" (244), photographed for the Royal Commissioners, as suggestions for the works in the gardens at Kensington, is such an application of the art as we have before now urged. A frame of portraits near these (249), consisting of a well-known explorer and five female heads, was well christened, by a learned Theban in the room, "Layard puzzled which to choose;" and gains interest under its new title. Herbert Watkins, amongst others, has as usual some excellent male portraits; and the specimens of "Nature's Engraving," by Paul Pretsch, show an advance, but are not yet up to the mark.

THE SOUTHERN OUTLET SEWER.

We have already given an account of the works proposed to be executed in connection with the southern outlet sewer contract just let to Mr. Roland Brotherhood, of Chippenham, Wiltshire, but may add a few particulars.

It consists of a brick conduit or sewer 39,400 feet in length, of a clear internal diameter of 11 feet 6 inches; 5,000 feet of this length being in a tunnel under Woolwich: there are thirty-seven ventilating shafts, twenty-two side entrances, seven bell-mouth junctions, and sixty gullies. Its course we have already mentioned.

The work is to be completed in two years. The brickwork is intended to be of 18-inch work throughout, with the exception of the tunnel, which is to be 22½ inches; all in Portland cement.

Provision is made in the specification for the defraying of extra works that will arise in the course of constructing such a large work, of various items, the most important being a sum of 45,000*l.*, 100 rods of brickwork in cement, and the same quantity in mortar.

It is calculated that in this contract alone 36,000,000 bricks will be required, and where they are to be obtained from appeared to be a question amongst contractors tendering. Mr. Lualgette, as our readers know, is the engineer-in-chief, and Mr. John Grant is the resident engineer, on this particular work, and others on the south side of the Thames.

VAGUE SPECIFICATIONS AND WIDE ESTIMATES.

You occasionally astonish your readers by a comparison of the highest and lowest tenders for particular contracts. A notable instance occurred only last week, when a firm of high standing required 413,000*l.* for work that another equally respectable party undertook at 252,000*l.*

A recent number of your paper contained an interesting report of a lecture on the duties of architects, and informed us that a conscientious man would even specify the weight of the hinges for every door in a house, and the number of screws. This may be the theory: now for the practice.

Some months ago, the guardians of a large union in the country, wishing to enlarge the house, advertised for designs, and selected from a number one as most deserving the premium. Tenders were advertised for, under different trades, and a great many contractors took out quantities and tendered. The sum total of the lowest being very considerably (say 50 per cent.) above the architect's estimate, that gentleman, to use a Persian phrase, ate dirt, and retired from view. The contractors, being common fellows, were not even thanked for the trouble they had taken, but were allowed to gather the state of the case from the newspapers. Some time afterwards, the guardians again appeared, under new guidance, and contractors were again informed that they might estimate for a totally new arrangement; of course involving a repetition of the labour of taking out quantities. Being desirous of seeing the play out, I inspected the specification (?) of the engineer's work, and took notes of all the material points in it, which I send for the benefit of your readers. You will observe I have dropped the formality of office language, but in other respects the summary is a fair condensation of the original, and gives actual dimensions and quantities wherever they could be found to copy. Now, sir, I appeal to you whether you would be surprised, with no better materials than this to work upon, if one tender should be double or even three times the amount of another. Being myself a contractor, I cannot afford to offend the architect by calling the attention of his employers to the shortcomings of their adviser; and, were I foolish enough to do so, should probably be abused by all parties. However, the fact is patent. The specification is a public document,

and possibly this notice of it may induce people who talk of the recklessness of estimating to think that there is often something to be said on both sides of a story. A CONTRACTOR.

N.B.—I hesitated for some time between the *Builder* and *Punch*, but decided to appeal to you first.

**Workhouse.**—Supply two boilers complete, of a good size, for cooking and washing, heating dining-hall, and pumping water from a well the depth of which is unknown.

**Steam-engine.**—Provide a good sort of engine, as big as we are likely to want.

**Heating.**—Supply as much pipe as you like, to make the place comfortable.

**Pump.**—Supply a good kind of pump for a well of unknown depth: the size is not particular, but it must have "all necessary barrels," so that it may be worked either wholly by the engine, or wholly by manual labour, or by a little of both; and mind particularly that it must be so arranged and contrived that you can take it all to pieces, excepting the barrel actually at work, and put it together again without stopping anything. The pumps will be fixed on the surface, with about 40 feet of suction pipe down the well; but this is not particular, and will very likely be more; therefore, suppose we say at per foot.

**Cooking.**—Refix and remove the old cooking vessels, and supply new ones just the very same as the old ones.

**Range.**—Supply Flaxell's, or any other kind you have in stock. The size is immaterial.

**Pipes and Cocks.**—Supply everything under this head that we have omitted to specify.

**Washhouse.**—Remove and refix old boilers, and supply two new ones exactly like the old ones. Supply any wrought-iron tanks you think will be useful.

**Drying Closets.**—We intend to have two: the contractor is to fit them up and heat them.

**Painting Closets.**—The contractor to fit them up on any plan that he thinks a good one.

**Tanks.**—Supply two 700-gallon tanks, six 300-gallon, one 500-gallon; all of boiler plates, bolted together. Refix the present cocks, and supply any new ones and cocks that you think we shall require: we leave the sizes and arrangement entirely with the contractor, and hope he will do it nicely.

N.B.—On consideration he had better state how many tanks and trees there will be in the whole job, and about how much a piece, to enable the guardians to form a comparison between the different tenders.

Carpenters and masons' work, or work of any kind that we have omitted to describe, must, nevertheless, be provided all the same. It will naturally occur to contractors that all the boilers may require to be set in brickwork: the engine will want a foundation, and the tanks will require graders of some unknown length; many other things will arise during the progress of the job, and therefore something had better be put down for contingencies.

Finally, the contractor (s) is to keep everything in repair for twelve months, and to give a very full, clear, precise, definite, and detailed specification of everything that is necessary for the completion of the whole of the work, accompanying his tender with all the necessary drawings, so as to show most completely how everything ought to be done. This is sometimes done by the architect: but, being very troublesome, he hopes contractors will not mind it; and the fund of information the architect will obtain may also be of service to him as some future day.

Give a separate price for every item in the whole job.

**Ventilation.**—Provide some gratings,—probably a good many.

**Wagon-Engine.**—Provide a wagon-engine, and fix, complete, with masonry. Any size will do; but it had better weigh about three or four tons.

#### SHEERNESS DRAINAGE AND WATER SUPPLY.

THE Local Board of Health have resolved to carry out plans of drainage and water supply, by Mr. Burns, of Ely, who has been appointed engineer to the board. His success at Ely appears to have induced the Sheerness guardians to urge his merits upon the inhabitants and their sanitary representatives. A tidal plan of drainage, which had been on the  *tapis*, has been abandoned on consideration of Mr. Burns's plans, although the board had theretofore been tenacious in their approval of that plan. The board, before formally adopting Mr. Burns's plan of water supply, have to recede, as it is said, they have determined to do, their orders in which Messrs. Hirkenshaw & Conybeare's plans were accepted.

The local *Guardian* is of opinion that the hideous picture of the sanitary state of Sheerness, drawn by Mr. Austin in his report to the Privy Council, on application by certain of the residents, was perfectly correct and justifiable, and that it constituted "a righteous retribution on the board for past neglect,—especially on the members who sat previously to 1858."

A report by Mr. Burns on the sanitary condition of the town, and on its drainage and water supply, has been printed (*Guardian* office, Sheerness), in which he opens with a strong exordium against the past and present state of things, which must, indeed, be bad in the extreme, as it is stated, in this report, that, during his investigations, Mr. Burns had several times been made sick, and even to vomit, with the nefarious stench in the streets, and had been twice seized by diarrhoea from breathing the noxious vapours from stagnant cesspools.

In pressing on the board, in this report, the urgency of the case, he says:—

"The Lord instituted certain sanitary laws, for the purpose of maintaining the Israelites in good health, and He threatened them with the most severe judgments if they neglected the sanitary condition of their camp. (Deut. xxiii. 12, 13, 14.) The Lord commands, 'Thou shalt have a place without the camp, and thou shalt cover that which cometh from thee, that He see no unclean thing in thee, and turn away from thee.' This command makes no exception in favour of pounds, shillings, and pence. The expenses are never contemplated. The command is, 'Thou shalt not defile the camp.' Whatever it may cost to keep it clean, it must be done, or they must abide by the awful consequences. That command, to keep the camp clean, is, I conceive, as binding upon us of the present day as it was upon the Israelites of old.

I consider it a greater crime to poison the atmosphere which we breathe than to poison a public well; because, when the water of a public well is poisoned, the well can be shut up as soon as it is detected, and the public can go to another source for their supply; but, when the air is hourly poisoned by emanations from cesspools and privies, the people who live in the vicinity of these cesspools and privies cannot avoid breathing the poison, and thus destroying their health and lives; therefore Boards of Health, Town Councils, and Guardians of the Poor, and all others who are in authority, and who allow the atmosphere to be contaminated with fith of any description, are guilty of culpable neglect of duty."

The estimate of the cost of sewerage on the plan resolved upon includes 4,450*l.* as the total amount for sewers, and 2,200*l.* for a pumping establishment; total, 6,650*l.* annual working expenses, 202*l.* By an alternative plan the total cost would be 5,220*l.*, and the working expenses, 295*l.*

The cost of the waterworks, complete, "including well, tank to contain 633,315 gallons, two engines and pumps (duplicates), each capable of working up to 60-horse power when required, a set of twenty-four public baths, board-room, manager's and engine-men's houses, and about eight miles of public pipes with 150 hydrants, all completed in the best style of workmanship, and with the best materials (exclusive of the cost of site)," will be 11,700*l.*, and the annual working expenses, 450*l.*, which will be about 0*id.* per thousand gallons.

#### CARELESSNESS OF GOOD.

PERHAPS you may think the following paragraph, which I extract from Louis Figuier's scientific *feuilleton* in *La Presse*, not unworthy of a place in your miscellanea. P. D.

"We live in the midst of the ease and comfort of civilization, nearly as fishes live in water, that is to say, without taking any notice of the medium which surrounds us, and without explaining what kind of influence it exercises upon us. Science presses us on all sides; but its yoke is so light and gentle that we scarcely feel it. We travel by steam, we correspond by electricity, we are indebted to coals for light and warmth; in order to shelter and clothe ourselves, we lay contributions upon minerals, metals, and the lumberless materials furnished by vegetable life; and, nevertheless, most men are still ignorant of the true nature of the air which they breathe, of the water which they drink, of the food which they eat, of the different elements which serve to sustain their lives, to satisfy their desires, interests, or fancies."

#### JOB AND TASK WORK IN WOOLWICH DOCKYARD.

A PRELIMINARY meeting of the operative shipwrights employed in Woolwich Dockyard was held on the 18th, for the purpose of conferring on the grievances under which they labour, with especial reference to those arising out of the system of "Job and Task Work."

It is asserted that great injustice has been done by the mode adopted in the payment of the shipwrights, which is now, and has been for some time past, regulated on the "job and task work" principle. Under this system the work is measured, and the price to be paid for it fixed by a measurer; and there being no recognized scale of charges, the workman has no idea as to what amount of wages his work will produce. It not infrequently happens, therefore, according to the speakers, that he receives at one time, for the performance of a certain task, about half the amount of wages which, at another time, he obtains for the same work. The remuneration of the workman, in fact, constantly varies according as his work is estimated by different measurers, and one group may receive the full or more than the full amount of wage for the labour performed, while another—working perhaps on the same ship, and doing similar work and the same in quantity—is positively paid a much smaller sum.

By the statements of several of the men who spoke, it was shown that the rate of wages at

present paid at Woolwich Dockyard is barely sufficient for the support of a man with a wife and family.

"The system," the chairman observed, "seems to possess a most elastic property, as proved by the fact that, in the month of April last, he had earned 8*l.* 8*s.* for four weeks' labour, while, working at the same work, and the same number of hours a day, and performing the same amount of labour, his earnings for the four weeks of December only amounted to 5*l.* 5*s.* 6*d.*"

Several resolutions were passed unanimously, empowering the committee to make the position of the men known.

#### STATE ARSENAL, NEW YORK.

THE New State Arsenal, on the Seventh Avenue, at the corner of West 35th Street, in this city, is one of the largest military edifices in the State of New York. It is built of brick and stone, three stories high, the corners on the streets being finished with towers, which are made useful as well as ornamental. The building is about 190 feet long, and 82 feet wide, within the walls. The ground story is designed to be used for ordnance and cavalry equipments; the second story for a depository of small arms and infantry accoutrements; and the third story for a spacious drill-room.

The trusses originally adopted for supporting the roof proved insufficient in strength, and the roof fell, bringing with it the upper portion of the walls, and crushing down the floors. It has, therefore, been rebuilt, and a different form of truss adopted. The American *Architect's Journal* gives an illustration of it. The span is considerable, and the peculiar uses of the upper story, as a drill-room, required that the roof should be self-supporting. The following are the scantlings of timber:—

	Feet.	Feet.
Tie beam .....	12 by 10 length 85.	
In two lengths, each .....	" " "	27 6 ins.
Collar-beam .....	12 " 8 "	" "
Queen-posts .....	11 by 12 " 8 "	16 "
Principal rafters .....	10 " 8 "	43 "
Auxiliary rafters .....	10 " 8 "	20 "
Braces .....	8 " 8 "	13 "
Small braces .....	8 " 8 "	7 8 "
Foot to upper braces .....	8 " 8 "	3 6 Oak.
Corbels .....	12 " 10 "	7 0 "
Wall plate .....	12 " 6 "	" "
Purlins .....	10 " 6 "	" "
Hips .....	11 " 4 "	18 "
Common rafters .....	6 " 3 "	48 6 "

Each truss has five tie-bolts from the principal rafter to the tie-beam of iron, 1 inch 6-8ths in diameter. In the middle of the span, the tie from collar to tie-beam consists of two tie-bolts each of 7-8ths inch diameter. The scarp in the tie-beam is 10 feet long, in three strips: it has three cogs, and is strongly secured by ten screw bolts of 7-8ths iron passing through broad iron plates 11 feet long on the top and bottom of the beam. The corbels are fastened to the tie-beam by two screw bolts; and a stout iron strap confines the toes of the principal and auxiliary rafters to the ends of the beam and the corbels.

#### ARCHITECTS' CHARGE BY COMMISSION.

COMMENTING on some observations made recently at the Institute of Architects, Mr. John Bull Gardner, who, though he has withdrawn from active duties, keeps an eye on the profession, writes as follows:—

"Elmes, with my assistance as to the introductory matter—which he was perfectly welcome to ask for—printed in his 'Annals of the Fine Arts' a true and faithful account of the often-quoted case 'Chapman v. De Tastet.' Now, whoever may read such introductory matter would see readily that in sober truth and reality the cause might have been handed down as 'Gardiner v. De Tastet.'—my late respectable and well-known uncle Chapman had really nothing practically to do with this individual matter.

In this our so noted case, the verdict was for 5 per cent. on the amount, with a small exception amongst the artificers' bills. Almost all the various works were done by separate tradesmen in their respective departments. The carpenter brought his action against De Tastet; so did the plasterer;—each of them obtained a verdict in the Sheriff's Court (judgment having in each case gone against the defendant by default), and both obtained their money. After this, De Tastet paid all the others; and this being accomplished, we then brought our action, and obtained, before the late Lord Ellenborough, a verdict of 5 per cent. on, save as aforesaid a small exception, the collected amount of what had been, on our part, so paid to the artificers. We had to

put every one of them (at last three at a time) into the witness-box; and we had respectable witnesses, since dead, of our profession, to speak to usage and custom. The defendant dared not bring a single witness to confront ours.

Who were our counsel I really nor forget, but De Tastet's lawyer (the late notorious Jimmy Lowe, of Southampton-buildings) had Scarlett (before, of course, he became Lord Abinger), and his son-in-law, Campbell (before also, of course, he many years afterwards became Lord Campbell).

The said exceptional item was this:—It appeared to me judicious to introduce in one of the country-houses or offices a descending stove,—an article not then universal,—one of Moser & Co.'s patent affairs. I, of course, had not only to make attendances at Frith-street, but also to confer with Moser's people at my office and at the works, in reference to this matter. Their bill for it amounted to 40*l*.

The verdict passed at 2*l*. less than the sum which, founded on a 5*l*. per cent. commission, had been sued for.

A Fishing Bill in Chancery was immediately put forward, under the auspices of the said Jimmy Lowe, as in bar against the verdict sued; and it put me every now and then into gidgets, *i.e.*, at the several stages of it, during thirteen years. The amount was then settled. We received it, minus 50*l*., through our respectable and truly conscientious solicitor; and De Tastet had paid, before the verdict sum, not less, certainly, than 400*l*. to his said confidential adviser."

THE DUBLIN WATERWORKS.

This discussion appears to have arrived at a climax for decision. For the necessity that exists of an additional supply of pure and wholesome water in the city of Dublin we might refer to many proofs. However, until comparatively recently (*viz.*, February, 1859), the project, which has now assumed a tangible shape, was not brought forward, and even at that time was condemned by its present promoters; not on account of its infeasibility, but from economical views; it being expected that as pure and abundant a supply, at much less expense, was obtainable conjointly from the canals, *viz.*, the Grand and Royal. The particulars of this scheme are briefly as follows: to place a weir across the river Liffey, at Coyford, in Blessington, County of Wicklow, and thence, through a reservoir in the vicinity, to conduct the water by a necessary aqueduct, conduit, or pipe, laid along the shortest practicable route to another reservoir at Templeogue, in the parish of Tallaght, county of Dublin (south side), and thence to the several parishes of the city by service mains. The sub-committee, to whom the corporation have confided the carrying out of this scheme, consists of three members,—Dr. Gray, J.P.T.C.; Mr. Francis Codd, J.P.E.C.; and Alderman Kinahan, J.P., each of whom has devoted much time and labour to the task.

THE STRIKE.

ACCORDING to the statement made at the weekly meeting of delegates held on Tuesday evening last, 2,300 skilled workmen are still out of work, and last week, the twenty-sixth of this unhappy struggle, they received a dividend of 4*s*. each. Who shall tell of the privations and distress that have been endured?

On the 11th instant a crowded meeting of the trades was held in St. Martin's Hall, Long-acre, to protest against the enforcement of the document. Mr. Ayrton, M.P., took the chair, and made a long address, after which, resolutions moved and seconded by Messrs. Potter, Macintosh, Dunning, and Arnot were unanimously adopted.

The "Conference" has issued a new appeal to the working classes, signed by their secretary, calling for further support to enable the men on strike to continue their resistance to the "document."

THE METROPOLITAN RAILWAY.

THIS railway appears at last to be fairly started; and the works, we are told, are to be forthwith vigorously proceeded with. The western portion, from Paddington to Euston-square, are contracted for by Messrs. Smith & Knight; and the eastern portion, from Euston-square to Victoria-street, City, by Mr. John Jay. The route will be from the Great Western Railway Station at Paddington along South Wharf-road, Praed-street, Marylebone-road, Euston-road, Bagnigey Wells-road, to Victoria-street, near the foot of Holborn-hill. There will be a branch in connec-

tion with the Great Northern Railway at King's-cross. The railway, nearly throughout, will be in a tunnel, the crown of which will be just under the surface of the present roads. Besides terminus stations at Praed-street and Victoria-street, there will be numerous intermediate stations along the route for the accommodation of passengers. The first essential work to be done of course is to provide for the necessary drainage of the railway and of the sewers intersected by it. For this purpose Messrs. Smith & Knight, the contractors before mentioned, have begun a new main sewer in Conduit-street, Paddington, which will be continued across Westbourne-terrace, and along Praed-street and South Wharf Road, to the Edgeware-road, at a depth of 30 feet below the surface. We understand that the workmen in Conduit-street have already laid bare an interesting relic of the past,—no less than the foundation of the famous old conduit that formerly supplied a portion of the City with the sparkling spring-water which abounded in the extensive bed of gravel and sand about Paddington.

WHO LOOKS TO THE METROPOLITAN SEWERS WORK?

I THINK the little (and very long) job in Park-road, St. John's-wood, deserves a remark. Much has been said about the difficulty of enlarging the sewer over the bridge; but why not have divided it into two by iron pipes, there being only about 7 feet from the crown of the arch to the surface of the road, instead of the startling piece of brickwork it is now being finished with? This consisting of two-arched courses of 4-inch work in Portland cement and sand, within about twelve inches of the surface of the road, filled over with loose granite rubbish, and with nothing in the way of an abutment.

A short time since a railway waggon sank down about 2 feet in North Park, several weeks after the road had been "made good" by the parish, and two teams were required to draw it out. Something worse will probably happen in Park-road, and the fault will, of course, be laid on "the weather."

Q.

The Sewer in the Fulham-road.—Several correspondents complain, and with justice, of the time during which their houses have been blocked by the works now being executed by Walker & Neave in enlarging, by tunnelling, the existing sewer. The road opposite one house that we have in our eye has been enclosed more than a month, being used for some weeks as a material store. It is time some one walked down from Greek-street, and looked into the matter. The nuisance is insufferable.

NEW CHURCHES AND SCHOOLS IN AMERICA.

THE Church of St. Joseph, Albany, New York, is nearly completed, and is said to be a good specimen of ecclesiastical architecture. Interiorly it has marble columns, a "sparkling roof," oilen wainscoting, stained glass windows, and the spaces between each are filled in with bas-reliefs representing "The Stations," and executed in Munich.

An Irish church has been built at Lafayette, Illinois, and is one of the largest in the city. In the same town the old county seminary property has been purchased for 4,900 dollars for church and school purposes. A female school, under the direction of the Sisters of Providence, will be built, together with a church, 160 feet by 65 feet, early in spring.

The new church at Weymouth, diocese of Boston, has been dedicated and opened for Divine service. It is 86 feet by 45 feet, and contains sittings for 500 persons. There are a chapel, vestry, and two upper rooms behind the altar, besides a gallery for singers over the western entrance. It was built by Mr. Butler, of South Boston.

A new German church has been dedicated at Poughkeepsie, New York diocese; also another (St. Patrick's) at Rosae's Point, diocese of Albany. The Roman Catholics of Camden have built a commodious edifice at the corner of Fifth-street and Taylor's Avenue.

"METROPOLITAN BUILDING COMPANY."—A general meeting of working men has been convened for this Thursday, 26th, at the Eclectic Hall, 17, Denmark-street, near St. Giles's Church, to establish a company to undertake building works and contracts. Mr. J. C. Arnand is secretary, *pro tem*.

STAINED GLASS.

Lincoln Cathedral.—In October last, the Rev. Augustus Stutton, and Mr. H. F. Sutton, commenced to place stained glass in the large window over the west entrance of this cathedral. The lower part of the window, which is in the Perpendicular style, is divided into five compartments, and the head of the window into eight; all the quatrefoils and cusps of the latter were filled in at that time. The upper centre compartment of the lower part of the window was filled in with the figure of King David, under a Gothic canopy, with a crown on his head, a sceptre in his right hand, and the orb and cross in his left; and as the Messrs. Sutton had not at that time prepared any further figures, the window remained in an incomplete state. Since that day, however, these gentlemen have been engaged in filling up the remaining portion of the centre compartments of the window with four figures of kings of Judah, representing Jehoshaphat and Josiah on the north side of David, and Hezekiah and Asa on the south side. The lower centre compartment has been filled in with a demi-figure representing Melchisedek, and four other figures of prophets will be placed in the remainder of the compartments before Easter. The reason demi-figures are being placed in the lower compartments is because the screen, which was put up some years ago to save the towers, blocks up the lower part of the window. This is the eighth window placed in the cathedral by Messrs. Sutton.

St. Blazey Church, Cornwall.—A stained-glass window has been placed in the north aisle of the parish church of St. Blazey, in memory of Major-general Edward Carlyon, and also of Anna Maria, his wife. The window is of three lights, with tracery above. The figures chosen are Faith, Hope, and Charity. These are placed under canopies; and at the foot of each figure is an angel bearing scrolls, with a Scripture text. The head of the window consists of two angels under canopies, each holding a Scripture text. The upper spandril is a device of Faith, Hope, and Love, represented with the anchor, cross, and heart entwined. The smaller spandrils are filled with ornament. At the base of the window is the inscription. The window is of the Perpendicular style of architecture, and has been executed by Mr. Charles Gibbs, of Marylebone-road, London.

CHURCH-BUILDING NEWS.

Winchester.—The restoration of the west front of the cathedral is progressing. The termination<sup>s</sup> of the north and south aisles are already completed, the former by Mr. S. Newman, and the latter by Mr. H. J. Gillingham. Mr. Newman is now engaged upon the central portion of the façade, which is accessible by a lofty system of scaffolding and stages. The work, which is carried on under the supervision of the architect, Mr. J. Colson, will occupy some months in its execution. —A new font is about to be placed in the church of St. Lawrence, in this city, through the liberality of the rector. The font, which is formed of Caen stone, is octagonal in shape, and partakes of the Perpendicular style in its mouldings and decorations. The sculptor was Mr. S. Newman.

Charlton (Devon).—A sepulchral cross, from the stationery yard of Mr. Thomas Lidsting, of Dartmouth, has been set up in Charlton churchyard, near Kingsbridge. It is made of Forest of Dean stone, and stands altogether fully 6 feet high. It is a pity there is not more regard paid to the designs for things of this kind, and for memorials in stone generally. The fault lies with the statuary themselves.

Worcester.—The Watermen's Church, intended, says the local Herald, as a memorial of the late Rev. John Davies, now approaches completion. The building is constructed of wood, with an outer casing of corrugated iron. The structure is in form an oblong room, with a recess at the east end for a chancel. The roof is pointed, having iron rods for girders and ties. Interiorly the walls are covered with canvas, strained tightly, to hide the shrinking of the boards, and the roof is protected with felt between the wood and iron. There is an entrance at each end of the south side, and a little vestry has been provided north of the chancel. In the side walls are two-light pointed windows, at the west end two long and two short lancets, and three lancets in the east window,—all the windows being edged with blue and red glass alternately. Local critics, with some reason, condemn such a "memorial" church.

Pershore.—Considerable alterations and improvements have lately been made at Wick Church, and an increase of accommodation, espe-

cially for the poorer classes, has been thereby afforded. The church, which is of the Early English style, is situated near to Pershore, and in a numerously populated district. The additions which have been made consist of a new aisle and gallery, and partial reworking of the whole edifice, according to the design of Mr. Whitfield Dawkes, the architect engaged in carrying out the improvements at Lord Ward's, whose services at Wick, it is stated, have been rendered almost gratuitously. The builders who have been employed are all tradesmen of Pershore, viz., Messrs. C. Coombe, John Nicholas, and J. Osborne and Son. There are four windows, with stone mullions, in the new aisle, one at the east end, another at the west, and two at the north side. There is likewise a porch at the entrance.

**Manchester.**—St. Peter's Church, Oldham-road, Manchester, has been consecrated. It is a district church, says the local *Advertiser*, and situated in Blossom-street. The church is from designs by Messrs. Holden & Son, architects, Manchester, and is built of brick, the style of architecture being Lombardic. Its distinguishing characteristic is the absence of anything like decorative stonework, the harmony of its parts being dependant entirely on the distribution of red and white bricks used in its construction. The building comprises nave, side aisles, gallery (extending along the aisles and across the west end), a semi-circular apse at the east end, and a lofty tower at the north-west angle. The extreme external length is 120 feet, and the breadth 66 feet. The tower is in three stages, the upper portion being formed of a truncated spire, covered with green and red slates. The height of the tower is 125 feet. The interior, which will seat 1,350 persons (500 free), is divided by two rows of ornamental cast-iron columns, supporting the clerestory arches, which are formed, like the other arches, of white brick. The roof of the nave, which is panelled, is divided into bays by semi-circular wood ribs. The ornamental ends of the benches are of cast iron. The organ is placed in the gallery, at the west end, over which there is a wheel window. The total cost of the structure, including the furniture, heating apparatus, lighting, and bells, is about 4,200*l.*, or 3*l.* 3*s.* per sitting. The general contractors were Messrs. Clark & Jones; and the contractors for the brickwork, Messrs. Rutherford & Lamb.

**Jarrow.**—It is proposed to enlarge and restore Jarro church, according to the *Shields Gazette*. As it at present stands it is of very different ages. The nave is considered an unsuitable addition, from its style or rather want of style, apparently built in the beginning of this century. This it is proposed entirely to remove, and instead to build a nave with a narrow south aisle, and a broad gabled aisle on the north. The tower was at one time claimed as Saxon, but is not now considered earlier than Norman times. At various dates new windows have been inserted in the chancel, and in perpendicular times a flat lead roof has been substituted for the high pitched one, whose mark still remains on the tower. These old parts of the tower, and the chancel, it is not intended to alter, except what slight repairs are necessary for their stability. Mr. Scott, the architect, has been applied to, and has furnished plans for the alterations. By his recommendation the tower and chancel should remain in their present state; while, for the present nave, he proposes to substitute another with a narrow side aisle on the south,—the old monastery buildings not permitting more; and a broad gabled aisle on the north. For the new nave he has chosen the earliest style of Pointed Gothic, while it is yet in its transition from the round-arched Norman, and while it retains many features in harmony with the Norman tower, its pointed arches giving it a relationship with the latter Gothic insertions in the chancel. The new nave is solid and quiet, but full of character. This work has been delayed for years, solely on account of want of funds. The congregation are mostly poor. The restoration of the church of the Venerable Bede, however, should be of more than parochial interest.

#### COMPETITIONS.

**Kersall Moor, Manchester.**—In a limited competition for schools connected with St. Paul's Church, Kersall Moor, near Manchester, the plans of Mr. William Walker were selected by the committee, and the architect is commissioned to carry out the works immediately.

**Croydon.**—The *New Cemetery Buildings*.—Last week, at the meeting of the local board, several architects were proposed to prepare plans or designs of the projected chapels, lodge, &c., to be

built on the new burial-ground lately purchased of the trustees of the Banahm Estate at Broadgreen. In accordance with a resolution passed at the last board, the number of candidates to be nominated was restricted to twelve: the following were therefore proposed.—Mr. Woodcock, proposed by Mr. Bean; Mr. Gough, by Mr. Rigby; Mr. Carter, by Mr. Swinburne; Mr. Nullens, by Mr. Crowley; Mr. Davidson, by Mr. Drummond (the chairman); Mr. Cross, by Mr. Sutherland; Messrs. Morpew & Green, by Mr. Parley; Mr. Robius, by Mr. Castledine; Mr. Berney, by Mr. Close; and Mr. Scott, by Mr. Crafton. The board agreed that each candidate should adopt some motto to his own design, and the successful competitor should receive twenty guineas, and a commission of 5 per cent. upon the outlay, which was to be limited to 1,000*l.*; the second best to receive a premium of twenty guineas, and the third ten guineas. Other gentlemen, including several of those proposed above, were then nominated to furnish plans for the laying out of the cemetery; and the designer whose plan should be chosen was to be remunerated by a premium of twenty guineas, with a commission of 5 per cent. on the outlay; while the second was to be paid ten guineas.

**Kinlock Monument.**—At a recent meeting of the subscribers held for the purpose of selecting a design for the above monument, according to *Dundee Warder*, Mr. Thomas Wighton moved, "That a selection be only made on the express condition that the plans selected can be executed by a competent tradesman for a sum not exceeding 400*l.*, and that offers to that effect, and with such security as the committee may think proper, be in possession of the committee before the selection be considered final." The motion was seconded by Mr. McDonald. There were twenty-five designs and two models shown, fourteen of which were not voted for; and, on the motion of Mr. T. Wighton, No. 24 was put aside, in consequence of its being too costly. Nos. 10, 12, 15, 23, and 31, a model were voted for again, they having obtained the highest number of votes. Out of these, No. 12 was unanimously selected by the meeting. The designer's letter was opened and read, from which it appeared that Mr. James M'Laren, architect, Dundee, was the successful competitor.

**Bishop Stortford High School.**—The trustees have selected the design submitted by Mr. Murray for their new buildings.

**The Hartley Institute at Southampton.**—Professor Donaldson has been appointed, by the corporation of the borough, to select a design for the building of the Hartley Institute from among forty-seven which have been sent in from all parts of the country. The whole of them, by arrangement, provide a great hall to accommodate 2,000 persons, for lectures, concerts, and other public purposes. It will be recalled that Mr. J. H. Hartley, a former resident at Southampton, left 100,000*l.* for the promotion of literary and scientific pursuits in that town, 60,000*l.* of which were spent in Chancery and in arrangements with the claimants of his family, leaving still the princely sum of 40,000*l.* for carrying out the purposes named in the testator's will.

#### "SO MUCH FOR BUCKINGHAM" PALACE.

SIR.—Such are the words of *Punch*, who, joking, says, sad havoc is being made with the façade, and that it is desirable a new face should be put on this stucco abomination, as it has been an eyesore long enough. Now, *Punch* is wrong in terming it a stucco abomination, for it is stone.\* One contemporary says, soon after the erection of the new façade, the stone was protected by many coats of paint, and the process of decay goes on. The *Times* of June, 1855, says, 2,000*l.* were expended in repairing and painting the stonework of the new façade. So much for stone. Now for stucco abominations. I know innumerable cemented façades or buildings that are unaffected by weather, after twenty or thirty years; and, with the excellent cements we now have, it can be and is in some instances executed to endure as long as any building stone, though of course much is very badly done for cheapness, and frequently by inexperienced or careless workmen, of which there are plenty. Sometimes the cause is that the work is under a clerk of works, or a master who is by trade a joiner or painter, and the workmen are guided by his notions of how it should be done. The proportion of sand is an important part, for the best cements require two or three

\* It was, nevertheless, to a considerable extent faced with cement.

parts of sand to one of cement, which makes it more troublesome and expensive to use, and too little sand is a very frequent cause of failure: hence the abomination, or, at least, the cements that get hard enough to form earl-horse stable floors, it need not become an abomination.

JAS. PULHAM.

#### THE SPURGEON CHAPEL COMPETITION.

SIR.—You have often directed attention to the great unfairness usually displayed both by committees and architects in reference to competition designs; and, unfortunately, it is so general that any additional fact scarcely needed to render it more glaring. However, that to which I am about to allude is so gross, I really think you should, by a circulation of the statement, try to awaken a condemnation in the public mind of so flagrant a departure from the principles of right.

It is respecting the "New Tabernacle" for the congregation of the Rev. G. H. Spurgeon that I pen these few lines. It will be, I doubt not, in the recollection of many of my professional brethren, that the committee distinctly stated that the cost of the building was to be limited to about 10,000*l.*

This induced several who sent in designs, myself among the number, to so arrange them that they could be executed for any practical price exceeding a few hundred pounds of the same. It was, however, very manifest, on the exhibition of the drawings, that a large proportion of the designs could not be carried out for anything like the sum proposed.

Well, the committee fixed on a design, the cost of which was stated by its author as 15,450*l.*, although I am certain that any practical price looking at the same would have said it was self-evident it could not be erected for some thousands beyond that figure. The result has been that this idea was quite correct; for, at a meeting of the friends of the undertaking, held for the purpose, it was stated that the total amount required for building and ground would be 30,000*l.*; and as the latter cost something under 7,000*l.*, it follows that the building is to be about 23,000*l.* I must say I think such treatment is enough to prevent any respectable architect entering on a competition; for, either he must be disingenuous enough to profess to get a design exceeding a sum which he must know to be erroneous, or submit to find he has pursued the more honourable course of sipping his design in accordance with the instructions given, that he has passed by in favour of a person less scrupulous.

MSA GORDIA FIDES.  
\* We have submitted the foregoing to the architect, and submit his reply:—

If your correspondent looks to your columns he will find the lowest tender was 18,800*l.* which, adding 5,000*l.* for the cost of foundations, and 600*l.* for heating, gives 24,400*l.* instead of 23,000*l.* as the cost. Then, the Tabernacle is 10 feet wide wider than designed, i. e. 30 feet instead of 20 feet; and the ceiling is 10 feet higher, 91,000 cubic feet more than in the design. In fact, the building, as designed, if taken at the same price per foot cube as the lowest tender, would have come to 27,700*l.* instead of 19,800*l.* which I consider moderately near to 16,450*l.* for a competition estimate.

But the building tendered for was worth more per foot cube than the design, for the whole of the walls of the interior were to be match-boarded instead of plastered, open iron gallery fronts substituted for deal framing, the ironwork gilt, the paving made more expensive, an extensive allowance for sundry omissions, added, as I estimate them, 1,500*l.* to the amounts of the tenders.

Lastly, materials and labour were both higher in July than January; the work alone was worth 200*l.* more than when I made my estimate.

W. W. POCOCK.

#### DECISIONS UNDER THE METROPOLITAN BUILDING ACT.

A CASE some time under investigation, in hearing and consideration, has been settled by Mr. Bingham, at the Marlborough-street Police-court, under the Metropolitan Building Act, 18 & 19 Vict., c. 122, and excited considerable interest.

The defendants were Messrs. Loible and Sonnhammer, the lessees of the London Pavilion, a building in Tieborne-street, Haymarket, which, with its appurtenances, has been recently opened for public amusements of a somewhat varied character; for, besides being a concert-room and *café*, it is a bowling-alley and shooting gallery, and the summons, taken out at the instance of Mr. Mayhew, district surveyor for the parish of St. James, sets forth in effect that the defendants had neglected, after expiration of the term of notice according to the Act, to cause certain alterations, in and about the building in question, to be made, to render the same fire-proof, for its own and the safety of contiguous premises, and to make the same stronger in parts the better to support any large number of visitors assembled.

Mr. W. Donaldson, solicitor, attended in support of the summons; whilst Mr. M'Namara, as counsel, instructed by Messrs. Paul & Co., of New Inn, appeared for the defendants, and Mr. Edward Lewis, of Marlborough-street, watched over the interests of the builder, Mr. Honore.

A question arose as to the builder; and Mr. M'Namara said his clients would, irrespective of Mr. Honore, the builder, abide the issue of the case.

Mr. Mayhew, the district surveyor, then stated,

in categorical order, the alterations which he required in the premises, which, by previous pulling down and re-erections to make the place what it is, had, within the meaning of the statute, it was contended, become a new building; for the 10th section lays it down that, "Whenever any old building has been taken down to the extent exceeding one-half of such building, such half to be measured in cubic feet, the rebuilding thereof shall be deemed to be the erection of a new building, and every part of such old building that is not in conformity with the regulations of this Act shall be forthwith taken down." In the present case, Mr. Mayhew said, it could be proved that considerably more than half the old fabric had been taken down.

Mr. McNamara said that to do what was required by the district surveyor would be to rebuild the structure altogether, which would be seriously interfering with ancient and vested rights and interests. The Act under consideration is to apply to new buildings, and he contended that the one in question had not been made so: it was still the old premises, with just sufficient alterations to adapt it for new purposes, and these were not one-tenth part of the whole, whilst the Act specified in clear and direct terms that half should be altered before it could be construed as a new building, and his worship had opportunity of proof of this in personal inspection. In the Loudon Pavilion place of amusement there were no galleries, the piano was on the ground-floor, where a few singers attended, under engagement, simply for the amusement of visitors to the café.

Mr. Bingham, in delivering judgment, said.—The defendants took an old coach-house and stables in Titchbourne-street, painted the walls, covered an intervening court-yard with a glass roof, obtained a license to sell beer by retail on the premises, and converted the whole into a large apartment, or coffee-room, for the sale of refreshments: with a view to enticing customers they added the attractions of a musical performance, a skittle-alley, and a rifle-gallery. The district surveyor, considering the premises occupied for such purposes to be a building within the meaning of the 30th section of the Building Act, 18 & 19 Vict., c. 122, summoned the defendants to this court for not having made certain portions of it fire-proof, or sufficiently separated by party-walls from adjoining occupancies, as required by that Act. He also contended that what had been done was such an alteration of the old building as brought it within the regulation applied by the Building Act to new buildings, whether public or not.—(See sec. 7.) It is difficult to draw a precise line between what shall be deemed a public and what a private building, within the meaning of the Act. A theatre, a church, a school, or any edifice which people are likely to frequent in great numbers at one time, such as a public ball-room or concert-room, would seem to be the objects contemplated under the words "public building" in the 30th section; but the application of the term in each particular instance must depend on the use to which the structure is applied. Here, the principal object of the defendants' occupation is the sale of refreshments: the music, skittles, and rifles are merely accessories to lead to the consumption of viands and liquors; and the apartment is no more a public building, within the meaning of the 30th section, than Evans's Rooms, or any other beer-shop or public-house where people assemble to drink beer and listen to jocular singing. Then, with respect to the alterations, which are said to be such as to bring the premises within the provision of the 7th section. After a careful inspection of them, I find there has been much superficial decoration, but no material structural alteration. There has been an addition of a glass roof over the open court; but that is admitted to be in conformity with the Act; and, therefore, my judgment must be for the defendants.

The real question appears to have been whether a building existing before the Act, and used as a public building afterwards, must be altered when works are being done on it to make its construction such as the district surveyor approves. In this case a decision was given avoiding the question, the magistrate holding that a place like the Loudon Pavilion was not a public concert-room within the meaning of the Act, as music was incidental to the sale of refreshments. It is difficult to reconcile the statements of the district surveyor and the magistrate as to the extent of works done.

SOUTH KENSINGTON MUSEUM.—During the week ending 21st January, 1860, the visitors have been in number 12,248.

Books Received.

Some of my Bush Friends in Tasmania. By LOUISA ANNE MEREDITH. London: Day & Son, Gate-street. 1860.

In this *livre de luxe* Mrs. Meredith, formerly Miss Twamley, depicts from life the flowers, berries, and insects of Tasmania, and accompanies them with some graceful compositions in verse. Although the greater number of the flowers there are new to an English visitor, members of many of the Old World families are found amongst them, and must gladden the eyes of the immigrant, and fill the mind with recollections.

Some will be surprised at not finding the flowers of a richer character than is presented here; but then, on the other hand, they will learn, contrary to an equally well-received opinion, that many of them have sweet scents.

This is an elegant specimen of Messrs. Day's skill in lithography and colour printing. Plate 4, the Waratah and native Arbutus, and Plate 7, the Tea-tree and Epacris, will serve as proofs. We can cordially recommend the book for the drawing-room table.

Gog and Magog: the Giants in Guildhall; their real and legendary history; with an Account of other Civic Giants, at Home and Abroad. By B. W. FAIRHOLT, F.S.A., Hon. M. of Societies of Antiquaries of Normandy, Picardy, and Poitiers. With Illustrations by the Author. London: J. C. Hotten, Piccadilly. 1859.

THE history of the legendary and civic giants is a subject of curious interest, and no one is better able than Mr. Fairholt to turn out a pleasant little book upon it, such as this is. Mr. Fairholt is an antiquary and draughtsman of distinguished ability, whom many of our oldest readers will remember as an occasional contributor to our columns.

The scope and purpose of Mr. Fairholt's present volume may best be given by a quotation from his own pages:—

"The popular love of giants led the municipalities of many cities in Flanders and Belgium to provide figures of the kind for grand fete days. Thus Antwerp, Louvain, Malines, Asselt, Brussels, Ath, Ghent, Bruges, Tournay, Lille, Dunkirk, Ypres, Poperingue, Cassel, Douai, &c., have each their communal giant, which, upon certain days, is carried about these towns. They are constructed in various styles, and habited in still more varied costumes, ranging from the Roman (as at Antwerp) to the court dress of the last century (as at Brussels). Sometimes they are formed of osier, as at Cassel, Hazebrouck, and Asselt; sometimes of elaborate wood-carving of a fine and expensive kind, as at Antwerp.

In directing attention, therefore, to the carved figures which so strikingly decorate the old Guildhall of London, it will be necessary to carry our researches far beyond the comparatively recent period at which they were fabricated; to look a little at the guild observances of the great commercial trading towns, as well as to take a retrospective glance at the once-popular fabulous history of the early foundation of London."

He has carried out his purpose very well, and the result is both amusing and instructive. The foreign giants have never before been brought together.

Miscellanea.

EARTH-BORING.—At Forbach, a shaft was bored by Kind, a few years ago, of a diameter of 14 feet, to a depth of 100 yards, by means of chisels fixed on iron arms, worked by a 12-horse power engine. At the Paris Exhibition, in 1855, M. Mulot exhibited a boring-cutting for a similar operation. At Rthort, in Westphalia, a short time since, a shaft was in course of boring of the diameter of 20 feet.—*Mining Journal*.

INAUGURATION OF THE CLIVE MONUMENT AT SHREWSBURY.—A grand demonstration took place at Shrewsbury, on Wednesday in last week, on the occasion of the inauguration of the statue erected in the Market-square to the memory of the great Lord Clive. The statue is of bronze, by Baron Marochetti, about 10 feet high, and stands upon a pedestal of Portland granite. The design of erecting this monument originated at a meeting held at Willis's Rooms, London, two years ago, on the anniversary of the victory of Plassey. The statue cost 2,000 guineas. A grand procession took place to the foot of the statue, a great many of the aristocracy of the district being in attendance. Earl Stanhope, on behalf of the subscribers, presented the statue to the mayor and corporation of Shrewsbury. The company afterwards adjourned to partake of a banquet at the Lion Hotel, to which they were invited by the mayor. The statue stood in Whitehall for some time previously.

GLASGOW ARCHITECTURAL SOCIETY.—The monthly meeting of this society was held on Monday, 16th inst., in the Scottish Exhibition-rooms, Bath-street. Mr. Salmon occupied the chair. After the reading of the minutes, and nomination of several new members, M. C. Bowie read a paper on "House Painting, its Means and Results." After comments by several members, a vote of thanks was awarded to Mr. Bowie.

LABOUR IN AUSTRALIA.—The *Melbourne Argus*, speaking of Victoria, says,—“We are in the midst of a renewed and more widely-spread struggle between the workmen and employers for the extension of the eight-hours system, and for other and perhaps more immediate advantages to the former. Men of different trades are out on strike for the eight hours in its integrity. The masses on the northern line of railway determined to leave their work unless Messrs. Coruish & Bruce would discharge all masons who did not belong to the union of their trade; and, as this demand was not complied with, they are out on strike too; and the bricklayers on some portions of the same works are out on strike for an advance of wages to the extent of 2s. a day. Tradesmen are still hanging about town in considerable numbers, complaining that they cannot obtain anything to do, and yet men who have employment throw it up thus foolishly in the hope of compelling masters to accept the very unreasonable terms dictated by the agitators at head-quarters, who are mostly men with other means of living than by the trades to which they nominally belong. The bad feeling against the contractors has been increased by the importation of masons and labourers from Germany under engagement at lower rates of wages than are current here, and the renewed agitation of the eight-hours question has been fostered and extended by the lately-formed Eight-Hours-Labour League.”

PORTLAND HARBOUR.—Once a Week contains a pleasant paper on the harbour of refuge at Portland. We take a paragraph: “The first object of the engineers here has been to construct a rubble bank; and with this view a temporary staging carried on piles into the water is erected in the following manner. A pile is loaded heavily and sunk into the blue waves; its lower end is shod with a large cast-iron screw, while its top is fitted with a cap, having long radiating arms of wood. The ends of these arms are notched, to carry a strong rope coiled round them, one end of which passes to the shore. The arms thus form a kind of large skeleton reel, or drum, wound about with a rope, the loose end of which is then hauled up by powerful machinery; and the pile steadied by guys, being thus made to revolve, slowly screws its way down into the solid earth, becoming firmer and firmer with each revolution. One row of piles is thus fixed, and another parallel row at thirty feet distance from the first is also screwed into the soil. Upon these as a foundation, longitudinal timbers are laid, and on the timbers a strong platform erected. We have thus progressed thirty feet into the sea, and the bauling machinery is now worked from the staging thus formed over the spot where the blue water gurgled uninvaded yesterday. Another row of piles at thirty feet distance from the last is now screwed in, and another thirty feet won from the water. Simply told, this is all that is requisite to carry out the wooden staging far into the sea. Of the practical difficulties involved in the work we say nothing here: that they are often considerable will be easily inferred, when we remember the great depth of water in which many of these piles are screwed, and the immense weight and size of the piles themselves. Strictly speaking there are now two separate breakwaters being constructed at Portland, the first running due east from the shore for about 1,800 feet; and an outer or main breakwater, which is to be about 6,000 feet long, separated from the first by an opening 400 feet in width, and sweeping in a circular curve away to the north-east. The first of these, now nearly completed, is not only a sea wall, but a landing and coaling stage for large vessels as well; while the outer or main breakwater is at present nothing more than a line of rubble stonework rising above the sea.

“THE LADS WITH THEIR APRONS ON.”—A reverend correspondent sends us a version of this “Masons' Song,” differing somewhat from that we printed. We can find room only for the last verse:—

“Now you masons bright, take great delight,  
In what is called sound masonry;  
Stake plain your signs, with squares and lines,  
And well maintain your mystery.  
But mind, though you may tramp and shift,  
And seek for jobs both here and there,  
No scamping work should e'er be done  
By the lads who build with their aprons on.”

**GLASS IN STONE.**—Sir: In reply to your "Subscriber," inquiring for the best cement for stopping glass in freestone frames, I can recommend mastic, mixed with boiled lincsed oil, to be well mixed and beaten to a tough consistency. The stone and glass, as far as the cement is required to cover, should be previously treated with two coats of boiled oil.—C.

**ELECTRO-ISOLATED CASTINGS.**—After all our knowledge, the uses performed by electricity, pervading everything as it does, are but little understood. Mr. Adams, of Pittsburgh, it is said, has discovered that in casting common iron, by insulating the moulds together with the man who pours the liquid metal into them, the castings are quite a different article—coming out as white as silver and as hard as steel. The value of the discovery has not been tested. As, however, there is doubtless a measure of electricity constitutional to, and which must become latent in, every formation, the idea is a promising one. Moreover, positive electricity, we have always maintained, is a concentrative or concrete principle, more analogous to cold, for example, than to the heat which electricity itself evolves.

**FALL OF A MILL AND LOSS OF 180 LIVES.**—On the 10th instant, at Lawrence, Massachusetts, the main body of the Pemberton Mill suddenly fell to the ground, and buried in the ruins several hundreds of the workpeople. The mill consisted of a large main building of six stories in height, and of two small wings. The mill employed about 600 operatives, some of whom had fortunately left, and others were in the wings, which were not destroyed. There were probably from 300 to 500 buried in the ruins. About one in four who were taken out were dead, and nearly all the others were more or less wounded, some of them probably fatally. Many of the rescuers were killed by the still falling ruins. The disaster was rendered still more terrible by the bursting out of a fire amidst the ruins about midnight. It is supposed that most of the lives were lost through the fire.

**COVERING THE WOLVERHAMPTON MARKET-HALL.**—At a recent meeting of the Wolverhampton Council, the minutes of one or two meetings of the Markets Committee were read by the town clerk, and stated that as the plans of Mr. Bidlake, architect, for covering in the Market-hall, could not be carried out for 2,006*l.* 10*s.*—Mr. Bidlake's estimate,—the lowest tender being 2,600*l.*—his plans had been returned, and the plans, specifications, &c., of Mr. Henry Lloyd, of Bristol, had been accepted, under the same conditions as those laid down in Mr. Bidlake's case, namely, that they could be carried out for the amount specified in his report. In this case the estimated outlay was 2,000*l.*, and of five tenders sent in that of Mr. R. Stap, of London, who agreed to execute the works for 1,670*l.*, had been selected, conditionally upon the contractor finding the necessary securities. A letter from Messrs. Deakin & Dent, Mr. Bidlake's solicitors, was also read, informing the committee that Mr. Bidlake claimed compensation for the loss he would sustain in not being allowed to carry out the works. After a good deal of discussion, chiefly as to Mr. Bidlake's claim, the minutes were adopted by a majority of 20 to 7, a few of the councillors refraining from voting.

**A NAIL SHOP BLOWN UP AT CRADLEY.**—One of those cowardly attempts to destroy property and life by the use of gunpowder, which have lately become so frequent at Sheffield and its vicinity, has just taken place at Cradley; and we are sorry to say, as far as the former count is concerned, with complete success; and the man whose property has been destroyed had a narrow escape of his life. A horse-nail maker, named Dunn, was aroused from his sleep by a violent shock. He of course got up, and found the walls of his room shaking to such a degree that he feared they would engulf him before he could get away. His nail-shop had been blown to atoms. The wall opposite was down, windows broken in all directions, and bricks sent by the shock to a distance of 10 or 50 yards. The wall of the bed-room in which he and his wife lay was forced in, and had not the wall been very strong, they must have been crushed in the bed in which they lay. Two men, Czerahiah Willets and William Feldon, were apprehended: they are both horse-nail makers, and were identified by Dunn as amongst four or five men whom he saw running from his premises immediately after the explosion. They are union men. A remand was granted, and the magistrates refused bail. The explosion was caused, it is supposed, by lowering a bag of powder down the nail-shop window with a cord, which was found at the top of the chimney. A long fuse would give the rascals time to escape in safety.

**ACCIDENT AT THE RAINBOW TAVERN.**—Last week the new wall of the Rainbow Tavern fell down. Unfortunately six poor fellows, who were at work, were injured, and were conveyed to King's College Hospital.

**THE VICTORIA RAILWAY BRIDGE AT MONTREAL.**—The English engineers sent out to Canada to inspect the Great Victoria Bridge have reported favourably upon the structure. The tests applied are said to have exhibited very satisfactory results.

**A FREE PUBLIC LIBRARY AND MUSEUM FOR BIRMINGHAM.**—A number of gentlemen who feel an interest in the progress of popular enlightenment are taking steps to secure the adoption in Birmingham of the Act for promoting the establishment of free public libraries and museums in municipal towns. They are said to entertain confident hopes of success.

**MARXON'S PATENT LADDERS.**—In these ladders the rounds are made with a shoulder, which is let into the inward side of the ladder about a quarter of an inch, and a smaller hole for the pin of the round is bored through to the outside. The hole is then made to taper inwardly, to allow for the expansion caused by a wedge which is driven into it from the outside. Ladders made on this principle appear to have an advantage, as the sides cannot be driven farther than the shoulders; and, being wedged on the outside, the pins obtain a dovetailed shape that keeps them firmly in their places.

**MEMORIAL TO BISHOP PEARSON.**—A proposal is made to raise a memorial to John Pearson, Bishop of Chester, author of "The Exposition of the Creed," who died in Chester, July 16, 1686, and was buried in the cathedral, within the rails of the altar. The memorial is intended to consist of a monument of stone, alabaster, or marble, in accordance with the architecture of the cathedral, bearing an effigy of Bishop Pearson. The promoters say, a canopy of rich metal-work may be erected over it, and the monument itself enriched with inlaid marbles, in the character of the improved style of the present day. This enrichment will depend on the amount of contributions. Subscriptions are being sought.

**SANITARY AFFAIRS IN CHATHAM.**—On the 20th instant, the shocking state of some property in Holborn-lane, belonging to Watt's Charity, was brought before the Local Board of Health, and the trustees were requested to appoint a committee to meet one from the Board to confer on the subject. The *Chatham News*, which appears to take an active part in the promotion of sanitary reform at Chatham, describes the state of this charity property as indescribable and horrible in the extreme, from want of accommodation for the poor people of the locality. The Board surely cannot fail to bring matters to a satisfactory state in dealing with the property of a well-to-do charity such as this appears to be.

**BRIDGEWATER SCHOOL OF ART.**—This school was opened on the 23rd inst., in the Public Room of the town. The walls were hung with works of art. As president, the mayor occupied the chair, and addressed the meeting. The committee reported that their labours had been thus far attended with success, so that the school is about to be opened under favourable auspices. Mr. Bowler, the Government Inspector of Schools of Art, afterwards addressed the meeting, in a speech fully reported, together with the whole proceedings, in the *Bridgewater Times*. In course of his address, Mr. Bowler said there was one great point which he wanted to refer to before going into detail regarding the course of instruction, which he might do more fully in the evening, when he understood there would be a second meeting, and more students would probably be present. It was a point in which schools of art did not stand alone. The workmen wanted occupation after their work: more than this, they wanted recreation, which must be provided for. It was in supplying these wants of the majority of the people that these schools were most valuable. Undoubtedly all active, smart, intelligent men could get through their wood and their timber, make sockets and window-frames, all in their degree of intelligence. But notice three or four intelligent men at their work, and look at them when their day's work was done—when they had knocked off at six o'clock: they would find a great difference between them. These Government schools would prove eminently useful to carpenters and blacksmiths, and furnish an innocent and suitable recreation after their work. He believed the man was more himself after work than during the whole day whilst at work. At work he must obey some one else, but after work he was no slave, but had his own pleasure to seek.

**THE BRUNEL MEMORIAL.**—Upwards of 1,600, have been subscribed towards the proposed memorial to the late Mr. Brunel; but, as this is scarcely sufficient to accomplish the design of the promoters, the subscription lists will remain open till the committee shall determine as to the specific appropriation of the fund.

**CASELLI'S PANTELEGRAPH.**—The *Pays* contains an account of a visit by the Emperor of the French to the establishment of M. Froment, for the purpose of witnessing experiments in the working of the Pantelegraph at the Abbé Caselli, of Florence, which reproduces, it is said, as exactly as can be done by a photograph, every species of writing or drawing.

**ALL SAINTS', WESTBOURNE-PARK.**—We hear that the presentation to the church of All Saints, adjoining Westbourne-park, erected by Dr. Walker, which has remained long unfinished, has been made, and that it will be completed and consecrated early in the summer.

**CONGRÈS SCIENTIFIQUE DE FRANCE.**—Will you please to announce to your numerous readers that the "Congrès des Délégués des Sociétés Savantes" will be held this year at Paris, on the 9th of April, in the Rue Bonaparte, as usual; and that the "Congrès Scientifique de France" will be held at Cherbourg, on the 2d of September. The presence of English antiquaries on either or both of these occasions will be particularly acceptable to their brethren in France. It is highly desirable that the leading persons occupied in the same pursuits in the two neighbouring countries should be personally acquainted, and ready to assist each other.—A. DE CAUMONT (Paris).

**VENTILATION: LIVERPOOL POLYTECHNIC SOCIETY.**—At the usual meeting of this society, on Monday evening before last, at the Royal Institution, Colquhoun-street, Mr. Scott in the chair, Mr. George Reid, of Bootle-lane, read a paper "On the Principle of Ventilation." He showed a series of experiments with his carbon test, rendering the effects of foul air visible, and with other apparatus demonstrated several improvements in the art of ventilating. A discussion followed, and a vote of thanks was accorded to the lecturer.

**WORKMEN'S INSTITUTE AND BENEFIT CLUB FOR LAMBETH.**—Endeavours are being made to establish, at 84, York-road, Lambeth, a branch of the new institution at 239, Euston-road, under powerful patronage; the Duke of Northumberland being the president; the Earl of Carlisle, Lord John Russell, Lord Overstone, Lord John Manners, Earl Spencer, and other noblemen, being vice-presidents; Baron Rothschild, Mr. H. E. Gurney, Mr. Thomas Hartley, Mr. Gladstone, and other gentlemen, trustees; Mr. St. Leger Glyn, treasurer; and Mr. Thomas Piper, Mr. C. Lucas, Mr. J. Nigby, and various other gentlemen, form the committee. The rules of the benefit club connected with the institute have been approved by the Registrar of Friendly Societies, and are now printed, and may be obtained, we presume, at York-road, Lambeth, or at Euston-road. The Lambeth branch was to be opened on the 18th instant. These new institutions are designed to extend their influence and advantages to workmen in all branches of trade, but particularly to the building trades operatives; and, without, of course, committing ourselves to all its details, and although we would like to see one powerful and extensive institution rather than many small ones, the endeavor to benefit the workmen in this way has our hearty good wishes.

**HOLLOW WALLS.**—Air is a poorer conductor than stone, and costs nothing save the box or hollow in the wall which holds it, and this is only a question of slightly increased labour in construction, and not a question of material; for the same amount of materials may be made stronger if hollow than if solid. Here we come to the great and common mistake which too often renders hollow walls no better than solid ones, viz., instead of absolutely confining the stratum of air, and isolating it from the outer atmosphere, they permit it to change, to escape when heated, and make room for fresh air from without; in short, to circulate, in which case they are worse than a single wall. Many attempts are made, especially in the country, to prevent the dampness of brick or stone houses by making hollow walls, and they generally fail because the contained air is not absolutely confined. Dampness does not come from without, through the wall, but is deposited from the air within when it comes in contact with the walls, which have been made cold simply because they are not thorough non-conductors. The greatest care should be taken to stop all holes, however small, especially between the outside atmosphere and the enclosed non-conducting stratum.—*Engineer.*

VOL. XVIII.—No. 87.

"The Handbook of Specifications."

H & C

properly educated architects write their specifications, may be seen in the two volumes recently issued by Professor Donaldson.\*

Amongst the other known buildings, the specifications of which are given, are the Wilshire Lunatic Asylum (Wyatt & Brandon); Fotherhill's Prison (E. Abraham); the City Prison, Holloway (Bunning); the High School, Edinburgh (Hamilton); Clothworkers' Hall, London (Angell); Wellington College, Sandhurst (J. Shaw); houses in Grosvenor-square, and elsewhere; St. George's Church, Doncaster (Scott); several works of smaller size by the author, including Messrs. Shaw's warehouse, in Fetter-lane, a very successful elevation; the Newcastle-upon-Tyne railway station (J. Dobson); new Westminster Bridge (Page); the High-level Bridge, Newcastle (K. Stephenson); various works on the Great Northern Railway (Brydson); and one French specification for houses in the Rue de Rivoli,

Paris (MM. Armand, Hittorff, Pellechet, & Rohault de Fleury, architects.) The last is a very elaborate composition, occupying seventy pages. The majority of the specifications have illustrations in the shape of elevations and plans; but these, for the most part, are not executed in a worthy manner,—indeed, some of them are positively discreditable to a hook of cost and character. It is evident that the author has not had control in this department.

In the introductory address the author alludes to the intention which was first entertained of reprinting the volume of specifications by Mr. Alfred Bartholomew, now out of print, and says,—

"But the state of science connected with construction has made large advances. Vast experience has been brought into play by the great engineering and architectural works which have been carried out during the last twenty years; a period rich in important improvements introduced by men of extraordinary capacity, skill, and experience, who have been engaged in operations of the first magnitude. It was felt also, that the preliminary matter of Bartholomew's specifications is now out of date; that the errors of taste and construction therein alluded to are confined to the inferior practitioner; and such a revolution has been effected in various operations, that the professional man required a work more in accordance with the improvements of the age and the actual state of construction at the present time."

We are most glad to have the present work. It is valuable as a record, and more valuable still as a book of precedents: nevertheless, we shall be rejoiced to see a reprint of Bartholomew's hook, or at all events great part of it. It is full of valuable observations and advice,—advice which, so far from being "out of date," is still much needed. It may be, as Mr. Donaldson says, that "the errors of taste and construction therein alluded to are confined to the inferior practitioner," but so many structures are raised under the inferior practitioner, or under no practitioner at all, that bad building—inferior building—is to be seen everywhere. Much of what Bartholomew says will never be out of date, and should never be lost sight of. His skeleton specifications, too, paragraphed, with side-headings and an elaborate index, afford great facilities for easy reference. In fact, we have no hesitation in asserting that it is one of the most valuable works that can be placed in the hands of the young architect. We say this of course in no disparagement of the new work before us, to the usefulness of which we have already borne strong testimony.

At the commencement Mr. Donaldson gives some suggestions on the Principles of drawing up a specification; a skeleton specification for erecting a building; hints for specification of dilapidations; a model contract; general conditions of contract for engineering work (drawn up by Mr. James Simpson); model forms of terms for letting building grounds (why does he describe the houses in this as "first-rates" and "second-rates" terms which have now no precise meaning?); notes on the mode of estimating the probable cost of a building by the cubical contents; and some observations on competitions. We give his notes as to valuation by cubical contents:—

"Measure from the bottom of the brick or stone footings of the walls to half way up the roof, and this will give the dimension of the height.

This should be multiplied by the superficial area, including all the walls.

The cubical contents so produced are multiplied by the sum, per foot cube, which it is supposed would be proper for the class of building to be estimated. The amount will be the probable cost, exclusive of fittings, which will of course vary according to the taste and requirements of the occupier.

Whenever a house, mansion, or other building has attached or detached offices, each erection must be taken and priced separately, according to the rate to which it properly belongs.

A dwelling-house in London of the third rate or class, and a plain country lodges, may be assumed to be worth 5d. or 6d. per foot.

An ordinary dwelling-house of the second rate or class may be supposed to be worth 7d. per foot cube.

A first-class dwelling-house may be supposed to be worth 2d. or 3d. per foot more, it being presumed that the construction is more solid, and the finishings of a superior character.

A plain country house, or club-house, with stone elevation and internal finishings of a high class, may be taken at from about 1s. to 1s. 3d. per foot.

The above may be supposed to apply to town houses; but villas and detached country-houses, having all the parts of an architectural character and no party-walls, may be taken at 1d. or 2d. per foot more, according to the difference of style and finishing.

In the case of any superior materials being employed, or of any decorations of a high sculptural class of art being introduced, a special sum of so many hundreds or thousands of pounds must be put down in addition.

The domestic offices may be taken at 5d. per foot. Thus stable buildings of the ordinary class may be calcu-

lated at that figure; but, if the finishings be expensive or fanciful, it may be increased to 1d. per foot more.

Workhouses, hospitals, warehouses, schools, and such-like buildings, having large internal spaces and few divisions, and with the architecture of a simple and substantial character, in brick-work, may be taken at from 4s. to 5d. per foot cube. Lunatic asylums and hospitals, requiring more special provision, and greater subdivisions, would be somewhat more expensive than ordinary buildings of this class.

Churches, chapels, or large rooms or halls for meetings of large assemblies, may be considered to be worth 6d. per foot cube; if, however, a tower or spire be added to the church, a distinct sum must be allowed for it. A Gothic tower of brick, faced with Kentish rag and with Bath stone dressings, and surmounted by a spire, rising to a height of 100 feet, would cost about 800l. or 1,000l., or if rising to a height of 130 or 150 feet might reach 1,500l. or 2,000l."

About 140 pages of the second volume are appropriated to an exposition of the Law in relation to the legal liabilities of engineers, architects, contractors, and builders, by Mr. W. Cunningham Glen, barrister-at-law; intended rather for these persons than for the legal practitioner. This part of the work treats of—1. Contracts generally; 2. Contracts with corporations; 3. Extra works; 4. Party walls and injuries to buildings; 5. Arbitrations; 6. The relation of architects and surveyors to employers; 7. The liability of contractors for damage done to works; 8. The liability of masters for injuries to servants in the course of their employment, and other persons; 9. Differences between masters and workmen; 10. Combinations of masters and of workmen, strikes, &c.; and, 11. The Truck System. No. 6, headed "The Relation of Architects and Surveyors to Employers," requires fuller treatment: it scarcely touches the subject. The chapter on Contracts with Corporations, and that on Extra Works, are valuable. Suffice it, in conclusion, to say in words, what our readers will have gathered for themselves from the particulars we have given, that Donaldson's Handbook of Specifications must be bought by all architects.

## LECTURES ON ARCHITECTURE AT THE ROYAL ACADEMY.

On Thursday, 26th of January, Mr. Sidney Smirke, R.A., delivered the following lecture at the Royal Academy, before a numerous audience:—

My distinguished colleague and coadjutor, Mr. Scott, two years since, addressed to you some interesting remarks on the transitional style that intervened between the Romanesque and Pointed styles of architecture, and noticed the peculiarly productive energy that appeared to have characterised the efforts of the artists who were then engaged in revising and moulding the forms of existing architecture, and laying the foundations of a new manner of building, which ultimately settled down into the regular, consistent, and beautiful style designated by later artists as the Gothic style. There is another very analogous period in the history of our art to which I wish now to invite your attention. Throughout that history no epoch appears to me more interesting and important than the Early Renaissance, or that which was marked by the first abandonment of this Medieval style. The Medieval style retained its beauty and consistency in Europe for about a century and a half. Between the years 1200 and 1350 European architecture was constantly enriched with buildings which have ever since been deservedly accounted the boast and glory of our art. At about this last date commences a downward course, that *facilis descensus* which is the natural, and, perhaps, inevitable, tendency of so many human inventions. At Milan, Nuremberg, Rouen, and elsewhere, we have to lament the degradation of styles which, though not without many claims to our admiration, displayed itself in a profuseness of ornament, indicating in its execution a greater solicitude about the quantity than the quality of the ornamentation, and in an addiction to surprising novelties, and to those *lours de force* which prevailed in the later days of Gothic architecture. The increasing pride and wealth of the Church, not content with the dignified moderation of earlier days, may have been one of the latent causes of this excess; or perhaps our art, in its excesses, was but obeying some great fundamental law of the human mind. It is not, however, my purpose here to enter upon such an inquiry. I have but to note the fact that a progressive degradation of style certainly took place; not, indeed, at a uniform rate, nor in the same manner throughout Europe, but still in a constant and very sensible progression.

In England the style lost its stern grandeur of manner, but it lingered on and became frivolous, feeble, nervous, and ungraceful. In France, as might be expected from the character of art in that country, it became exaggerated and even violent in its efforts at effect, and departed widely from the quiet dignity of former, better times. In Italy the style was straitened in its birth. Life departed nobly in its veins for a short time and threw out a few very brilliant scintillations; but in that classic land the style died away before it had time to reach a complete and consistent maturity, as I shall have occasion to mention hereafter to remark, it became so adulterated by the mixture of generically different modes of art that men like Montevera and Robert de Luzarches would hardly have admitted, but their brotherhood such heterodox practitioners as Arnolfo or Giotto.

In Germany, the deterioration of this style was marked by aberrations of taste equally extravagant, and the classic art in the style and its accessories, such as such as Vischer and Eisinger, became a sort of legerdemain, such as we see it in the extraordinary works of those artists at Nuremberg and Ulm.

The Medieval style had reached this stage of its decadence, when one of those great revolutions com-

\* Handbook of Specifications, or, Practical Guide to the Architect, Engineer, Surveyor, and Builder, in Drawing up Specifications and Contracts for Works and Constructions. Illustrated by Precedents of Buildings actually executed by the following eminent Architects and Engineers:—E. Abraham, Angell, H. Baker, Sir J. Barry, I. W. Brydson, C.E., J. B. Bunning, T. Cundy, J. Dobson (Newcastle); B. Ferrey, T. Hamilton, Hittorff, Locke & Kerrington, engineers; G. Muir, H. Mawley, T. Page, C.E., J. G. Scott, J. Shaw, James Simpson, C.E., Robert Stephenson, C.E., Y. Thomason (Birmingham); W. Eite, M.P., T. H. Wyatt. Preceded by a Preliminary Essay, Forms of Specifications and Contracts, &c., &c., and explained by numerous Illustrations. By T. L. Donaldson, Ph.D., Architect, Professor of Architecture and Construction, University Coll., London, M.B.A., Correspondent of the Institute of France, Member of various European Academies of Fine Arts. With a Review of the Law of Contracts, and of the Responsibilities of Architects, Engineers, and Builders. By W. Cunningham Glen, of the Middle Temple, Barrister-at-Law, author of various legal works. London: Archley & Co., 106, Great Russell-street.

menced its course which form the epochs of art, and which we are sometimes disposed to attribute to accident, perhaps because our powers of vision are too faint to let us perceive the true connection and sequence between causes and their effects.

Various attempts have been made to account for the great change of style which I am about to advert. The irresistible power of the Turks drove out and scattered the remnants of the Greek people over Europe, and thus were sown the seeds of Classical art as well as of literature, in the territories over which Medieval art had been exclusively dominant.

Then Span and Genoese merchants imported from the ruins of Athens and Greece fragments of the ancient to be regarded first as the trophies of war and then as lessons and models of art. We must also bear in mind, when seeking for the causes of this great change, that the pride of ancestry will survive the wreck of fortunes; and even in their darkest times, Italians never ceased to cherish the proud recollection that they were the direct descendants of the dictators of the civilized world. Could they, then, regard the material relics of the world's masters otherwise than with reverence and admiration, and ultimately with the desire to imitate them? At all events, whatever may have been the cause, a combination of causes, we find the first germs of the Renaissance budding out in Central Italy as early as (perhaps earlier than) the middle of the fourteenth century.

It is not for me to turn aside from my own proper path in order to show you how a similar revival became contemporaneously established in six other parts of Europe. Vasari traces even to the early days of Bramante the first dawning of a Classic taste, that master having, with especial honour, studied at Pisa a certain fragment of antique sculpture which seemed to have been made to serve as a tomb in the cathedral there; a study which no doubt materially modified not only his own style of design, but that of the great school of sculpture which he founded, and which subsequently exercised so important an influence over the whole domain of art. I suppose it may fully be inferred that it was in the Pisian school that the light of the Renaissance first appeared. Those who are piecied to trace to insignificant causes events of great importance may, perhaps, bid us pause and reflect, that if a noble remnant of Classic art, like this, had been lost or had happened to escape the destruction of N. Pisano; or had there been no sculptor at Pisa capable of appreciating the value of that marble, how widely different might have been the destinies of art! The marble, however, did attract the attention of Pisano, artist, and no doubt other similar arguments soon became the object of his interest and study. N. Pisano was then at the head of the most important school of art then existing in Europe, and his recognition of the merits of this Classic relic may be said to have first awakened the attention of men to the study of the antique, and laid the foundation of that style of art which has been characterized as the Renaissance, or new birth of ancient genius.

That this revival should spread itself from sculpture to architecture was inevitable, for at this time architecture and sculpture, as in the days of Phidias, were twin sisters, and the same minds conceived, and the same hands executed works in both arts.

In architectural design the result of this new light was at first a singular combination of Classic and Gothic details; an imitation which, commencing in subordinate parts, gradually extended to the more important features of design. I think, indeed, it may be observed that all the great changes in style that mark the progress of our art, have in like manner, become discernible first in the details rather than in the masses.

It must be admitted that the architecture of Italy was well prepared for this change, for it had ever retained a very perceptible trace of the Classic forms and modes of design. It is true that close observers of Italian medieval art recognize two varieties as contemporaneously prevalent, designed respectively by architects like Giotto, Iabana and la Giotto, Fiesoles, by which latter term they meant to describe a style, still traceable in a few surviving examples, very nearly allied to the Gothic, while the former described an indigenous variety of Gothic. Of these, the one exhibited more unity and consistency of character, while the other was distinguished by its greater elegance and variety of detail. But besides the revival of Classical types, which would naturally operate to modify Italian medieval art, there was the important element of climate, which must have exercised an influence on the Italian manner, causing it to deviate widely from the type of its northern congener. The highly pitched roofs, suggested by the requirements of a climate to the Teutonic nations, were out of place in the genial south, and were totally at variance with the oblique pediments which had been transmitted to them by ancient tradition, and examples of which must ever have been extant before their eyes. These discordant elements had to be harmonized, but there is reason to believe that if this composite style, the result of antagonistic principles, had been allowed to continue unshaken by external causes, it would, in the hands of such aesthetic genius as then abounded in Italy, have developed itself into a perfect unity of character, and have probably rendered this Italian variety of medieval architecture one of the most admirable of all the varieties of the Gothic style.

Such, however, was not to be the fate of architecture; a new phase was given to all the arts of design; and our art, like the rest, was destined to receive a new impulse, and await fresh impressions from the reanimated vestiges of Greek and Roman art.

It is very interesting to watch the rise of the coming style, and to record its progressive advances.

As far as we know, the public buildings of the Loggia dei Signori, in Florence, is the earliest example in Europe of a tendency to return to the ancient Classic type. It is a building to many minds known to all here to need from no many description; although strongly tinged with the feeling of the Renaissance, it is yet a curious specimen of the transitional state of the art. The date assigned to this Loggia by Vasari is 1355; the author, Andrea Orcagna. Although 50 years have passed since its erection, the work stands but little impaired in time, bearing testimony at once to the fine taste and great constructive ability of Orcagna. It may be seen reproduced with great accuracy in the Maximilian Strasse at Munich.

That to the genius of Orcagna may be traced the earliest efforts to give our art a new path may be inferred from the fact that his earlier works are peculiarly Gothic; if, indeed, that can be correctly said of any Italian Gothic. Florence, known as the Or San Michele, the conception

and elaboration of which was to Orcagna truly a labour of love, yet we perceive in it exclusively the canopied heads and slender columns which we find in the mouldings and other details which mark Italian Gothic architecture. Still to Orcagna certainly is due the merit of being among the earliest pioneers of Classic art. His great genius enabled him to perceive that there was a region of art to be explored, more nearly allied to nature than that rigid mannerism which had then prevailed for centuries. The Pisa and Giotto had, it is true, already led the way in this respect, but it was Orcagna who corded, and sapped the basis of medievalism in architecture also.

What he conceived, Brunelleschi, another great and original genius, may be said to have accomplished. Orcagna had evidently become alive to the dignity of the works of ancient Rome; but Brunelleschi realized the aspirations his predecessor, and by the time he had closed his career, in 1446, the great revolution in art had been effected, and the new style firmly established, at least in his own country.

The onward movement, however, was not that of any one individual, but of the spirit of the age. Neither was it, as we have seen, effected abruptly; for there is generally a *raison d'être* in art which is not easily overcome, but yields reluctantly to change, so that new styles have never been the result of a slow partition. Influenced perhaps, by some accidental discovery (and such was the Greek tomb seen by Nicolo Pisano), and the antique remains exhibited to Raphael, an original genius, so influenced, gave birth to some new conception: the same intellect, and power which Michel Angelo realized this conception, enable him also to clothe it with those claims which secure for it popular approval: a herd of imitators follow close behind, and perchance, among them one appears who is able to improve upon the ideas of his predecessor, and thus a fresh advance is made.

It is so that extensive and important changes in the social fabric may be brought about, gradually and without any such convulsion as we witness in the revolutions in the political world are sometimes effected.

Almost contemporaneously with Orcagna's work, other faint indications may be traced of the approaching change, especially in Florence.

In the fresco decorations by Taddeo and Memmi of the Cappella del Spagnuolo, in the church of S. Maria Novella, of the date of about 1350, we may trace the first of the new style to be detected. At San Miniato, which dates from the latter end of the fourteenth century, may be seen very characteristic illustrations of that bigamous state of art, where the forms peculiar to the past are not just and the future; the hard, angular lines suggestive of the early mosaic work of Medieval times, being intermingled with the flowing foliage of the new style.

In the painted windows of the cathedral at Florence, stated to have been executed in 1434, by Domenico Gaddi, we will trace a strange intermixture of the Pointed and the Renaissance feeling; where the Gothic canopies, crocketed pediments, and other Middle Age forms occur with paintings and mouldings belonging to the Revived style. The same mixture occurs in the church of Sta. Croce, bearing a date early in the fifteenth century, where the Virgin is represented sitting on a throne designed under the influence of the Renaissance, in immediate juxtaposition with decorations unequivocally Gothic.

Again, the silver altarpiece preserved in the cathedral at Florence, which was commenced in 1366, and not finished till 1477, is perhaps in itself an epitome of the history of the revival of Classic architecture; for whilst its leading features are strictly and perfectly Gothic, there is represented upon it—human and arched interior architects as completely classical as any design of the sixteenth century.

The frescoes of Benozzo Gozzoli, in the Campo Sato at Pisa, afford us many curious examples of this Early Renaissance, and among the drawings belonging to his Majesty is a remarkable evidence of the ambiguous state of the art of design at this period, in a delicately executed drawing by Fra Giovanni, in which a figure is introduced where a statue is placed in a niche of pure Renaissance, surmounted by a foliated and crocketed canopy of strictly Medieval character.

It would be easy to multiply examples of the same transitional character, and I would point it out to you as an interesting and profitable study to search through the works of the revival of Classic architecture; for whilst its leading features are strictly and perfectly Gothic, there is represented upon it—human and arched interior architects as completely classical as any design of the sixteenth century.

I say that this would be, if wisely conducted, a profitable, as well as interesting study; for we may be able to derive some valuable suggestions for our own guidance. It is impossible not to perceive that at the present day our art is in a similar, transitional state; we also, are dissatisfied with the present; we also, are averse to tread in the footsteps of our fathers, and are pressing forward in pursuit of untrodden paths of aesthetic excellence.

Upon the wisdom with which our present onward course may be directed, and the right spirit in which our present studies are pursued, must mainly depend the result of ultimate success or failure.

The enthusiastic and labour-loving artists of the fifteenth century succeeded in creating a style which may justly and unquestionably be regarded as one of the most successful emanations of architectural genius that the world has yet seen.

Let us hope that the aspirations of the present generation may be rewarded by a like measure of success. In indulging this hope, let us not be lulled by the perils that beset our future. The pursuit of mere novelty is not more likely to produce effective and striking results than to betray us into deplorable failures.

There is also a spirit of paritizenship abroad, even in the most remote parts of the world, which is leading to conflicting opinions on the comparative value of the various known styles of art for modern requirements, and which stands, indeed, in a critical position, almost ready to give its latitude to the judgment and taste of the generation which now presses on, and which has not yet hastened to revert to the more legitimate subject of my discourse.

The genius of Italy, at the period to which I have been adverting, had been rekindled into such ardent life, and human invention had been stimulated to such extraordinary activity, that a surprising rapid progress was made in all the arts of design; and by the close of the fourteenth century we find the new style, in Decorative style, at least, nearly emancipated from the still and conventional forms of the preceding centuries. There was a long period of conflict; for it was not until the middle of the fifteenth century that the graceful, and, in

many respects, original style which I have selected as the special subject of my present address had reached its highest and its happiest equipment.

As Italy is the birth-place, so also it may be said to have been the most successful, among European States, in the cultivation of the revived style, and to the present day may be justly regarded as the storehouse of the richest treasury of examples of the re-animated art. It happens that this epoch was coincident with, perhaps, the most flourishing and pre-eminent period of Venetian history.

Towards the close of the fifteenth century, that Republic had reached its loftiest elevation. Her subsequent course, though often brilliant, was a descending curve. By a coincidence that can hardly be regarded as accidental, this period, I say, of political eminence was distinguished by a corresponding aesthetic excellence; and whilst eminent statesmen and warriors were extending the political influence and commercial relations of the Republic far beyond the limits of Europe, the most renowned artists were rendering her capital one of the fairest cities in the world.

I am tempted here to read to you, from an English translation of the date of 1506, the remarks of Philippe de Comines, who, towards the close of the fifteenth century, visited Venice as ambassador from France. He says, referring to the Grand Canal:—"Sure, in mine opinion, it is the goodliest streets in the world, and the best of all that I have seen. The buildings are high and of state, and of fine stone. The ancient houses be all painted, but the rest, which have been built within these hundred years" (that is, during the fifteenth century) "have their front all of white marble," and are beautiful with many great pieces of porphyre and serpentine. In the most of them are, at the least, two chambers, the ceiling whereof is tiled; and the windows are high and of fine stone, with a graven marble; the bedsteads are of the precious painted and varnished with golde, and marvellous well furnished with stuffe." To be short, it is the most triumphant city that ever was, and where all nobles, princes and strangers are most honourably entertained, the commonwealth best governed, and God most devoutly served and worshipped."

Such was the Frenchman's opinion of Venice at the period of which I am speaking, and we can well understand that the observant traveller, whose eye was accustomed to the dreary and uninteresting buildings of the north, must have been struck with surprise and admiration by the magnificent and festive architecture of the Gran Canal.

To those who are not personally acquainted with Venice, the great work of Cicognara, and the many readily accessible photographic representations of its buildings are well calculated to give an idea of their singular, yet graceful architecture.

Other northern states of Italy also are rich in examples of the style. One of the most conspicuous of these, as indeed, it is one of the most beautiful and imposing buildings of the north, must have been struck with surprise and admiration by the magnificent and festive architecture of the Gran Canal. To those who are not personally acquainted with Venice, the great work of Cicognara, and the many readily accessible photographic representations of its buildings are well calculated to give an idea of their singular, yet graceful architecture.

Other northern states of Italy also are rich in examples of the style. One of the most conspicuous of these, as indeed, it is one of the most beautiful and imposing buildings of the north, must have been struck with surprise and admiration by the magnificent and festive architecture of the Gran Canal. To those who are not personally acquainted with Venice, the great work of Cicognara, and the many readily accessible photographic representations of its buildings are well calculated to give an idea of their singular, yet graceful architecture.

I admit, therefore, readily, the viciousness of ornament in the very remarkable building just adverted to. But, from its great comparison with its neighbour, it is an elegance of manner and style, which, in my opinion, disarms the critic—an excess almost pardonable for its beauty; and whatever censure it may have to its profusion, and its want of attention to the conditions, it is to be pronounced upon the equally overladen and inappropriate ornamentation of some buildings in the later Gothic style. If, for example, we turn to Henry VII.'s chapel, we see excessive surface decoration presenting the most monotonous effect—a fatiguing repetition of the same unmeaning forms of the same frivolous ornaments, whilst at this Certosa at Pavia we are charmed by the most surprising variety, and by the richest and most luxuriating over the whole structure.

It is too true, as I have already stated, that, notwithstanding their eminent individual beauty, the ornamental details of this building are excessive; but to the student of ornament they are, indeed, a mine of wealth. There is a power of execution, a grace, a vigour, and an originality of design, which exact our warmest praise and deserve our most careful study. Let me not, however, fail to add that to erect a building for a fraternity of religious men as their place of retreat from the cares and frivolities of the outer-world, where they are, presumably at least, to devote themselves exclusively to a contemplative life and to the services of religion, and to convey that into the architecture of their sacred buildings, a profuse ornament, is a violation of decorum and consistency which no beauty of design or dexterity of execution can justify.

Added to the ornamentation, the architects of the early Renaissance period certainly were; for men will ever love to do that which they know how to do well. Yet men will also, in a distant and a distant way, be attracted by which present great simplicity of character. Indeed, in their general outlines, buildings of the best period of this school are usually simple. It is in the ornamental details applied to these simple forms that the excess to which I refer occurs.

An instance of eminent beauty exists in the church of San Francesco, at Rimini, by Leo Bal. Alberti, which, I think, may be regarded as a masterpiece of the style. It is an extreme severity of outline, unenlivened, nevertheless, by enrichments of great purity of design, in this case very judiciously introduced in a discreet and judicious manner. The church of Sta. Maria dei Miracoli, at Venice, by the elder of the Lombardi, is another example of great characteristic beauty, full of elaborate details of a rich and lively fancy, although the general form of the building could hardly be more simple or severe.

to the workmen of other countries. It is, I think, very doubtful whether, in practice, the constructive arts have not rather retrogressed than advanced in this country within the last quarter of a century.

No doubt we owe much to science during that time, and many most important improvements have been introduced into the practice of building. New materials have been made available, and the principles of construction have, perhaps, become theoretically better and more generally understood. But, notwithstanding these modern aids and increased facilities, the building art has, in practice, I fear it must be said, at the present day, generally deteriorated.

I am well aware that this is not a fitting place to inquire into the causes of this deterioration. It may be that our impatience to raise huge piles in the least possible time precludes the exercise of that forethought and care without which no good work is done: it may be that in our struggle to reduce expenditure to its lowest level, we are tempted to run dangerous risks, to introduce erroneous principles of construction, and to encourage the employment of inferior, slovenly, and dishonest workmen. At all events, I apprehend that to urge the necessity of improving the art-education of workmen is by no means an inappropriate subject of exhortation within these walls.

I am fully sensible of the efforts now, at length, being made to promote the art-education of the working classes; efforts which are already bearing good fruit. To further these efforts, and to express my own humble conviction that upon the success of them will depend the advancement of our art in this country, is my only motive, and must be my apology for now touching on this subject.

We turn to the example of our nearest neighbours on the Continent, we shall find a far higher scale of qualification generally prevalent among workmen engaged on such works; and we extend our views to the Continent, and symptoms of a far more eager desire of self-education than is usually met with among our own artisans.

I think it well to avail myself of this occasion to repeat to you the words, carefully translated, of a distinguished friend holding a high public appointment connected with the fine arts in France, whose position affords him peculiar facilities of observing the artistic acquirements of that class of workmen on whom the architect must depend for the just and faithful execution of his designs. My friend thus writes:—"With regard to our countrymen, it is but just to say that for some years past much has been done to extend a taste for study among the working classes. There are, in various parts of Paris, gratuitous drawing schools, where are taught arithmetic and geometry. At the Conservatoire des Arts et Metiers there are various courses especially frequented by workmen, where very superior professors give them lessons on the application of the sciences to industry. All these establishments are open at such hours as will enable workmen to attend them after their ordinary day's work, and these educational courses are much frequented and highly prized by them.

French workmen, especially those who live in Paris, differ greatly in their habits, their manners, and their origin. Most of the stonecutters come from Normandy; they are an intelligent and prudent class of men, who love their work, and are ambitious to become not only thoroughly acquainted with their business, but also to qualify themselves to undertake works on their own account, which they frequently succeed in doing. The carpenters are also a very intelligent class, although, perhaps, not quite so steady a character as the stonecutters. In other classes, however, value highly the advantages of instruction, and strive to acquire some knowledge, at least, of geometry and design.

"They are, moreover, fond of travel, and, according to an ancient custom, they consider themselves bound to make a tour through their native country, and to visit a certain number of celebrated ancient works, and especially as the Pont du Gard, and other similar monuments, before they can enter into full companionship with their fellow workmen.

That which French workmen shun above all things is idleness in their labour: they are especially anxious to undertake some novel work, involving difficulty in its execution.

So, also, in the execution of public works, we often find men willing to receive lower wages than they might obtain elsewhere, solely for the pleasure of doing something which is considered extraordinary or difficult.

"It has been observed that the workmen so engaged are never found to take part in *casualtes*, the deep interest which they feel in their daily work engrosses all their attention. It is *ennui* that gets them into evil ways."

Such are the very important observations of a gentleman eminent for his profound knowledge of art, his extensive experience, and most reliable judgment.

I would that those observations were applicable to the like classes in our own country. It must in candour be admitted that the voluntary acceptance of low wages expressly in order to secure an opportunity of triumphing over the difficulties of some new or unwonted piece of work implies a degree of enthusiastic attachment to his craft that does not, I fear, very commonly distinguish the ordinary English workman. Many honourable exceptions no doubt exist, and probably every one of us could, within his own experience, point to individual workmen of an intelligence and of aspirations not inferior to those of the workmen of any other country, and, perhaps, of more indefatigable powers of application; but as a body I fear we must admit, that our building artisans are far more eager to shorten their hours of labour, than to improve their hours of leisure.

I ought to apologise for this digression from the special subject to which I have appropriated the evening; but the education of art workmen is a matter not only of professional, but of national importance, and considerations bearing directly upon it can hardly be inappropriate within the precincts of the Royal Academy.

It trust that the remarks which I have addressed to you will lead you to study well the beautiful conceptions presented to you in the architecture of the fifteenth century, but in doing so I would beg you to understand that I am by no means disposed to encourage a tame, unthinking, servile practice of mere copying, or to tempt you to indulge in an indolent repetition of existing examples of art.

It certainly behoves the student in his early essays to make most careful transcripts, and so long as he copies, the more correct and faithful his transcripts the more useful and profitable will be his studies. But the making of such copies must be regarded only as supplying the means and materials of his ulterior aim. I think it may be said of all the fine arts that no one has ever become a really great artist who has been an idolatrous worshipper

of any one master, or school, or style. He may have laboriously obtained such an intimate knowledge of a manner as may have enabled him to reproduce work closely resembling the original exemplars, and he may attract the admiration of his contemporaries by the perfection of his type. But such imitative dexterity (except by way of exercise and practice) is not a worthy occupation of real genius. It is inconsistent with that freedom which is the life of art, and contributes little to that progress which is alone the result of freedom.

I repeat, therefore, that your attention is invited to the works of art of the fifteenth century, not that you may merely learn to repeat them, but because they are full of beauty and freshness and originality, and were the produce of an epoch in the history of civilization that has been, perhaps, more fertile in men of genius than any period before or since.

I will ask you to devote a few minutes to a contemplation of the phenomena which distinguish this epoch. It was within the limits of this fifteenth century that printing was invented, that oil painting became generally practised, and engraving first known as a fine art. To the same age belongs the beautiful mode of decoration known as *terza vita*, and the revival of terra-cotta work, which had slept since classic times, but which was now carried to a degree of excellence never again equalled.

Then, too, was effected the disintegration of the long-hidden remains of Roman decorative painting led to the brilliant conceptions of Raffaele and Giulio Romano.

Were we to extend our view beyond the limits of the arts, we should find the fifteenth century distinguished beyond others by its vast acquisitions in every realm in which man has sought to extend his intellectual conquests. But I am sure that the magnitude and the importance of the events and discoveries of that date must be too familiar to my hearers to need any enumeration by me.

Combining, therefore, our own feelings to art, it is impossible not to recognize the ardent aesthetic impulse which marks this period.

There was in the twelfth and fifteenth centuries, no doubt, a deep feeling which moved men to raise the magnificent ecclesiastical edifices which ennobled those times. A certain devotional fervour and a profound submission to ecclesiastical institutions were, doubtless, the bottom of these striking manifestations of architectural genius; but in the fifteenth century the development of the fine art in all its departments was due less to any religious impulse, or to any striving after otherworldly grandeur, than to a real living, loving, enthusiastic attachment to art for its own sake.

It is difficult, indeed, to form for ourselves any adequate conception of the state of feeling in this respect which prevailed on the revival of art in Italy. The love of art was at that time no isolated taste, cultivated by a few selfish individuals, and coldly regarded by the great body of the people.

When Cimabue exhibited his picture of the Virgin, painted for St. Martin Novello, the population of Florence locked in crowds to see and admire it. It was conveyed to its destination with all the accompaniments of music and festivity, and the whole city seemed to be party to a great professional triumph. Can we wonder that art triumphed in so congenial a soil?

Descending now to a somewhat later period, when Venice was alarmed at the anticipated approach of a Turkish invasion, and taxes were levied on the city for the national defences, that renowned republic, in the midst of all these alarms and anxieties, remained still mindful of the interests of art, and especially exempted Sansovino and Titian from the poll-tax, in honourable and grateful recognition of the meritorious claims of their countrymen to public distinction.

The day is indeed remote when we, in England, can hope that the tax-gatherer shall be forbidden to cross our thresholds, or to remit his calls upon even the most favoured of our countrymen.

Art has certainly not yet acquired, among us, such valuable privileges; nor does it ask or need them. We value our independence too highly to require more from the State than may justly be expected from its pledged faith, and our acknowledged public services.

Let us look hopefully, then, to the future, and let us endeavour to secure public favour by learning to deserve it.

#### CAMP HOSPITALS A HUNDRED YEARS AGO.

It is only within the last decaunium that, after a long pause, the practice of establishing standing camps in this country has been revived; and in the course of that short period the idea has, so to speak, passed through three distinct stages of development. First, we had the canvas camp at Chobham; then the streets of fragile huts at Aldershot and elsewhere; and now there is a barracks town of stone, brick, and mortar, springing up in the midst of it. It seems as if, in these matters, we must always recur to a bad type, and that, however free from fault our first conception of a *Castra Stalina* may be, we must always end in the contractor's and bricklayer's type, and reproduce, no matter where, the huge, solid barrack, with a fermenting reservoir of fust just in rear of it, polluting the atmosphere and even obscuring the light; and that is just what we see in the very latest, and, it may be added, most expensive style of camp architecture. But at the date of this present writing, when, within some six months, so many soldiers of one sort or another have been added to the fighting strength, and when already a talk is springing up of the necessity of massing large bodies of the soldiers of the new sort and brigading them with the regular troops, it becomes a matter of no little moment to consider how best and least expensively the housing of a few thousands, for temporary purposes, is to be accomplished. Further, there are now more men under arms, by very many thousands, than there is accommodation for. Were there an occasion to arise now for calling into active service every available and enrolled fighting man, the

very first difficulty would be to find some place in which to put them. To say, in a loose and

ignorant way, that such a difficulty can never be felt in a densely-populated country, is just to put an argument into the hands of those who may wish to cry down the popular movement. It is almost as foolish as to say that an armed population before an enemy need never fear for its commissariat, when, as a matter of fact, those who are well able to judge have predicted that an English army of any size, and under these circumstances, would, under the present system, be starved in less than a week. That by the way, however. Our present purpose is to say that this time seems to be a very proper one for looking back and trying to find out how these things were managed by our great grandfathers,—at a time, too, when they were invading France, and, in their turn, looking out for French invasions. Such information we possess in a little book which is not known so well as it deserves to be,—not at all, indeed, beyond the range of a few old medical libraries,—Dr. Brocklesley's "Medical and Economical Observations." As a matter of mere curious reading, it is interesting to know something of the actual life of the men whom Hogarth, and Smollett, and Sterne painted, who could speak of Fontenoy and Dettingen, and who were so soon to speak of Minden and Quebec; but there is much more in the little book that might be turned to useful account at the present time.

No one who is familiar with the most charming biography that ever was written, can need to be told who Dr. Brocklesley was. Every one who counts *Boissell's Johnson* among the select number of books to which he gladly returns at any season, and with always greater pleasure, must remember the friend and physician whose name so frequently recurs in the narrative of the later years of the great sage's life.

It is with regard to the provision for temporary accommodation of the sick that we wish to speak, and, in this respect, Dr. Brocklesley gives us three distinct experiences.

In the autumn of 1758 a large number of sick who had belonged to the unfortunate expedition against the French coast, in the previous summer, were landed at the Isle of Wight, and billeted around Newport. There was terrible crowding, and the hospitals themselves were the most wretched hovels and outhouses. The result was an outbreak of fatal disease. On this, "the ill-fated spot underwent a most rational purification; vinegar fumes, burnt gunpowder, kindled resinous substances were used in abundance; all the contiguous parts were scraped, washed, and fumigated." It was all without effect on the pestilence. Then it was ordered that "no more men be lodged there till after a longer interval than seven or eight days." Still the disease was not stayed. Driven by this necessity, a bold experiment was had recourse to, and the result should be described in Dr. Brocklesley's own words. "Some gentlemen of the hospital proposed to erect a temporary shed with dead boards, upon the open forest, and to have it thatched over with a coat of new straw, thick enough to keep out wind and rain, and capacious enough to hold 120 patients or upwards; for doing which, and the use of the boards, the country workmen exacted 40*l*. Although the hovel was finished in a fashion the most slovenly, and apparently inadequate to the end proposed, upon trial it was found that, notwithstanding much extraordinary cold, as well as moisture, which the sick there lodged had suffered, remarkably few died of the same diseases, though treated with the same medicines and the same general regimen, than did anywhere else; and all the convalescents recovered much sooner than they did in any of the warmer and closer huts and harses hired round Newport, where fires, and, apparently, better accommodation of every sort could be provided for them." While the sickness continued to a certain extent, and remarking "that this currency of fresh air had such amazing salutary effect on the men huddled in the forest," the inspector of infirmaries "procured an order to convert Carisbrooke Castle itself, situated on the extremity of a very high ridge of land," into a hospital for 400 sick." For the result of this experiment we shall again quote the words of Dr. Brocklesley. "At first it was expected the sick brought to that place would do better than their comrades who were lodged up and down in the miserable huts of the town, or than those upon the wild bare forest near Newport, under that occasional hovel; yet the event verified our conjectures only in part; for, though the castle was more prosperous to their recovery than the small rooms in low-roofed houses, yet more proportionally of the foresters were recovered, and that much sooner than any of the rest; and it evidently

appeared that all the damage and inconvenience from cold and redundant moisture in that place was much fiercer to be tolerated upon the whole than the mischiefs complicated on the sick by huddling together three or four hundred men and upward under one roof, and in the outhouses adjoining to the castle."

Our author's next opportunity of observation was at Sandhead Camp, near Guildford, where, in 1760, he found a great prevalence of "putrid, petechial fever." The hospital at Guildford being crowded with more than four times the number it ought to have contained, he "strenuously remonstrated against that pernicious practice of building so many sick in so closely confined a place," and, having obtained from General Cornwallis full powers to act as he pleased, he proceeded as follows:—"I drove perpendicular stakes, about 6 feet high, and placed wattles between them, well coated on the side next the weather with fresh straw: rafters were laid over in a workmanlike manner, and coated thick, like the sides: this made it spacious and airy overhead, and yet abundantly warm and dry for the intended purpose. On this plan, at an expense to the public of only ten guineas, the thatchers in the respective regiments covered in an ample and comfortable hovel, capable of containing about forty sick." The effect on the progress of the disease was most marked and immediate, and the doctor concludes his description by saying, "I candidly ascribe their fortunate escape more to the benefits of a pure, keen air they breathed therein every moment, than to all the medicines they took every six hours, or oftener."

At Winchester Camp, in the following year, the troops were found to be suffering to a great extent, and, for the use of one militia regiment, Dr. Brocklesley was enabled to introduce an improved form of his wattled huts, which he adapted to some special requirements of the ground. Again, with the best results. The same regiment carried the system out more fully in the subsequent year, and was able to congratulate itself on a very light sick-list and low rate of mortality, while "some other regiments of the brigade who had inveterate prejudices against the above practice, lost several more of their sick proportionally; and all that time the militia themselves were known to give ten guineas or more for a good recruit to supply the place of the deceased."

It is worthy of note that, a hundred years ago the register kept of the mortality produced by fever of various kinds, in military life, showed that full eight times the number of men had been lost from that disease than had fallen by their wounds in battle." And this was in the time of the greatest war minister that England has ever seen, at a time of great wars in both hemispheres!

Dr. Brocklesley's "putrid petechial fever" is the disease to which Pringle, a few years previously, had applied the term *gaol fever*, a term subsequently adopted by Howard, when publishing his prison and workhouse revelations. It is what we now call *typhus*. The distinction was not recognized in those days; indeed, it is only within the last twenty years that it has been accurately defined; but we must be careful to remember the essential difference, in respect both of cause and phenomena, between that disease and what we now call *typhoid*, or *pythogenic fever*. The former is the result of overcrowding and destitution; the latter of the decay of animal excretions. The first is the disease of towns and dense populations, and times of general depression. It selects for its victims the middle-aged, the robust, the bread-winners of families. The second lurks in smiling villages, and in places that often seem to be most healthy. Like its congener, *diphtheria*, it smites down children and young people. It is of it, under the name of *gastric fever*, that we read in the papers as slaying young women in isolated country-houses. Where it is present there will always be found a choked water-closet or an open drain.

The prejudices and superstitions from which Dr. Brocklesley was enabled to disentangle himself, but which he found potent for evil on all sides of him, are by no means extinct in these days of progress and enlightenment. For instance, the Secretary for War has recently published a series of rules and the particulars of a process which is to be uniformly followed "in disinfecting hospital bedding and clothes used in cases of *yellow fever*, small-pox, or other contagious diseases." The process is, simply, to close the doors and windows, and then to proceed to make a very nasty smell in the room. Nothing is said about incantations or weird dances to be performed around the stinking cauldron. The gentlemen at

the War Office are too prosaic to admit the introduction of the poetical element, the one thing that might have saved their plan from being quite ridiculous; and yet it is possible that they may have been able to preserve the dramatic unities by finding among the ranks of what is quaintly called "medical administration," some of whom there may be reason to say, as Macbeth said at Forres, that they

"Should be women,  
And yet their beards forbid us to interpret  
That they are so,"

and who would have acted the parts of first, second, or third witch with, probably, as much benefit to the commonwealth as results from the discharge of their more ordinary functions.

In view of such an evidence of retrogression as this order displays, it is not uninteresting to look back and remember that, a hundred years ago, in the days of dress wigs and gold-headed canes, there were men of enlightenment who knew,—and acted on the knowledge,—that the best disinfectant is to open the windows,—that it would often be better to lay a patient out on the barrack-field, *sub jovo frigido*, than to leave him in a reeking ward,—that the first essential in the prevention or treatment of disease is not pills, potions, or globules, but the best and cheapest of all medicines—one which Heaven bestows on us in boundless profusion—fresh air. CWM.

THE PROPOSED MEMORIAL OF THE GREAT EXHIBITION.

OUR readers will be glad to learn that there is at last reason to believe the long-talked-of Memorial of the Great Exhibition of 1851 will now speedily be raised. A meeting of the general committee was held on the 20th at the Mansion House, Alderman Challis in the chair, when the following report, which sets forth the course of events, and shows the difficulties the sub-committee have had to contend with, was read:—

"In 1855, when the sum of 5,212l. had been subscribed and paid in for the erection of a 'Memorial of the Great Exhibition of 1851,' circumstances occurred which led to the postponement of the proposition. The money was invested, and the matter remained in abeyance for a year. In June 1856, the Rev. Dr. Booth and George Godwin, Esq., at the request of the executive committee, consented to act as honorary secretaries, and a sub-committee was appointed to endeavour to carry out the original design of the subscribers,—the erection of a commemorative monument of the Great Exhibition of 1851. Various obstacles were removed, and the then Chief Commissioner of Her Majesty's Works, now Lord Llanover, undertook, so soon as a design should be submitted to him, to decide if a site in the park could be given for it. Advertisements and a circular were accordingly issued, inviting artists of all nations to submit designs under certain stipulations, and these were translated and published in several foreign journals. In reply, twenty-two models and twenty-seven drawings were sent in. With the permission of the committee of Privy Council, these were exhibited to the public, during five weeks, at the museum of the department of art at South Kensington; and the committee of the Architectural Museum allowing the use of their gallery for the purpose. Earl de Grey and Ripon (then Lord Goderich), Lord Montagu, Mr. Pitt, M.P., Mr. Westmacott, R.A., and Mr. Maclellan, R.A., agreed, on invitation by the committee, to assist them in coming to a decision on the merits of the various designs. Several meetings were held, and ultimately design 29, afterwards suggested by Mr. Joseph Durham, was selected as the best. This was submitted to the then Chief Commissioner of Works, Lord John Manners, who after some time gave the committee to understand that, if pressed for an official reply, he should not be disposed to recommend to Her Majesty the appropriation of a site in Hyde-park for its erection; but would willingly decide on any fresh design that might be submitted to him. Under these circumstances the committee looked about for some other course, and, an impression prevailing that an obelisk design would be more favourably received, invited one of the competitors who had submitted an obelisk, Mr. John Bell, to co-operate with Mr. Durham, in order that a design including that feature might be laid before the Chief Commissioner. Such a design was accordingly prepared and submitted to the Chief Commissioner, no longer Lord John Manners, but the Honourable Mr. Fitzroy, since deceased; and after various interviews, letters, and long consideration, the committee were informed, on the part of the Chief Commissioner, that, inasmuch as all permanent structures within the limits of the Park were in his opinion undesirable, he could not grant the permission they sought!

While these negotiations were going on, the determination to form a permanent gallery for the Horticultural Society, on part of the land belonging to the Royal Commissioners for the Great Exhibition, in South Kensington, was arrived at, and the sub-committee have reason to believe that an application being made to the proper authorities a prominent and fitting site for the original design, modified to suit the altered circumstances, would be granted, with the full concurrence of the Royal Commissioners. Under these circumstances the sub-committee have thought it right to lay this statement before the general committee, and to obtain their concurrence in making application for a site on the land of the Royal Commissioners. The amount now in the hands of the committee is 6,045l. 6s.

They entertain a confident hope that if this step be taken, and no fresh difficulties intervene, a memorial will yet be raised creditable to the arts of the country, and satisfactory to those illustrious and eminent persons who carried out to its successful issue the Great Exhibition of 1851.

January, 1860.

GEORGE GODWIN, Hon. Sec.

The Chairman explained that, after payment of all expenses, the interest on the money which had been invested left the amount in hand larger than the sum originally subscribed.

On the motion of Colonel Wilson, seconded by Mr. F. Fuller, the Report was received and adopted; and the committee were empowered to apply for a site on the land named. Thanks were voted to the chairman and sub-committee, and the meeting broke up.

Application has since been made to the Council of the Horticultural Society, who have appointed a committee of three to confer with the promoters of the Memorial. The Royal Commissioners have also expressed their willingness to concur in the proposed arrangement.

STEAM NAVIGATION.

A PAPER "On the Rise and Progress of Steam Navigation in the Port of London," by Mr. P. L. Simmonds, was read by that gentleman at the meeting of the Society of Arts on 25th January. From the mass of statistics, of which the paper largely consisted, we may quote a few items:—

The total number of steamers owned and registered in the United Kingdom, exclusive of the colonies, on the 1st of January, 1859, was 1854. London, the true empire city, stands, as might be expected, at the head of the list, having a fleet of 510 steamers, of 282,403 collective tonnage, and 68,951 horse power. But many of the steam vessels registered here scarcely belong to the navigation of London, as they sail from other ports.

In 1858, 2,254 seagoing steamers entered the Thames, registering 736,365 tons. Of these, 2,200 vessels and 700,761 tons were engaged in the home and foreign trade, and 54, of 35,604 tons, in the colonial trade.

On the 1st of January, 1859, there were registered in the port of London,—

154 steam-vessels under 50 tons measuring	4,677	Tons.
591 " " " " " "	199,588	" "
545 " " " " " "	195,265	" "

Comparing other ports with London, from the last return of steamers, we find they own respectively the following numbers:—Liverpool, 210 vessels, 91,411 tons, and 21,000 horse-power; Glasgow, 161 vessels, 95,116 tons, and 25,632 horse-power; Shields, 115 vessels; Newcastle, 107; Sunderland, 74; Hull, 67; Dublin, 48; Leith, 41; Bristol, 37; Stockton, 34; Greenock, 30; Cork, 29; Southampton, 27; Aberdeen, 14; and Dundee, 11.

Of the entire number of British steamers, 992 (or more than half) are of iron, 861 of wood, and one the *Rainbow*, of steel. 1,263 are propelled by paddles, 559 by screws, and one, the *Great Eastern*, by combined paddles and screw.

The largest and the smallest steamer belong to this port, the *Great Eastern*, of 18,915 tons, and the *Disowned*, of 4 tons.

The importance of steam transport to the metropolis may be estimated by the fact that, exclusive of the larger imports, the declared net value of the exports of the produce of the United Kingdom, from the port of London, in 1858, was close upon 29 millions. Rather more than one-half of the whole of the customs duties received in the United Kingdom is collected in London; for out of the 24,155,852l. gross duty received in 1858, 12,332,061l. was paid in London, and 3,622,503l. in Liverpool.

We own in the United Kingdom and Colonies, at the present time, 2,239 steamers, of 488,415 gross tonnage.

The introduction of steel for building vessels is a novelty, which dates in London from 1857, when a vessel was built by Messrs. Samuda, Brothers, for the *Russians*, to be employed in carrying troops on the Caspian rivers, and she answered admirably. The largest seagoing steel vessel yet built has also been constructed by the same firm, the *Jason*, of 450 tons and 120 horse-power, for the *Russian Steam Navigation Company*. This vessel, though built much lighter than an ordinary iron vessel, was found to be thoroughly seaworthy in every respect, and, though a very light draught vessel, she was found to agree perfectly in this respect with the original intention. Some small steel gun-boats have lately been constructed for the *Spanish Government* by Messrs. Remie and by Messrs. Samuda, and have the peculiarity of being driven by two screws, one at each quarter, the shafts being supported by two wrought-iron brackets, bolted through the skin plates. [As for ourselves, we modestly appropriate a solitary one, as already seen.]

It is scarcely possible to give a very accurate

estimate of the number of persons employed in the various steamship building yards on the river, but the following may be regarded as a pretty close approximation to the number employed, varying, of course, with the amount of work on hand:—

The Thames Iron Works	2,000 men
Samuda, Brothers	1,000 "
Westwood and Ballie	1,000 "
J. Scott Russell	600 "
C. J. Mare and Co.	600 "
Langley and Co.	200 "
Joyce and Co.	200 "
G. Rennie & Co. in the ship department	200 "
	6,000

The largest steam traffic from London is with France, 634 vessels, and 150,134 tons; the next, with Holland, 553 vessels, and 185,490 tons. After these follow Belgium, 332 steamers, and 105,760 tons; and the Hanse Towns, 296 steamers, and 100,896 tons.

It may be interesting to compare the steam navigation of the other principal ports of the Kingdom for the same year. In Hull the foreign entries were 1,187 vessels, and 357,002 tons; the coasting entries 577 vessels, and 105,305 tons. Liverpool, foreign entries, 500 vessels, of 354,217 tons; coastwise, 3,810 vessels, 1,556,073 tons. Southampton, foreign entries, 621 vessels, and 268,506 tons; coastwise, 92 vessels, 33,221 tons.

The immense importance of the steam shipping interest to this port and to the country needs no self-evident, from the statistical details I have laid before you. The improvements that have already been made within a few years are many and great, and I see no limit to the progress which experimental science and practical experience may bring about. The introduction of iron, the adoption of the screw, of superheated steam, and the economy of fuel and working, are evidences of the advance which steam navigation is gradually making; and the enterprise of our builders and engineers will, I am sure, always command for us the supremacy in this important branch of the mercantile marine.

#### THE GRAVE OF LADY MORGAN.

A MEMORIAL has been placed over the remains of this gifted lady in the Brompton cemetery. It consists of a flat slab, supported by six pillars: below is a block of polished white marble, on which is inscribed "Sydney Lady Morgan," and the date of her death in April last. The time of her birth is not mentioned. Above the inscription is an Irish harp of ancient form resting on two volumes, on one of which is written "Irish Girl" and on the other "France." The tomb is backed by trees, which add much to the effect. The Polish firs which line the main avenue of this cemetery are growing rapidly, and promise, in the course of a few years, to be a beautiful feature. In laying out grounds of a gravelly soil, this species of tree should not be overlooked in burial-grounds: the dark foliage both harmonizes with the spirit of the place, and aids the effect of the monuments.

#### THE PICTURES AT BROMPTON.

THE Vernon, Sheepshanks, and Turner galleries of pictures, now afford an intellectual treat. Here, well lighted, are some of the best works of Landseer, Mulready, Leslie, and other famed artists. The student of art may trace the progress of various painters, the variety of their styles, the advance of some towards perfection in the truthful imitation of nature, and the expression of poetic fancies, and the decline of others in the truthfulness of nature. Now, the public have an opportunity of forming a true estimate of the value of Turner's gift to the nation, and can see how much reason they have to be proud in having belonging to our school so great a painter. Two large rooms are filled with Turner's works. Here are the purely painted pictures, somewhat feeble, but yet remarkable, in consequence of their unaffected and matter-of-fact imitation of nature. These pictures, such as the "Bay of Bains," the production of the prime of life, are executed with such care, that they will be as lasting as some of the most remarkable works of the Flemish school. How remarkable are the cool, clear, grey tints of some of these works. How wonderfully the daylight and freshness of nature are shown; how exquisite are the forms. Then there are pictures of a grander kind, such as "Haemihal crossing the Alps," "A Snow Storm amongst Mountains," that wonderful representation of "A Shipwreck." Look where you may, how harmonious is the colouring, and how remarkable are the composition and arrangement of light and shade. The pictures of the latter

part of Turner's career contrast strongly with those to which we have referred: more luminous, more imaginative, these are less truthful in natural colouring, and less careful in detail. How poetical, however, are the fancies, and how wonderfully, in a peculiar way, they are expressed. None can dwell on these pictures without both pleasure and instruction.

It is satisfactory to notice, while passing through this and other galleries, that in most instances the mechanical execution promises that they will for long remain in a perfect condition. The cracking of the pigments which so much disfigures the works of Reynolds, and some other masters, is little seen. In this respect, the "Choosing of the Wedding Gown," the "Crossing the Brook," and others of the best pictures by Mulready, are useful examples for the art student. Carefully glazed and protected from varieties of temperature, and the dampness and smoke of the atmosphere, the colouring, in all probability, will some centuries hence be as bright as at the present time. The pictures by Webster, Lance, and several others are remarkable in this respect.\*

#### RAILWAYS AND CITY THOROUGHFARES.

THE applications to Parliament for powers to construct railways in the City, or affixing the people inquire how the thoroughfares will be affected? Mr. Heywood, the City surveyor, states that "the total area, within the City, scheduled for these various projects, is about fifty-three acres; the number of public ways of all classes to be spanned by arches is about seventy; and the number to be entirely absorbed and stopped up, about forty-two,—a larger area affected by new schemes than in any previous year since 1846."

It is quite evident that, unless great care be taken, the "blocks" of the City will be enormously increased, and railways, instead of being a convenience, will, in many respects, become a source of nuisance. The subject should be thoroughly ventilated, and the various applications examined as a whole. The street accommodation of London is seriously threatened.

#### HOW COINS ARE MILLED.

THERE are few things on a small scale in the mechanical way which more puzzle the popular mind than what is called the "milling" on the edges of the gold and silver coins of Great Britain. Everybody is familiar with milled money; but few know how the milling is produced. The very term, indeed, is likely to mislead, and the uninitiated would naturally imagine that each particular coin, with its circumference serrated, had been put into a lathe and impressed by a revolving "milling tool" as are the screw heads of mathematical and other instruments. This, however, is far from being the fact. The process is much more simple. We saw it the other day at the Mint, where they are now coining sovereigns by wholesale, as it seemed to us, and will attempt briefly to describe it.

Our readers will perhaps be good enough to picture to themselves a number of shankless brass buttons, which have been double gilt and burnished on both sides. They will thus have a tolerably correct idea of what, at the Royal mintage, are known as "blanks" for sovereigns. These blanks are slightly smaller in diameter than finished sovereigns, and when self-acting machinery has carried forward one of them to the surface of a die fixed in the stamping press, and intended to imprint one side of it, a steel collar, which has been bored out to the precise size of a coined piece, and interiorly milled in the lathe, rises, by force of a spring upon which it rests, and encompasses, loosely, the embryonic coin. Next, another die, affixed to the moveable screw or pin of the press, descends with much rapidity upon the blank, which being as soft as fire can make it, inevitably takes two impressions—head and tail—from the dies between which it is pressed, and expands until it thus also takes its own milling, from which it thus also takes its own milling. The collar becomes, therefore, an edge mould, into which the plastic metal is squeezed by the self-same power, which makes it copy, like sealing-wax, a stamp, the engraved devices of the stamped steel dies. When one blank has been thus stamped and milled, the collar is made to descend, and permit the mechanical finger and thumb, which is

It is a practice of the last-named artists to thinly varnish their pictures soon after they are finished, and after three or four years have passed, to rub the varnish carefully off by the friction of the hand, and then delicately apply more varnish.

advancing with another blank, to push the coin from its seat into a pan placed to catch the precious deposit. At the rate of seventy per minute, at each of eight presses, are the blanks converted into what may be called *pieces*, by the coiners of the Mint; and a collar such as we have endeavoured to describe will mill many millions of sovereigns before becoming unfit for use. Such is the mystery of milling money. As the art of money-making is highly interesting, it is possible that some day we may relate some more of our impressions of the Mint.

#### THE SOUTHERN OUTFALL SEWER CONTRACT.

At a recent meeting of the Board, Mr. Tite, in answer to comments which have been made on the difference between the tenders for the Southern Outfall Main Sewer, £22,550*l.*, and 431,715*l.*, showed that such differences were not uncommon, and said he considered that it was no part of the duty of the Board to investigate the differences between contractors, or to inquire why one contractor required 431,000*l.* to do works which another firm, equally respectable, was willing to execute for 290,000*l.* He conceived that all the Board had to do was to see that the work was properly executed according to the contract; and, if they were to ask those gentlemen why they charged so much more than other contractors, of course they would refuse to assign their reasons for doing so.

The amount of security required for the performance of the contract was reduced from 20,000*l.* to 10,000*l.*; but Mr. Brotherhood, it is stated, has not succeeded in obtaining parties willing to be bound in that amount. A private meeting of the Drainage Committee has been held to consider what should be done under the circumstances, and the committee will report to the Board this day, Friday.

#### COMPETITION.

Croydon New Cemetery Buildings. — At a meeting of the Local Board of Health, held last week, the following architects were named to prepare designs for the projected chapels, lodges, &c., to be built on the new burial-ground, in addition to those mentioned in our last impression, viz. Mr. Dawson, Mr. Henman, and Mr. Fuller.

#### SOCIETY OF FEMALE ARTISTS.

THIS Lady-painters hold their fourth exhibition in the gallery of the New Water Colour Society, in Pall-mall, and have brought together 317 drawings and two busts. Without being strikingly better than the last year, it is at any rate not worse. Fifty-six of the works are copies; the remainder original works. Mrs. Elizabeth Murray has several pictures of more or less excellence: the principal, "Adoration and Admiration" (185) shows a female devotee on her knees before a crucifix, which is being exhibited to her. The female head and other parts are exceedingly well painted, but the position of her lower limbs is doubtful. Mrs. E. M. Ward sends two good works (274) "Howard's Farewell to England," and (281) "Sunny Hours," which includes some sunny faces. On the same scene, "Five original drawings," by the Misses Taylor, in one frame (288), deserve mention. Miss Gillies has two pictures, "Waiting for the return of the Herring Boats" (130), and "Rebekah at the Well" (196), both works of great merit, the latter especially. Mrs. Valentine Bartholomew, who is always charming, has several drawings. Mrs. Rayner, in architectural drawings, stands alone; witness (90) "The old Conduit in the Market-place, Wells," "Canterbury Cathedral," and several others.

Mrs. Swift and her daughters, Miss Kate Swift and Miss G. Swift, are considerable exhibitors. (48) "Expectation," by Mrs. Swift, is a very charming head; and Miss Kate Swift's "Divided Interests" (70) is one of the best pictures in the collection. Mrs. E. Dundas Murray, who acts as secretary, has two pictures, "Dysart, Fifeshire" (120), and "Entrance to the Kyle Sku" (192), both noticeable. Mrs. Oliver has become more solid and precise in her painting. Mrs. Withers' flowers are admirable, and not less so are those by Miss Emma Walter. If the faces were as good in their way as the lace-collar in (68) "Olivia and Sophia in their Sunday finery," by Mrs. Margaret Robinson, it would be a capital picture. "Gladstons and Ceramiums" (75), by Miss Florence Peel; "Road between Capel Curig and Llan-

beris" (109), by Miss Gastineau; Miss Baines's enamel, after Herbert (111); "Still Life," by Miss James (166); the grapes in 318 by Miss C. James; Miss Bridman's "Blind Beggar" after Dyckman (239); all aid in making it true in two senses, that an hour may be spent pleasantly in the society of Female Artists.

#### THE WORKS AT WALTHAM ABBEY CHURCH.

THERE is no place for a day's excursion, in the neighbourhood of London, more interesting to the architect and antiquary than the town of Waltham Abbey, with its church attributed to one who was the last of the Saxon kings, and other remains of minor interest. Within a moderate distance, on the opposite side of the railway, is the town of Waltham Cross, which is even better known for its principal relic of old architectural work, now presenting little of its original condition,—though, in "restoration" and different materials, sufficient of its original beautiful character and details, to make it deserving of a visit.

At Waltham Abbey Church works of reparation have been in progress during the past year, under the direction of Mr. Burges; and others still necessary are proposed. During the last year also, a discussion has been going on, and which is still continued, in the pages of the *Gentleman's Magazine*, on the question of the actual date of the earliest portion of the church, which controversy originated in a paper by Mr. E. A. Freeman, that we find printed in the second volume of "Transactions of the Essex Archaeological Society," where also there are some "Notes" by Mr. E. Littler, accompanied by plans and other illustrations of the antiquities of the Abbey and the town, and a note by Mr. W. Stubbs, on the date of the dedication of the church, not altogether conclusive.

The discussion has proved interesting, and is important with reference to the question of date of the earliest work, commonly called Norman by architects, the same question to which Mr. Scott contributed some elucidatory matter from his examination of the remains of the Confessor's church at Westminster in the paper read at the Institute of British Architects, and recently printed by us. As regards Waltham Abbey Church, it being undoubted that there was a church by Harold, substituted by him during the Confessor's reign, for an earlier one, or between 1059 and 1060; and Mr. Freeman having shown the probability of truth in the tradition that Harold's body was conveyed there after the battle of Hastings, and interred; the question is whether any of the existing work is of the Pre-Norman period, or whether it does not belong to the time of Henry I., or Stephen, when it is known that considerable works were undertaken. The points of the controversy have been summed up by Mr. Burges, in a succinct report just about being issued, in which also we find matter relative to the dates of different portions of the later work, and to what might have been the original arrangement of the plan. Mr. Burges's details, as in reference to the triforium and vaulting to the aisles; and his suggestions regarding the form of Harold's church, are more satisfactory to us than his restoration of the eastern arm of the cross of the church of the time of Henry I.; but we gladly avail ourselves of the opportunity to lay before our readers the illustrations which accompany his report, and to furnish some further particulars of the question which is at issue. The external elevation of the east end, together with one of the two sectional views, show the church as it is at present, or the nave which remains, of the original structure; and the plan will explain also what have been the additions of fourteenth century and later date. The other sectional view (with the addition of the lady-chapel) shows the original arrangement of the triforium and its decorative character, as well as the vaulting of the aisles, as established by discoveries made in the progress of the recent works.

Premising that the church by Earl Harold was undoubtedly a building of much importance, having a leaded roof, and decorations to the capitals of the columns of gilt brass-work, it is to be mentioned that, according to the author of the account "*De Inventione Sancte Crucis Walthamensis*," of which parts have been published in the "*Chroniques Anglo-Normandes*" of M. Francisque-Michel, some work of considerable importance was going on in the reign of Henry I. or Stephen, which rendered necessary the removal of the body of Harold. Without deeming it safe to come to any conclusion on the subject whilst evidence is being brought to light in the course of the present works, Mr.

Burges thinks that the repairs or rebuilding in Henry the First's time, and the removal of the body, may be perfectly consistent with the fact of the present building, that is the ancient nave, being of Harold's time. He says:—

"In all probability the same thing happened as at Canterbury, where the contemporary of Harold, built a church consisting of a nave, transepts, and a shallow apsidal chancel, the which latter a few years afterwards was taken down, and a long choir added. Thus at Waltham, Harold's church might have ended with an apse immediately eastward of the present church, or it might have had transepts and been continued, as shown in the dotted line on the accompanying plan. Somewhere at the beginning of the twelfth century, i.e. when the author of the *De Inventione* was writing, the old apse was probably taken down and a long choir with aisles, chapels, &c., added, the transepts (if any) being likewise enlarged. I have ventured to mark on the plan an imaginary idea of this new choir, availing myself as much as possible of the foundations shown in Mr. Littler's plan, published in the Transactions of the Essex Archaeological Society."

The main point in doubt as to plan, would be the reasonableness of this conjecture of an apsidal form of the east end with chapels; since Mr. Burges's discoveries, partly indicated on the plan engraved (near the apse), would seem to favour the view of a different arrangement.

The subsequent works of the church and abbey date from 1177, when Henry II. remodelled the foundation, substituting monks for secular priests. The north clerestory of the present church, with the exception of the two eastern bays, and a vaulted building called "the potato-house," which is almost the only relic of the conventual buildings may be referred to this time. In the reign of Henry III. it appears that work of some importance was completed. Mr. Burges says:—

"The long Norman choir was not destined to last long, for Matthew Paris tells us that in 1242 the church of the canons at Waltham was solemnly dedicated. This dedication, which implies that some important part of the church had been rebuilt, could not apply to the nave, for we know that it remains nearly in the same state as it was left in the eleventh or twelfth century; it must therefore have been the choir, which had been either reconstructed or so altered that a new consecration had become necessary."

This, as we understand it, is the ground for believing that the foundations discovered by Mr. Littler, which would seem to be those of a square-ended choir, were, at the eastern extremity at least, those entirely of work of the time of Henry III.; the principal Norman choirs having apsidal termination.

In the reign of Edward II. a fine western end was added; and in the two westernmost bays, the nave arches and triforium were thrown into one composition, and pointed arches substituted for original circular arches—the vaulting of the aisles, which had pushed out the side walls, being destroyed. A strong-framed strut, which it was necessary to put up at that time, to prevent accident, still remains. The Lady Chapel on the south side, is of the time of Edward III. Its west window had a double plane of tracery. Below the chapel is a crypt. Later in the reign, a window of four lights was inserted in the north aisle of the nave; and something was done to the Abbey buildings—portions of the work having afterwards been inserted in the west tower. Of the fifteenth century, there is a window in the north aisle. In the next century, at the dissolution of the monasteries, the choir and transepts were destroyed, the nave, as belonging to the parishioners, being left. The present western tower was built in the time of Queen Mary, out of materials procured from the remains of the central tower, and others.

At the beginning of last year, the area of the church was found filled with pews, and furnished with two western galleries, and with another gallery on the south; the majority of the original windows on the north side had been cut away, and large square ones had been inserted; the columns were cracked and split, and also injured by the beams of the galleries; and there was a low-witched roof above a plaster ceiling. A porch had been added on the south; and the tracery of the windows of the chapel had been destroyed, its walls covered with plaster in imitation of rustic work, and the interior converted into a school-room. The western doorway and western end of the south aisle had been restored, however, under Mr. Poynter's direction.

The whitewash and plaster have been, or are being, removed internally and externally, throughout the church; and the pillars and clerestory repaired. All the pews and galleries have been removed; oak seats of appropriate character are being constructed by Mr. Burrell, of Norwich; and a contract is entered into for lowering the pavement of the church, to show the bases of the pillars. Before the church can be fit for the religious service, it is considered necessary that

the whole north wall and windows, and parts of the south aisle, should be repaired, besides what is necessary for the lighting and heating.

Other works, however, of great importance, are advised. But "Restoration" is deprecated: no old work would be destroyed; new work would be added only when necessary, and then only in such manner as to be distinguishable from the old work. For the whole, it is estimated that 4,000l. will be required. It is not contemplated to restore the vaulting or filling-in of the triforium; but the plaster-ceilings would probably be removed, and the ceiling-joists covered with boarding—decorated, perhaps, in manner similar to the work which there is at Peterborough. New doors; the removal of the south porch, and substitution of a penthouse, as shown in the view; plastering to the rubble-work; a new east end and window, in the style of the thirteenth century, as preferable to an attempt at restoration of the Norman; a vestry formed of the materials of the so-called "potato-house" removed; extensive repairs to the exterior of the southern clerestory; reinstatement of the original flint and stone work to the upper part of the tower, as shown in old prints; considerable works, structural and decorative, at the Lady Chapel; and a drain round the church and water-pipes, are considered as needed.

It is impossible for us now to enter further into the interesting question of the date of the early Norman work unless by quoting Mr. Burges's summary of the points of the controversy. Mr. Freeman, however, it may be well to say, holds that there was an Anglo-Saxon style, and an Anglo-Norman style, the one contemporary with the other; that there are Saxon buildings later than 1066, and Norman buildings earlier; and that Waltham Church is a Norman, though an early building. Much of the question, as in other cases, has been supposed to turn upon the manner of execution of masonry, whether with chisel or axe; though, in such cases, taking the nature of the tool as settled, does not make clear the fact that work done with the axe was necessarily rude, and, therefore, early; and it is maintained in favour of the early date, at Waltham, that there is nothing that could not have been executed with the axe. Mr. Burges says:—

"The following are among the principal arguments used against the presumption that the nave of the church is the work of Harold:—

1. That the architecture is far more ornamented than any building contemporaneous with Harold,—such as the remains of Edward the Confessor's Abbey at Westminster; the lower part of the west front of the *Abbaye aux Hommes*, Caen, built by William the Conqueror; and the chapel in the Tower of London.

2. That the common practice of those times was to build a choir, and to consecrate that, leaving the nave, &c., to be built by the piety of succeeding generations.

3. That an obscure passage in the *De Inventione Sancte Crucis* would imply that the church (*ecclesia*) was rebuilt somewhere in Henry I. or Stephen's time, when there was occasion to move Harold's holy.

4. That there are sundry joinings of masonry and differences in detail, which would imply that the two easternmost bays are of a different date from the rest of the work.

To this it has been replied:—

1. That the richness of a building is no certain criterion of its date, and that there is no portion of the ornament that could not be done with an axe; whereas at St. Bartholomew's, Smithfield, time of Henry I., there are mouldings which must have been done with the chisel.

2. That the practice of building and consecrating a choir first of all, was generally confined to the monastic churches, but would not equally apply to secular ones, more especially to those built by one wealthy person; and there is every reason to believe that Edward the Confessor completed his church at Westminster; why not Harold at Waltham?

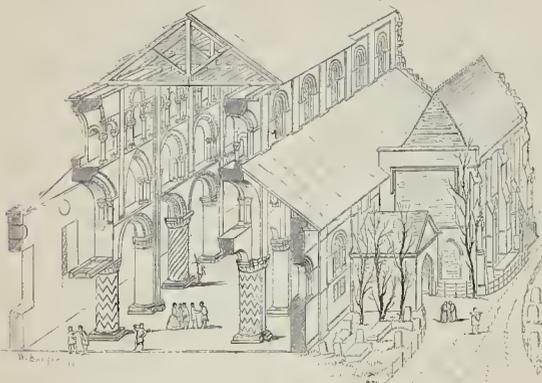

3. That the obscure passage from the *De Inventione* proves nothing beyond the fact that some rebuilding took place in the time of Henry I.; but it by no means implies that the nave was the part reconstructed; on the contrary, it would rather point to the choir, where the body of Harold was no doubt interred.

4. That it is very true that there are sundry breaks in the work at the second pillar from the east end, but it is very doubtful whether the two bays in question are earlier than the rest of the work; on the contrary, there is some reason to believe them later.

To sum up, although it can scarcely be denied that the architecture of the nave of Waltham more resembles the work of the time of Henry I. than that of those very few remains of buildings contemporary with Harold, still it is quite within the range of possibility that Harold might have built it, and there is no distinct proof to the contrary."

Many curious features in the masonry have been lately discovered. With the reference to these we must be content, and will merely add, as we are requested, that subscriptions towards the work are received by Messrs. Fuller, Banbury, & Co., of Lombard-street, the Rev. James Francis, incumbent, and members of the committee; and add the expression of our wish that so interesting a relic as the church of Waltham Abbey, may be preserved as an illustration of passages most interesting in our history, and a link of which the exact place will no doubt be shortly fixed, in the chain of progress of our architecture.

## WALTHAM ABBEY CHURCH.

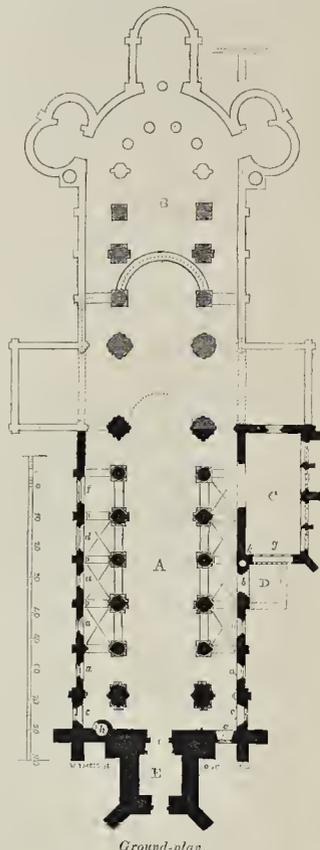

Section and View of the Church: 1859.

External Elevation of the East End: 1859.

Section and View, showing the probable appearance before the alterations in the Fourteenth Century, but with addition of the Lady-Chapel.

Ground-plan.

## REFERENCES TO THE GROUND-PLAN.

The dotted lines show the presumed extent of Harold's Church.

- A. Nave.
- B. Presumed Choir, temp. Henry I. or Stephen.
- C. Lady Chapel.
- D. Modern Porch.
- E. Tower, temp. Philip and Mary.

- a a a. Norman Windows.
- b. Norman South Door.
- c c c. Decorated Windows, early fourteenth century.
- d. Ditch, late fourteenth century.
- e. West Doorway, early fourteenth century.

- f. Perpendicular Window.
- g. West Window of Lady Chapel, with two planes of Tracery.
- h. Staircase to Tower.
- k. Staircase to Room over Porch, now destroyed.

## KIOSK FOR THE VICEROY OF EGYPT.

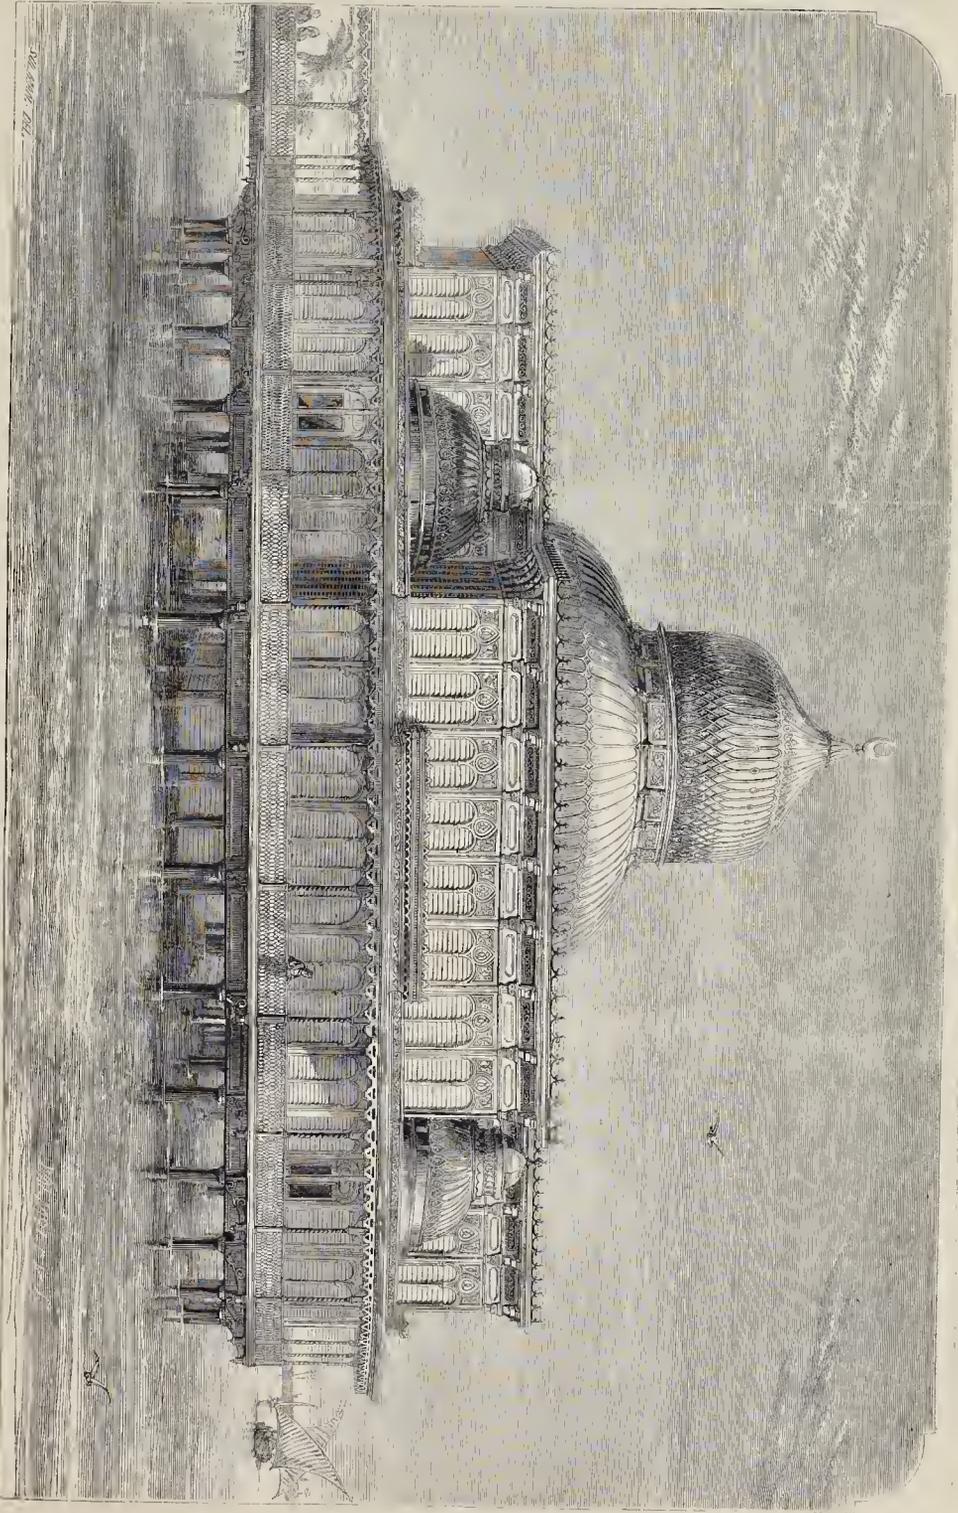

The kiosk for the Viceroy of Egypt, of which we give a view, has been constructed in London, and is still in the Isle of Dogs. It is intended for erection, as we understand, at Kâfrellais. It will stand at some distance in the water, the depth of which is 60 feet at its highest rise, and 30 feet at the fall. The foundations are of cast-iron cylinders, which will be deeply imbedded in the sand, and will be raised about 8 feet above the highest water-mark. On the top of these are to be laid girders, for supporting the platform, which is of a circular form, and measures 120 feet in diameter. Projecting from the outer ring of cylinders are

brackets, on which the balcony rests. The form of the upper part of the building is that of a cross. It has five domes: the largest, which is in the centre, is surmounted by a crescent.

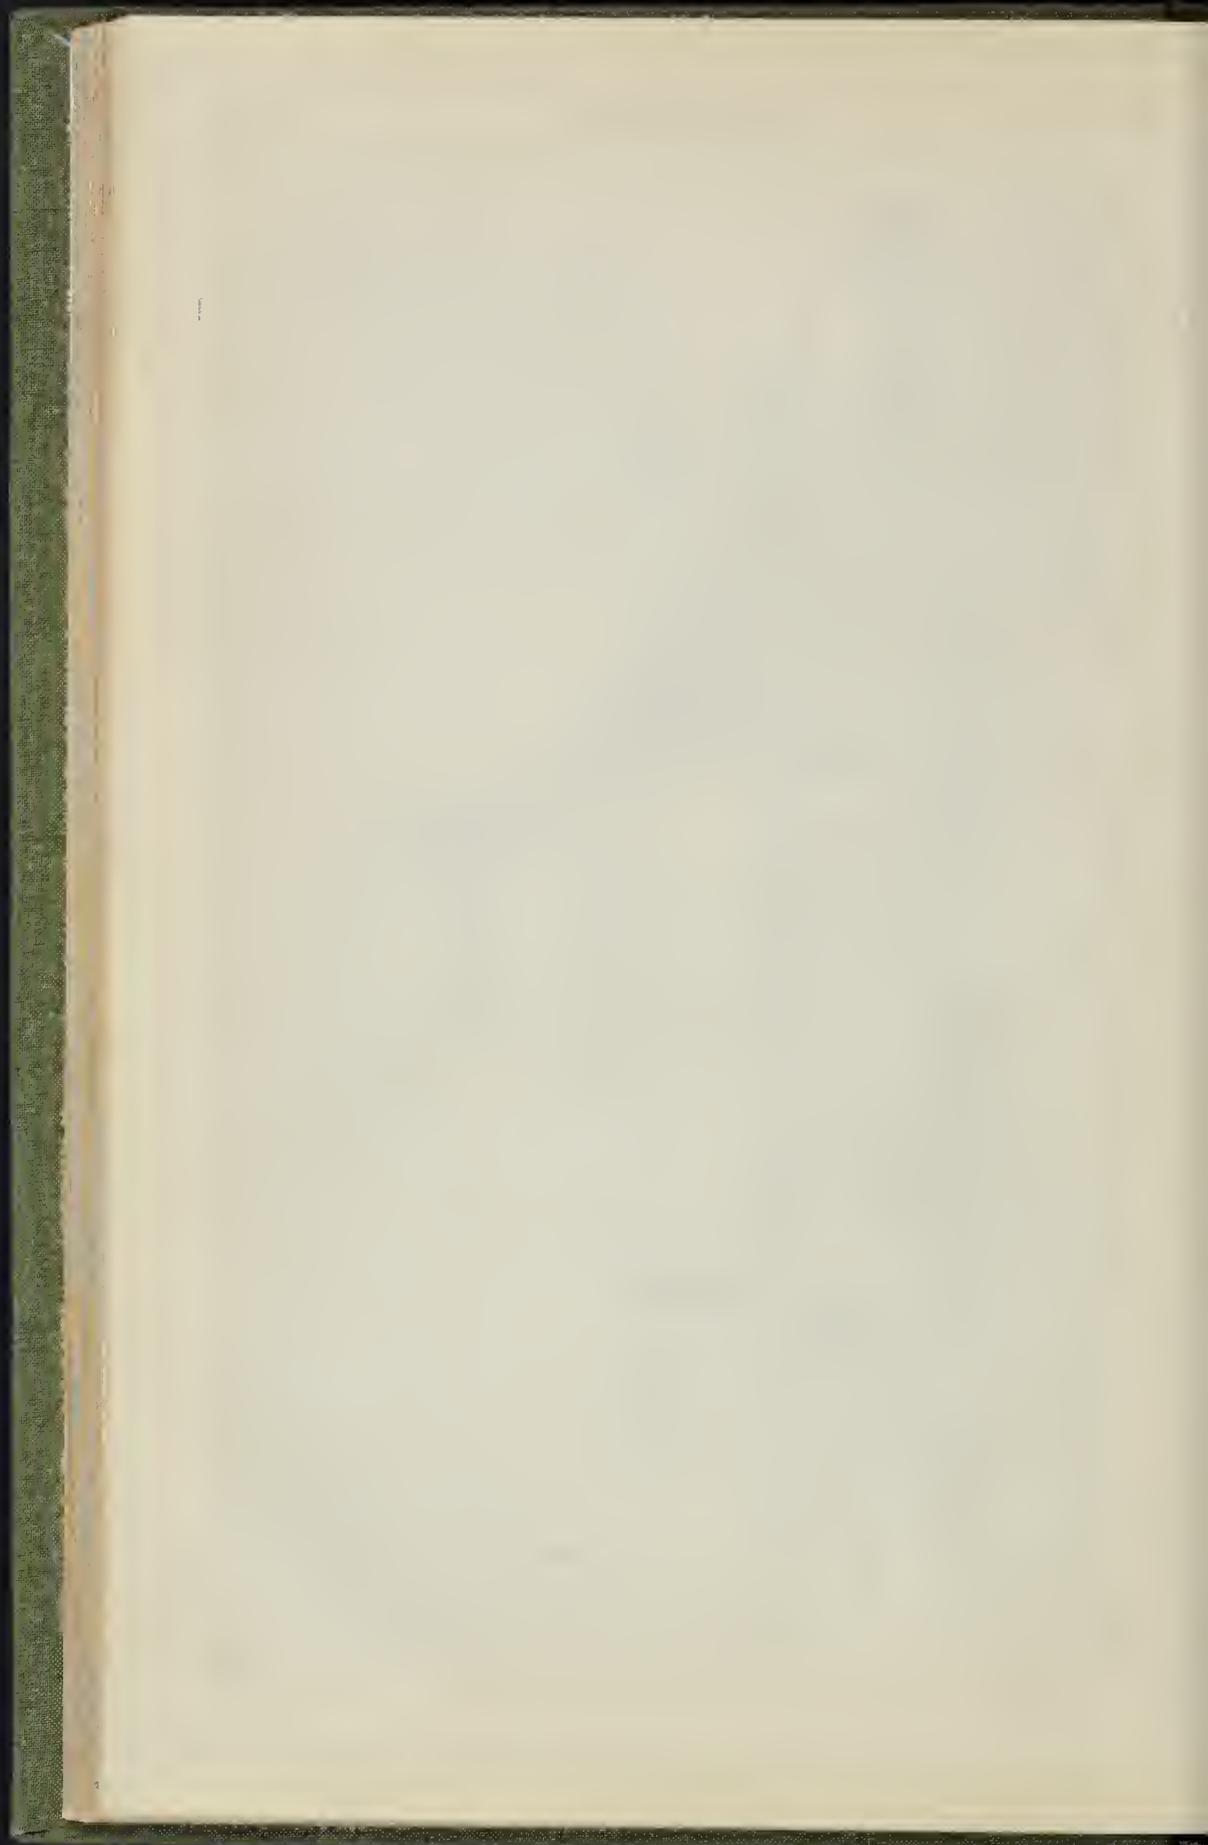

The bath is to be suspended from the centre of the dome by an ornamented chain, which will pass along the top over concealed pulleys, and then be attached to winding machinery—the object being to suit the level of the bath to that of the water of the Nile; and, in order to enter the bath at any level, there will be a square well staircase surrounding the bath space, which space will be inclosed below the building, and under the water, by rough plate glass jalousies. The various rooms

will be lighted in the daytime by windows with glass casements, provided with louvres, to shade off the sun; but at night they will be illuminated by chandeliers suspended from the ceiling. The four small projecting portions of the building are to be fitted up as divans. The main part of the building is of iron and glass, but the interior will be lined with plastering, and have decorations of appropriate character.

From the shore to the kiosk there will be a platform, supported by columns similar in character to the building itself. There will also be a landing-stage, with stairs for the accommodation of parties entering from the Nile.

IRON KIOSK FOR THE VICEROY OF EGYPT.

## AN ESCAPE FOR WORKHOUSE GIRLS.

A PROPER and sufficiently extensive means of disposing of the children reared as paupers in the workhouses of the metropolis and large cities would undoubtedly cause a great decrease of pauperism and crime. The training of the workhouses does not well fit the young, particularly of the female sex, for study and useful employment in after life.

As regards the girls who have been brought up in these places, but a small portion continue steadily in domestic service; and they return, to the great cost, in several ways, of the parishes. On summer evenings groups of young females, of the ages of from 15 to 20 years, may be seen in the workhouses exhibiting the most abandoned language and conduct. Many of these young women are driven into the streets, become inmates of the prisons, and spread to a wide extent a large amount of contamination. A better class of persons—those who have not been accustomed to pauperism,—should be appointed to superintend and manage the training of both boys and girls than are now usually employed.

The additional charge would in the end prove a saving. At present, however, it is certain that affairs in this respect are far from being satisfactory. We have before directed attention to this subject, and are glad to notice that the ladies of the Workhouse Visiting Society, of which Miss Burdett Coutts and Miss Louisa Twining are members, have endeavoured to form a Female Home for workhouse girls above the age of 16, where they could be properly trained for service, either at home or in the colonies, as an intermediate step between the workhouse and a domestic home. It appears that the ladies above mentioned having suggested the great need of such an institution to several of the metropolitan parish authorities, found that the Poor Law Board consider that such a plan is illegal. It is impracticable therefore, except fresh power be given by Parliament to open such Homes. It will surprise and grieve many, who have considered this subject, that such should be the case. We trust, however, that measures will be long before taken to enable those who are anxious to do so, to try this important experiment.

## INSTITUTION OF CIVIL ENGINEERS.

On January 24, Mr. Bidder, president, in the chair, the paper read was a "Description of the Works and Mode of Execution adopted in the Construction and Enlargement of the Lindal Tunnel, on the Furness Railway," by Mr. F. C. Stileman.

It was stated, that the Furness Railway, of which Messrs. McClean and Stileman were the engineers, had been principally projected for the conveyance of minerals. In August 1854, it was decided to widen the line, and to enlarge, or open out, the Lindal Tunnel. The latter alternative was entertained, in case it should be considered necessary to resort to that plan, in order to ensure the regular passage of the trains during the progress of the works. But as it was found that the cost would be doubled, it was determined to enlarge the tunnel; the tender of Mr. William Tredwell being accepted for that purpose.

The original tunnel was 563 yards in length; of which 176 yards were in solid rock, and 387 yards in loose material, lined with sandstone, rubble masonry. The contract price for the portion in solid rock was 64. per lineal yard, giving about 6s. 2d. per cubic yard, and for the part that was lined 157. 10s. per lineal yard. The length of the enlarged tunnel was reduced to 460 lineal yards; of which 123 yards were in solid limestone rock, and 337 yards in loose material, lined with fitted limestone rubble, 2 feet to 3 feet in thickness, set in Atherhall lime mortar, the stone being obtained from the adjacent cuttings. The additional cost of that part of the tunnel which was in rock amounted to 214. 4s. per lineal yard, and of the portion which was lined to 387. per lineal yard.

The tunnel was increased in width equally on each side of the existing single-line tunnel, the level of the rails remaining the same. The works of enlargement were commenced in June, 1855, at No. 3 old shaft. This was widened, and divided down the centre, so that it could be worked as two separate shafts,—one in connection with each side of the old tunnel. Top headings were driven for short distances, at the proper levels, above the existing tunnel, when the material was found to consist of dry, hard clay, and gravel. It was observed, however, that the ground had become set

and broken up, from previous mining operations, to a much greater extent than could have been anticipated. The crown was kept sufficiently high to allow of the ground being excavated without interfering with the original tunnel. The cills, for the support of the bars, were placed 3 feet above the crown of the small tunnel, and rested upon it and the material forming the sides. A portion of the masonry between the cills was then removed, and the excavation for the side walls was proceeded with. The working by shafts being afterwards dispensed with, it was necessary, in order to obtain another "face" to work at, to break through the original tunnel. A man-hole, sufficiently large to admit a miner, was made through the soffit of the arch, and this was carried up until the heading was reached; the ordinary method of tunnelling being then adopted. The cills were supported by two upright props, passed through the haunches of the old tunnel, and by raking struts, or stays. After the excavation had been completed to the level of the cill, and the materials had been removed, the arch and side walls were taken down, and the excavation at the sides proceeded with. Small cills were placed about halfway down the side walls, to carry the props supporting the ends of the first cill, and these again were propped from below, as the material was removed. A hack cill, to assist in carrying the crown bars, and a framing, called by the miners a "Horse-head," to relieve the pressure on the cills, were also frequently used.

From the commencement of the works in June, 1855, to their completion in November, 1856, nearly seven thousand five hundred passenger trains passed through the tunnel, without the slightest casualty to either description of train, or accident of the most trivial character to any individual.

## NEWPORT BOROUGH SURVEYOR.

At a recent meeting of the Town Council, there were in attendance the following candidates selected from between forty and fifty:—Mr. W. A. Dixon, Newport; Mr. Gordon, Stratford; Mr. Barry, Liverpool; Mr. Fox, Bristol; Mr. Conyers Kirby, Gloucester. These gentlemen were severally introduced to the Board, and questioned as to their qualifications. In the discussion which ensued, a question arose as to pupils being allowed the surveyor, and it was debated at some length. Mr. Lyne moved, and Mr. E. J. Phillips seconded, "That the surveyor be allowed one pupil at a time." An amendment was moved by Mr. Shepherd, and Mr. Morgan seconded it, "That the surveyor be permitted to take no pupils." The amendment was lost, only six bands being held up in its favour. The resolution was then declared to be carried. It was agreed to submit the whole five names to the Council at once, then to strike off the lowest, and so on until one candidate should obtain a majority of the votes of the members present. Ultimately Mr. Conyers Kirby was declared elected.

## FOREIGN ENGINEERING WORKS.

THE concession of the railway from Quitanilla de los Torres to the mines of Orho has been adjudged without any subvention to Don Santos Guindarillas.

The contract for the works of the fortifications of Antwerp has been adjudicated to the firm of J. Powell & Co., called, "La Compagnie Générale des Matériaux de Chemins de Fer."

The works of the line from Maestricht to Liège are to commence at once, inasmuch as the plans have been approved of by the Government. The contract has been let to a general contractor, and the land is being settled for.

The Spanish journals announce that M. Salamanca, to whom the concession of the Portuguese lines has been granted, has formed a company to carry them on. Among stranger capitalists figure the names of the Count de Morny, M. Chatelet, Delalande, and other founders of the ancient Grand Central of France, which has been merged into other lines.

M. Lalanne, engineer-in-chief and director of the works of the Northern Spanish Railway, is at this moment visiting the whole line to give fresh impulse to the works. The transport of the immense quantity of rails now lying at the port of Santander can only proceed slowly by the Isabella II. Railway, on account of the gap which yet exists on that line between Moranca and Barcelona. Consequently, the permanent way of the Northern line will experience some delay. The rails are laid between Valladolid and Palazuelos; the section from Valladolid to Alar is to be open

at the end of February. In the course of this spring the line from Madrid to the Escorial will have its earthworks completed. Contracts have been let to parties at Agen to construct the four tunnels between Tolosa and Legorreta.

An experiment has been just made on the Barcelona and Saragossa Railway of a new railway break, the invention of Don Agostin Castellvi de Molins de Rey. A train at full speed was stopped in twenty yards without any shock.

The following are some details as to the state of the works at the tunnel under the Alps on the Victor Emmanuel Railway:—The necessary buildings for the Bardonecche end of the tunnel are nearly completed. They are of very large proportions. The same works have been erected at the Modane, or Savoy end, but of a totally different design. Within the last two months, at Bardonecche, 2,000,000 of bricks have been made. The leading is being driven, as we have before stated, from each end, by the ordinary means: 820 metres have thus been carried on with arch sheeting to about two-thirds of that length.

A French review, "La Libre Recherche," published at Brussels, gives us the following details on the Italian railways:—"Up to the present time 1,757 kilomètres are completed; 2,339 are in construction; 634 kilomètres have been conceded to companies, and 329 kilomètres have been decreed. In ten years hence, 5,000 kilomètres will have been completed, which will give at the rate of one kilomètre for every 53 square kilomètres of territory, about the same proportion as exists in France, and more than in Austria, where there is only one kilomètre of railway, for every 80 kilomètres of imperial territory. The Italian state possessing the greatest length of railway communication is Piedmont; whereas in 1848 it had no railways. Those least gifted with railways are the Roman and Neapolitan states. In the course of 1860, the Piedmontese group will be, on the one hand, united to Stradella by the Central Italian railway, which will itself rejoin, at Pistoja, the Tuscan railway group, and will unite Plaisance with Bologna; on the other hand, the Piedmontese lines already nearly in complete communication with the Lombardo-Venetian railways will be placed in communication with the Austro-Germanic group at Ralresina, when the section which traverses the valley of the Tagliamento and the Isouzo will be terminated. When the tunnels of the Col de Frejus and of Luemmanier will have been completed, Genoa will be nearer Geneva and Constantinople than are Marseilles, Trieste, or Venice." The Orleans railway company has just opened for public traffic the section of Montluçon to Moulins. M. Didon, chief director of the company, presided at the inauguration, and was accompanied by two other directors.

## WORKMEN'S INSTITUTE AND BENEFIT CLUB, EUSTON-ROAD.

THE opening meeting of this club was held in the recently finished room of the institute, 239, Euston-road. The meeting was presided over by the Hon. George Byng, member for Middlesex, and the following gentlemen, connected with the management of the institute, were on the platform, viz.:—H. E. Gurney, Esq.; W. A. Wilkinson, Esq.; Jervoise Smith, Esq.; St. Leger Glyn, Esq.; John Lulloock, Esq.; and G. J. Bowyer, Esq.; also the Rev. Canon Dale, the vicar of the parish; and the body of the room was filled with workmen. After the Rev. Canon Dale and the chairman had spoken,

Mr. W. A. Wilkinson addressed the meeting on the importance of life assurance, which, he said, necessitated savings; adverted to the benefits offered by this club, the payments for which were as low as possible compatible with soundness. To ensure this, he added, the best authorities had been consulted in forming this club, which would secure a certain provision for those belonging to it.

Mr. Jervoise Smith followed the last speaker at some length, explanatory of the objects and the origin of the institute, the principal features of which, he said, were the benefit club, affording relief in sickness and old age; reading-rooms, libraries, rooms for lodgings, and houses of call for those out of work; a guarantee fund, applicable for additional relief in case of accident; no entrance fees; and, moreover, the rules and tables were compiled from the statistics of five leading assurance offices, and certified respectively by Mr. Tidd Pratt, the registrar, and Mr. Tucker, the actuary.

Mr. H. E. Gurney, in the course of some observations, offered, with a view to afford a little relaxation to the members of the club, to afford

them in the summer (month of June) a trip to the Crystal Palace, and refreshment there.

Mr. Bowyer, in acknowledging a vote of thanks to him as organizer of the club, wished to correct a report as to the origin of the club. It had been said that it was a masters' movement; but this he distinctly refuted, as it sprang directly from a deputa- tion to him of workmen, who having convinced him of the want of such a club, he made it known to Mr. Gurney, who magnificently promised fifty guineas and his further support in aid thereof.

#### SOCIAL BRIDGES.

##### LIBRARIES.

We are glad to see that the "social bridges" in the building of which we have helped, are duly fulfilling the task that devolves on them. Not only in the by-lanes of this great metropolis is a desire manifested for improvement, but the working classes generally are making advances in the social status, which claim the respect of all who have the progress and well-being of this example-setting nation at heart. In our present number we record the opening meeting of a Workmen's Institute and Benefit Club, attended by members of Parliament, dignitaries of the Church, bankers, and others of the higher classes, with a large number of workmen kept them company, and paid the utmost attention to what was said. Social science meetings are being held in all parts of the country with equal success; and though in many instances the initiative is taken by gentlemen of influence, we see that the working population are exerting themselves in the right direction, and self-improvement is eagerly sought. We noticed some time since the means afforded in the establishment of Messrs. Cox and Wyman, the printers, of Great Queen-street, where an excellent library is established. At a meeting of the members, lately, in the course of an address, the committee prided themselves on the fact that they had seen so early the desirability of such institutions, and that other establishments had made inquiries of them, and were taking steps to follow in their path; and quoted from our Christmas number a remark that "everywhere now—in printing-offices, in great libraries, and even in the homes of the humblest laborer, the ghost of our old friend Caxton flits pleasantly about, suggesting wholesome thought and material for the diffusion of knowledge."

The chairman then proceeded to show, that wherever libraries had been founded, the most favorable anticipations had been realized. Operatives had consecrated their spare moments, and jotted down the experiences of their practical lives, printers being always to be found among the competitors. Such were some of the results of libraries and rightly-directed leisure, foretold by Cowper, who said,—

"Behold in these what leisure hours demand,—  
Amusement and true knowledge hand in hand."

In the course of an interesting address, describing and giving selections from this library, which has been most liberally supported by the firm, he informed the meeting, that Mr. E. W. Cox, on attaining his majority, in December last, had marked the event by a present of books to the value of 20*l.*; and thus this "Office Library," originally consisting of only a dozen or two books, had in the course of a few years increased to no less than 800 volumes, including works on almost every subject, whether for instruction, reference, or amusement, besides some of the most popular serials. They were also now in a condition to reduce the subscription to the trifling sum of a halfpenny per week.

#### GAS.

THE gas at Clatham, according to the *Chatham News*, has been examined by Dr. Lettley, who says it is the worst he ever tested, being no less, on one occasion, than seventy per cent. below the average of London gas. And no wonder, since the gas company are said to admit that they have at times to send it to their customers from the retort direct, without any purification at all! A movement is in progress for the provision of better gas at a fair price; but it has not yet assumed any definite shape.

A new light company, called "The Universal Lime Light Company," has been started in London for the purchase and working of the new lime light patent, recently exhibited. A single jet of it is said to be equal to forty argand or eighty fish-tail gas-burners. For places and purposes where a powerful light is desirable, it is promising, if price and trouble in management prove no obstacle to its extension; but for par-

lour and kitchen, or, in short, for ordinary dwelling houses, there are other new lights coming into use which seem likely, in one form or another, to shut out the ordinary gas, as well as other lights from oil and candle. These are the liquid gas lights, to one of which (a very inferior kind to others now before the public) we some time since drew attention. Having purchased one of what appears to be among the best of the latter, the writer shall give it a fair trial and report progress.

In the Court of Queen's Bench, "*Hipkins v. the Birmingham and Stafford Gas Company*," it has been found that a gas company is responsible for injury to a well, rendered noxious by reason of washings produced in the making of gas, thereby subjecting themselves to a penalty of 200*l.* The Court gave judgment for the plaintiff, holding that the incorporation of the defendants for their own benefit amounted to a contract with the public to prevent any ill arising from their works.

A meeting of gas consumers at Manchester have resolved to memorialize the corporation for a reduction of gas to 3*s.* 9*d.* per 1,000 cubic feet.

A movement has taken place at Stow-on-the-Wold for the introduction of gas to the town. The estimated cost of works is 1,200*l.* of which 800*l.* have already been subscribed.

A correspondent of the *Cornish Telegraph* says:—"I notice a report of the Plymouth and Stonehouse Gas Company, and find that for the past year they have been supplying gas at 4*s.* per 1,000, paying a dividend of 10 per cent. to the shareholders, and giving notices to the consumers that only 3*s.* 9*d.* per 1,000 will be charged for the present year. I contrast this with the price of gas in Falmouth, for which 6*s.* 3*d.* per 1,000 is charged, and that for an inferior article. If the Plymouth company can pay such a handsome dividend, I would ask if it is just that in a rising town like Falmouth the present price should be maintained, where coals for the manufacture of gas can be bought at a much cheaper rate than at Plymouth? Why, sir, if the proprietor of the works here would reduce the price to 4*s.* 6*d.* per 1,000, I firmly believe—taking into consideration how much more would be consumed—that at the end of the year he would find it a better paying concern than now. Of one thing I am quite certain—that if the present high price be continued, we must either have another company, or get our gas from Penryn."

#### CHURCH-BUILDING NEWS.

*Canterbury*.—It is proposed to erect an appropriate mural brass to the memory of Archbishop Laud, in the cathedral church of Canterbury. A design for this memorial has been given by Messrs. Waller, which has been approved of by the Dean and Chapter, and the brass will be erected as soon as a sufficient sum can be raised for the purpose.

*Worcester*.—The Ecclesiastical Commissioners have granted 15,300*l.* for the reparation of Worcester Cathedral, and 800*l.* a-year to be henceforth set apart for the same purpose. The work of restoration will therefore be actively commenced in the course of a few weeks, and meanwhile supplies of stone are being procured, of sandstone from Hadley, and weather stone from Bath. The south side of the cathedral, with its upper transept, which is in a very dilapidated state, will be the first portion of the building opened upon, and the cloisters and chapter-room will be included in these repairs. Then the work of restoration will be carried round to the north front, which is not in so decayed a state as the other portions of the edifice. It is hoped that the plans include the reopening of the west door of the nave and removal of the organ. The new work now to be effected, says the local *Herald*, will be a rigid and legitimate restoration of the fabric in accordance with its original style, the commissioners not sanctioning any ornamentation beyond the absolute requirements of that style. They have approved of the repairs so far as they have hitherto been carried out, and the further prosecution of the work will also be under the superintendence of Mr. Perkins, the architect to the Dean and Chapter.

*Bristol*.—It is expected that, soon after Easter, the cathedral will be closed for the prosecution of the alterations, enlargements, &c. in the interior. The plaster, yellow wash, &c. have been scraped from some of the ornamental carving in the Lady Chapel and south aisle, and it is found to be sharp, and clear, and well preserved. Some of the disengaged shafts on the north side of the nave, that have been covered over with yellow wash, turn out, says the local *Journal*, to be Parbeck marble, while the foliage of the bosses, apparently so blunt

and indistinct, is discovered, by the cleaning of one or two, to be executed with great delicacy and freedom.

*Market Harborough (Leicestershire)*.—The church here has received an embellishment in the shape of an alabaster pulpit. The Rev. F. O. Johnson, the incumbent, says the *Leicester Advertiser*, has eight brothers, all in the army, and six of these were in active service throughout the whole of the Indian rebellion. This worthy band of brothers have presented this pulpit as a thank-offering for having, by God's Providence, passed unscathed through the ordeal. The general design is by Mr. Slater, and the masonry by Messrs. Poole, of London.

*Levenshulme (Lancashire)*.—The new church of St. Peter, at Levenshulme, has been consecrated by the Bishop of Manchester. The church is of stone, in the Transition style. It consists of a nave, two aisles, chancel, and tower, and is almost a perfect square, being 60 feet in length and 58 feet in breadth. At present, building operations have not been carried beyond the tower; but, when completed, the church will have a spire 135 feet high. No decoration has been attempted in the interior, which is without gallery, and the seats, which have open ends, will accommodate 600 persons; 400 of the seats to be appropriated, and 200 free. The entire cost is about 3,000*l.*, which have been raised by private subscription, with the exception of 200*l.* contributed by the Church Building Society. The architect is Mr. Alfred G. Fisher, of Manchester, and the contractors are Messrs. Longson, of Heaton Norris.

*Keswick*.—The new Congregational Chapel, Keswick, the foundation-stone of which was laid on the 28th of July, 1858, has been opened for divine service. It is placed on a slight eminence in the Lake road, and is a prominent addition to the edifices of Keswick. Erected from designs prepared by Mr. John Hogg, of Ilulifax, it is in the Geometrical style, and simple in its details. The plan consists of a parallelogram, 54 feet by 26 feet, with a projecting vestry on the north side, 17 feet by 9 feet, over which is placed a gallery for children, provided with a separate entrance. The chapel is entered from the west end by a coupled doorway, opening into an inner porch communicating with two sides 3 feet wide, running the entire length of the building, having pews on a raised platform on each side. The total accommodation provided is for 300 persons. Externally the chapel is divided by buttresses into four bays in length, having two-light windows between them with cusped heads and pierced trefoils. The west or principal entrance-front has a slightly projecting gabled porch and coupled doorway, with a two-light window on each side and a circular tracery window over it. The walls are formed of a kind of porphyry, with freestone dressings to buttresses, &c., and the woodwork throughout is of deal, stained and varnished.

*Dundee*.—The foundation-stone of John-street United Presbyterian Church was laid on the 7th October, 1858, and it has now been opened for public worship. The architectural design of the church, according to the *Dundee Warbler*, is of the ornate Roman. Lofty Ionic columns, with intercolumniated plate-glass, support an architrave, frieze, and parapet of corresponding proportions. The basement is of composite rusticated masonry, and the principal entrance, which is towards John-street and Cochrane-street, as well as the arched windows, are in keeping with the appearance of the building. There are five windows towards the north, of stained glass, the ornamentation being also Roman, to harmonize with the design of the edifice. The church measures 94 feet by 66 feet, and its height from floor to ceiling is 40 feet. The ceiling is copiously adorned with a variety of designs in plaster-work, and it is to be further enriched by several designs, already approved of, in polychromatic colouring. The seating of the church can accommodate about 1,400 sitters, and many of the seats are of the width of 3 feet. The heating and ventilation have been attended to. Beneath the floor of the church provision has been made for a vestry, a school-room, a meeting hall, a library, and manager's and ladies' rooms, &c. The designs were prepared by Mr. J. T. Roched.

*Map of Morocco*.—Mr. James Wyld has, of course, published a map of Morocco, or, as he terms it, Marocco; and those who would follow the graphic account of the doings of the Spaniards there in the columns of the *Times* should obtain it. At the Great Globe, in Leicester-square, there is an affluence of instructive entertainment.

## STAINED GLASS.

*Mickleover Church, near Derby.*—A memorial window has lately been erected in the east end of the above church. The window is composed of three openings, with spandrels in the head of the window. The three openings have six subjects from the Beatitudes, inserted into geometrical shapes on mosaic backgrounds of deep red and blue, with bosses of various designs. At the foot of the window is placed the following inscription: "To the memory of Augusta Marian Curzon, wife of the Rev. F. E. Curzon, and daughter of E. M. Mundy, Esq. Died August 10th, 1827, aged 21 years." The artist employed was Mr. Charles Gibbs.

*New Church at West Derby.*—The same artist has put up a stained glass window here for J. P. Heywood, Esq. of West Derby, to the memory of his niece. The window consists of three openings and several spandrels. The whole of the openings are occupied by the subject of the "Resurrection." In the centre opening, Christ is represented, clothed in white, coming out from the rock, holding a banner, on which is inscribed the words, "O grave, where is thy victory?" Beneath, on the foreground, lies one of the soldiers. Above the figure of the Saviour is seen an angel, holding a scroll with the words, "Blessed are the dead which die in the Lord." The left-hand compartment has the "Angel sitting on the stone." The right-hand compartment shows the "Three Marys coming to the tomb."

## THE FALL OF MILL IN AMERICA.

It is to be regretted that little precise information as to the construction of the Pemberton Mills, at Lawrence, in the United States, which recently fell, has reached this country. The building is said to have been originally of bad construction; the foundations were imperfect, the walls were weak, and pierced by numerous apertures, which detracted still further from the strength of the fabric. As the weight of the machinery was added to that of the numerous workpeople engaged in the business, it will not be thought surprising that the mill should have fallen. The five stories of the building fell in, one after another, upon the heads of 600 or 700 workpeople, who were assembled at their trade, and then, to make the disaster more horrible, fire broke out and consumed the living and the dead. This dreadful disaster should not be without its effects on this side of the Atlantic.

## VENTILATION VENTILATED.

THERE is hardly anything more necessary to be attended to in the arranging of buildings, both small and great, than ventilation. It is a subject to which some attention has been given, and many extravagant theories have been advanced in support of schemes which seem to have been failures in proportion to their intricacy; those based upon simple data having the greater chance of being successful.

Let us inquire,—What is Ventilation? Is it the displacement of hot air by cold air, or *vice versa*? or is it the expulsion of foul air in favour of fresh air? It may be answered, that ventilation is a combination of these. It is the giving a supply of pure air at a proper temperature with as little palpable displacement as possible, the foul air being afforded means of escape so that the oxygenated or "fresh" air may take its place almost imperceptibly, and currents and draughts so be entirely avoided.

True ventilation is based upon certain natural laws, having as a starting point an elastic fluid—common atmospheric air. This has to be manipulated in such a manner for the comfort and health of human beings in their dwellings and halls of assembly as to comprise what is commonly called ventilation.

It is well known that common air consists of two gases, one giving life and the other destroying, and called oxygen and nitrogen respectively: when these two gases are received into the lungs in combination (as they are at every inspiration) the cells effect a division of them; the oxygen being retained to mix with the blood, and the nitrogen (with a small proportion of carbonic acid gas) being returned back again into the atmosphere. It thus follows, that persons breathing in an air-tight room would soon consume all the oxygen or life-giving air and leave only that which is foul, the breathing of which induces stupor, and ultimately death.

There is the familiar example of the bird in a cage hung over a bed having curtains closing it in

all round: the mere contamination of the air caused by a person sleeping in the bed would kill the bird before morning.

Again, there is the doxy congregation in a high-pewed, non-ventilated church,—the very construction of which renders it almost physically impossible to prevent—not a natural sleep or repose, but—a suffocating stupor, caused by the stagnation of the noxious air in the boxes in which the erring mortal is deposited.

Carbonic acid gas is specifically heavier than common admixed air, but they combine. When pure, however, it is so heavy, that a jar filled with it may be emptied into another jar from which it will displace the common air, and so entirely supplant it, that a taper will be extinguished when inserted therein. A deep well is a familiar example of this, at the lower parts of which it congregates, and many deaths have taken place in consequence of men incautiously descending without previously testing the air by lowering a lighted candle. They are first attacked with stupor, and if not speedily drawn up, death quickly ensues. It is this gas which is so freely emitted from charcoal fires, and which has proved fatal in so many instances. All ordinary fires, lamps, gas-lights, &c., consume an enormous proportion of oxygen, leaving the azote mixed with carbonic acid gas. And it should be remembered that this oxygen, which gives life and animal heat, forms only 22 per cent. of the ordinary atmospheric air; which, therefore, cannot afford to be much deteriorated by artificial means.

The effect of foul air is shown in its most violent and deadly form in the choke-damp of mines.

Air expands by being heated—that is, it occupies more space when hot than when cold. It also becomes lighter in proportion to the increase of its temperature—that is, it has a tendency to rise above a colder stratum.

A heated room upon a cold day may be likened to a heavy vessel of air being kept down in a cistern of water. The water, by its greater density, will endeavour to rush into the vessel at the most minute pore. So with the heated room, which is surrounded by a disproportionate bulk of denser fluid, and which makes every effort to rush in at all chinks and crannies.

What more familiar instance of this can be urged than an ordinary room with a good "old English" fire? All the doors and windows closed as rigidly as the state of the joinery will permit, with sometimes the addition of corded string and sand-bags. Now, first, the fire, to be kept burning, must have air. Oxygen again. The inmates must have air—oxygen also. Every known source of supply being cut off, what is the consequence? Great pressure is exerted by the cold air outside, and draughts, thin little corkcrewy, gimletty currents of concentrated cold air find their way in, in spite of the elaborate attempts made to keep them out, and strike us, and wind themselves about us, making the shrillest music the while, asserting their prerogative in the most unmistakable manner, as is the case in any instance where it is sought to subvert the working of a natural law, by barricades, or any other popular description of impediment.

It will thus be readily seen that ventilation of buildings is of the utmost importance, as tending not only to the comfort of the inmates, but as an imperative sanitary duty,—indeed, as much a necessity as good drainage or abundance of light.

The ordinary method of constructing dwellings gives plenty of opportunity to supply and circulate fresh air, as may be known by the facility with which they burn when once they take fire. The great difficulty is to supply it in such a way, and at such a temperature, as shall not be felt an inconvenience, or, indeed, a nuisance. A house should be taken as a whole, and legislated for accordingly. A basis of operations should be established, by which the general object of ventilation should be encompassed. *Warm*, fresh air must be introduced into the apartments in cold weather, if we wish to have a feeling of comfort, not only in the rooms, but in going from one part of the house to another.

It has been shown that heated air ascends. Following out this simple natural law, a heating-chamber should be formed in the basement, to which a supply of pure air should be brought from the exterior. It will here be warmed, rarefied, and will rise by its own impulse and fill the upper portions of the house. Now, this heating-chamber need be nothing more than a cellar with a flue to it, containing a good self-feeding stove, over which should be a grating, to allow of the heated air ascending and filling the large spaces, the hall, passages, staircase, area, &c.

In most instances the staircase forms a natural ventilating shaft, an open window or skylight at the top affording ample means of egress for the used air which will find its way up. This opening should be capable of easy regulation, as, under some circumstances, and in very cold weather, scarcely any egress at all will be required; and here a commonly accepted theory must be combated. It is supposed by many that if a window be opened at the top, the heated air will go out; but in most cases it is not so. The cold air rushes in, and *condenses* and *contracts* the heated air, the which, if it could be cooled in an air-tight chamber, would cause a partial vacuum, and, if the sides of the chamber were sufficiently attenuated, they would be collapsed by the pressure of the cooler air upon their external superficies.

By heating the hall and passages equal to the temperature of the apartments, perceptible draughts will be prevented to a considerable extent, as there will be no cold air to find its way in. The matter next to be attended to is the supply of fresh air to the open fires in the rooms; and this is easily effected by having an air-brick inserted in the external wall between the floors, and a small register grating let into the floor next the hearth, and under the fender. This will again further reduce the cause of draughts; and almost any room, no matter what the position of the doors and fireplace, may be made generally comfortable thereby, and in many cases smoky chimneys, and puffs of smoke at every shutting of the door, will be entirely obviated. The fire is thus rendered independent for its supply of air of the opened door or other casual vacancy.

The ordinary construction of the register-stoves (those most commonly in use) is such that heat is given forth by radiation only. The fire is bemmed in on three sides by heat-absorbing material, all of which has to be warmed by conduction before any considerable benefit is felt in the apartment. This defect has been remedied in many instances by establishing a current of air round the back of the stove constructed on purpose, communicating from the outside, and which is warmed in its passage, and admitted into the room in the front of the stove over the fire-box, and in this way assists the ventilation. But when sitting near, you have a stream of hot air playing upon your features; so this method is but partially applicable and suitable only for large public rooms, where the congregation is confined to certain seats and positions. Individual stoves are, however, of secondary importance when the whole house is heated.

Where gas is used there should be an external ventilator near the ceiling, to keep the air cool and divert the sooty particles from it, thus keeping it cleaner for a much longer period, and a supply of oxygen is introduced for the combustion of the gas, the use of which is thus rendered entirely unobjectionable. The ordinary chimney valve will be found sufficient to draw off the upper stratum of used air.

Ventilators in the windows themselves are of little use when most needed, *i.e.*, when the blinds are down and curtains drawn.

A house need not be ill-ventilated on the score of expense. It merely requires forethought in the first arrangement to render it doubly comfortable in all weathers. THOS. GOODCHILD.

## CHAPEL AT GREENWICH HOSPITAL.

In your last number (page 49) it is stated, at the end of the article entitled "An Erumed Architect," that "We remember that the old Greenwich pensioner who used to show the chapel of the hospital always recounted, with something like martial pride, the narrow escape of the painter's life in the execution of the allegorical decorations of the ceiling."

I had considered this piece of traditional information as forgotten long since, not having heard or read it for some time. The last time I remember hearing it mentioned was some years since by my father, who related it in the following manner:—That his brother Thomas, many years before, being with some friends at Greenwich, whilst inspecting the chapel, was assured that the principal artist employed had fallen from the scaffold, and was killed; on which he turned to the pensioner and said "he was very glad to hear it." On the man's expressing his astonishment, Thomas observed that he was the person referred to, and, being alive, could doubt the fact asserted.

If I remember aright, there are not any paintings on the ceiling; but as it is at least fifteen years since I was in the chapel, I may be wrong. The ceiling, however, is richly ornamented; and

when there I was assured by the then showman (who did not relate the accident) that the enriched guilchee-work was *carved* on the beams. On mentioning this to my father, he stated that the whole of the ornamentation was in stucco-work, as it had been executed by his father and brother, under Athenian Stuart, the architect. The chapel appears to have been finished about 1789. My father, then a lad, often took down the money for the weekly wages of the men. This chapel is a very fine example of plasterers' work done by hand, a trade now superseded by cast-work, and which I fear is quite extinct. The chapel is also a good example of the proper introduction of a gallery.

WYATT PAPWORTH.

#### ARCHITECTS AND AMATEURS. THE WORKS AT BLODWEL.

SIR,—A correspondent of the *Builder*, in a letter headed "Architects and Amateurs," dated Dec. 3, 1859, p. 797, has almost avowed that he writes with a strong feeling of professional jealousy against amateurs in general, and although, as one of the latter class, I avoid controversial writing, yet as my name has been brought forward in an offensive manner by him, I shall on this occasion defend myself, with your permission, from the attack of my anonymous opponent, whom I suppose, although unacquainted with him, to be resident in this neighbourhood, and, apparently, my personal enemy.

He declares himself to be "a legitimate practitioner, and judge of these matters;" I am surprised, therefore, he is not aware that the Blodwel spire is not by any means the first example of a convex outline, for Caythorpe, in Lincs, and Fribrigg minister, in Germany, show the same construction, and I believe I could name several others; but when they are slightly convex in outline, the artist or engraver may not always have represented them correctly. The domical curvature of the Fribrigg spire I ascertained myself by personal examination. When I limit the Blodwel spire, I think its rather unusual form would be likely to promote a fair discussion of the question as to whether the *dome* or the *spike* should be preferred for our highest architectural outlines. But small indeed must the experience of any one be, who does not recognize in my spire the essential form of the German Fribrigg, and in the window treatment of my octagonal tower an evident imitation of the well-known example at Sedgeberrow. Never until now, that I am aware of, has it been made a matter of reproach to a clergyman, that he has turned his attention to architecture, as a branch of knowledge connected with his profession.

If the school and master's house at Blodwel, which I have built and paid for, are unlike the ordinary type of national schools in other places, they are intentionally so; and I can still appeal to them as true specimens of English Gothic feeling; nor have I ever permitted the features of any other style to neutralize my treatment of the pure Gothic.

I consider if our own appropriate, living style, dwindle beyond all others; and in adopting it I lay myself under stricter obligations than those who offer, with perfect indifference, to build in any style that may suit the caprice of their employer.

But how could I act otherwise than I have done? The professional architect, after supplying ground plan, elevation, and working drawings, &c., will hardly visit the spot more frequently than twice in the twelvemonth. I, as an amateur, think it my business to be present there almost every day, and no stone of any size is put into its place without my personal superintendence.

If after works of this kind have been carried out at my own cost I am to be reproached with violence for daring to act in such a manner, and my professional assaunt is abetted by his brethren, it lowers the standard of practice throughout all departments of the profession.

My opponent refers to a hundred others, out of whom he has done me the honour to select me for his first victim.

A course of a hundred letters duly printed in the *Builder* will no doubt annihilate the volunteer corps, and we shall be forbidden ever after to express our practical opinions otherwise than on paper, unless we are willing to have all the bitterness of reproach and calumny.

However, before I am utterly destroyed, I have one appeal to make. I appeal, not to the architectural world—at present so hopelessly divided

\* Damaged by lightning, Dec. 30, 1859, and somewhat incorrectly represented in the *Illustrated London News*, January 14, 1860.

between the contending styles—but I do appeal to the Gothic world, which is at unity with itself; and the living, native, growing style, now passing under that name, is the only one I care to practise, or am anxious to see employed by others.

In conclusion, Mr. Editor, I cannot avoid observing that I consider your correspondent's "threatening letter" as a very dangerous precedent. Perhaps even his professional exclusiveness might allow the deans of our cathedrals a legitimate voice in the disposal of their "fabric funds," and he will perceive, by my signature to this letter, that I also have some official excuse for meddling with matters of architectural and parochial expenditure.

JOHN PARKER,  
Vicar of Blodwel, and Rural Dean  
of Llangollen.

January 7th,

#### SCHOOL VENTILATION.

SIR,—Your paper being open to any improvements in construction, some time since you introduced an interesting notice on the important system of ventilation and warming, of Dr. Van Hecke. A number of the *Montleur Belge* has just come under my notice, containing an account of its application to the commercial (parish) schools at Nivelles. If you consider the extract worthy your observation, you will oblige me by inserting it.

"An official commission, composed of the committee of Public Hygiene of Nivelles, to which were associated M. Froment, professor of mathematics and physics, assembled on Tuesday last, to examine the effects produced by the apparatus of Dr. Van Hecke, placed in the commercial schools in that town. This school accommodates four large classes of 100 each, and the cubical contents are about 79,000 cubic feet.

The administration required a renewal of the air at the rate of 140,000 cubic feet per hour; heated air in winter, cooled air in summer. The experiments made by the commission gave the most satisfactory results. The apparatus is capable of supplying, and this without perceptible draught, 420,000 cubic feet, winter or summer, or three times more than the quantity contracted for.

From this datum, it is calculated that the daily expense will not exceed two francs.

To arrive at the same results by ordinary or natural means, the expense of combustible oil would be eight francs per day."

#### A RAFT FOR THE WRECKED.

Of the best mode of rescuing lives, in the event of shipwreck and disaster at sea, we know but little, as each successive shipwreck painfully proves. Would not the organization of a general system of raft-constructing materially aid our advances in this direction, a system by which every spare yard, plank, and spar, not in actual service, might be made available in a few moments, so as to form a large and commodious raft, the framework of which should be so strong as not to be easily stove, and too broad to be easily capsized. To accomplish this object, every yard and spar in the ship should be numbered, and the ends of each so prepared that the one should fit in and receive the other. Many plans might be suggested by your scientific readers, which might result in a satisfactory solution of this difficult and important question. Is not this a fit subject for the Admiralty?

NEMO.

#### DECISION UNDER THE METROPOLITAN BUILDING ACT. PUBLIC BUILDING.

SIR,—In your last publication you gave a report of the case relating to the Pavilion in Tichborne-street, Haymarket, lately decided by Mr. Bingham at the Marlborough-street Police Court, and you attach to the end of the report a note that "it is difficult to reconcile the statements of the district surveyor and the magistrate as to the extent of the works done," and I do not wonder at it, because the report of what I said is incorrect. I did not state that the premises, "by previous pulling down and re-erections, to make the place what it is, had, within the meaning of the statute, become a new building;" nor did I quote the 10th section; nor did I state, "that in the present case it could be proved that considerably more than half the old fabric had been taken down." The counsel for the defendants quoted the 10th section, amongst others, and stated in effect what I am reported to have said, and that it must be so proved before the building could be brought under or made such as to the requirements of the Act; and as such was not the case, the 10th section did not apply; and that it was not such a building as could be called a public building within the meaning of the Act, so as to bring it under the 30th section. And as the worthy magistrate has so

decided, the remainder of your remark is quite correct, namely, that the real question upon which I proceeded against the builder, as to "whether a building existing before the Act, and used as a public building afterwards, must be altered, when works are being done on it, to make its construction such as the district surveyor approves," is avoided, and upon it no decision is given.

CHARLES MATTHEW,

Surveyor of the District of St. James Westminster.

#### CRYPT OF GERRARD'S HALL.

SIR,—I should like to remind the public that, when the crypt of Gerrard's Hall was taken down, the stones were made over to the Crystal Palace Company to be re-erected on their grounds. Such, certainly, was the talk of the day. The crypt is not to be found at Sydenham. Would it not be possible to urge on the directors the necessity of carrying out their promise? You may remember that, a century ago, Holbein's Whitehall gate was made over to a royal duke, who professed an intention of rebuilding it at Windsor; and the gate has disappeared. It would be a pity to lose this crypt entirely.

W. H.

#### THE ARCHITECTURAL MUSEUM PRIZES.

SIR,—The number and quality of the works submitted, in competition, for the recently-awarded wood-carving prize, are, I think, sufficient proof that the interest of our class, so long apparently dormant, is to a certain extent awakened.

May I be allowed, through your columns, to express a hope that the subject for the prize for the ensuing year may be of a character that will include a wider range of competitors. I do not of course know what may be in contemplation by the gentlemen of the committee, but I have good reason for the conviction that a prize for *models* of figure studies for architectural purposes, and for stone carving, would bring a large number of competitors into the field.

I am not sure that it is not rather an ungracious thing for one of the competing class to offer any suggestion on the matter, but I trust it will be received in the spirit in which it is made, and, after all, the chief good of a prize is the development and stimulation of many and various talents; and whatever extends the circle of such emulation must help the object of the donors.

A STONE-CARVER.

#### HOLLOW WALLS.

SIR,—Your last paper contained an extract from *The Engineer* on the subject of "hollow walls." Will you allow me to state the following facts on the same subject, which, unless I have misunderstood the extract referred to, seems somewhat irreconcilable with it?

Having to erect several houses in a situation much exposed to severe south-west storms from the sea, and the bricks procurable being *exceedingly porous*, the hollow-wall expedient was resorted to—(half-brick outer wall, a 2-inch hollow, and a 9-inch inner wall,—the two tied together with wrought-iron cramps.) At the line of the chamber window-cills, however, two through-courses were improperly introduced. The work advanced, and was completed during the fine part of the season. Just previously to the return of the wet season the plaster seemed quite dry; but immediately afterwards a hand of damp appeared on the inside of all the chamber-walls having a south-west aspect. As the season advanced the damp increased, so that the whole of the south-west walls became literally *drenched* with wet, from the line of the upper cills down to the ground-floor: even the floors half-way across the rooms were quite wet.

On visiting the work, a question or two disclosed how the specification had been departed from in building the walls: the through-courses at the upper cills were the cause of the whole mischief. They were immediately cut out; the separation between the outer and inner walls rendered complete; frequent openings, the thickness of a joint, made in the outer walls at the bottom where the hollow work commenced, and since then (now twelve months ago) "the storms have not ceased to beat upon the houses," but damp has certainly ceased to penetrate to the inner walls in the very slightest degree.

If the rain penetrated the 16-inch solid work, must it not also penetrate the 4½-inch outer wall? and would it have ceased to penetrate the inner wall if no openings had been left at the bottom?

W. B.

ACCIDENTS.

On the London and Chatham Railway works, at Bealesbourne, an extensive fall of earth has taken place, burying three or four of the navvies employed. Directly the fall had taken place, operations were commenced for their rescue, but without success. The enormous mass of earth to be removed was not the only difficulty. The sides of the cutting are, it is said, in a most dangerous state, and threaten destruction to those who are working beneath. It was found necessary to erect boarding, and pursue the work in a more systematic manner. Had the fall taken place a quarter of an hour earlier, there must have been five times the number killed.—At Cleveland-square market, Liverpool, some old premises had been condemned by the building surveyor as insecure: workmen were consequently employed in pulling them down; and whilst so engaged a wall that had been left standing fell inwards. The upper work had been stripped to the second floor, and on this the mass of bricks fell, and forced it down to the floor of the shop below. This, in turn, gave way, and the whole crashed down into the cellar. Three of the workmen were carried down with the debris, and buried in the ruins; but they were speedily rescued, one with his thigh fractured. The premises are being taken down with the view of erecting in their stead a concert-room.—At the Raglan Hall, in Theobalds-road, London, a few days ago, a poor fellow was killed by the fall of a piece of old brickwork. Mr. John Wretton, the builder, is engaged here in the execution of some works which necessitated the removal of two brick vanits. In cutting away the brickwork at one part another portion was shaken down, and fell on a labourer and killed him. It was purely an accident.

ARCHITECTS' ACTIONS.

BOTH AND ANOTHER R. HALL.

THIS was an action (in Court of Exchequer, before Mr. Baron Bramwell), brought to recover 2½ per cent. upon the sum of 2,000*l.* The defendant paid 25*l.* into court in satisfaction of the plaintiffs' demand.

Mr. Hawkins and Mr. Day appeared for the plaintiffs, and Mr. Serjeant Parry and Mr. J. Brown represented the defendant.

It appeared that the plaintiffs were engineers and surveyors, and the defendant was a gentleman of property. The plaintiffs, by his order, prepared plans for a music-hall, which was to be erected by the defendant's tenant, occupying the Beehive and Canterbury Music-hall, at Aldershot. For some reason the building was not erected, and the plaintiffs now sought to recover a usual percentage upon 2,000*l.*, the total cost.

The defence was, that the building proposed to be erected by the plaintiffs would have cost 2,500*l.*, and that the defendant, not being prepared to lay out so much money, had declined to let them have anything to do with it.

His Lordship having summed up, The jury returned a verdict for the defendant.

Books Received.

LAW BOOKS.

*Personal Wrongs, and Legal Remedies.* By W. C. SLEIGH, Esq., Barrister-at-Law. London: Longman & Co., 1860.

*A Handy Book on the Law of Master and Servant, Employer and Employed, as regards their Civil Rights.* By J. W. SMITH, Esq., LL.D., Barrister-at-Law. London: E. Wilson, Royal Exchange, 1860.

THESE are, both of them, very useful books for all and sundry to know something about. Those prone to libel and slander others (and there are too many such in the world) would do well to study the former as a check on them, although it might scarcely be of sufficient avail in itself to those seeking a remedy for wrong done them. Mr. Sleigh is an able barrister, and doubtless such a book as this by him is a reliable authority. No less useful is Dr. Smith's Handy Book of the Law as regards Master and Servant: there are few beyond its pale, either in the one capacity or the other, or indeed in both.

VARIORUM.

THE articles, in the current *Quarterly*, which will more immediately interest the special readers of the *Builder*, are an essay on the "Australian Colonies and the Gold Supply," and a paper on

"The Roman Wall through Northumberland and Cumberland." Of "this ghost of a fallen empire," as the writer calls it, adopting an idea of our own, a graphic account is given by one who knows the locality, and has well studied Mr. Maclauchlan's recent survey and Dr. Bruce's well-known works.

—In "Leisure Evenings; or, Records of the Past: a Collection of Prose and Poetical Miscellanies," by Mrs. Alfred Miles (late S. E. Hatfield), authoress of "The Wanderer of Scandinavia," "Moments of Loneliness," &c. (Phipps, 25, Upper Ranelagh-street, Eaton-square, &c., publishers), our readers who peruse her pages will doubtless recognize the pleasant and lady-like effusions of one familiar to them in our own, as "S. E. M." The thoughts which appear in a poetical garb, in this little volume, are interspersed, here and there, with descriptive and suggestive sketches from her pen, in prose. Mrs. Miles has an artistical leaning, as will appear from the following brief extract from a longish poem on "Gothic Architecture":—

"Why should the home where warm affections meet  
Appear so rude, so bald, so incomplete,  
So graceless in exterior, so debased,  
Now by vulgarity, now fraud disgraced;  
Possessing nought to win the admiring eye,  
Or breathe one thought of human sympathy?  
Which roof less seem save for the unsightly stack,  
Which indicates that roof it dares not lack,  
Less England's winter snows and frequent rain,  
Unfriendly entrance to the inmates gain,  
Here too may Gothic Art (so much reviled)  
Defend its claims, before the man or child;  
For intellect matured, or youthful mind,  
Its dignity and use will quickly find."

—A pamphlet on "American Securities," containing "Practical Hints on the Tests of Stability and Profit, for the Guidance and Warning of British Investors;" by an Anglo-American (Nephew, 33, Cornhill, &c.), shows very ably how to discriminate between those worthless securities for which Brother Jonathan has become somewhat notorious, and those of a more substantial character,—whether in consequence of their comprising land within railway or other reach of markets, or otherwise,—of which there seems to be no lack either, in the United States, if one could only get safely and securely at them. As it is, and somewhat on the principle of burnt fingers avoiding the fire, "with what might almost be designated a species of reckless overcaution, we indiscriminately reject the good, lest we should involve ourselves with the bad, instead of exercising that judicious discrimination, that careful investigation, which would be quite sufficient to guide to a safe choice, and which, in so important a proceeding, ought surely not to be considered too troublesome."—The *Gentleman's Magazine* illustrates Mr. Scott's recent lectures on Westminster Abbey, with a plan of the Abbey and adjoining buildings, and a variety of details.—The first article in the new number of the *Universal Review* is a sensible comparative view of the works of Brunel and Stephenson, with the initials T. H. The writer does not differ from our own estimate of the merits of the two men. A paper called *Verbal Landscape-Painting* goes to prove the growth of an admiration for the wilder and more beautiful scenes of nature in the books which are every day issuing from our national press.—The *Ecclesiologist* contains a large view of Kilmore Cathedral.

—"The Welcome Guest" is a good ninepenny-worth of amusing reading, illustrated. It is edited by Mr. Robert Brough, and published by Houlston & Wright.

Miscellaneous.

THE SPARROWS AND LONDON ARCHITECTURE.—At the British Museum, the Marble Arch in Hyde-park, and other public buildings, the sparrows at this season of the year take possession of the ornamental part of the architecture. In the foliage of the capitals, and other portions elaborately wrought, thousands of them may be seen fighting for space, and busily employed in nest building. In some instances the details are completely filled with grass, straw, and mud, which is a great disfigurement. So in the country, in halls and churches, the same thing is to be noticed, and the removal of the nests is often a great trouble and expense. The nests of swallows, are also a cause of annoyance in many buildings. Could any of the readers of the *Builder* suggest a remedy for the matter complained of, besides netting up the exposed parts?

\* "Let any person of ordinary observation," remarks the authoress in a note, "make his choice between the appearance of a roof and the non-appearance of a roof, by taking a walk along the King's-road, Chelsea, and noticing the effect on his own perceptions of the flat roofs, and the intensely ugly chimneys which emerge from them in every conceivable variety of uncouthness and multifariousness which can be perpetrated in a chimney."

THE ROYAL ACADEMY.—On Tuesday last Mr. O'Neill and Mr. Dobson were elected associates of the Royal Academy.

ST. MATTHEW'S, BETHNAL GREEN.—The restoration of St. Matthew's, Bethnal Green, is placed in the hands of Mr. T. E. Knightley, architect.

A CRISIS IN A CLOSE DWELLING.—In the house situated at High Blantyre, occupied by John Robertson, gaffer on the Hamilton and Strathaven Railway, says a Glasgow paper, a painful scene has occurred. Robertson's wife awoke about five o'clock in the morning, in a very exhausted state, and found her infant child, aged nine months, lying dead in her arms. She immediately aroused her husband, who also felt in a weakly condition, but had strength enough to get out of bed. They then discovered that their next eldest child—a boy named Allan, aged about three years—was also dead, and the third, a girl nine years old, seemingly approaching dissolution. The father removed the little girl into an adjoining apartment, and she thus, fortunately, in a short time recovered. The wife was likewise conveyed thither, and is progressing favourably. The deaths of the two youngest children were occasioned by suffocation: the family all slept in one bed—five human beings huddled together—in a small, dingy, smoky dwelling, consisting of one apartment, without sufficient ventilation. Here is a startling result of want of ventilation; but, to a minor extent, the same sort of evil is going on, unobservedly, in probably three-fourths of all the dwellings in the country, bringing about death by slow and imperceptible degrees, in a way that comparatively few believe.

STEAM TRAFFIC ON CANALS.—At a meeting of the Royal Scottish Society of Arts, a communication "On Steam Traffic on Canals," by Mr. Thomas Lampry, F.R.S., and S.A., London, was read by the secretary. After premising that it will be believed, he readily conceded that the future success of canals, and the value consequently of canal property, are dependent entirely upon the possibility or impossibility of the substitution of steam power for the haulage of boats, the author compares the relative advantages of canal and railway conveyance as regards the transmission of merchandise, and expresses an opinion that if steam haulage could be successfully applied to canal navigation, canals would, in a pecuniary sense, become as valuable as they have ever been. The author proposes to remove the difficulty hitherto existing to the introduction of steam-boats on canals, viz., the washing away of the banks by the swell, by lining the upper part of each side with coarse rubble stone; and states that this may be effected by a simple apparatus, without stoppage of the traffic. Presuming the canals to have been prepared for their reception, the author proposes to use steam tugs of a horse power determined by the traffic, and of light draught of water, each of which would haul a flotilla of canal boats dependent in number on the traffic and the power of the engines.

THE DRINKING-FOUNTAIN MOVEMENT.—A drinking-fountain has been put up on the south side of Blackfriars-bridge. The Lambeth Water Works Company supply the water.—Another fountain has been opened at the Triangle, Southwark-bridge. This fountain is the gift of Mr. Alderman Hale, in connection with the London Drinking-fountains Association. It was designed and executed by Wills, Brothers, sculptors, of the Euston-road.—The first drinking-fountain in Taunton has just been erected in the centre of the open space between East-street, East-reach, and Silver-street. The fountain was provided and erected at the expense of Mr. W. Rawlinson.—At the recent holiday assemblages in the Crystal Palace, it was really painful to observe whole flocks of little ones surrounding some fortunate individual possessed of a drinking-utensil, and charitably dealing out water from amongst the aquatic plants and fishes, from want of anything like drinking-fountains or even taps. Two or three small affairs, which seem to have been put up for behoof of those connected with the palace, had the water actually slat off from them altogether, on, at least, one of these occasions. If the object were to increase the demand for stronger liquors, we should think that object was effected: at least, we saw little boys tossing off their tumblers of ale at the counters, who, doubtless, would have been quite well satisfied with "the pure and sparkling water," could they have got at it. The managers should have heard, as the writer of this note did, the mutterings and grumblings to which this want of a free supply of water to families and youngsters "out for the day" gave rise.

**EYIL DRAUGHTS.**—Alcohol, says Liebig, is a bill drawn on the workman's health, which he is incessantly compelled to renew, as he has not the funds to meet it. The bankruptcy of the body is, accordingly, the inevitable result.

**ARCHITECTURAL INSTITUTE OF SCOTLAND.**—A special meeting of the Architectural Institute of Scotland was held in George-street Hall, Edinburgh, on Tuesday, the 31st ult., for the purpose of taking into consideration the propriety of memorializing Government to proceed with the erection of the General Post-office for Scotland, at Edinburgh, upon the site acquired for this purpose. At an ordinary meeting of the Institute, to be held on Monday, the 6th inst., a Notice of the Life and Works of the late Mr. William H. Playfair, architect, by Mr. John Murray Graham, will be read.

**CONSECRATION OF ST. PAUL'S CHURCH, HAGGERSTONE.**—Last week the Bishop of London consecrated the new church of St. Paul, Haggerstone, in the parish of Shoreditch. The parochial district of St. Mary, Haggerstone, of which St. Paul's forms a part, originally part of Shoreditch, has long held a prominent place among the parishes of the metropolis, on account of its dense population. A site sufficient for a new church, school, and parsonage was obtained nine years ago by the Diocesan Society, who paid 750*l.* for the leasehold interest, Sir W. F. F. Middleton, Bart., giving his reversionary interest. Mr. Arthur Blomfield is the architect: Messrs. Holland and Haumen are the builders.

**FIRE IN SANDBACH CHURCH.**—During a recent Saturday night's storm, the parish church of Sandbach, restored within the last few years at a large expense, was found to be in flames. In the interior the flames had reached the gallery at the western end, and were rapidly approaching the organ and roof, when an entrance was gained. The engines were worked with vigour, and after a time the power of the fire began to slacken. An amount of damage was incurred of 500*l.* The chancel, and the stained glass throughout the building have escaped; and the carved roof, being of oak, has met with but little damage. At a meeting of the most influential inhabitants, resolutions have been unanimously come to for an immediate restoration by voluntary contributions. The origin of the fire is (as usual) traceable to a defective flue, and to the Saturday night's beating for Sunday morning.

**THE SMALL POX IN SCOTLAND.**—It will surprise many, that up to the present time there is no regular system of vaccination in Scotland; and in a great measure it is owing to this cause that this epidemic in this part of the kingdom is the means of destroying many lives. At a meeting of the Medico-Chirurgical Society at Edinburgh, the subject was taken into consideration. All the speakers agreed in expressing unabated confidence in vaccination, if properly performed; and proposed an interview with the Scottish members of parliament resident in Edinburgh, with a view of having a vaccination bill for Scotland introduced into Parliament. Considering how intimately the interests of England, Scotland, and Ireland have, by the facilities of communication, become assimilated, it seems singular that separate enactments are required. The result is very incon- venient.

**NORFOLK AND NORWICH ARCHÆOLOGICAL SOCIETY.**—The annual meeting of the members of this society was held in the Guildhall, Norwich; Sir J. P. Hoileau, the president, in the chair. The attendance was numerous. The president, in his address on this fifteenth anniversary of the society, stated that their funds were in the most healthy condition—very much better than he had ever known them to be before, while the number of subscribers had augmented from 80—the number at their first meeting in 1816—to upwards of 300. The publications of the society had now amounted to five thick Svols. volumes. The meet- ing was also addressed by Lord Arthur Hervey, vice-president; and after the usual elections of office bearers and other business, the Rev. J. Bulwer proposed that 50*l.* be appropriated to the engraving of the late Mr. Musket's series of camera drawings of the Norwich gateways. The meeting referred the matter to a committee, as it was doubtful whether they were thirteen in number or twenty-three. The Rev. C. R. Manning then read a paper on "A Brass in Methwold Church," and Mr. Harrod one on "The Earth- works at Castlereac." The Rev. J. Gunn gave an account of his recent excavations at Hoxne, the result of which had been "to bring the bones of extinct animals to a much higher stratum than ever supposed, and to bring the flint implements to a much lower one."

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The usual fortnightly meeting of this society was held at the Royal Institution, Colquitt-street, on Wednesday evening, the 25th, Mr. H. P. Horner, the president, occupying the chair. The papers for the evening were the following:—"The Principles of Ventilation, with Experiments," by Mr. G. Reid, and "Some Remarks upon the Metropolitan Drainage, with Illustrations," by Mr. Barry.

**FALL OF A HOUSE.**—On the night of Monday an accident occurred, by the sudden falling of a two-story house, in the occupation of Mr. John Smith, at Troy Town, Rochester. According to the newspapers, the utmost excitement prevailed in the vicinity, and large numbers quickly set to work to remove the ruins, when, after a delay of some two hours, the sufferers were extricated, provisionally without loss of life.

**RESTORATION OF THE STRAUBERRIES IN HYDE-PARK.**—At the weekly meeting of the Marylebone representative council, on Saturday, letters were read from the members for the borough, Mr. Edwin James and Lord Fernoy, on the subject of the destruction of the shrubberies in Hyde-park. It appears that Lord Fernoy has had the assurance from Lord Palmerston that the shrubs will be replaced and the grounds immediately laid out. Thus this much-agitated question is to be satisfactorily set at rest.

**COLOURS BY REVOLUTION.**—A correspondent writes to say that a mechanical contrivance has been invented by Mr. T. Goodchild, architect, for exhibiting coloured patterns by means of a rotating coloured radial disc, over which is fitted a fixed perforated pattern, merely cut in black paper: the perforations with the disc beneath fully tinged the revolution has been forestalled by the "Colour Top," described in our pages some months ago.

**ARSENIC IN PAPERHANGINGS.**—Three children, living near Tipton, have been all but poisoned. On removing to a new house, according to a Manchester paper, they became strangely and unaccountably ill. At nights they were worse than in the daytime, and always very restless, the muscles of the face being marked by a kind of twitching. Medical assistance was procured, but without effect, until the medical attendant discovered that they were suffering from poison. He subsequently examined the bed-room, and finding the walls covered with a green-coloured paper, tore off a small piece, in which he discovered an extraordinary quantity of arsenic. The children were removed into another room, and are now fast regaining their usual health.

**THE COUNTY SURVEYORS OF IRELAND.**—A memorial to the Lord Lieutenant has been circulated by the county surveyors of Ireland, and approved by some of the principal members of the two branches of the Legislature, the prayer of the memorial being, that his Excellency would cause such measures to be taken as will bring their grievances, as to amount of salary and want of provision for superannuation, or retiring allowance, before the Legislature during the present session, and so give effect to the recommendations of the elect committee. The salary, after deduction of travelling expenses, is said to amount at present only to 200*l.* in the smaller counties, and much less in the larger.

**SOUTH WALES INSTITUTE OF ENGINEERS.**—The General Meeting of the members of this institute was held at Cardiff on the 26th ult. when a discussion took place on a paper by Mr. Wilson on steel, which the *Cardiff Guardian*, of 25th ult. reports at some length. At the close of the discussion, Mr. Byott said he hoped it would not go forth that all their best iron was brought from Russia and Sweden, as a great deal was imported from the East Indies, the importation of which he hoped to see extended. Mr. Wilson said such was the fact; they also imported from Newfoundland and other British provinces, but the bulk came from Sweden and Russia. Some of the papers were discussed, and one by Mr. Maynard, on the Crumlin Viaduct, was read, but the discussion upon it was postponed.

**CAMBRIDGE GUILDHALL.**—The Cambridge Independent Press says:—"The committee, after much labour, have decided upon a plan, which is indeed an amalgamation of the two plans 'Utility' and 'Ten and Fest,' but it is found that to carry it out, and obtain the necessary amount of light, some part of Mr. Livermore's premises must be purchased, at a cost of 400*l.*; and for this purpose application will be made to the Town Council on Thursday next. It is then expected that the plan will be completed, and in a fit state to present to the Council for its approval at the following meeting. The greatest care has been taken not to exceed the stipulated expense."

**DILAPIDATIONS IN GLEBE HOUSES.**—Viscount Dunsannon, according to notice, inquired on Tuesday whether any Bill was proposed to be introduced during the present session under the sanction of the episcopal bench to alter and amend the law relative to dilapidations in glebe houses. The Archbishop of Canterbury, in reply, announced that a measure was in preparation, which he hoped soon to lay before the House. The Bishop of Oxford said that, as the Bill alluded to was in some respects a taxing Bill, it would be introduced into the House of Commons with the understanding that it was supported by the heads of the Church and the great body of the established clergy.

TENDERS

For new Church at Cowley, Oxford, Mr. George Edmond Street, architect. Quantities by Balcan & Lee:—	
Jackson & Slaw .....	£7,970 0 0
Norris .....	7,925 0 0
Wheeler .....	7,739 0 0
Byatt .....	7,500 0 0
Holland and Hannen .....	7,370 0 0
Myers .....	7,220 0 0
Symonds .....	6,989 0 0
Wyatt .....	6,850 0 0
John Castle .....	6,725 0 0
John Castle (accepted) .....	6,472 0 0

For alterations and additions, Commercial-street, Whitechapel, for Messrs. Venables and Sons, Mr. Isaac Clarke, architect. Quantities by Mr. Masland:—	
Reed .....	£3,530 0 0
King .....	3,464 0 0
Ring & Sanger .....	3,274 0 0
Thomson .....	3,240 0 0
Downs .....	3,239 0 0
Coleman .....	3,169 0 0
Wheeler .....	3,069 0 0
Carter .....	2,979 0 0

For Clarendon Hotel, Watford, for Mr. J. Simpson, Mr. J. Liveck, architect. Quantities supplied:—	
Parker .....	£3,980 0 0
Mathews .....	3,492 0 0
Nelson .....	3,479 0 0
Noble .....	3,265 0 0

For house and offices at Emmetts, Kent, for Mr. Richard Gibbs. Quantities not furnished. Mr. John Jenkins, architect:—	
Gannon .....	£3,915 0 0
Bowens .....	3,549 0 0
Tongue .....	3,207 0 0

For the new Police Station, Ladywood-lane, Mr. Edward Holmes, architect. Quantities supplied:—	
Nelson .....	£2,050 0 0
Nowell .....	1,999 0 0
Hardwick .....	1,935 0 0
Jones .....	1,919 0 0
Creswell .....	1,890 0 0
Webb & Son .....	1,877 10 0
Stall .....	1,859 0 0
Matthews .....	1,847 15 0
Barnes & Sons .....	1,845 0 0
Goilrey .....	1,840 0 0
Stokes .....	1,798 0 0
Smith, Brothers .....	1,795 0 0
Chambers & Hilton .....	1,750 0 0
Geary .....	1,747 0 0
Stockett & Field .....	1,737 0 0
Burkit (accepted) .....	1,733 0 0
Cole & Son (sent in error) ..	1,681 0 0

For St. Jude's Parsonage, Commercial-street, Whitechapel:—	
Woods .....	£1,415 0 0
Ashby & Horner .....	1,370 0 0
Reed .....	1,368 0 0
Piper .....	1,360 0 0
Kelley .....	1,350 0 0
Maldett .....	1,349 0 0
Oathwaite .....	1,338 0 0
Little .....	1,320 0 0
Jacobs .....	1,299 0 0
J. Pritchard & Sons .....	1,279 0 0
Heath .....	1,090 0 0

For building additional fever wards for the Torrey Infirmary, Mr. E. Appleton, architect. Quantities not supplied:—	
Thomas Goss .....	£230 0 0
W. A. Goss .....	90 0 0
J. Harvey (accepted) .....	898 4 0

For work to be done at premises, Jermy-street, St. James's, for Messrs. Isaacs, Campbell, & Co. Messrs. Elliot & Chamberlain, architects. Quantities not supplied:—	
Couder .....	£81 0 0
Wills .....	867 0 0
Fish .....	860 0 0
Cannon .....	835 0 0

For finishing nine houses in Bowater terrace, Blackheath, for Messrs. Nickoll. Mr. C. Bradley, architect:—	
Liddiard (accepted) .....	£715 0 0

For alterations and refronting the Custom-house Hotel Chapel street, Salford, Mr. James Evans, Borough Surveyor, architect. Quantities supplied by Mr. F. Taylor, Manchester:—	
W. Dallas .....	£419 0 0
H. Southern & Co. .....	411 0 0
J. Marshall .....	410 0 0
J. Jones .....	405 0 0
R. Pary .....	350 0 0
Statham & Sons .....	337 0 0

For works to be done at Coal Office, Holloway-road, for Messrs. Rickard, Smith, & Co. Messrs. Tiltot & Chamberlain, architects. Quantities not supplied:—	
Couder .....	£370 0 0
Jennings .....	354 0 0
Wills .....	343 0 0

# The Builder.

VOL. XVIII.—No. 888.

Blue Books made Useful.

THE recent sessions of Parliament have not been, by any means, wanting in subjects having particular interest for those who are the ordinary readers of the *Builder*; the like state of things will, and ought to, constantly recur; and the session just commenced will probably not pass by without discussion of numerous questions relating to new buildings and metropolitan street improvements, the sewerage of towns and other sanitary works, to harbours and docks, the conservation of shores and rivers, and railway communication, and to works of many other kinds, in which both the

art and the structural and scientific part of architecture will be concerned. We can at once specify some of these subjects, to show the importance for us which the proceedings of Parliament now ordinarily possess; and we need not allude to increasing attention paid to education, and amounts voted for the advancement of science and art, or generally to the growth of the pursuit of "social science" in the very widest sense, not merely amongst the leaders of political parties, but as manifested in the proceedings themselves of the House of Commons and by the inquiries from time to time instituted there. We may instance the question of a new building for the National Gallery; that of the provision of quarters for the natural history collections, which, it is now decided, shall be removed from the British Museum; the question of the Government offices; that of the metropolitan street communications with reference to the present exigencies, and those further which will accrue from projected railway stations; the embankment of the Thames; the cleansing of the Serpentine; the harbour-works in progress and to be undertaken, and the fortifications, and many more that could be named. We might also refer to views that were expressed by some authorities during the progress of the strike, as to the need of further legislation, to protect the interests respectively of employers and employed. Every week, in Parliament, one or other division of the wide field, where art and practical architecture, engineering and sanitary science, are working for the national progress and the benefit of the people, is cultivated to some extent. Mistakes are made in legislation, as well as by expressions of individual opinion; but each session leaves an addition of some value to the crop of statistics and information, embodied or imbedded, in the accumulating mass of Parliamentary literature. It is our present object to inquire whether this body of matter, which has little effect in proportion to the labour and the cost with which it is got together and printed, might not be made more accessible to the class numbered amongst our readers, and of greater productiveness in results for the world at large.

The question indeed,—"What shall we do

with our Blue Books?" has been often put, and not long since by Lord Stanley,—the point of whose reply in his pamphlet, however we have lost; whilst the particular suggestion we shall offer, has before appeared in print,—though little noticed and not supported by the reasons which we think may now be brought to bear in favour of it. It may be well to show what are the principal facts as to the issue of "blue books" interesting to ourselves and our readers, so far as regards the publications in recent sessions. The Parliamentary papers to which chiefly our remarks are intended to apply, or excluding the journals of the House of Commons, the Daily Votes (to which, however, are appended railway reports), the papers of the Lords, now obtainable, and the Statutes or Acts, are divided into "Reports and Papers," "Bills," and "Papers presented by command." In the first of these three divisions are comprised the returns which are made to the motions of members of the House of Commons; and the reports of Select Committees, with or without the evidence. The bills we need not further mention. The papers presented by command of her Majesty comprise copies of treaties, or correspondence, and reports of commissions, with evidence and appendices. The rule, up to within the last two years, as regards the reports and papers printed by order of the House of Commons, was to print a moderate number of copies beyond those required for the members, say in all 1,000 copies; but of the reports of commissions, often very costly, as many as 5,000 copies were sometimes ordered by those who assumed the duty of ordering, or those to whom it was left. On the occasion of the vote in 1858 by the House of Commons, of the amount, 401,357*l.*, for printing and stationery for various purposes, the case was mentioned of one report where an order for 2,500 copies had been reduced to 1,000 on the chairman's attention being called to the matter. This reminds us of an anecdote that has been told by one of the firm of Longman & Co. of a country clergyman who, receiving a request from some members of his flock that he would print a particular sermon, went into an estimate of the number of clergy in the United Kingdom, assumed (to be on the safe side) that one-half or a third would be purchasers, gave the order for printing accordingly, and was alarmed on hearing that the sale had been about twenty copies; though he was fortunate enough in having publishers who had not adhered literally to his instructions. The waste, more especially in the case of the Reports of Commissions, has been enormous; and much of the same sort of thing still must be said to exist as regards Parliamentary publications of all kinds, so long as they do not become disseminated largely, except through the agency of the hatterman, and do not serve, relatively to the value of what they contain, the work of public education. It has been stated that the sum realized by the sale of waste paper has been 5,000*l.* per annum, as shown by the public accounts. Recently, restrictions have been placed upon the number of the copies printed of the "papers presented by command;" and disposition is shown in Parliament to limit the expense in other directions; but, before the alteration—not in all respects to be approved of—which limited the number to fifty, of copies of a departmental paper printed for gratuitous distribution, it was common for a considerable expenditure to have been incurred for some set of bulky volumes which not more than five or six persons read. The Report of the Commission on Endowed Schools (Ireland) cost 5,201*l.* 2*s.* 2*d.* for printing and paper only. There were four folio volumes, each of 600 pages, as stated, the paper weighing thirty-four tons. The copies printed were 4,250 of each volume; but no English or Scotch member sought to obtain a copy, and the chief application of the outlay seems to have been the supply of 104 copies to Irish members. We have now before us returns of the cost of paper, printing, and binding, each paper "presented by command," during the sessions of 1856, 1857, and 1858. They are defective so far as they do not state the number of pages in each report, so as to allow a full examination of the items named, but it appears that in the last of the years the

amount, 29,331*l.* 8*s.* 5*d.*, was spent in those items, on such papers, by the authority of nine Government departments. In February, 1859, it was stated in the House of Commons that the expenses of printing amounted to 150,000*l.* or 160,000*l.* a-year. It must be recollected that neither of these statements covers the office expenses, as of the commissions, which must amount to the largest sum. The Report on Metropolitan Main Drainage, by Captain Galton and Messrs. Simpson and Blackwell, wanting the usual index, thus cost the country 8,836*l.*; and, apparently, printing and paper not included. The Report, subsequently, of Messrs. Bidder, Hawksley, & Bazalgette to the Metropolitan Board of Works cost between 2,000*l.* and 3,000*l.* Is it likely that any multiple of 1*l.*, or the price at which each copy of the Government Blue Book was sold, realized by such sale, would deserve a moment's consideration? The matter of the Blue Book, at least what was appended to the Report, was matter calculated to be of the utmost service in the settlement of the sewerage question, if perused by all who were giving thought to that subject, and were capable of making suggestions, whilst avoiding such loose and ill-considered ones as were substituted by correspondents of the newspapers. Yet, an outlay having been incurred, enormous in amount, but which we assume and believe to have been an outlay necessary and judiciously incurred; just so much of a tax is imposed as will defeat the object and render impossible the benefit, and not return a single hundred pounds of that expenditure. It is not surprising that the real value of such Blue Books is little known, and that the very matter which they contain has to be again and again got together by committees and commissions,—to increase unnecessarily expenditure, and swell the mass of printed matter obstructively to future investigation.

The figures we have given, and the known facts that the vast majority of the papers, from mere mass, are not and cannot be read by members of Parliament, and only go to form a heap to be cleared away and become the perquisite of a footman, who gets at most 2*s.* per cwt. for them as waste paper; and that, notwithstanding, some of those of permanent interest are quickly not to be procured; show that some change of system is needed to render justifiable the expenditure. Rightly, the course is not to stint the expenditure in the first instance; but to take means to insure that the particular object of the publication is attained. Such means are not to be found in the purchase of copies by the public, albeit the nominal price may be fixed low; because, first, there is not and cannot be sufficient information given by advertisement, of the nature of the matter, or even of the publication, of these papers; and, secondly, because, taking into consideration the number of the papers on a single subject, and the actual cost of some of them, or such as have plans, the expense does stand in the way of the dissemination and proper utilization. It frequently happens that just when the value of the paper becomes known to the public, the price has risen from causes to which we have alluded. Thus it has been stated that a report on stone (perhaps that on the stone for the Houses of Parliament) which was published at 6*d.*, would now fetch a guinea. There are several such cases: the report of the commission on iron applied to railroad structures, is hardly procurable at any price; and the money value of particular papers, or the costliness of a set on any subject, is, from the nature of the circumstances, rapidly increasing. To obtain all the reports on harbours, or on workhouses, or prisons, would require a small fortune; yet no architect or engineer can feel that he has possessed himself of his subject till he has either himself gone through such documents, or is assured that he has the result of a similar operation of research and analysis performed by others. It is obvious, therefore, that there must be some contrivance better calculated for the educational object, than such a one as the refusal to medical men who have contributed matter to the Registrar-Generals reports, of copies of those reports. The fact that the object for the nation is not primarily the reduction of cost of

the printing and paper, was pointed out by Mr. D'Israeli, some time ago, and must be admitted. We have shown that the representation, as contained in the Treasury minute of November, 1858, in answer to Dr. Pickford, of Brighton, that the weekly reports of the Registrar-General could be bought for 1½d., and the quarterly reports for 4d., is by no means an accurate one of the point at issue, as it concerns ourselves, and the profession we represent. The Main-Drainage Report alone, as we have said, was issued at 17s.: and we repeat that, whoever has sufficient interest in such papers to read them, is generally one who can give some return to the nation, far greater in amount than the price which legislative or departmental narrow-mindedness so much fears to lose. The object for Government and Parliament should be, not to impose any tax whatever on the use of the publications, though it is necessary to check abuse and waste: but the object should be to get the books read. People usually do not buy books, even at the cost of mere pence, unless with some view, to be furthered by matter which the books are supposed to contain; and they want preliminary information. Such information of what is to be found in parliamentary publications, given on their appearance in the newspapers, is much confined to subjects which happen to have been prominent; and the omission is not supplied by the lists of the printer to the House of Commons, which are little known, and, for the publications of past sessions, have to be very much improved, as well as cheapened, to make them of the proper use for purposes of general reference. One new and comprehensive catalogue is required; but arranged with divisions, as alphabetical and classified; and better models for these could not be found than Mr. Woodcroft's catalogue of patents. A list which is regularly announced as comprising the titles of papers of several sessions, was not purchasable at our last application; and, to show that improvement in other respects is required, it may be sufficient to state that on another occasion, when papers were wanted by us for immediate reference, our messenger was put off to the following day, either for the convenience of those in charge of the papers on sale, or from defects in the system of arrangement and cataloguing. The daily journals, when they mention publication of a parliamentary paper that would be interesting to ourselves, confine themselves to a paragraph which often omits much that may be technical, but is at the same time of great value to particular inquirers. Our remarks as to the defects of the catalogues are not intended to apply to those indexes which are appended to reports themselves: these are prepared with great labour and skill—it is unnecessary to say to those who have occasion to use the class of papers; and without them, usually, the evidence and other data, often more deserving of attention than the mere compromise of opinion which forms the report, could be turned to slight account.

The importance of the dissemination of the matter of parliamentary papers has been so far seen by many persons, as to have led to suggestions for the gratuitous supply of these publications to popular institutions, in the same manner as the specifications of patents are now supplied, through the exertions of Mr. Woodcroft. But few of those institutions, and as a rule not those which exist in rural districts, have the space for even a moderate proportion or selection of the papers, or would appreciate them or any similar class of literature. Certain individuals would be interested in particular subjects; and the populations in some localities would feel interest in what concerned their means of livelihood, or their own condition. In such cases, however, the object would be better obtained by sale of the papers, than by the other opportunities given; but towards this there must be some better devised means of advertising the matter of the publications than is now comprised in advertising some of them. Again, it has been thought that certain learned societies, or persons requiring such papers really for a scientific or literary object, should be allowed to prefer a claim to have them gratis; but to this it is replied,

that the money payment (here considered as small in amount) affords the only security that the papers will be valued and turned to their intended use, and likewise that the time of public officers would be taken up in determining what individuals or societies were entitled to the papers, or in answering applications; and that it is impossible to draw any line between the different classes of persons. To this it may be observed, that the point we now advance, one apparently somewhat at variance with views held by those who are disposed, praiseworthy enough, to check the waste, is that it would be better that no amount whatever should be realized towards cost of paper and printing, and which return yet we apprehend is insignificant, than that the objects, educational and otherwise, justifying the publication, should be in a great degree limited or impaired. We do not profess to know whether the fifty copies before alluded to as still printed "for gratuitous distribution," are absorbed by the requirements of the Government offices, or departments themselves: we only know that none of these, however important the subject-matter to architects and engineers, ever reach ourselves without purchase or sending for them; and we think that the Institute of British Architects, and the Institution of Civil Engineers, are in a similar position. Surely this, which at least occasions delay, and also operates as an impediment to the diffusion of information and opinion, if not by ourselves, by many who would be contributors of information to the general fund through the medium of our pages, might be corrected; for, we need only instance the daily papers, to show how necessary it is that contributions and correspondence, resulting in this supposed case from the "blue books," should be added to the exertions of those whose difficult duty it is to get to know, first, what has been published, and then what the publication contains. Only five persons having read a particular "blue book," no result may have been obtained to compensate for the cost; but a method might easily be suggested by which the publications could be made accessible to a much greater number of persons not members of Parliament, with the probability that amongst the number would be found five who would have time and ability to digest the matter of the reports, and to produce work of some description that would contribute to progress, and alone justify the national expense.

Our suggestion, therefore, is, that, whatever be the course maintained in reference to the gratuitous distribution, there should be established a public library devoted specially to Parliamentary publications. This institution might be most conveniently located in the neighbourhood of the Houses of Parliament: it should be open throughout the year, might be a lending library, and should be at least as accessible as the reading-room of the British Museum: it should contain perfect sets of all the past publications, several copies of each of recent issues, well-compiled catalogues, and every convenience for writing and reference. We would include in the collection, or the reading-room, some maps, and statistical charts, and books of reference, such as commercial and geographical dictionaries, without, however, losing sight of the main and definite object. There might also be arrangements for the display of maps, showing lines of railway, and other works before Parliament. We would further include in the collection all documents and reports of importance, relating to the metropolis, not presented to Parliament, such as the reports presented to the Common Council of the City, to the City Commission of Sewers, to the Metropolitan Board of Works (with all streets), to the District Boards, and of those Metropolitan Water and Gas Companies who might be disposed to contribute. It is obvious that then the expense which is involved in printing, might be reduced without detriment, and might be avoided altogether, in some instances, by the substitution of an attested manuscript copy of the return which a member now often moves for, more for his own information than for an object which would immediately require the expense of printing. It has several

times happened of late, that a member of Government has had to appeal to the forbearance of a member of Parliament, against what seemed a waste of public money, though the object of the motion for the return was admitted to be a proper one, and important to the public. We believe also that with the public eye constantly upon the matter of "blue books," a more efficient check upon the printing of returns previously printed, would exist than is to be expected from the Librarian of the House of Commons, if he be now charged with any duty in the matter.

It may be remarked that the objects of such a library as we propose, are attained at the British Museum, where there are preserved copies of all Parliamentary publications. The fact, however, that there the papers are not obtainable immediately on publication, or at the time at which much of their chief interest exists, is an answer to such an argument; besides, the extent of a large general library, excellent as is the management of the Museum reading-room, causes much delay to students and inquirers, and has been the reason for our arguing on several occasions in favour of other libraries devoted to special subjects, such as those already existing at South Kensington for books on art; at Jernyn-street, on general science; and at the Great Seal Patent Office for its class of subjects. No change should be made in the system of supply of the papers to the British Museum, unless for diminishing loss of time there; but special libraries, that we now recommend, as well as others of a different sort, should be multiplied: they would result in great progress as regards the subjects themselves, and they would lessen the inconvenience at the British Museum. It is true that access may be obtained to the libraries of the two Houses, by persons engaged in business before Parliament; but this involves difficulty, and obviously would not suffice for the public object in the matter above dwelt upon.

We had thought of giving a list of titles of recent papers on subjects in which our readers are interested; but some of them have been mentioned by us on publication, and we have no further space at present. We have, however, we hope, succeeded in showing the importance to our readers which there is in this matter of our present article, and that the interests of the tax-paying, whilst enlightened, public, are all in favour of the dissemination of parliamentary publications, rather than in the concealment of their light, which we apprehend would be involved in the narrow view of the money expenditure. We have shown, however, further, that there is one simple mode by which the light may be further disseminated, whilst the expense is even reduced; and we hope that our observations may attract the notice of Mr. Wm. Ewart, or some member of the committee of the House of Commons, appointed the other day to assist the Speaker in matters relating to printing.

#### ON THE RATIONALE OF GOTHIC ARCHITECTURE.

MR. SCOTT'S FIRST LECTURE AT THE ROYAL ACADEMY.

IN my former lectures I have endeavoured to trace out the history of that course of transition by which the rude arcuated architecture which prevailed in western Christendom during the Dark Ages, between the fall of the Roman empire and the rise of modern civilization, commonly known as the "Romanesque" style, first emancipated itself from its semi-barbaric character, and became a consistent round-arched style, and subsequently, by a perfectly logical series of changes resulting from the suggestions partly of scientific construction, and partly of artistic refinement, developed itself into that new, original, and beautiful style which has in more modern times received the very absurd, but now unavoidable, name of Gothic architecture.

Having traced this development up to what I consider to be its culminating point,—the form which it arrived at towards the end of the thirteenth century,—it had been my intention, before I proceeded further with the historical view of the subject, to have given a series of short practical treatises on several of the more important ele-

ments of the style whose history I have traced out; as, for instance, on the principles of Gothic vaulting, on tracery, on the system of mouldings belonging to the style; on roofing, on architectural carving and sculpture, &c., &c. Circumstances, however, having rendered it impracticable for me just now to devote to it the time which would be necessary to do justice to these subjects, I purpose on the present occasion to content myself, at the risk (I may say with the *certainly*), of repeating what I have already stated, with an inquiry into the *rationale* of the style of architecture of which I have been treating.

Such an inquiry is the more necessary from the extraordinary contrariety of opinion which we find to exist as to the real character of the style, as well as the external and internal causes of its development. Such opinions assume the most contradictory forms. One class of them may be denominated the *religious* view of the question. Under this head one party describes it as Christian, and another as Roman Catholic architecture. One attributes to its various parts a deep symbolization of Christian truth; another discovers in them nothing but the mystic arcana of Romanism; while another enters the knot by protesting that it is Mahomedan architecture. A second class of opinions assumes an *ethnological* form. Under this head some have thought the style especially English; some pre-eminently German; some, again, in the most exclusive and straightened sense of the term French, and others in the widest sense, Teutonic; while the entanglement is again cut through by the champions of the *Saracenic* claim.

Then comes a *political* class of disputants. One declares the style to be nothing more or less than the visible exponent of feudalism. If the system of Durandus were applied to this view we should perhaps have the orders of the arch shown to represent the divisions of feudal aristocracy. The point of the arch to be the king; the outer voussours the great, and the inner the lesser vassals; the clustered pillars to be the bishops surrounded by their clergy; the ashlar stones the freemen, the rubble stones the villains and serfs, and the mortar to be the bond of union or of slavery by which the whole system was cemented together; and the painted glass to be that clerical monopoly of learning by which the pure light of knowledge was imparted through an artificially coloured medium. Others have, however, shown that the style developed itself just when feudalism was giving way, and just among those very communities who were most resolutely exerting themselves for its overthrow; and that, in England especially, it synchronizes with the foundation of those institutions to which we owe our liberties and our greatness; while our knot-cutting friends would contemptuously pool-pool the whole question by saying that it had nothing to do either with feudalism or Magna Charta, but was simply the natural result of the Crusades.

Again, as to its more practical characteristics; one party claims for it the most unbounded liberty, another denounces it as curling the free following of practical and artistic requirements. The very same party sometimes describes it as excluding the light of day, and sometimes as offering no protection against the glare of sunshine. In fact, without going further into these contrarieties, it may be sufficient to say that among those who have not gone much into the subject, no opinions are too inconsistent either with one another or with facts to find ready advocates.

My object in this and the succeeding lecture will be to show that the style originated in no occult influences; that if it can be called either Christian, Teutonic, French, English, German, or Western European, it is so only in a plain, straightforward, and historical, and not in any hidden, exclusive, or mysterious sense; but that it, in fact, arose from the application of plain common sense to plain practical requirements; that many of these requirements were not peculiar to the period, but belong to all time; that many were not limited to a race or climate, but are common, with certain modifications, to different races and countries; and that the application of the same class of common sense to altered requirements would produce results by no means militating against those thus arrived at, but, on the contrary, tending to enrich, to amplify, and to add new life, variety, and harmony to the art which it had first suggested.

To judge of the practical reasonableness of a style of building, it is not enough to prove that it answers its purpose: we may presuppose that all civilized people would effect as much as that,—indeed, that all people would do so who can construct at all; for if uncivilized, their aim would be more simple and more readily attained.

The question is, whether the purpose is provided for by means consistent with common sense, with the laws of nature, with the properties of the materials at hand, and without an expenditure of labour and material disproportioned to the result. In this I do not restrict the question to merely utilitarian results, but admit the artistic element in a degree proportioned to the rank and purpose of the edifice. I would also wish to guard myself against being understood to imply that the superior reasonableness of a style of architecture proves a higher state of civilization among the people who use it. Inventions are often accidental, and independent of high civilization. Thus, though an arch is a more rational means of spanning a wide opening than a single block of marble, the early Romans who used the arch were probably much less civilized than the early Greeks, who were ignorant of it.

The Egyptians and the Greeks used most nobly the means of spanning openings with which they were best acquainted, and for which their numerous quarries of granite and marble supplied them so liberally with the materials, but such a mode of construction is manifestly costly,—dependent upon natural facilities of the most exceptional kind, and extremely limited in its application. The use of the arch obviates all these difficulties, and consequently a mode of construction which admits the arch is more rational than one which does not.—Roman architecture, in short, than Greek.

The Romans were, in fact, eminently a practical race, and their architecture is in its construction in a high degree practical and rational: they by no means limited themselves to the use of costly and bulky materials, but united in their structures the use of all the materials of which their world-wide dominion gave them command, and were equally successful in employing in them the most stupendous masses of marble, as at Balbec, the granite of Egypt, or the flint-nodules of Kent; and never hesitated at spanning the widest structures with vaults or domes of such solidity as almost to defy the ravages of the elements and of time.

The two great defects in the *rationale* of their architecture were—first, that, as the conquerors of the world, the resources at their command were so unlimited that economy of material seems to have been almost dismissed from their consideration, and their principle of statics seems to have been rather that of passive and inert resistance than of equilibrium of forces; and, secondly, that having adopted the artistic features of Greek architecture, they attempted to unite them with their own totally different system of construction, in a manner which cannot always be said to be consistent with reason.

When the nations of modern Europe began to emerge from the chaos of centuries, and to generate for themselves a new civilization, their aim, as regards architecture, seems rather to have been the recovery of ancient Rome, which they may all along be considered to have continued a dormant state of existence, than to generate a new style for themselves; but their limited resources, and unfamiliarity with what is now denominated "classic" art, freed them from the tendency to follow their great masters in the two defects which I have mentioned. True, they often built with needless massiveness; but this was not the result of profuseness, but of want of experience; and when they imitated or re-used the details of Roman architecture, they applied them with more regard to practical utility than to classic precedent.

At first the Romanesque builders were at a low level, both as to constructive and artistic skill; but all their efforts being directed to practical improvement, they, in course of time, succeeded in generating a very consistent round-arched style in which every feature may be said to have resulted, in a greater or less degree, from practical reasoning on immediate requirements and on their experience of preceding details.

The observations I have to offer on the developments thus reasoned out are intended to apply mainly to those of the countries north of the Alps, but may in many points be found to be of general application.

One of the first practical principles aimed at throughout the whole range of Medieval architecture was so to arrange their designs as to facilitate the use of small materials, and to render themselves independent of the accident of having quarries at command which would supply vast blocks of stone. It happened that in the great seats of early art this was of less consequence, for both Egypt, Syria, Greece, and Italy contain such quarries in tolerable abundance, though even the Romans resorted to concealed arches for the security of their architraves; but in northern

Europe, though building stone in most parts abounds, it is quite exceptional to find it at once in blocks of great dimensions and of strength which would render it a trustworthy covering to openings of any considerable bearing. With all our increased facilities at the present day, we never find the trabeated system carried out in its integrity when on a large scale: either the middle stones of architraves are suspended by concealed arched joints, as is the custom here, or are visibly arch-jointed, as in France, or the entire architraves consist of brick arches plastered over to mimic the construction they affect, but cannot follow. Even in our Gothic buildings, where every facility exists for the use of moderate-sized stone, it is often with much difficulty that blocks of a size suited to all purposes can be obtained. Thus with the Houses of Parliament, after the whole kingdom had been ransacked by a geological commission, not only was the quarry they recommended summarily rejected as "ineffectual of furnishing stone of any reasonable size," but the second quarry, which was adopted in its place, and which produced an admirable material, was, after a time, abandoned and a third selected, the productions of which have, in other respects than size, proved so lamentably inferior. The fact is that it is only here and there that we find quarries uniting *quality* and *size* which suit even our moderate requirements; and if such is the case now with all our mechanical advantages and facilities of transit, how much more must it have been felt in days when the mechanical appliances of the ancients had been in a great measure lost, and the Roman roads broken up, while the means, which were to supply these deficiencies, were yet in their infancy.

While, then, at all times and everywhere, it is a desideratum to a rational system of construction, that it should offer every facility for the use of ordinary and easily-obtained material, such was the case in a more than usual degree in these early ages of modern art.

Though the universal use of the arch by the Romanesque builders obviously promoted this object, it would not of necessity lead to its fullest attainment. Arches may be, and often are, constructed of enormous blocks of stone, and it had to be studied how to make good construction with small materials.

The most obvious means of doing this, was by building the arches in *rims* as we do our brick arches,—a deep arch, consisting of several distinct arches laid one over the other, each forming the centre on which the next is built. By this mode of building, an arch of any degree of strength may be built of stones of the most moderate dimensions. This system consequently became general in the Romanesque buildings.

Now, a deep arch so constructed, and built square through the wall, has a heavy, clumsy appearance, and forms a dark and cavern-like recess. You may ornament the voussours, and vary their colour as you please, but still it is heavy, wanting in play of light and shade, and obstructive to the free passage of the rays of light. This was early felt and early obviated.

In an arch built in several rims, it is not necessary that any but the outer rim should be of the full width of the wall. This suggested the system of *subordinating* the rims, or recessing them one behind the other, so as to divide the arch into what are called orders.

This gives us at once a new and beautiful mode of arching, economical, and adapted to all varieties of material, giving great play of light and shade, offering the greatest freedom for the admission of light, and suggesting (as we shall see), a perfectly new system of decoration.

This division of the arch into receding orders necessitated a corresponding form in the piers which supported it.

The first means of relieving the plainness of this block-form, was the introduction of an impost at the springing, defining the line which separates the pier from the arch. Afterwards the orders of the jamb would receive pilaster-capitals, and finally, decorative columns would be inserted in their place;—thus completing the general idea of the pier and arch as made use of during the Romanesque period.

The arch itself was at the same time subjected to various systems of decoration suited to its *normal* construction.

It is clear that the extreme angles of the orders contribute but slightly to their strength. These might, therefore, be rounded, chamfered, or moulded at pleasure. It became common to form them into large rolls between two hollows, and also to cut the order into various mechanical or other forms, as zigzag, &c., &c., according to the

fancy of the architect, from which arose the whole system of Romanesque arch decoration, and as the junction of the arch with the wall above was but slightly marked by the change in the direction of the joints, a small projecting moulding was introduced between them, which we call the drip-stone or label, which not only drew the line more emphatically, but also served to prevent the water which ran down the face of the walls from discolouring the arch mouldings.

It will readily be seen that this logical and reasonable mode of constructing arched openings, would, when applied to arches carried on pillars, lead to the clustered column.

If the wall was not thick, the arch might certainly continue to be of one order, and the most natural mode of supporting it would then, as heretofore, be a single column. Where, however, the wall was so thick as to give it a clumsy look if the arch ran square through it, it would be divided into two orders, and would assume at its springing a cruciform plan. The impost must break round this figure, and though the column might still remain (and often did remain) round the abacus, only assuming the cross-form, the most natural thing would be to form a complex pillar, composed of four shafts united in one, each apparently supporting its own order of the arch.

If the arch were divided into three orders, a more complex form suggested itself, containing eight shafts; and as the system was carried out many other combinations arose not necessary to enumerate.

Thus we see that the adoption of the arched system of construction, unbiassed by any pre-existing laws of art, but aided only by the very rational desire to utilize the materials most abundantly provided by nature, led to two of the most important characteristics common to Romanesque and Gothic architecture, viz. the subordinated arch and the clustered column, with the whole system of decoration derived from them; than which no two features can be pointed out which have been more richly fruitful of architectural forms, the most original and beautiful.

Again, in the mode of bringing down the arch upon columns the Romanesque builders exercised a sound discretion. The Greeks and Romans in their trabeated construction, reasonably enough, made their architraves only as wide as the upper diameter of their columns, so that whatever projection the capitals had from beyond the shaft they had the same beyond the architrave also. When, however, you substitute two arches for two architraves, you bring down the weight by two opposite forces; its footing, therefore, on the capital requires as much steadiness as possible.

The Romans, as many of their modern followers, were for a time so inconsistent as not only to limit the arch, like the architrave, to the thickness of the upper diameter of the column, but actually interposed, without a shadow of use, a bit of entablature between the column and the arch; thus, instead of doing all they could to give steadiness to the spring of the arch, they made it as tottering in its construction as possible. This was corrected by the Romans of the Lower Empire, and the arch was placed by them, as reason would dictate, directly upon the capital, or (still more sensibly) on a strong flat impost laid on the capital, and for this most reasonable step they have in after ages been pronounced barbarous. The Romanesque architects, taught by common sense rather than by precedent, followed their example. If they imitated or re-used the Corinthian capital, they laid upon its fragile abacus a more trustworthy impost, and to give greater steadiness to the foot of the arch they made it somewhat wider than the diameter of the column,—a practice which pervades Medieval architecture, and contributes greatly both to its good construction and its beauty.

The system of constructing doorways is directly derived from what I have already described; as many recesses being given to the jambs as the arch has ribs,—and these decorated with columns if thought good. The head is often filled in with a tympanum supported by corbels in the jambs, both as a foil for sculptured decoration, and to make the door itself square instead of arch-formed. If this is not done, the inner arches are made to spring from a higher level, to allow the doors to open without catching against them.

The windows show the same regard to reason. The inside is nearly always widely splayed, to spread the light evenly in the room. The external recess depended partly on the degree of architectural character aimed at, and partly on the depth required for the arch. Where the openings were but narrow and the resources small, one arch-rim

would suffice, and this would often be chamfered at the edges to prevent obstruction to light.

If the opening were wider, and so required a deeper arch, or if the architectural effect aimed at were greater, we find two or more such orders as the above, with, perhaps, columns supporting the outer ones, the receding orders, in either case, doing away with undue obstruction of light or view: the eill always well sloped, to throw off the water, and having usually a string course below, to prevent it from running down and discolouring the walls. In all this, a strict regard to practical reason and utility is manifest: every step is argued out on the basis of construction and requirement, and every decoration is founded on, and results from, the conclusions come to on these practical grounds.

In domestic architecture, if a window were beyond the width of a single casement, a small pillar was often interposed, and the inner order of the window was divided into two arches, while the impost, if there were any, was in one, the casements or shutters falling into rebates in the back of the column, by which a window of double width which would otherwise have been inadvisable was produced. In window-like openings in which glazing was not needed—as in triforiums, cloisters, and manders for the same reason, and in which no divisions were often increased to three or four under our comprising arch.

In other instances of the same kind, where light arching was needed, as in cloisters, and the wall was too thick to rest upon a single capital, two small columns were placed one behind another, or a sort of bar or double corbel placed on the piers, to support the spring of the arch, for the sake of avoiding the use of thick piers, which were not needed for strength, and would obstruct view and light, and all these practical contrivances were made elements of beauty and varied effect.

Another legitimate exercise of reason, on the part of the Romanesque builders, was the retention of the fixed rules of proportion observed by the ancients between the diameter and height of their columns. These rules were good in their place, but they had been worked out for a totally different system, and we know that the ancients themselves were anything but so slavish in their adherence to them as their modern imitators. In a purely practical sense, however, it became clear that such rules were out of place and inconsistent with reason. In some instances, in a majority of cases, prescribed the height of a column, from reasons wholly irrespective of the question as to its fitness. It followed then, that the height was regulated rather by the load than the height, so that every variety of proportion became admissible. Take, as an example, the crypt under the choir of York Minster. Its height being prescribed by the ancient canon, and the height it required for the vaulting being fixed by the width of the arches vault, it followed that the height of the columns was also rigorously defined; but some of these columns had to carry through the vaulting, and with them the whole superstructure, while others had only to lead to the vaulting of the crypt and the floor of the church. Surely, then, the simplest exercise of reason dictated that their diameters should vary with their load, irrespective of their height. The system of clustering columns both helped to meet the extremes of such variation in proportion, and, at the same time, introduced still wider liberty; for, though a pier destined to carry a great load might be subdivided, and its apparent proportions thus lightened, the individual shafts which composed it not having each its own proper load, might be viewed as decorative only, and be made exceedingly thin for their height. The use of such thin shafts did not, however, originate in the Middle Ages. The painter shows in his work on Domestic Architecture decorated with "Ornaments of a Light Form," that it was frequent among the ancients, though not often adopted by modern classical architects. Even for really constructive pillars, as in the case of metal columns, and in a less degree with those of marble or granite, where the load is very great, and it is especially so where the columns are of a decorative rather than a functional character, in which case it is not only lawful, but correct to show this by making them of slender proportions. The liberty, however, which I here defend, must, as all other liberty, be kept within reasonable bounds, and must be regulated by a correct eye and sound judgment.

Another sound exercise, as I think, of reason and liberty, which was universal among the Romanesque and Byzantine architects, was the departure from the rule of the ancients that all capitals and other recurring objects of a like nature should be worked to one and the same pattern. It may be that the unity of a colonnade, united by a single and unbroken entablature, demanded this. I do not find fault with it in Grecian or Roman architecture, but where the capitals are separated by arches, or did not form a continued range at all, the effect would be most painfully monotonous if the sculptural heads were all alike, as if cast in a mould by the universal law that accordingly it established as a general law that, though moulded or other mechanically formed capitals were imposed upon the sculptor; but that he should have the widest scope, within the reasonable limits suggested by the requirements of the general balance, and harmony of mass and outline, for the freest exercise of his own imagination.

Now, though these and other developments of the Romanesque period were to be founded on a thoroughly practical and logical course of reasoning, it by no means followed that a perfected form of arched architecture and system had been arrived at any more, than that the decorative system had been brought into a thoroughly refined or artistic form.

Towards the middle of the twelfth century the efforts of the architects were resolutely directed towards the attainment of these two objects, and the advances made, both in correcting defects in construction and refining the decorative system, were most strenuously followed up, and all improvements made were conducted strictly on reason. The great constructive difficulty met with on reason, was the outward pressure of the round arch when of great span, or carrying any great load, and especially so when used in situations where it was difficult to give it any very massive abutment.

The cases of failure from this cause were most frequent, so much so, that, besides the numerous instances recorded in the history, wholly, or in part falling from the failure of the arches, we have in the buildings still remaining abundant evidences of the insufficiency of the round arches for their load, and of the abutments to resist their outward pressure. In the case of the towers of bridges, viaducts, &c., give our arches, in an abutment proportioned to the pressure whatever it may be, are limited in our means of doing this by immovable cases: thus, in a central tower, the arms of the cross have aisles, the natural abutments of the tower arches are reduced to the frail aid of a continuous arcades upon detached pillars, and even if there are no aisles, the abutting walls are perforated with windows. The abutments, again, of a chancel arch, are perforated either by arches or windows, while the cable over the arch loads it heavily at its weakest point. The abutment of an arch, again, has often to infringe upon a pier at half its height, as in the case of a nave arcade abutting upon the detached piers of a central tower. In all such situations the undue pressure of the round arch was found to be most prejudicial. Still more strongly was it felt where the nave was spanned by stone vaulting. The Romans had got over this, as in the baths of Diocletian, by breaking the continuity of the arches by the aisles, and by crossing them. But in a church this was impracticable. Its uses demanded continuity of aisle, and moderation in the height of the vaulting. The same occurred from these adverse causes, and the ingenuity of the architects was naturally directed to obviating the defect.

I have, in a previous lecture, described the series of tentative experiments, and the course dictated by constructive and practical requirements, by which we succeeded in avoiding these difficulties, I will not weary you by recapitulating them. The two obvious desiderata were an increase of resistance, and a reduction of pressure, and these were the two objects aimed at in most of the succeeding developments. The first demand was met at the pointed arch, the second by the systematized use of the buttress, and the third by the use of a wide winged pier. It was perfectly well known that the outward thrust of an arch diminished as its height increased; that the resistive power of a clustered pier depended mainly on its extension in the direction of the pressure, and that where sufficient extension of abutment could not be obtained without inconvenience or disight, the deficiency might be compensated for by a buttress, or a pier, or by arguing on these three facts, the constructive characteristics which distinguish Gothic from Romanesque, or the modifications of the round arch into Gothic, were logically worked out.

The strictly mathematical mode of increasing the height of an arch, would, I suppose, be by using a semi-ellipse. Its major axis, however, being fixed, the minor axis, by impressing to the eye, and troublesome execution from its constant variations of curvature, so that by far the most natural and practical means of effecting the object, is the adoption of an arch of two centres, or what is commonly called the "pointed arch." We accordingly find, as I have shown by ample evidence in a former lecture, that this form was in the instance used just in those situations in which a reduction of pressure, and an increased power of bearing weight were of the greatest importance. I have shown that this form was not adopted at first as a matter of taste, or of fancy; nor even as a means of meeting the difficulties arising from the mechanical necessity, but simply from structural and constructive considerations. It was, however, as we saw, new or old, whether it occurred to them without external suggestion, or whether they saw it in the East, in the form of the semicircular arches, or in the first proposition of the pointed arches, or in the first proposition in any manner which caused its introduction, but the simple fact, that they had arrived in the course of their constructive progress, to a form which was demanded for practical reasons, that it began to be used as a matter of taste in other positions.

Had the second object—an arch of reduced pressure—the second, viz. the abatement of increased resistance was attained by the systematic development of the buttress, a feature very much neglected by the Romanesque builders; and, as the vaulting of a lofty nave could not be directly supported by the ordinary buttress, the arches or flying buttress was introduced, the spanning the aisles and conveying the pressure to the buttress beyond. That this was introduced for utility only, and not from taste, is proved by the attempts in early instances to conceal it, so that we may with certainty conclude that all these beautiful features of Gothic architecture originated, not from taste or caprice, but from reason upon practical and urgently pressing constructive requirement, and that the beauties to which they gave rise proceeded from the application to them of the great principle of Gothic architecture, the decoration of constructive or useful features.

Let us, however, suppose for a moment that our building is not vaulted, but has a flat roof. The flat roof remains an advantage in the use of the pointed arch. If it has, for instance, a central tower, the demand for an arch of reduced thrust is greater than if the tower arch had been vaulted, for the arms of the cross from their reduced weight are less effective as abutments. The chancel arch, again, demands height, and the more the height is increased, the more necessary it becomes that the nave arches are better pointed than round, as are any others carrying any considerable weight. Buttresses remain the necessity of the arches, and are, of course, desirable as a steadiness to the structure, and in any case where roofs without a direct tie are made use of, and are further useful as permitting the introduction of larger windows, and in all cases, where roofs or floors are so constructed as to concentrate pressure upon points, it is clear that buttresses are desirable; and when the efficient use cannot be given them, the defect is not without remedy. It is equally clear that the deficiency may be readily compensated by leading them with lofty pinnacles. It is wrong to use buttresses without any object, but appearance, but there are numbers of cases where they are clearly demanded besides those in which we know them to be indispensable. If so many of our ancient and vaulted buildings in these days were not mere specimens in lath and plaster

we should have more practical experience of the need of the buttress and of the pointed arch. I was once told by the English commissioner in Seinde that the European engineers had used in an early period frequently divided ribs believe that any but a pointed arch will stand.

Let us now inquire as briefly as may be into the rationale of *ribbed vaulting*, as distinguished from the arching of the Roman and earlier Romanesque builders.

A groined vault does not of necessity demand the use of ribs any more than the plain wagon-head vault. The latter was from an early period frequently divided into compartments or bays by transverse ribs, which were useful as a means of giving it rigidity, but in groined vaulting they were of nearly constant use both for the same reason, and because the vault, being reduced at its springing to so narrow a footing required this additional strength. The arches, however, or diagonal lines of intersection were always left without ribs.

Why, then, was the custom changed? For two important reasons. The first was this: that the intersection forms naturally a feeble line both from the difficulty, particularly with the rough materials usually employed, of making its construction sound, from its forming an arch of greatly increased width without corresponding increase of height, and from its reduction at the springing level to a plain's point.

The second was of a more intricate nature, and requires to be explained more in detail. When the two intersecting vaults of a groin are similar and equal in their section, the line of intersection falls in a plane. When vaulting, however, the members are unequal in height, and in which spaces would have to be so covered, and would present problems of considerable difficulty, in which it would be impossible in all cases that the vaulting surfaces should be equal in vaulting, but in which the vaulting surfaces of the intersecting lines could not, without much twisting of the surfaces, be brought to fall into planes.

The introduction of the diagonal rib met both of these difficulties. It gave the angle and gave a substantial footing; and it at the same time gave to the lines of intersection a certain degree of independence of the vaulting surfaces, so that instead of the surfaces being in all instances of equal height, the vaulting was by the ribs, and the latter could be made to fall into planes and to avoid unsightly forms even in vaulting spaces of the most irregular and abnormal forms.

The second way in which the rib was worked as great a revolution in the principles of vaulted construction as did the pointed arch itself. Nothing in the way of vaulting was now impracticable or unsightly; the architect was able to do anything he might desire to do, with the vaulting. The facilities it offers are quite marvelous in the eyes of the modern practical man when once they are opened to them. I have myself found one of the most practical men I ever met, who had for years taken the leading management of the business of the greatest builder of our day, though hitherto uninitiated in Gothic construction, almost in ecstasies at finding a difficult problem in vaulting he had been puzzling over for days and making models of in vain, solved in an instant by seeing the absolute liberty of action exercised in a similar case in Westminster Abbey. The old builders themselves were perfectly satisfied that they had discovered liberty; not only could they vault spaces of any conceivable plan, every dimension and angle of it varying, and the difficulties increased by the necessity of pushing up windows in their places, but they could do anything they could make the result so pleasing and apparently so straightforward and natural, that not one observer out of a thousand ever finds out that there was any difficulty to be got over at all. Sometimes, indeed, we find them rejoicing so much in their freedom as to set themselves needless puzzles for the very luxury of solving them. There is a most remarkable instance of this in the crypt under Glasgow Cathedral, where the pillars which support the floor have been placed in a variety of intricate positions for no reason but to produce curious perplexities in the vaulting, and creating strange problems for the mere pleasure of their solution and the beauty of the puzzle when solved.

It has been argued that the Gothic vault is less refined than some of the previous forms, because less strictly mathematical; that a relative degree of construction should in all cases possess an exact mathematical solution, though the builder may, when once master of the true theory, depart from it in execution; that the work, in its original form, should be perfect and should be perfect and mathematically accurate in its theoretical type.

I agree with this doctrine in the main; but I hold that the Gothic vault complies with its conditions.

The square groined vault, with semi-circular arches, is perfect in its theory, and gives elliptical arches for its arched lines. The same, if vaulted with the pointed arch, is equally true in theory, for the diagonal ribs may be pointed arches, formed each of portions of two ellipses. The oblong vault, again, is perfect if the wide arch is a semi-circle, the narrow one a vertical semi-ellipse, and the arched horizontal semi-ellipses of the same height; but the ancient generally chose to set the narrow arch instead of using the vertical ellipse, and by doing so threw the diagonal arched out of the plane and out of shape; but the theoretical form remained, nevertheless, perfect. In like manner, if the same figure be vaulted across its widest span by a pointed vault, and if the narrow vault have a pointed arch composed of two portions of ellipses, and the intersections be of the same figure as resulting geometrically from the intersection of the two vaults, the theoretical form is perfect. Now, if in either case the architect thinks the elliptical pointed arches inferior in beauty to those composed of parts of circles, and by using ribs divides the vaults so as to throw the error resulting from the substitution of the latter form into the vaulted surfaces where it will be invisible, surely he is only using his discretionary power in producing irregularities from a perfect theory which he claimed as his right; and this is exactly what the Gothic architects introduced.

The fact is that, besides its unpleasing form, especially when of the pointed arch, the use of the ellipse entails such an annoying series of difficulties as greatly to increase the trouble and consequent cost of execution. The constant change of curvature, the troublesome nature of striving to find the true lines of the arch-joints, not to mention the mathematical fact that the same joint line is never true both for the extrados and intrados, and that, if the rib mould remains unaltered, the extrados and intrados cannot be both true ellipses at all; all these furnish quite sufficient practical reasons for its rejection in cases where, not only is there no necessity but an abstract mathematical necessity for its use, but the beauty of the work is greatly improved by dispensing with it.

Though the pointed arch was introduced from purely constructive reasons, there was another of a more æsthetic nature which rendered its adoption more general when once introduced. It was a double one: not only did the general tendency towards lofty proportions render it necessary to make use of an arch more in harmony with the general feeling of the architecture, but the rejection of a fixed code of proportions for pillars and other parts demanded for the arch an equal power of varying its own proportions. The semi-arch is absolute and invariable, and though the use of smaller segments would meet the case in one direction, there were no means of proportioning it to features of increasing height. This was attempted both in Romanesque and Byzantine works by the expedient of *stilling*; but this is, after all, more a semblance than a reality. As in cases already cited the mathematical solution of the problem is the ellipse; but only imagine any thing so unpleasing as a series of elliptical arches placed the length-way upwards! Good taste would not suffer it; but the pointed arch at once met the difficulty. To illustrate my meaning I will beg you to take an internal bay of a Norman Cathedral—and to suppose yourselves to have to increase its height throughout in the ratio of one-third.

You, first, after setting out your widths as in the original, increase the whole height and that of each story by one-third; you then increase the piers and the jambs of the triforium and clerestory windows in the same proportion: this brings you to a stand, for the arches being semicircles are invariable. Either you must leave them unaltered and throw all the extra height into the wall above them, or you must increase each to the extent of one-third of their height; unless you can make use of an elastic arch which will change its proportion at pleasure. The ellipse occurs and meets the case, but it offends your eyes. At length, however, a device is hit upon by which itself and gets rid of the whole difficulty. So similar are a Romanesque and an Early Pointed bay in all other respects, that the change of proportion which I have described seems at once to effect the whole change in style.

Had the constructional motive alone existed, the pointed form would have been confined to arches of considerable span, and the desire for a variable arch, adding æsthetic to the constructional claim, caused its speedy adoption in positions where strength alone would not have demanded it, though the semicircle, the plain segment, and the segmental pointed arch, were, at all subsequent periods, of the style used side by side with the true pointed form.

I have been the more particular in showing the true reasons for the demand for the form of the arch, because the great majority of writers treat it purely as a matter of taste, and of altered fashion; indeed, two generally excellent writers on the history of Medieval architecture have strangely imagined that the elevation of the piers, and a greater outward thrust than the round, and that the increased projection of the buttresses was necessitated by its use: instead of the two being simultaneously introduced as a double means of avoiding the evils experienced from the great thrust of the round arch and the small buttresses by which it had during the Romanesque period been accompanied.

I will now close my present lecture, but hope in the next to carry on the same inquiry into a number of other details, as well as into the general spirit and principles of the architecture of which I am treating; and to add some practical remarks on the application of the rationale thus traced out to our present revival of the style, and such developments as it may give rise to.

ON THE CONSTRUCTION AND REBUILDING OF THE ITALIAN OPERA HOUSE, COVENT GARDEN.\*

It having been represented to me that some description of the recent rebuilding of Covent-garden Theatre might prove interesting to members of the Institute, I have readily consented to place them in possession, as far as it lies in my power to do so, of all the means adopted to that end; and, although I could certainly have wished that the task might have fallen to some one less directly interested in the matter than myself, I am the more disposed to address myself to the question from a feeling that our transactions ought to contain not only those interesting essays of an archaeological character which are so extremely valuable to all of us as artists, but should also have a claim to be considered as in some measure a record of contemporary works, more particularly with reference to the peculiarities of modern building operations. Acting upon this principle, I propose to confine my observations to-night almost exclusively to the constructive features of the new theatre, merely glancing at its architectural character in those cases where its form and appearance have been directly influenced by means of a peculiar or utilitarian character. And before I enter upon my description, I must, to prevent misapprehension, state distinctly that I claim no novelty or peculiar merit for any of the methods of construction adopted; and if, as must be the case, many present may find much to criticise and probably to condemn, I can only plead that, owing to the limited time allowed for the work, the imperious necessity of action has often interfered with that calm reflection and discriminating thought which are necessary for the production of any noble and enduring work. My object, therefore, is, not in any way to forestall criticism, but simply to lay before the members of our profession some more authentic accounts of the progress of the works of the new theatre than they have been able to

obtain from the newspapers, some of which have even informed a curious public that the building was erected with hot bricks and boiling water, while others have contained descriptions more credible to the imaginative than the scientific element in the minds of their writers.

Covent-garden may almost claim to be considered by Londoners a household word, as far as theatrical associations are concerned,—a theatre having existed on the site for nearly a century and a half. The first playhouse of which we have any records was commenced in 1730, and opened in 1733,—the distance from the stage to the back wall of the boxes being 54 feet or 55 feet, which dimension was then considered large. The theatre was erected to rival Drury-lane, and from that day to the present a constant competition has been carried on between the two great dramatic houses. After extensive alterations and a partial rebuilding, in 1792, the theatre was burnt to the ground,—the cause of the fire remaining, as is not uncommon in such cases, an unsolved mystery. The last representation was a "Pizarro," in which many guns were used; and it was thought that ignited fragments of the wadding might have settled upon inflammable portions of the scenery or decorations, and thus have caused the catastrophe. Be this, however, as it may, the destruction of the building was complete, and nothing remained to be done but rebuild. The proprietors decided on the latter course, and were fortunate enough to secure the services of Sir Robert, then Mr. Smirke, from whose designs and under whose guidance was erected, in less than one year, the admirable theatre so lately destroyed by the same element which had proved so fatal to its predecessor. Sir Robert Smirke's design is so well known to you that I need not describe it further than to say, that whatever may be our opinion of the applicability of such forms of architecture to the purposes of a theatre, we must all feel that Sir Robert Smirke, while adopting the style fashionable at the time, brought to its execution a thorough knowledge of its capabilities and details, combined with most eminent constructional skill. I mention this the rather, because I saw, with regret, some time since, allusions made to bad construction, as evidenced by the use of wood bond in the walls by Sir Robert. Doubtless, this is a mode of building very faulty, and now very properly discarded; but, as regards the bonds at Covent-garden, they were only in the insides of the walls, and used, apparently, for convenience in fixing flusings; and as they were only half a brick wide, the strength of the thick walls of four or five bricks was but slightly diminished. In all other respects, the construction of Sir Robert Smirke's theatre appeared to me excellent; and the arrangements of arches and voids, piers, and footings, were such as might be most advantageously studied by the architectural student, while the great thickness and solidity of the walls were such, that in removing them, the contractor for the excavations often found many reasons to wish their construction had been of a less permanent character. The first stone of the new theatre was laid on the 31st December, 1858, by his Royal Highness the Prince of Wales; and a brass box containing a bronze medal, with the Prince's portrait upon it, and a selection of the current coins of the day, was placed under the foundation-stone at the north-east corner of the building, where it was found by the workmen engaged in removing the ruins. The theatre was opened on the 18th September, 1859, having occupied only eight and a half months since the laying of the foundation-stone. The cost of the building was, I believe, 180,000*l.*; and on the occasion of opening an attempt was made by the management to raise the prices of admission about 30 per cent. This was resisted by the public in a manner to which we are happily unaccustomed, and the famous O. P., or old price, riots ensued, and continued about two months. During their occurrence the performances were impossible. Picnards of the most ludicrous and offensive descriptions were hung out from all parts of the theatre; the performers were interrupted by continual noise and missiles; and a kind of combined movement among the rioters, termed the "O. P. Dance," rendered all restoration of order impracticable. It might have been hoped that such a mode of evidencing dissatisfaction by the public had become obsolete, but it may be questioned whether we have much to congratulate ourselves upon as an improvement, if we have only banished it from our theatres to permit it in our churches. So long continued and so determined were the riots at Covent-garden, that the proprietors were at length obliged to make a compromise, after which the performances were per-

\* Read at the Royal Institute of British Architects, by Mr. E. M. Barry, as elsewhere referred to.

mitted to go on without interruption, and the theatre was used for English dramatic representations until a few years ago, when it was determined to convert it into an Italian Opera-house. To carry out this resolution, extensive alterations were required, both as to the form and size of the auditory, and they were placed under the professional guidance of Mr. Albano, who gutted the audience portion of the theatre, and rebuilt it according to his own designs. I have had prepared plans showing the old theatre, the re-arrangement by Mr. Albano, and the new Opera-house to the same scale, in order to facilitate comparison of their respective sizes. Mr. Albano's alterations consisted, as may be seen, of an enlargement of the auditory, both longitudinally and transversely, and of some modifications of the entrances and staircases rendered necessary thereby. The theatre, as altered, was opened with the opera of "Semiramide,"—in which Grisi and Mario filled the principal parts, and when Albani was first introduced to a London audience,—and it continued from that date till the time of its destruction to be devoted to the purposes of the Italian opera, with occasional performances of other kinds during the recess of the opera season. The fate of so many theatres, however, soon overtook Covent-garden; and, in March, 1856, it was burned to the ground, during the absence of Mr. Gye, in Paris, and while it was temporarily occupied by Anderson, the so-called "Wizard of the North." The fire was supposed to have first arisen in the carpenter's shop, in the roof, but the uncertainty attending its origin has never been satisfactorily cleared up. In noticing the catastrophe, it must be felt that the subject of fire-proof theatres is one well deserving the attention of members of our profession. At present, so regular a fate appears to hang over these buildings, that it is almost considered a matter of course that they should be burnt down. The fires at Covent-garden have been already alluded to. Drury-lane was burnt down in February, 1809,—not more than five months from the destruction of its rival. The King's Theatre (as her Majesty's Theatre was then called) was burnt some years before, and Astley's, the Strand, the Olympic, and, I think, some others, have been burnt down in our own times. The peaceful pulling down of the Old Adelphi, to make room for its present graceful and commodious successor, is an event not often paralleled in theatrical annals. Those who have had opportunities of inspecting the working of theatres can be at no loss to account for their danger; but though much peril might probably be removed, there are few places where innovation is less welcome than within the walls of a theatre; and many prejudices will have to be removed, and many novelties introduced, before the public can possess a place of entertainment absolutely fire-proof, although much may be done, and, in fact, has been done, both at the New Adelphi and Covent-garden, to reduce the danger and to protect life. The spectacle presented by the gigantic ruins of Sir Robert Smirke's theatre, after the fire, was very striking. The massive walls and beams of rubbish, with here and there huge fragments overturned by the fire, reminded the spectator of some of the ruins (such as the baths) of ancient Rome, while the picture of destruction and desolation was enough to cause despair to most men who looked at it with a view to rebuilding an opera-house upon the same site. Mr. Gye, however, with characteristic energy and decision, soon entered upon the arduous task, and, to his great ability and untiring exertions, the public are indebted for the existence of the present structure. The ground landlord, the Duke of Bedford, gave every facility for proceeding with the enterprise, and has taken much interest in its accomplishment. By the conditions of the lease, his Grace is entitled to a private box and ante-room, with a separate entrance from the street. These are obtained adjoining her Majesty's box and entrance; and, owing to the limited space available at this part of the house, their provision was attended with some difficulties. The ante-room is in the portion of the house behind the curtain, and is approached from the ductal box by a sort of covered bridge thrown over a corner of the stage. The design of the building had also to be submitted to his Grace's approval, and it was made a condition of the latter that the exterior should be covered with Portland cement. It will be readily understood that many difficulties had to be encountered before so large a work could be commenced under private management, but all was at length arranged; and, in the autumn of 1857, Messrs. Lucas, general contractors for the building, and Mr. H. Grissell, contractor for the iron-work, were enabled to begin their operations.

Before describing in detail the construction of the several parts of the new building, it may be useful to glance at the general principles which determined its design. After so dire a calamity as that which had just befallen its predecessor, it was but natural that it should be sought to render such a catastrophe less likely to recur. It was consequently determined to carry out a system of fireproof construction wherever practicable; and though perhaps it is hardly possible at present to render a theatre actually fireproof, the new building was intended to be an advance in that direction. The Building Act most properly requires all corridors and staircases in such structures to be of incombustible materials, and these requirements had of course to be observed. In addition, as it had been noticed in previous cases of fire that the roof served as an easy means of connection between the stage and the auditory, it was sought to avoid this source of danger by making the roof decided to use wood as little as possible in the construction of the interior. Regarding the danger of staircases with open well-holes in public places (which has since received a lamentable illustration in the case of the Polytechnic), all staircases used by the public were arranged to consist of solid stone steps, built into a wall at each end. There were to be no windows, and the well-holes were to be filled up with walls carried up from the bottom, after the custom so common in Italy, and which, from its advantages to the stability of the edifice, as well as to the safety of its occupants, appears to be well deserving the attention of architects who have to provide for the reception of large crowds of persons liable to sudden panics. The shape of the auditory was a matter of much consideration, the faults of a horseshoe shape being obvious as regards the position of the side-boxes. Plans, more or less approaching to a circle or ellipse, were tried and laid aside, and different schemes of arrangement canvassed. The result was, that the horseshoe form was at length resolved on, notwithstanding the disadvantages above alluded to. The requirements of a London theatre for the Italian opera are very peculiar, and differ in many ways from those of ordinary play-houses. As regards the latter, the great desideratum is of course that all the visitors may see and hear to the greatest possible advantage; and so that this be achieved, the relative position of the audience to each other is of comparatively small consequence. In an opera-house, though similar objects are sought to be attained, there are other circumstances to be considered, which in some measure counterbalance them. The royal box being on the grand tier, the latter is the great resort of fashion; and insubstantial about the boxes on the grand tier that a drawing-room floor does to a second floor, it is obviously a great desideratum to obtain as many boxes as possible in this level, where it is found that even the side boxes (in spite of drawbacks of position), are always eagerly sought for. The system of separate boxes likewise presents the possibility of gaining accommodation by opening the dress-circle, so as to get several rows of seats. For these and other reasons it was considered that assuming the dimensions of the Proscenium to be fixed at 50 feet as the maximum admitting of convenient working, a horseshoe, more or less elongated, was the fittest form in this particular case, although it might possibly be modified with advantage in other structures with less peculiar requirements. The alleged acoustical advantages of a horseshoe plan were likewise supposed to have some weight, and certainly her Majesty's Theatre is an encouragement to any architect to adopt it in this respect. In order to illustrate the differences of shape, I have had prepared a plan of her Majesty's Theatre to the same scale as the other places before alluded to. It will be perceived that in the old theatre the Royal box was on the left-hand side of the auditory, and that in the new house it is placed on the opposite side. It will readily be seen that as regards Covent-garden, facility of access from Hart-street governed this arrangement, which, as it involved a departure from time-honoured precedent, was submitted to her Majesty for approval, before the building was commenced. Another peculiarity of plan in the new theatre may here be noticed as regards the crush-room or saloon. This is situated at the top of the grand staircase, and forms an anteroom, through which all must pass on their way to the boxes. The refreshments are placed at the farther end of the room instead of being in a separate saloon, inaccessible to ladies. The ob-

ject sought by this arrangement was by rendering a passage through the crush-room imperative to all, to cause it to be forbidden to none, and the result has fully answered the expectation, inasmuch as all classes of spectators may now be seen to resort to this apartment for refreshment between the acts, or during the performances.

It may be observed, on examining the plan, that, owing to the shape of the site, the building was not rectangular, the corners in Bow-street being respectively obtuse and acute. By constructing the principal entrance from the crush-room not in accordance with the centre line of the auditory, facilities are obtained for the formation of a grand state box in the centre of the house, on special and extraordinary occasions, by taking in the boxes on either side and the corridor in the rear. The iron beams over the centre boxes are fixed with bolts and nuts, instead of rivets, to allow of their removal on such occasions, so as to give to the state box the additional height which its importance would demand. Entrance to the state-box would probably be obtained by the grand entrance for the royal party and suite, and the public could be admitted from the Floral Hall, from Hart-street, and through her Majesty's ordinary private entrance. It will not escape observation, on comparing the plan of the new theatre with that of its predecessor, that although the dimensions both of stage and auditory are larger in the former case than in the latter, the size of the whole building is less at present than was the case formerly. This reduction of size was caused by the determination to devote the southern portion of the site to the erection of a building of iron and glass, to be called the Floral Hall. Inasmuch, however, as the large stage and auditory necessarily require adjuncts of appropriate capacity, it became obvious that the only way to make up for deficiency of area was to increase the height. There are eight stories of rooms on either side of the main building, and in these are placed the green-room, the dressing-rooms, the lavatories, wardrobes, armories, music-rooms, private sitting-rooms, and the numerous other apartments necessary for the working of a large lyrical establishment. In addition to the space obtained by the above arrangement, it was considered that important structural advantages were gained by carrying up the side-buildings to the same level as the principal walls, instead of having the latter isolated for their upper portion, as is the more common arrangement. regard being had to the well-known strength of hollow columns, it was thought that the arrangement adopted of two longitudinal walls, 11 feet from each other, and connected together by frequent cross walls, would possess all the advantages of a series of rectangular columns or piers, if the tenacity and cohesion of their parts could be effectually secured. In good brickwork, when perfectly set, this would necessarily result; but as, in the case under notice, the building required to be occupied before the mortar was dry, and the roof and other great weights would come upon the green walls almost before the bricklayers' scaffold could be removed, it was determined, as a temporary measure, to assist their cohesion by iron ties passing through the cross walls and connecting together the two main longitudinal walls. These were inserted about every 12 feet in height, and were each composed of 2-inch square rods, placed 9 inches from each other, so as to avoid the flues, and secured at the ends, by screws and nuts, to strong iron plates. These ties have now served their purpose, and, the walls being thoroughly dry and the mortar set, are independent of extraneous assistance. The arrangement and design of the roof called for some consideration. It is customary to place the carpenter's and other shops in this portion of the building, and the ordinary plan is to construct the roof with queen-truss principals, so as to get as much accommodation as possible between the queen-posts. The truss used by Sir Robert Smirke was of this description, and deserves the most attentive study as a piece of careful and excellent carpentry. From what has been said as to the comparatively small area covered by the new theatre, the importance will easily be seen of gaining as much accommodation as possible in the roof, and it soon appeared that a system of beams passing from wall to wall, with small roofs between, offered peculiar advantages as regards space, when compared with the limited area allowed by the queen-truss arrangement. The iron beams supporting the roof are 96 feet long and 9 feet deep, and the credit of their design is due to Mr. Henry Grissell, who undertook to make, fix, and guarantee them. He successfully accomplished in an extremely short time; and it is to me a pleasure as well as a duty

to acknowledge the obligations I am under to him, as well as to Messrs. Lucas and the other contractors, for the ready help and co-operation they have at all times been willing to afford.

As may be perceived from the drawing, the beams are of the description known as trellis, in eleven compartments. The flanges are composed of a combination of angle iron, wrought-iron plates, and a section which may be called double L iron. The diagonals in compression are composed of double flat bars, each 6 inches by 3 inches, and the diagonals in tension are formed of double flat bars, varying from 7 inches by  $\frac{1}{2}$  inch to 7 inches by  $\frac{1}{4}$  inch. It was considered that the open-box form of the upper and lower flanges would give a considerable amount of lateral stiffness to the girders, and that by the adoption of the trellis form, a lighter and more convenient girder could be obtained than by using one with a solid web-plate. The necessity before alluded to of using the roof as workshops determined the depth of the girders, which it was found could not be less than 9 feet, without causing inconvenience to the workmen; and the facilities of passing through the girders, wherever necessary, was also thought a desideratum. The accessibility of the various parts of the girder to the painter's brush was also obtained—a great point where wrought iron is used, and the importance of which, considering the great tendency of this material to rust, is, perhaps, hardly always sufficiently recognized by iron practice.

There are eight main-roof girders, 21 feet apart, and on the top of each is a cast-iron gutter 16 inches wide: wrought-iron principals of the usual character, and 21 feet span, connect the girders together and support longitudinal purlins of T-iron, and the whole is covered with slab slate half an inch thick, with laps and fillets constructed in the ordinary manner. The workshops are lighted by skylights in the apex of the roofs, all of which, with the exception of the necessary woodwork of the skylights, are thus of an incombustible character. The girders occupying the whole side of the workshops, it became necessary to consider how large pieces of framing made in the shops could be lowered to the stage, as the interstices between the vertical struts and diagonals of the girder could only allow pieces of small size to pass through them. The object was sought to be attained by fixing the girder immediately over the proscenium, its own depth lower than the others. Advantage was taken of the necessity for a sound-reflector at this portion of the ceiling to effect this, and the top of the girder over the proscenium is level with the workshop floor. On the top of this girder two cast-iron stanchions are fixed carrying intermediate girders and the roof, and three spaces 25 feet, 40 feet, and 25 feet wide, are thus left open to allow of the passage of bulky articles. The girder at the stage end of the building is 30 feet from the wall, and the space between is covered by a lean-to roof, also of cast-iron, with a large skylight over the painting-room. A lean-to roof was here adopted from its giving the maximum of height to the wall on which the painting-frame hung, and from its readily allowing abundance of light to fall at the proper angle on the same. There are no floors between those girders which are over the stage, and the scene can therefore be raised as high as the tie-beams of the 21-foot span roofs. The weight upon the girders is, as may be supposed, very large; and the mode in which it is calculated may be seen by the table exhibited, which shows a weight of 150 tons to be provided for as regards each girder. Before any were fixed, the completion of two was hurried on at Mr. Grissell's works, and when finished they were placed side by side on his wharf and loaded with 300 tons. Special foundations were formed of concrete, and the girders placed about 9 feet apart on balks of timber resting upon brickwork and concrete. Cross pieces of iron were introduced between the girders to act as stays or braces, and to serve the office rendered in execution by the transverse roof principals and floor beams. The preparations being completed, pig-iron to the amount of 300 tons was beaped upon the girders, an occupation which consumed several days. The girders were constructed with a camber of  $2\frac{1}{2}$  inches, and, when the weight was on, a deflection of  $1\frac{1}{2}$  inch was observed. On the removal of the weight a permanent set was found of  $\frac{3}{4}$  inch in one girder and  $\frac{1}{4}$  inch in the other; a result probably attributable to all the parts having been brought to their bearings. It had been my intention to have allowed the weight to remain upon the girders for ten days, but after it had been on for twenty-four hours signs of weakness

appeared in the wharf wall immediately adjoining; and it was found that unless this was quickly relieved, girders, foundations, and wall bid fair to find a resting-place in the Regent's canal. The pig-iron was therefore removed in all haste, but the result of the proof was considered so satisfactory, that the whole of the other girders were constructed like the two first, without any alteration. During the week before last I again tested one of the roof girders, to ascertain whether two years of work had produced any effect. I found the camber reduced to  $1\frac{1}{2}$ , showing a set, consequently, of  $\frac{1}{2}$  of an inch.

Having now described the construction of the roof, and leaving the mode of fixing it to be explained presently, it may be as well to point out some peculiarities of construction resulting from the determination to render the theatre available for other purposes than those of the Italian opera.

The arrangement of the theatre for the latter is so peculiar, owing to the special requirements before alluded to, that it is not suitable for other performances without considerable modifications. In rebuilding the Opera-house, however, Mr. Gye resolved that it should not be erected with a view to one destination only, and it therefore became necessary to consider how his wishes could best be carried out. The boxes being entirely supported by iron beams, cantilevers, and columns, the divisions between them are formed of 13-inch wood framing, and are all moveable. The backs of the boxes are likewise capable of being removed, so that a portion or the whole of the corridor may be taken into the boxes, if required, to form an extended dress-circle. On the pit tier, the boxes, with the floors, fronts, sides, and backs, can be entirely taken away, giving facilities thereby for forming a very capacious pit, extending under the dress-circle to the semicircular wall at the back of the corridors. The entrances to the theatre are so arranged that they are suitable for this arrangement of the auditory without modification; and the whole of the pit floor is so constructed that it can be raised or lowered at pleasure in a few hours. I hope I have not trespassed unduly in thus detailing the various considerations which to so great an extent have determined the design of the work, but I have felt that to render intelligible the reasons for such arrangements as are obviously peculiar, rather more than a mere description of them was required.\*

#### PROVINCIAL NEWS.

*Hoddesdon (Herts).*—It is proposed to erect here, by shares, a new Town-hall, on the site of the present clock-tower. Increased population, and improvements in the town, render a public building of the kind necessary.

*Chewenig.*—The new National School lately erected at Chipstead, in the parish of Chewenig, has been opened. The school is in the Gothic style, and is 51 feet in length, 20 feet in breadth, and 39 feet to the ridge of the roof, which is of stained deal. The school has been erected by private subscriptions from landowners and others in the parish, the principal subscribers being the Earl Stanhope, F. Perkins, esq., Earl Anlierst, and the rector.

*Bristol.*—The probable expense of the proposed new workhouse for Bristol, varying from 16,000*l.* to 24,000*l.*, has somewhat alarmed the ratepayers; and a discussion is going on in the local papers as to it.

*Newcastle-upon-Tyne.*—Workmen, says the local *Courant*, have commenced to level the ground for the foundations of the approaches to the High-level Bridge, and the open space at the head of the Side has already been boarded off.

*Jedburgh.*—The movement for the erection of a corn exchange at Jedburgh progresses favourably, upwards of 2,100*l.* having been already subscribed towards the object in view.

#### ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

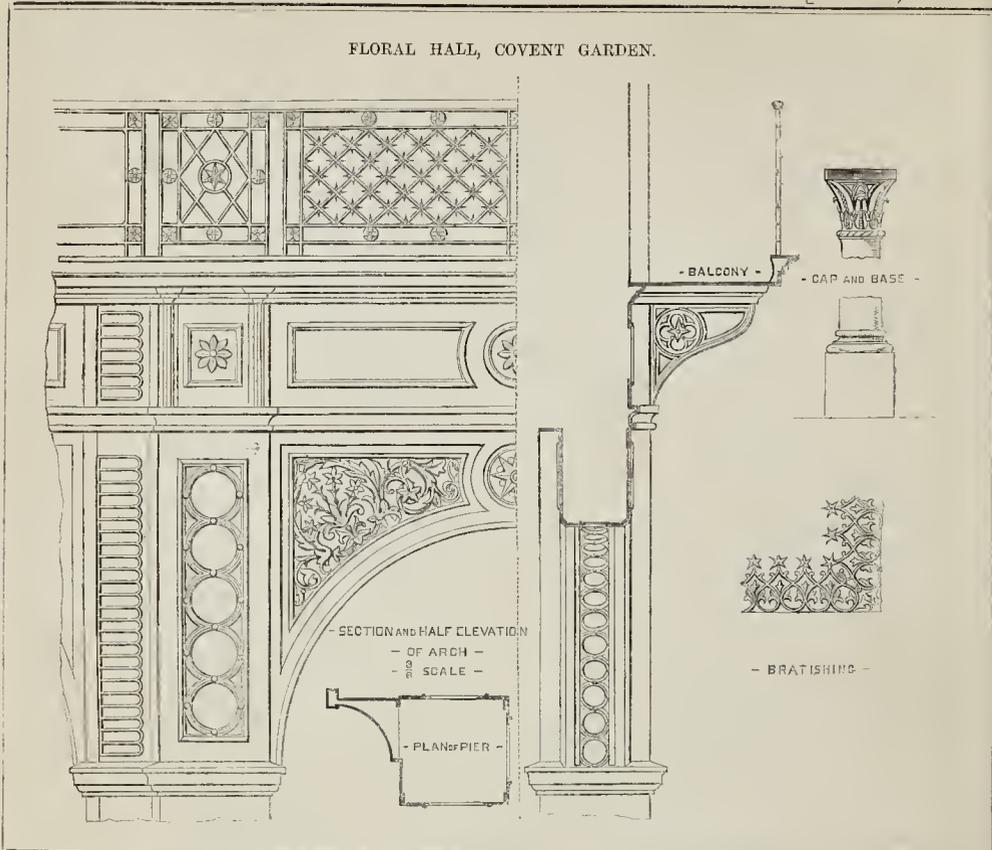

The third annual exhibition of this Association was inaugurated on Wednesday evening last, at 9, Conduit-street, by a meeting of the subscribers and their friends. The photographs, of which there are 510 in all, are thus classified:—France (by Balduz Bissot, Cundall & Downes), 77; the Netherlands, Germany, and Switzerland, 8; Constantinople (Robertson & Beato), 11; Jerusalem and the neighbourhood (Robertson & Beato), 24;

\* To be continued. Numerous illustrations of the theatre will be found in our previous volumes.

Roman States (Macpherson), 30; Northern Italy (Ponti), 110; Spain (Clifford), 26; England (Fenton, Cade, Melhuish, Greenish, Cocke, Cundall & Downes, Dolomere, Bullock, Bedford, Robinson, and Piper), 224.

Shortly after eight o'clock the chair was taken by Professor Cockerell, who said that he was sure all present could not but feel gratified at the result of the exhibition, which was the best that had yet been inaugurated by the Association. The photographs were all excellent, and reflected the light and shadow in a manner which he had never seen surpassed. Although a member of the committee, he regretted to say he had not exerted himself as much as he ought to have done, but looking at the exhibition with the eye of a stranger, he thought he would be justified in asking for the approbation of the meeting on behalf of the committee who had worked so zealously to make the exhibition a success. It might perhaps he thought that in a commercial country like this, an enterprise which was in itself self-supporting must also have some commercial object in view. Such, however, was not the case. The association had been promoted purely in the interests of art, and it was extremely creditable to the younger branches of the profession to find that its success was to be attributed to their zeal and perseverance in the pursuit of the beautiful. He was therefore sure that their motives would be understood, and that the public, in appreciating them, would perceive that the undertaking was purely a work of love. He was induced to make these observations because it had pained him exceedingly to find that some of his colleagues on the committee had been treated more like tradesmen than as persons who were anxious to develop an instructive and fascinating art, with a view to obtain a better knowledge and wider experience in the profession of which they were members. In looking round the room he had recognized with much pleasure objects of art and antiquity which he had not seen for forty years. In early life he had visited Constantinople, and he now beheld the photographs of monuments which he had then witnessed with the enthusiasm and admiration of a student. He would not trespass further on the attention of the meeting, but would call upon Professor Donaldson, who had kindly promised to illustrate by some remarks a portion of the interesting sun pictures with which the walls were covered.

Professor Donaldson, who was very warmly received, then proceeded to make some observations upon the progress of the photographic art, and its application to many of the most interesting monuments of Rome, Venice, Spain, and other continental States. The learned gentleman commenced by observing, that in the year 1840, when happening to be in Paris, he had the privilege of making the acquaintance of M. Daguerre, the discoverer of the process subsequently known as the daguerrotype. He repaired, by invitation, at six in the morning, in company with a friend, to the modest dwelling of the artist, who received him with the courtesy and attention for which he was so much distinguished. M. Daguerre described the whole of his process, and expatiated on the development which his discovery would have upon future art productions. He was then in the enjoyment of a pension of 240*l.* per annum; but had he survived to see the results to which his discovery had been carried, he might, indeed, have regarded them with feelings of no ordinary exultation. Although our own countryman, Mr. Talbot, arrived about the same time at results similar to those achieved by M. Daguerre, it should be remembered that the latter was the first person to seize, as it were, the passing image, to stamp it with the fidelity of nature, and to give to the world an invention, the utility of which was so widely recognized that there was not now a single village in the empire which did not contain the means of photographing portraits, objects, and places. The value of photography to the architect was incalculable, and he (Professor Donaldson), when travelling in Asia-Minor, had often turned some miles out of his route to inspect some ancient monument, the image of which he had neither time nor opportunity to sketch. A photographing apparatus under such circumstances would have been a treasure which an architect and a lover of the picturesque could alone sufficiently appreciate. Professor Donaldson then proceeded to refer to the photographs of Rome by Messrs. Macpherson & Anderson, which included views of the Coliseum, the Theatre of Marcellus from the Piazza Montanara, the Forum of Trajan, the Temple of Clitumnus, the Arch of Constantine, the Julian Basilica and Tabularium, the column of Phocas,

and other famous monuments of what was once the mistress of the world, and the metropolis of the proudest and most powerful nation of the earth. The ruins of these structures still bore testimony to the mind and taste of the Roman people, who had endeavoured to impress on their architecture the religion, state, laws, commerce, nationality, and common purposes of life. Having pointed out the principal features of interest in the architecture of ancient Rome, and glanced at the historical associations connected with them, Professor Donaldson directed attention to the series of photographs representing Venice, including the Church of St. Mark, the Church of Santo Stefano, the Grimani Palace, and many other public and private buildings, in which the architect had laboured to produce grand and striking effects. He remarked that the unbounded expenditure of the three centuries, known in history as the Medieval Period, furnished many striking illustrations of the piety and munificence of our forefathers. At that time there were no compulsory enactments for the building or repair of churches. The voluntary principle was the only one acknowledged, and many were the cases in which the poor Franciscan or Dominican friar had devoted many years of his unostentatious life to collecting, at the castle of the noble and the cottage of the peasant, those free-will offerings by the aid of which so many of the magnificent cathedrals of the twelfth and thirteenth centuries were erected to the glory of God and the service of His Church. It would be idle to dilate upon the advantages which photography would have given in past ages, but to the student of art in the present day, it was an unending source of interest and instruction. Among the collection now exhibited were some magnificent views in Spain from the camera of Mr. Clifford, one of the most accomplished masters of this delightful art. They included the ruins of the celebrated Roman aqueduct at Merida, the ruins of the Roman theatre, the Roman bridge at Alcantara, the monastery at Placentia, and all that remained of

that fantastic and captivating building, which the Moors constructed on the retirement of their Roman conquerors, and which had been so wonderfully reproduced at the Crystal Palace,—the Alhambra. Professor Donaldson concluded a very interesting lecture, which repeatedly evoked the plaudits of a numerous auditory (including many ladies), by announcing that, on a future evening, other speakers would direct attention to the views in France, Constantinople, and Jerusalem, reference to which would exceed the limits of a single paper.

At the conclusion, the Chairman observed, that he was sure he but spoke the sentiments of all present, when he begged, in their names, to thank Professor Donaldson for the able, erudite, and instructive paper which he had just read.

A vote of thanks having been accorded unanimously,

Mr. Mair moved a similar compliment to the chairman, which having been acknowledged by Professor Cockerell, the proceedings terminated.

The exhibition will remain open daily from the 9th of February to the 10th of March (inclusive), from nine o'clock till six; and on Tuesday evenings from seven till ten. We shall speak of it again next week.

#### THE FLORAL HALL, COVENT GARDEN.

This building, which is now nearly completed, was described by us at length on a former occasion: we now give a view of one of the principal entrances, that in the "Market," with some details of the iron front, and a block plan to explain the position and shape of the edifice, which is 220 feet long and 75 feet wide. Our readers will remember that the Floral Hall adjoins the new opera-house, and communicates with it. It resembles on plan the letter L, and is covered with a semicircular roof of iron and glass. A dome of 50 feet span, with pendentives, rises above the two roofs at their intersection, and

forms a prominent object in the view. The public footway of the Piazza is continued under the end of the short arm of the building; and a gallery, with a separate staircase, has been constructed over the footway. The whole of the fronts towards Bow-street and the Piazza are of iron and glass; and, indeed, the entire building may be said to be constructed of these materials, brick-work forming a very small portion of the superstructure. The dome and roofs are principally of wrought iron, and the columns, arches, and piers, are of cast iron. There is a basement story extending under the whole of the buildings, 17 feet 6 inches high, available for vaults or stores. The works are now being rapidly pushed forward, and the building will be ready for opening in a few weeks. Mr. E. M. Barry is the architect. The contractors are the same who carried out the new Opera-house, namely, Messrs. Lucas, Brothers, for general matters; and Mr. H. Grissell, for the iron and glass works.

Stalls will be let to various tenants for the sale of plants, shrubs, flowers, seeds, &c.; others will be dedicated to the sale of ornamental glass, flower-vases, terra-cotta flower-pots, flower-baskets, syringes and watering apparatus, garden tools, and, in fact, all articles appertaining to the garden.

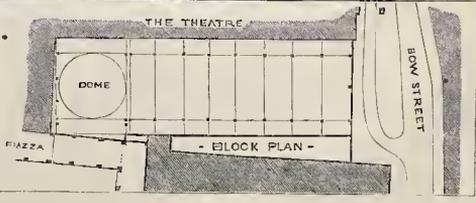

In the *Builder* of December 15, 1855,\* it will be seen that Mr. Gye proposed the erection of a glass flower-market as long as eighteen years since, in connection with his gigantic glass arcade scheme. As far as the flower-market is concerned, he has now realized his project, and adorned the neighbourhood.

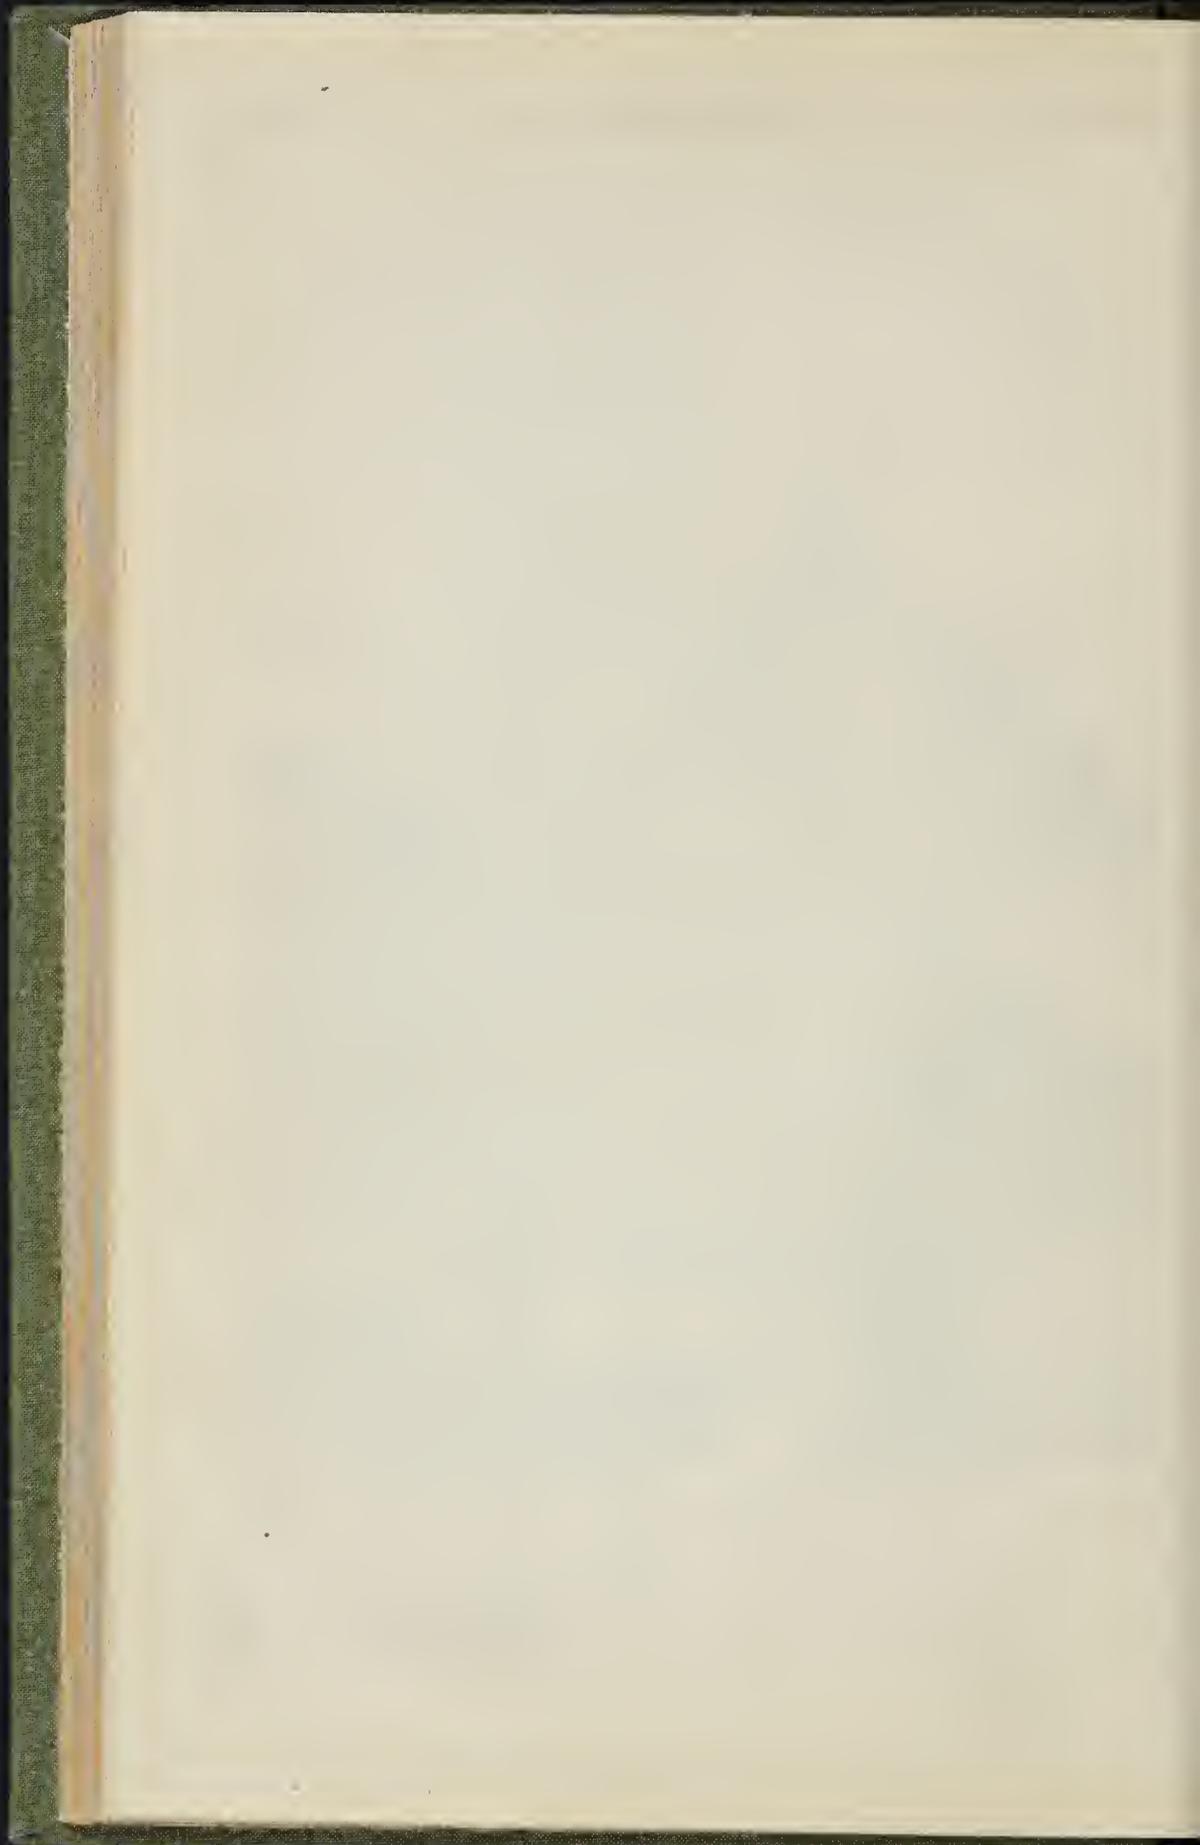

INDUSTRIAL AND FINE-ART EXHIBITION AT PORTSMOUTH.—The Portsmouth and Portsea Athenæum Exhibition of Industrial and Fine Art has been opened with a good display of valuable and useful objects of science and art, in the lecture-hall and other apartments of the Athenæum, in Bishop-street, Portsea.

 EDWARD M. BARRY  
 ARCHT

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The ordinary general meeting was held on Monday evening last, at the house in Conduit-street, Hanover-square, Mr. Hussey, V.P., in the chair.

Certain donations were announced, amongst them some portraits of eminent architects, including that of Sir Christopher Wren, and others of ancient date.

Thanks were voted to the several donors, and it was proposed that special thanks should be voted to Mr. C. C. Nelson (hon. secretary) for framing these portraits, which the Institute had possessed some time.

The Chairman said Mr. Nelson was deserving of the thanks of the Institute not only for what he had done on that occasion, but for the services he had performed ever since he had been connected with the Institute.

Professor Donaldson then rose to explain a piece of mosaic work which he had brought from Venice, and which he had caused to be placed in the room for the inspection of the members. This piece of mosaic came from an old church, where the mosaics were in a most dilapidated condition. Some time ago a person was employed to repair the mosaics, but it appeared that his mode of operation was to take away the old mosaics in order to be paid for replacing them by new ones. The present piece, which was a head of St. Peter, and was of the eleventh century, he (Professor Donaldson) purchased in a shop near the Basilica San Marco, where it had been lying some time. The church was on one of the outlying islands of the Lagoon, and was almost deserted. Indeed, the churches in Venice itself were becoming very dilapidated.

Mr. E. M. Barry then read a paper on the building of the Royal Italian Opera House, Covent-garden, which we give elsewhere (see page 85).

Professor Donaldson said it was with very great pleasure that he rose to express the great satisfaction with which he had heard the lucid statement of Mr. Barry upon this very difficult and complex subject. Mr. Barry had proved himself entirely master of it, and he thought that, although doubtless most of those present on entering the room believed that it was a most difficult thing to construct a theatre, yet they would all leave it with the impression that it was a very easy matter. The remarkable modesty of Mr. Barry, and the generous tribute he had paid to the talent of those who were associated with him in this work, did not at all diminish his merits. This was no common work. There were so many contingencies to provide for, and so many contradictory elements to reconcile, that it must be a matter of great congratulation to Mr. Barry that he had succeeded in erecting such a work with such distinguished ability and success. He (Professor Donaldson) had visited the works, and he was struck with the skillful arrangement of what he would call the skeleton of the building. All the parts were admirably arranged to meet the pressure that might be brought upon them. Every precaution was taken not only to provide against any settlement on the columns, but for any settlement of the columns themselves. The arrangement of the staircases was also very satisfactory, and was admirably adapted to meet any sudden panic arising from fire or other causes. In fact, the whole arrangements were carried out with very considerable skill; and when he was upon the roof he saw in the vast combinations forming it a very imposing mass of construction, which carried with it a sense of solidity extremely satisfactory. Mr. Barry had in all parts explained himself so thoroughly and clearly that there was hardly an observation to make upon it or question to suggest. He had anticipated everything upon which any observation might have been made. It was therefore with great pleasure that he proposed a vote of thanks to Mr. Barry.

In reply to an inquiry, Mr. Barry said the cost of the theatre was something under 80,000*l.*; and relative to the porous slab and the material made by Deschery, he said, as far as he knew, they had answered very well indeed. The fibrous slab had shrunk a little since it was fixed, as almost anything would placed over the chandelier. As to the matter, of course, he added, I cannot say as yet, but as regards its lightness and convenience for hanging, I think it can hardly be surpassed.

Professor Donaldson said he was going to make some observations upon that. He had visited the theatre of San Carlo, at Naples, and a very ugly thing it was. It was short as compared with the width, and the audience could hardly hear the

music in it. It seemed as though it had been constructed haphazard as to whether the audience could hear well or ill. La Scala, at Milan, was of a very different character. It was as pretty a theatre as any in all Europe, and the hearing was perfect. The width of the proscenium was 43 feet, and the width between the boxes was 66 feet. The length from the curtain to the centre of the boxes was 88 feet; and the theatre was a very graceful one indeed. Mr. Barry had followed that plan. He had given 50 feet to the proscenium, and 80 feet as the depth—about the same proportion as La Scala. The theatre at Bologna was by a master-mind—Viviano was his name: he had built many theatres in Italy. He (Professor Donaldson) recollected being struck by the painting. It was white and gold, and the manner in which the two were arranged was very pleasing, the quantity of white and gold being proportioned in the most elegant manner. In other theatres they found an immense quantity of colouring introduced without harmony, but those at Bologna were blended in a simple way, and with elegant effect.

Mr. Jennings said,—In the description of this building, it appeared that there were cast-iron girders used of greater length than in any other building, I believe, in London. Are they one continuous gutter the whole length, to allow at each end for contraction or expansion; or is it not found necessary to make allowance under such circumstances?

Mr. Barry.—They are in one length, 96 feet, bolted together.

Mr. Jennings wished to know if any portion of the under side of the ceilings was painted—the ceiling of the corridor. Why he mentioned the subject was that it very frequently happened that after the architect left the work the painter came in and painted these places, the absorption was done away with, and the architect suffered.

Mr. Panson said that Mr. Barry had read a highly practical paper. It was common for them to hear papers of an æsthetic character, but that evening they had had their attention drawn to the solid and more useful part of the profession. It was not often that they had the opportunity of hearing a description of this importance by the construction of a building of this magnitude. He heartily concurred in, and he begged leave to second, the vote of thanks to Mr. Barry.

Mr. Kerr wished to be allowed to ask Mr. Barry to explain the table of strain in the wrought-iron girders. It was a very interesting thing, and they might seek to understand a little more in detail of what was represented, no doubt, perfectly well upon that table. At the same time he would be glad to ask Mr. Barry to explain the precise principle involved in the connection of these great girders in two pieces; that was to say, in the middle. He must say that, during Mr. Barry's description of these marvellous works, his attention was particularly directed to these girders, and it struck him that perhaps some scientific principle might be involved in the arrangement adopted of hoisting these two, and joining them in the middle. It had struck him that there would be weakness in joining them in the middle, as the middle was the weakest point, and it was desirable to avoid any additional weakness. At the same time it must be seen, that to have joined them in three would have made a double chance of weakness at those points. Perhaps the occurrence of any weakness was effectually provided against in the mode in which the beams were connected. He would add his humble testimony to the very great pleasure the Institute had received from the paper read by Mr. Barry, and he hoped that it would be the first of a long series.

Mr. Barry said he was afraid he could only give a somewhat general answer. The amount of strain was six tons to an inch, and as far as regarded the details of the different parts, Mr. Grissell, if he had been there, would have explained them better than he could.

Mr. Baker said there was one other point of interest, and that was with regard to the brickwork. The brickwork was carried up remarkably quickly, and to a great height. Mr. Barry had had now some experience of it, and perhaps he could tell them what had been the effect on the brickwork. About five years ago, he (Mr. Baker) carried up a wall about 30 feet high, and at the same season of the year, about November. The brickwork had been taken down this season, and it proved to be perfectly sound, and the mortar was as hard or harder than the bricks, and in many cases there was very great difficulty in taking down the wall. He would be glad to hear what had been the effect on the brickwork in this case.

Mr. Barry said he was not aware that any effect had taken place since the house was opened, but, no doubt, while it was going on, a settlement was of course to be looked for. In order to observe how that went on, he had small rods made of an inch and a half square, and fastened end to end in the wall, as the wall went up; and as it settled, he could observe whether there was any undue settlement. After the roof was on, he had all these rods taken out and shortened, and from that time he had found no further result, and so he had them all taken away. He was not aware of any settlement of any kind since the building was opened.

The vote of thanks was then unanimously passed, and the meeting adjourned.\*

## GLASGOW ARCHEOLOGICAL SOCIETY.

The usual monthly meeting of this society was held on the 6th inst., Mr. Sheriff Strathern, presiding. Dr. Scoullar read a paper on the "Remains of certain circular Buildings at St. Blane's, in Butte." From the character of these ruins, and various notices of St. Chattan and St. Blane, or Blain, gathered from Colgan and other sources, he had arrived at the conclusion that these were the remains of ecclesiastical buildings erected some years before Columba settled on Iona. Mr. Honeyman, hon. sec., read "A Description of the Church of Killochland, near Campbelltown." He was of opinion that the original building, measuring 32 feet by 15 feet 6 inches inside, was erected towards the commencement of the tenth century; that the chancel, measuring 16 feet 6 inches square, had been added during the thirteenth century; and that a great part of the east and south walls had been re-erected during the sixteenth century, or probably even at a later period.

## BRITISH INSTITUTION.

ALTHOUGH the walls, on entering, have a pleasant-enough aspect, and present some pretty pictures, there are wonderfully few works of mark and likelihood in the present exhibition. It consists of 632 paintings and 17 pieces of sculpture. No. 3, "Joy," by T. F. Dicksee, is a well-painted young head, to pair with "Sorrow" (25). The same artist, who is strong this year, exhibits a more elaborate work, entitled "A Labour of Love" (385). No. 33, "The King's Artillery at Marston Moor," by John Gilbert, though full of movement, and not without interest, is so carelessly painted, as scarcely to come under the denomination of a picture. Two other works testify to Mr. Gilbert's industry and fecundity. Mr. Jutsum is less successful than useful in (53) "Norbury,"—a bit of Mr. Thomas Grissell's beautiful place; the reflections are disagreeably green. No. 62, "Nottingham," by H. Dawson, is the most satisfactory landscape in the room: the sky is a study; the more noticeable because some of our *photographic* painters ignore the feature. Ansell's "Spanish Flower-seller" sadly wants life. (81), "The Nile," by F. Dillon; (141), "A Quiet Evening on the Thames," by W. W. Gosling; (180), "The Decline of a Summer-day," C. Leslie; (376), "Westminster Palace, from the Thames," J. Danby; and (603), "Under the Pine-trees at Castel Lussano," F. Lee Bridell, are amongst the best landscapes, and have, each, good qualities. Miss Stannard is admirable in "Fruit painted from Nature" (39), and Lance as good as ever, which is saying a great deal, in (115), "Black Grapes," and (193), "Before the Masquerade," the title of the latter, however, is a puzzle. In "The Dawning of Genius" (119), Joseph Clark,—a quietly-painted picture, with much expression,—an incipient artist is sketching a dog held by a mischievous girl. "Fondly Gazing" (135), G. Smith, a mother watching the cradle of her little one—

"With anxious thoughts of future years,"—is an admirable and beautiful work. No one quite disregards the opinion of any living being, and so the poor artist behind the door in Mr. T. P. Hall's picture, "Criticism" (243), is by no means indifferent to the comments of the servants of the house gathered before his easel. If Mr. Hall wants our opinion of his picture he shall have it: it is very nearly very good. "Antwerp in the Seventeenth Century" (293),

\* A special general meeting of the members will be held on Monday evening, the 13th of February, to take into consideration the recommendation of the council with respect to the award of the Royal Medal, the Medals, and other prizes of the Institute for the year 1859; and their recommendation with reference to the Medals for the year 1859.

Hendrick Schaeffels, is a richly-coloured and well-grouped picture, wanting mainly in the faces. If all these were as good as those of the old inn-keeper and his wife, there would be no occasion to qualify the praise. H. Weigall has some well-painted heads. L. Haghe's light shines less brilliantly in oil than water, though "The Interior of the Church of St. Miniato, Florence," (177), a candle-light effect, will have many admirers. "Fishing Boats, Venice," by V. de Fleury (90); "The Petitioner" (157), W. J. Montaigne; "Shadows" (195), E. C. Barnes; "Pycneth's Nest" (278), W. H. Ward; "Scene from Auld Robin Gray" (340), J. Craig; "A Welsh Drinking-Fountain" (362), W. S. P. Henderson; "The Fairy's Barque" (431), J. A. Fitzgerald; "Flowers" (502), St. Jean (price only 420*l.*); and a dozen other agreeable works may be pointed to.

#### AGAR FIELDS, ST. PANCRAS.

IN years gone by we placed fully in the light the miserable condition of the huts and dens in Agar-town,—huts undrained, ill ventilated, unwholesome, and demoralizing. Changes and removals have taken place since then, and some improvements have been made. The place still, however, calls for supervision. The condition of the Agar Fields, or Finneras Fields, is terrible. The whole space is covered with large and small pools of water; in fact, forming an extensive bog, very dangerous to the public health. The roads across the fields are impassable from deep mud, although there is considerable traffic to and from Camden New Town. Dead dogs and cats are thrown into the pools; and, with the refuse from the houses in Durham-street, in summer the stench is terrible. On the opposite side of the King's-road to Cook's-terrace, close by the turnpike, is a very old and dangerously rotten piece of footway, very dark at night, and impassable from water-pools in wet weather. The arrangement of the King's-road and the gullies is such, that in a heavy fall of rain stones and mud choke up the gullies, and often half the road is covered with water. We shall certainly have a return of the ague unless something be done by way of prevention. In fact, cases of ague have been by no means uncommon during the last few years in the metropolis, for which it has been difficult to account. Add to all that we have said, the stench derived from cat's-meat boilers and those factories of Belle Isle of which we have often spoken, and it may be imagined what a salubrious neighbourhood that of Camden New Town is.

#### LIVERPOOL BY-LAWS AND THE LIVERPOOL ARCHITECTURAL SOCIETY.

A SPECIAL meeting of the society was held on the 30th ult., to take into consideration the by-laws regulating the erection of buildings in the borough, proposed to the town council by the Health Committee. Mr. H. P. Horner occupied the chair.

Mr. John Hay, as one of the gentlemen signing the requisition for the holding of the meeting, said the matter was of interest to the whole profession, and he was really at a loss to conceive that any one could be indifferent to such additional power being granted to the officers of the borough as were proposed to be conferred upon them by the new by-laws. There was no doubt but that there was at present a staff of very able men in the capacity of surveyors; but at the same time there were many professional architects not one whit behind them in a knowledge of building operations, and he thought it would be a very hard case that the profession was to be disturbed by the borough engineer or his subordinates, in erecting a building upon any foundation which they, as professional architects, thought sufficient for the purpose. The responsibility of the architect was quite sufficient to make him careful to guard against any recklessness, because his professional character would be at stake. It was unfortunate that there was no proper recognition of the architectural profession, for at present there was no legal distinction between Sir Charles Barry and the lowest "jerry" builder. The powers which were proposed to be conferred by the by-laws were of such an extensive kind that they would be a very great grievance to every member of the profession. Mr. Hay referred more especially to the laws as to concrete foundations, and as to the restrictions in the use of iron for the support of superstructures. He urged that the latter clause had been framed in utter ignorance of the use of iron in substructures; and he had not the slightest hesitation in saying that he would undertake to put St. George's Hall upon a

substructure of iron, and make it in every way as safe as it was at present.

Mr. Weightman objected to the laws *in toto*, on the ground that they were indefinite. There was no definition as to the meaning of "solid ground"—and who was to decide what was solid ground? There was likewise no definition of what was "sufficient concrete." He thought a schedule should be given referring to these standards, which in the present state of scientific knowledge could be easily fixed.

After a two hours' discussion, in which the chairman, Messrs. Barry, Alderman Bennett, and others expressed their dissatisfaction at the proposed reforms, and the great vagueness with which the laws had been drawn up, it was at last agreed, on the motion of Mr. Wylie, "That a respectful memorial be presented to the town council, at a meeting on Wednesday, asking them to postpone the passing of these by-laws for one month, in order to give architects and others sufficient time to consider them in their general bearing." There appeared to be only one dissentient from the resolution.

#### THE HARTLEY INSTITUTION COM-PETITION, SOUTHAMPTON.

FORTY-FOUR designs for the proposed Hartley Institution were sent in by forty-two persons. According to the report upon them, made by Professor Donaldson, none of those which give the required accommodation and display sufficient artistic skill could be executed for the stipulated sum, 8,000*l.* The two which, in his opinion, meet most nearly the requirements are those marked respectively "Stella" and "Argonaut," and he recommended, we believe, that the authors of these two designs should be communicated with, and invited to submit modified designs. A certain small number the referee put aside as so defective or inappropriate as to be beyond consideration, and he named twelve as the best in an artistic point of view.

The committee, if we are rightly informed, were to recommend to the council that a suggestion should be made to the designers, whose plans have been so far approved by Professor Donaldson, that they shall be at liberty to send in a guarantee in each case from competent practical persons who will undertake to carry out their designs for an amount not exceeding 8,000*l.*, according to approved specifications; and that no such guarantee shall be entertained unless it be accompanied by the names of two responsible persons, willing to be sureties for the performance of such contract. What course was actually taken by the council we do not yet know.

The great hall is required to accommodate 2,000 persons; the 8,000*l.* is not to include the expense of lighting and heating the institution.

#### BURNING OF FIREPROOF MILLS AT MANCHESTER.

IT is much to be desired, as we have often said, that fireproof premises were made fireproof in reality, or in some more complete and thorough way than they often are. A serious fire has just occurred at Manchester, in the Hanover Mills, which consisted of two adjoining portions, one new, and with fireproof floors and other arrangements against fire, but with a wooden roof; the other portion was old and not fireproof. The fire originated in the old part of the premises, which it soon converted into a ruin, and the fire caught the roof of the new premises, which it rapidly destroyed, together with everything in the upper floor. This, however, was by no means the whole of the mischief done to the new and fireproof premises. Great difficulty was experienced in preventing the fire from penetrating the partition wall. Although the iron doors intervening between the old premises and the new were very thick, the intense heat cracked them, the flames found their way through the shaft-holes in the masonry, the continuous shafting became red hot, and it was only by incessant vigilance that the new mill was saved from being on fire in every story. But all danger to the new mill was not even yet at an end. The wooden binders in the partition wall were all burnt away, leaving it full of holes and fissures, and the intense heat had warped it to such an extent that it became detached from the side walls of the new mill, and left the buttresses of the brick arches sustaining the floors at that end of the building without support. They consequently hulged outward, and it was found that two bays of arches were cracked. In the fourth story the cracks were slight, but they increased in width as they ascended to the top; and

a few courses of brickwork had actually fallen from the seventh story into the sixth when the rent was discovered. The hopes that had been entertained that the new mill might soon be placed in a working condition again were soon dispelled by the unexpected fall of the two bays already mentioned. The side wall, towards Buxton-street, to the length of two windows from the old mill, came down with a fearful crash. The men who had been employed in the new mill had been ordered to withdraw about an hour before; but Mr. David Bellhouse, who, with two other gentlemen, had been examining the building, had withdrawn from it only a short time. The machinery in the part where the fall took place was totally destroyed. The damage from this cause alone will amount to several thousand pounds. It was feared that the whole of the new mill would fall. It is hoped, however, that the remaining arches will stand until supports can be placed against them; and, in that case, it is believed, there will be no necessity for pulling down the portion of the new mill at present standing.

Of the damage only a rough estimate can at present be made. It is probable, however, that it will amount to from 30,000*l.* to 40,000*l.* Insurances had been effected on the old mill and its contents to the extent of 24,000*l.*

#### GENERAL MEETING OF THE CENTRAL ASSOCIATION OF MASTER BUILDERS.

##### WITHDRAWAL OF THE "DECLARATION."

A GENERAL meeting of the Association was held at the Freemasons' Tavern, Great Queen-street, on Tuesday, the 7th, and was very numerously attended. On the motion of Mr. Lucas,

Mr. Thomas Piper took the chair, and stated the business of the day. He regretted that Mr. Lee, who had presided at the first meeting, was not there to take the chair again; but he, the chairman, might yet congratulate himself, that while, when Mr. Lee presided, the struggle was beginning, now he hoped it was brought to a close. I am sure, he continued, I speak the feelings of all present when I say the circumstances preceding our meeting in August were of such a character as to compel us to assume a position which was not only adverse to our best feelings, but to all our interests. At that time everything was against us. We were not only embarrassed by the nine-hours question, but by a whole host of smaller but most important questions, which were hampering us to an extent that rendered it impossible for us to conduct our business. It was painful and injurious to us to be placed in a position of antagonism to those associated with us in our common daily pursuits, whose faces we were accustomed to see from day to day, and with whom we had common interests. As the committee said in their report, we draw our resources from a common fund, and we are all embarked—the lowest working man and the highest employer—in the same enterprise and for the same objects. Had the movement which compelled us to form our central association confined itself to legitimate aims—to the quiet discussion of matters in difference—we should never have been placed in circumstances of apparent hostility to our workmen. But when they, who originated the movement, called out the men at work for a certain firm—when they took an illegal position and compelled working men to leave their employment—the duty before us was clear; namely, to devise means by which, without resorting to any offensive movement, such as a "lock-out," we could make a bridge, as it were, by which those who were willing to join with us might come, and leave those who were leading them into error. That overture was not received with much affection, and it became eventually a subject of great obloquy and violent vituperation. But we are met here to-day under circumstances which, I think, entitle us to say, that our association has been efficient for the purpose for which it was established, and that we are now able to conduct our business in spite of all opposition to the now famous "Declaration." I am exceedingly anxious—and I am sure I speak the sentiments of all present—that nothing should be said here to-day calculated to rekindle for one moment any of those feelings of exasperation which have been cultivated—I must say cultivated—by those who have been active agents in the nine-hours movement, and fostered by persons in a position to have known better. The Executive Committee of the Association have had most anxious duties to discharge in watching the phases of this protracted strike. A report emanating from them will be read, setting forth in detail all that has taken

place from first to last. But there is this striking feature to which I would advert—namely, that during the whole of the strike, notwithstanding gentlemen in various positions—one a member of a profession with which we are most connected, and others who occupy seats in the Lower House of Parliament—have been busying themselves, with the view apparently and ostensibly to make up and accommodate the differences which have arisen,—not one single suggestion, nor anything approaching to conciliation or concession, has been made to your committee, which enabled them to say that they could fairly rest upon it, or adopt it as a mode of amicably settling the matters then in dispute between us and our workmen. Nevertheless, we have worked steadily on in the course you prescribed to us, and are enabled now to feel that we have sufficiently accomplished the objects we all had in view; and we now come forward with such a recommendation as will place us on the footing in which we were before the strike happened,—not regretting the position which we assumed at the commencement of the struggle.

Mr. Wales then read the report, which gave an account of the strike from the commencement, and quoted the various documents which have been issued including the "suggestions for settling the strike," made by Lord St. Leonards, and the digest prepared by him of the several Acts of Parliament bearing on the subject, to which we first gave publicity. With all the stages of the struggle, indeed, our readers are acquainted, and we need therefore print only the conclusion of the report, which is as follows:—

"An opinion by Mr. Edwin James and Mr. Gordon Allen on an essay submitted has been published by the Conference, which pronounces the laws of the trades' unions, with one exception, to be legal. On this the committee have to remark, that the police magistrate, the Court of Queen's Bench, and the Court of Exchequer, have pronounced and confirmed a sentence of imprisonment on the London secretary of one of these trades' unions for acting under and in accordance with the laws referred to. In other cases where individual members of the Association have sought the protection of the law against the proceedings of trades' unionists, your committee have the satisfaction to report that the views entertained by the Association have been amply vindicated by the tribunals of the country.

Your committee deemed it expedient to print the rates of certain of the trade societies, for the use of members; and the present edition has been published with extracts containing details of some of the more objectionable laws and practices.

On a calm review of the painful events of the last few months, your committee are fully of opinion that the time had arrived when it was imperatively necessary to grapple with the whole question of the rights of master and workmen, the legitimate control of their business, and that the demand of nine hours' pay and nine hours' work was only another illustration and further development of the arbitrary and extravagant demands which the building trades of London had been forcing on their employers during recent years.

The hostile attitude still assumed by the leaders of the Conference, and the threats they still issue in the columns of their organ, render it necessary that you should continue to be on the alert; and your committee therefore recommend that the Central Association of Master Builders should not be dissolved, but that further experience shall show that it may be no longer needed.

Your committee have satisfaction in congratulating the Association on the success of the measures they were intrusted to adopt. The nine hours movement has been suspended, the strike is entirely revoked by the Conference, and the members of the Association have been enabled to resume their work.

Your committee are of opinion that the opportunity of expressing the opinions and feelings of the public on the grave questions of capital, labour, and trades' unions, and of scrutinizing the acts and reasonings of the mistaken leaders of this movement, afforded by this struggle, will have diffused a large amount of valuable information which cannot but result in a better understanding of the great and important questions involved; and they trust that, in the end, the workmen will themselves see that, by separating them from their societies (as at present constituted), the masters have proved themselves their best friends. By order of the committee.

12 February 6, 1860. G. PLUCKNETT, Chairman."

Mr. Plucknett rose to move the adoption of the resolution which has been passed. He said that your committee from first to last have given their earnest consideration to the various important subjects brought under their notice during this protracted struggle. On the subject of the nine hours' pay and nine hours' work, it is a course that might have imperilled the success of the objects for which the association was established, and, in the other, to avoid anything that might be considered as one of them in the least, even should it have been necessary to resist, and are now at an end; and I hope and trust that the measures which have been adopted, and the proceedings here to-day, will be forwarded tend to settle the nine hours' pay and nine hours' work, and that the men will see that all legitimate objects can be attained by the simple force of public opinion, without having recourse to the calamitous alternative of a strike. I am sorry to see that the report of the proceedings of the Association, Mr. Lucas, in seconding the motion, said the report is so fully related the proceedings of the committee,

that it would be a waste of time in him to do more than formally second the resolution for its adoption. He would only say to the committee, while engaged in going to justice to themselves, never forget what was due to the men.

The Chairman asked if any gentleman wished to speak on the subject, and if any gentleman desired to put it to the meeting, when it was carried with acclamation. Sir Samuel Martin Peto, M.P., who was greeted with cheers, said,—The result to which I have to move is as follows:—That the objects contemplated by the declaration having now been accomplished, its further formal administration is unnecessary; that the suggestions of Lord St. Leonards be adopted in substitution for the declaration, and that it be remitted to the executive committee to take the steps necessary for giving effect to this resolution." Gentlemen, after an association of upwards of thirty years with the master builders of the metropolis, I felt when this great question was agitated, that I could not, as I was one with you in sentiment and feeling, for one moment hesitate to be one with you in action. I was aware the course I then took as a public man would render me open to great misapprehension and much misrepresentation. Both of these I have experienced to the amplest possible extent; but I do not for one instant regret the course I then took. On the contrary, were I not to-day to be permitted to put to me as to my conduct in connection with this matter, I should say I am prepared to intore all that the committee has done, and I rejoice that your kind friendship has permitted me to be associated with you in this affair. The course I took was not so much from old friendships which have subsisted, and I am proud to say, still continue with so many in this room, but from an anxious regard for the welfare of the metropolis. I have seen the course here experienced, in the conduct of trades' unions in this country, a course of proceeding adopted which is more injurious, if possible, to working men than to any other class of the community. I have seen the course here, that a system which strikes at the root of all independent action and feeling, which impedes the working man in the free exercise of his labour, and the master in the free exercise of his capital, is being introduced, and prejudicial to the interests of the whole community. When I have seen artisans in this metropolis repeatedly "blacked" because they could not conscientiously see their own interests advanced, and their own rights invaded, I have seen a strike recognized and adopted as a legal strike because one man, working at a building and, not being a member of a trades-union, had refused to enter one, had refused to work for one. I have seen a man who felt that I should be identified with you on this question, not so much, as I said before, from old friendship with you as from the interest I take in the working man himself. I am not ashamed to say that I have in connection with a great number of my friends in this room, worked at almost every handicraft in the building trade, and that much of my success in life is simply attributable to that fact. But my association with working men has caused me to feel a deep debt of gratitude to them, and I felt that I could not do better than join with you in offering the most determined resistance in my power to the course which you are now proposing. I have seen the despotism of the many opposed to the rights of the few. I propose now the adoption of a course which gives me unmixed satisfaction in recommending as I hope it will afford you in accepting it, following the suggestion of Lord St. Leonards, no injustice will be done to those who have come in under the "declaration." This is neither more nor less than a simple recognition, expressed in clear language, of the law as it now stands, though it has been misrepresented in a great variety of ways, and I do not think you can do better than adopt it in your various works. I recommend it as much to those who are out of employment at the present moment, as to those who are not, and who are not under any new conditions. It simply states in lucid terms what the law is; and we, in a spirit of good feeling towards our workmen, only desire that they will all acquiesce with it. I think that is a just and a grateful thing for us to do at the present moment. The "declaration," I know, is a most unpopular thing. I do not regret your adopting it; I believe it has answered the purpose intended; but I think the time has come when you may substitute for it the advice of Lord St. Leonards, with a most perfect feeling that you are doing justice to all parties. I am sure now can be more anxious than you all are to do the greatest act of justice to the workmen in your employ. We cannot do them a greater act of justice than to inoculate on them the necessity of saving, and of pinning their savings in a position where they would be available in the time of their need. The report refers to a benefit club about to be opened in connection with the Workmen's Institute recently established. This club has been set on foot by among other gentlemen, Mr. St. Leger Glyn and Mr. Jervoise Smith, capitalists and bankers in the City, most of them young men, anxious to discharge the responsibilities attaching to their position, and to promote the interests of working men in general; and the committee commend it to your consideration to-day, in order that you may, in your turn, if you see fit, move in future, as in times past, take every possible care to slow the men in our service that we are not simply using them as so many machines, but that, in the relative positions in which we are now placed, we have an anxious desire to see them and their families living in comfort while in our employ, and in a better position when leaving than on entering it. This benefit society seems an admirable mode in which the objects may be carried out practical effect, and I commend it to your notice. Let me say a word on another point. You have inaugurated a new era. You have now determined that you will pay no more labour than is worth. If a man is a good workman, and able to show by his ability and talent that he is worthy of promotion to a better position, I am sure you will all feel with me that you are obliged to the best man for his services. It is a struggle to do such a man, and every man in like circumstances in your employment, the largest amount of justice in proportion to his deserts. We all know that underlying this protracted struggle, there has been a battle of spirit of Socialism, which simply aims at dragging all men down, regardless of their individual merits and abilities, to one common level of mediocrity. We say that every man should be promoted to his labour, and skill; and that is the great point at issue. Among the men in our employment, let us endeavor to discover talent, and while we take care to pay the inferior workman what he is worth, let us endeavor to pay the better man of this Association required the skilled artisan with less than his due. During the strike an attempt has been

made to vilify the firm with which I have the honour to be connected. We are engaged in works in almost every part of the world, and we feel bound to take care of the men in our employ should not suffer from any want of provident regard on our part, or their own, for their welfare. Notwithstanding, I could scarcely ever walk the streets of London during this strike without its being said in my hearing—"Who is it that robs his workmen every Saturday night?" We have a sick fund for the men in our employment, and on looking through the accounts, I find that during the existence of our firm, the total amount of subscriptions to that fund, by workmen, has been 31,000*l.*, while the aggregate disbursements have been actually 50 per cent. in advance of that sum. Let me just say here that I hold in my hand a letter from the Bishop of Montreal, addressed to Mr. Hodges,—a person in my own employ, and who, sixteen years ago, was only a journeyman carpenter. To him the superintendance of the works at the Victoria-bridge in Canada, constructed by my firm, was entrusted, involving the discharge of most important duties; and the late Mr. Robert Stephenson said of him that he was one of the ablest mathematicians of our age, and the first practical engineer of the day. The Bishop writes thus to Mr. Hodges, under the date of the 14th of November last:—"My dear Sir,—As the great work of the Victoria-bridge, which you are now engaged in, with such ability and zeal for the contractors, is now so nearly approaching completion, I wish, before your connection with Montreal altogether ceases, to express to you, on behalf of the church, my warmest thanks, and to place, my grateful thanks for the readiness with which, as the agent of the contractors, you have at all times assisted us in making provision for the spiritual oversight of the numerous persons in your charge. I have no doubt you felt that in the circumstances in which you were placed, you were simply discharging your positive duty; but it is by no means the role that such duties are always to be performed cheerfully and ungrudgingly, and I trust that the very liberal example thus set by you and your principals, in providing salaries for the clergy and schoolmasters who were to have the care of your people at Saint Anne's and at Point St. Charles, and your own large contributions recently given, will influence those who shall succeed you, and that it will lead to the permanent establishment of the church and schools in connection with the railway and depot works at the latter place." My object in adverting to this circumstance is to show that we do not stand in a position of anything like exclusion which has been so blindly and malignantly imputed to us. But you are not to be deterred by this, and I trust that no one shall ever point to the master-builders as a body who desire to raise themselves in prosperity and comfort at the expense of those below them, who do desire rather that every man shall have opportunities of rising in the world, in proportion to his abilities and good conduct.

Mr. George Smith in seconding the resolution, said the committee, which he was a member of, had been accused out of doors of tyranny and all sorts of harsh conduct. He had attended every committee meeting, and he could honestly say that he had never heard an observation drop from any member of the Unionary way likely to injure the workmen. Their anxious wish, all through, had been to carry out what he believed to be imperative on them, but with as little harshness as possible. Adverting to the remarks of Sir Morton Peto, as to opportunities being afforded to workmen to better their position, Mr. Smith said he knew of no trade that offered so many facilities for that as the building trade, although the capital required for large works was undoubtedly great. He had been struck with the unceasing objections which deputations of workmen who had come before the committee made to pieces-work, while in almost the same breath they urged the apparent impossibility of an artisan raising his position. Mr. Smith proceeded in factious terms, which caused some merriment, to describe the various attempts made at conciliation by persons not concerned in the dispute; especially mentioning on the manner in which Mr. Marsh Nelson and Mr. Ayrton had put themselves forward with that view. He denied in indignant terms that when the committee had an interview with Sir George Lewis, the Home Secretary, their object was to ask for Legislative interference. Mr. Piper, on the contrary, told Sir George Lewis that they were there for no such purpose, and yet Mr. Ayrton, who thrust himself into the room during the interview, had heard it asserted over and over again, that their object in going there was to ask for Legislative interference, and had never had the malice to contradict it. He (Mr. Smith) thought it was to be believed that of all the metropolitans members Sir Morton Peto was the only one who had had the malice to come forward and state what must have been their conduct on this question. If they were men of sense they ought to have come forward months ago, and told the people what must have been the inevitable result of this struggle. But what did they do? Why, they wrote meaningless letters bounding on the men to destruction; when a little more malice, a little more of what he called English spirit, on their part, might have shortened the duration of this unhappy dispute by months, and saved the lives, probably, of many individuals.

The resolution was then put, and carried unanimously. Mr. W. F. Palmer, with much feeling and sympathy for the workmen at large, commended the benefit club to the support of the meeting as a means of ameliorating their condition, and he moved. "That this meeting cordially welcomes the efforts of those gentlemen who have originated the Workmen's Institute, and pledges itself to its support."

The motion was seconded by Mr. W. Norris, and carried *unanimously*.

On the motion of Mr. W. Horner, seconded by Mr. J. Abbott, the thanks of the Association were unanimously voted to the executive committee for the efficient manner in which they had transacted the business of the Association.

The cordial acknowledgments of the Association were also passed by acclamation to Mr. Thomas Piper for his conduct in the chair, on the motion of Mr. J. C. Lawrence, seconded by Mr. R. Haunton.

The chairman briefly acknowledged the compliment, and with that the proceedings terminated.

**THE CHIEF STONE OF VICTORIA BRIDGE, MONTREAL.**—The builders have left a stone unlaidd—a corner stone—of the great railway bridge at Montreal, in hopes that one of our royal princes may pay them a visit in the spring, and inaugurate the completion of this great work,

## THE WAR OFFICE AND "CONTAGION."

Sir,—In the last *Builder* there is a good letter signed "Cwm," on Camp Hospitals, containing a curious piece of information to me, although I am pretty well *à couvert* in sanitary matters. He says that the Secretary of State for War has issued a regulation for carrying out the old witch incantations over dirty linen, including fumigation and other absurdities, with the view of exorcising the evil spirit known in modern times, under the esoteric name of "Contagion." I at first thought your correspondent had got hold of an order of the time of the hundred-year-old book he discusses, but on making diligent search I have actually obtained the circular dated from the War Office, on Waterloo day, 1859. The better day the better deed. In this paper, Secretary Major-General Peel actually issues special directions, under the hand and seal of Sir Benjamin Hawes, giving the most minute details of how the devil is to be got rid of!

It is clear that sanitary reform had not reached Pall-mall even at that date.

I have also looked through the new army medical regulations to see how the contagion affair is disposed of by them; and I find that within less than four months, namely, on the 7th of October last, Mr. Herbert undoes all this, and not having any faith in the evil one in question, simply prescribes that "hedding which has been used by patients affected with epidemic diseases should be steeped in water, dried, and exposed to the air, and afterwards washed with soap and water." This is a good, healthy rule, and it shows that in the War Office it is possible to pass over a century of superstitious observances in a quarter of a year. Would that all other equally antiquated War Office observances were passed over as speedily.

X.

## FRENCH AND ENGLISH INVESTIGATORS.

READING the interesting article in the *Builder* on M. Benli's papers on Greek art, translated from the *Revue Générale de l'Architecture*, I was sorry to find that M. Benli has been guilty of a plagiarism. In 1851, I published, in my "Museum of Classical Antiquities," a proto-Doric column (one of three), which I discovered at Thebes, and I gave a plan, in which I pointed out their position. To my great surprise and concern, I discover that M. Benli has copied this cap in the *Revue Générale de l'Architecture*, and calls it "from Elephantina," in order to conceal his theft and make his own discovery the more important.

Another Frenchman, M. Ernest Breton, was equally dishonest in his wretched compilation on Pompeii. He copied the plates I published of the house which I excavated at Pompeii, without referring to me either as the excavator or author, and altered the names, pretending that I was mistaken in my appellation, although, had he been able to read English, he could not have made such a mistake as not to know a trichium from any other room. EDWARD PALMER.

## THE PROPOSED GARRISON HOSPITAL AT WOOLWICH.

In the *Builder* of 3rd September last it was stated that it had been determined to build a garrison hospital at Woolwich, for 650 beds, and the several suitable sites which present themselves in the immediate neighbourhood of the barracks,—close neighbourhood being an essential point of advantage,—were very briefly enumerated. On the 5th of November, the newspapers having announced that a particular site had been fixed on, it was pointed out that there is an insuperable sanitary objection to that site, it being the one side of a narrow, closed valley. It now appears that that has been abandoned; and we quote a very well-accredited local rumour when we say that Kidbrook-common has been purchased by the War Department, and that on it the hospital is to be erected. Mystery and reserve are the shields with which un-official feebleness naturally endeavours to protect itself from criticism; and perhaps we shall not know the exact truth until the Army Estimates are laid on the table of the House of Commons; but it is certain, at any rate, that, if not actually purchased, the ground mentioned is that to which official eyes are now turned.

Kidbrook-common is the strip of furze-covered clay land which is immediately on your right hand as you turn from the Dover-road towards Eltham. It is just below Sevendroog Castle, on Shooter's-hill, well known to all Cockneys. It is a gentle slope, just in front of which is a conical hill, presenting, on its nearest face, the Greenwich and Deptford burial-ground.

If the ground has been purchased, and if there is no chance of a withdrawal from the decision to build there, perhaps all that need be said is that the future building will be, as far as mere situation goes, and provided the eyes and nose can be kept free from the near graveyard, one of the most agreeable residences in the neighbourhood of London, replete with "residential amenities," as George Robins used to say, quite sheltered from the bitter north wind, and from the Kent Cray country on one hand, and, as to the other, that when the whole system of waterworks at the Crystal Palace is in full play, with the great volume of water gilded by the setting sun of an autumn evening, there will be so charming a prospect that the sick must become well, and the whole must strive to become sick to enjoy it. So much may be safely said; but if there is still time for a little friendly criticism, there are two or three questions that may not seem to be irrelevant. For instance, why should a hospital be built on a piece of ground where, bore as deeply as you please, you find nothing but clay and water? Why divert the Common from the purpose for which nature intended it,—that of a brick-field; a purpose properly and profitably carried out within a few hundred yards? When the line of separation between the barracks and the proposed site, why should you select that side of the line on which the clay lies, and which is most remote from the barracks? How is the water supply to be obtained? If, by the had method of sinking wells, it can be safely said that there is every prospect of an abundance being found: if, on the other hand, the water is to be procured at high-pressure, is Shooter's-hill, the only higher ground within a large circle, relatively high enough? Above all, and before all, why is a Woolwich Hospital to be built at Shooter's-hill? And this objection is a quite insurmountable one. The fact that it can be urged sufficiently shows that this new site can have been sanctioned by no one who knows anything whatever of the requirements of a regimental hospital, or of the interior economy of a regiment, in the routine of which the hospital is so important a feature.

One would almost suppose that the gentlemen charged with the duty of selection had caught the echo of a recent discussion, and were determined to carry out the mere words of it, quite irrespective of the meaning, and altogether ignoring the very substantial grounds on which it has been raised. Some persons have proposed, on strictly sanitary grounds, to remove the large civil hospitals of densely populated towns towards the country. Others, again, among them Mr. Kingsley, prominently and, it need not be said, very eloquently, have carried the idea further, and have proposed to remove the town population of labourers and hand workers in the same direction. Excepting in the interest of details of convenience and expense, there can be nothing but sympathy with the proposal. One can quite understand that if St. Thomas's Hospital, for instance, were moved along the South-Eastern line to some breezy upland down in Kent or Sussex, it would be a very great sanitary advantage. But the case of a regimental hospital is in all respects and altogether different. Any one who knows the constant,—more than hourly,—communication that must be carried on between the regiment and the hospital, how much more is transacted between them than what affects merely the sick men in hospital, must know that if the hospital is at all remote, the routine of duty becomes, of necessity, injured and stagnant. It is a primary and essential necessity that the barrack and the hospital must be in close contiguity one to the other. If the one is moved, the other must be moved. In this particular instance, if it appeared that it was impossible to find a suitable place for the hospital in the neighbourhood of the barrack, so absolute is the rule that has just been laid down that very serious questions would arise; but that is not necessary, because, as has been pointed out before, there are admirable sites in the immediate neighbourhood.

And, assuming that Kidbrook-common has not yet been purchased, one would like to say a word or two in favour of the piece of ground which was called site D, in the *Builder* of September 3, viz., the field on the right of the road to Charlton, as you go from Woolwich, and between Maryon-road and the Charlton Park-wall.

Every one who has travelled lately up or down the river must know that a Marine Hospital has just been built, immediately on the proper right of the Marine Barracks. It is so high that it dominates over the town and neighbourhood.

When one stood on the paddle-box of the *Great Eastern*, off Deptford, last summer, the two proudest looking buildings that the eye could see were St. Paul's and this new hospital! Now wishing to advocate site D, what we would as any one who is interested in the matter to do this,—to place himself at one of the windows of the architectural front of the Marine Hospital, and then to look to his front. He will thus have a capital view of the extensive field suggested; and will see, at a glance, its many capabilities; and will proceed to discover, it may be safely asserted, that there cannot be a single sanitary objection raised to it. He will see, too, that this field is on much the same level, and that the building at which he is standing, and that he can allow his imagination to picture the effect of two such buildings, facing each other; the one representing the most recent efforts of one great public department, the other of the other. In the Marine Hospital there is too little interval between the pavilions. The space was very limited, and a certain amount of sanitary advantage has been sacrificed for the sake of close neighbourhood to the barracks and dockyard. Site D would admit of any amount of space. If, however, Kidbrook-common is to be the site, every consideration that ought to be taken into account will have been sacrificed, and—for what?

CWM.

## BUILDERS' ACTIONS.

HERONBOTS QUANTITIES.

*Sherren v. Harrison*.—This action was tried in the Court of Queen's Bench (Seymour Court), before Mr. Justice Blackburn, and a special jury. Mr. M. Chambers, Mr. Day, and Mr. Martin were counsel for the plaintiff; Mr. Hawkins and Mr. Archibald for the defendant.

The plaintiff, a builder, sued the defendant, a clergyman, to recover a balance of 1,488. 17s. 9d. for extra work done beyond that specified in the contract and specification. The defendant paid into court 292s. 18s., and said that that sum was sufficient to satisfy the plaintiff's claim.

It appeared that the defendant was a clergyman of the Church of England, and was desirous of building a small church at Northumberland-park, Tottenham, Middlesex, and in January, 1857, inserted an advertisement accordingly for plans, &c., in the *Builder*, for a small church, to cost 2,000l. Mr. Mumford became the architect, and, as the plaintiff stated, induced him to become the builder and sign the building contract. The working drawings and estimated quantities were supplied by Mr. Mumford to the plaintiff, and there was sufficient evidence given to establish that he was acting as agent on behalf of the defendant. But the plaintiff's case was, that the estimates and quantities so supplied to him by Mr. Mumford were so incorrect and false that they amounted to a species of fraud done by means such as were very likely to induce him to sign the contract to do the work for 1,600l., whereas, when the work was subsequently done and quantities calculated, the cost was found to amount to 2,000l. The misstatements had been shown by Mr. Mumford to be such as were very likely to mislead, corroborated by Mr. Lewis and Mr. Lee, of the Adelphi. Mr. Mumford's estimates were said by the plaintiff's witnesses to be such as were very likely to mislead the plaintiff, who had been chiefly engaged in building public-houses, and had never previously built a church, and were, therefore, in their quantities were quite incorrect. The written contract contained a stipulation that no extras were to be done or charged for without a written order from the defendant, and signed by Mr. Mumford. For extra work done in this case there were no such written orders.

Mr. Hawkins, at the close of the plaintiff's evidence, submitted that there was no case, and that the plaintiff was bound by the written contract, however improvident the bargain he had made might be; and that as there was no written order for the extras by the defendant, and no certificate by the architect, the plaintiff was not entitled to recover.

Mr. Chambers contended that the plaintiff was entitled to recover on this ground,—that Mr. Mumford's drawings and estimates amounted to a fraud practised on the plaintiff, and that the defendant, having employed Mr. Mumford as his agent, was bound by his acts, and that, in fact, the case was the same as if the defendant himself had prepared and submitted the drawings and estimates to the plaintiff, and, further, that the contract, not being one under seal of the parties, it was competent to them to waive it by parole, and that there was evidence that the plaintiff had so required a written order for extras had been waived.

The learned Judge ruled that there was no evidence to go to the jury on the question of fraud, and that, as to the extras, the written contract was binding, and that there was no evidence of waiver. He then directed the plaintiff to be nonsuited, reserving leave to the plaintiff to move the court above to set aside the nonsuit on the ground taken as above by Mr. Chambers.

Some will think that the action was brought on the wrong person.

CO-OPERATIVE ASSOCIATIONS.—A co-operative association has been formed amongst certain of the artisans of Wolverhampton. Their numbers are not larger than thirty, and their capital about a many pounds; but the society is yet in its infancy. A store has been established for the sale of groceries. The brickmakers and colliers of parts of South Staffordshire and East Worcestershire are discussing the feasibility of forming similar associations in connection with their respective trades.

Books Received.

*Recent Practice in the Locomotive Engine (Being a Supplement to "Railway Machinery"), comprising the latest English Improvements, and a Treatise on the Locomotive Engines of the United States: illustrated by Plates, and Engravings on Wood.* By DANIEL K. CLARK, C.E., and ZERAH COLBURN, C.E., New York. Blackie & Son, Warwick-square, London, 1860.

THIS able and useful supplement to Mr. Clark's treatise on "Railway Machinery" is now completed with the tenth part of the series. The work is designed to illustrate and investigate the practice of English locomotive engine-makers at the present day, and to present the most recent attainments in American practice. One important object, treated of at length, is that of the use of coal in locomotives, which, Mr. Clark thinks, will in a few years be general: the opinion is now in rapid progress of fulfilment.

The American division of the work, by an American engineer of good repute, may be studied with advantage by the English engineer. It is interesting for the research and originality it displays, and valuable, as Mr. Clark's own share of the work is, for the really practical information it affords.

*The Year-Book of Facts in Science and Art.* By JOHN TIMBS, F.S.A. London: Kent & Co., 86, Fleet-street, 1860.

MR. TIMBS'S Year-Book is as fresh and full of interest as ever, and affords us some of the pleasantest reading and reminiscence of the whole year round. But really we have now so often had occasion to speak in similar terms of this valuable compendium of the year's labours in scientific and art discovery, that the simple announcement of a new issue we are sure is all that our readers require, as to induce them to make it their own, or the investment of the small sum demanded for it at the hands of its publishers. The present volume is illustrated with a fine engraving of Captain McClintock, R.N., the Arctic voyager, and a wood-cut of the new naval "bruiser," called "The Warrior."

*Manual of Domestic Economy; with Hints on Domestic Medicine and Surgery.* By W. B. TEGGEMEIER. Fifth edition. London: Groombridge & Sons, Paternoster-row, 1860.

OUR large editions of this little work, it seems, have now been sold, and a fifth is called for, and now issued after revision and enlargement; thus justifying the good word we have now spoken for it. As our readers may recollect, it was prepared at the request of the Committee of the Home and Colonial School Society, by the author, who is the lecturer on Domestic Economy at the training Institution in Gray's-inn-road; and the book is published, indeed, for the School Society's name.

Miscellaneous.

**WHOLESALE COMMEMORATION.**—It is stated at a society has been formed at Antwerp which intends erecting a colossal monument to all the celebrated men of that town, in the shape of a pyramidal structure, bearing forty-four statues, with an allegorical figure at the top, representing the city of Antwerp crowning her sons. The monument is to be 200 feet high: the expense is calculated at 300,000 francs. It is to be erected on the crossing of the principal avenues on the boulevard Leopold. M. Cuyper is the sculptor. The architect, M. Redig, has undertaken the architectural part of the monument.

**MONUMENTAL.**—A monument, of Peterhead granite, from a design by Mr. Scott, of Aberdeen, executed by Wright, of Aberdeen, has just been erected in Broughty Ferry, near Dundee, in memory of the late Dr. Dick. The design consists of an obelisk, 14 feet high, upon a pedestal of corresponding character. The ground is laid out with plants, and enclosed with chains, hung upon tall obelisk pillars, in harmony with the monument. — A raised altar-tomb has been placed in Friary churchyard, Brecon, to the memory of the late Major Linnley. The tomb, which is from a sketch of Mr. W. Jennings, sculptor, Hereford, is in the Medieval style. It is formed of red sandstone from Springfield, in Yorkshire, and is ornamented by a plain white marble cross, in keeping with the style of the tomb, as is also the railing which surrounds it. The panel bears the inscription.

**THE MONSTER ANVIL BLOCK AT NEWCASTLE-ON-TYNE.**—The enormous casting, by Morrison & Co., on the Tyne, weighing upwards of twenty-one tons, intended for the new ordnance works, Woolwich, under the control of Sir William Armstrong, was removed from the casting-house, on Tuesday last, on a wagon weighing above seven tons, well constructed, and drawn by a magnificent team of twenty-eight horses, some of them 17 hands high, belonging to Carver & Co., carriers, in Newcastle, to the Trafalgar station.

**ASSOCIATION OF FOREMEN ENGINEERS.**—At the meeting of this Society, held on Saturday, the 4th inst., at their rooms in the city, Mr. Newton was re-elected chairman for the ensuing year. Several new members, honorary and ordinary, were afterwards elected. A "rate in aid" of the library fund of the society, which it seemed, was at a low ebb, was put and carried, and a Library and Printing Committee nominated. The announcement of a paper, to be read by Mr. Robertson, on the History of the Iron Trade, at the meeting on the 3rd proximo, closed the proceedings.

**LONDON SHOE-BLACK SOCIETIES.**—At the annual treat of the boys of the various shoe-black societies of the metropolis, held on Monday evening, Mr. G. Oliphant said, that the boys of the shoe-black brigade had earned such a sum of money during the past year as would astonish the public. The Ragged School Shoe-black Society, consisting of 60 boys, in red uniform, had earned 1,746l.; the East London Shoe-black Society (blue), 104,—1,094l.; South London Shoe-black Society (yellow), 40,—669l.; North-West London Shoe-black Society (white), 16,—140l.; West Kent Shoe-black Society (green), 13,—120l.; West London Shoe-black Society (purple), 15,—216l.; Islington Shoe-black Society (brown, red facings), 26,—210l.; Notting-hill Shoe-black Society (blue, red facings), 26,—200l.; Union Jack (Linehouse) Shoe-black Society (red, blue facings), 18,—133l.; making a total of 318 boys, and the earnings 4,548l.

**THE STRIKE AND COUNCILS OF CONCILIATION.**—A public meeting, numerously attended by operatives of various trades, has been held in the Town-hall, Macclesfield, the object being "to devise means of raising subscriptions in aid of the London lock-outs, and to adopt Mr. McKinnon's Bill on Boards of Conciliation, so as to prevent such calamitous lock-outs in future." Mr. John Baneroff, weaver, occupied the chair, and besides the Rev. E. A. Verity, "Honorary Advocate of the London Lock-outs," there were on the platform several working men representing different trades. Mr. J. H. Patching, Advocate from the Builders' Conference, London, gave an outline of the history of the builders' strike in London; and resolutions were unanimously agreed to in support of the operatives out of employment on account of the strike, and also in favour of Councils of Conciliation, as desired to be established under Mr. McKinnon's parliamentary bill.

**DRAINAGE AND DRYING OF WELLS.**—The new River-Water Company, in making a drain at Hertford, happened to withdraw the water from some wells there, and the local magistrate found them liable in damages to one person to the extent of 27. 16s. Against this decision the Company appealed to the Court of Queen's Bench, who have quashed the magistrate's order, but without costs, holding that no action would lie, as "the company must be considered, under their Act of Parliament, in the light of owners of the adjoining soil," whether as regards the interception of water before it reached the respondents' well, or its abstraction after it was collected there. The decision, according to the *Herts Mercury*, imposes the necessity of sinking their wells deeper at their own cost, upon a large proportion, of the townspeople of Hertford.

**PURIFICATION OF THE THAMES.**—A proposal for the purification of the Thames has been communicated to the French Academy of Sciences by M. Grimaud, of Caux. M. Grimaud's proposal is to make two sewers parallel to the river's course, down to the point where the water is perfectly salt. A bar constructed across the Thames above London would bring the sewers in communication with the river, and enable them to be flushed at low water every day. M. Grimaud thinks that a frightful pestilence will one day be the consequence of sanitary neglect in London, as the city is built exactly where the stream becomes stagnant by its meeting with the water from the sea. He takes his project from the method practised at Venice, which, he asserts, has kept the canal wholesome, although the whole sewage of the city is emptied into them.

**ROYAL LYCEUM THEATRE.**—We have been waiting an opportunity to mention the transformation-scene at the Lyceum, now under the management of Madame Celeste, one of the few managers who has the art of improving actors. It involves a looking-glass lake amid a grove of ferns, and is singularly artistic and beautiful. Mr. William Calcott is the artist who produced it. "The Tale of Two Cities," whatever it may have been on the first night, is now an effective and interesting piece, exceedingly well acted by Madame Celeste, Mr. James Vining, Mr. Villiers (a promising artist), Mr. Walter Lacy, Mr. Rouse, and Miss Saville.

**WIDENING THE HOLBORN END OF CHANCEY-LANE.**—A new opportunity, occasioned by a fire, it seems, has occurred for the widening of this thoroughfare, which has long been a desideratum; and Mr. J. R. Taylor is again endeavouring to effect the object in view, by presentation of a petition, through Lord Brougham, to the House of Lords. Considering the great improvement such a widening as is required would confer on the locality, owners of property in the lane, including the Society of Lincoln's-inn, Lord Radnor, and others, ought to do something in the matter in the first place, and the Metropolitan Board of Works might then be called upon to assist; but we suspect that an application to the House of Lords is beginning at the wrong end. There is great need of the improvement in question, as Chancery-lane is a constant omnibus and cab route, and vehicles and their drivers are continually coming into conflict and obstructing each other at the Holborn end of the lane.

**ARCHITECTURAL CONVERSAZIONE AT WORCESTER.**—A gathering of the members of the Worcester Diocesan Architectural Society and their friends took place last week at Sansome Lodge, where a suite of convenient rooms has been placed at the use of the society for similar meetings, by Mr. A. J. Hopkins and Mr. J. S. Walker. This was the first of a series. About forty persons were present. Mr. Walker, one of the honorary secretaries of the society, explained that the intention of these meetings was, to bring the members of the society and their friends together for the discussion of architectural and antiquarian subjects, not so much by formal papers as by conversation. The Rev. J. D. Collis, however, read a paper "On the Styles of Gothic Architecture," and afterwards Mr. Walker pointed out the principal examples of the various styles to be found in the district. The company then devoted their attention to the various objects of interest, such as architectural drawings, photographs, &c. Next they took tea and coffee, and the chairman read a paper "On Block-printing." Some conversation followed; and the meeting broke up.

**BITUMENIZED "PAPER" PIPES.**—The ingenious idea of hardening paper by means of an admixture of bitumen under the influence of hydraulic pressure, so as to convert it into a substitute for iron, is due, it appears, to M. Jaloureau, of Paris. The world has already become familiar with the utility and value of *papier maché* as a substitute for stone or marble in moulding, architectural castings, busts, and statues: it has also heard recently that the Chinese constructed their cannon of prepared paper lined with copper, and that they even make paper pipes,—that an eccentric character at Norwood has built himself a house of paper,—and that our American friends have invented a veritable paper brick;—but nothing, it is believed, has lately come before the British public, in the way of paper, so curious, and yet practicable, as these bituminous paper pipes. Testing experiments, conducted under the great clock-tower at the Houses of Parliament, are reported to have "proved that the material, while it possessed all the tenacity of iron, with one half its specific gravity, had double the strength of stoneware tubes, without, moreover, being liable to breakage, as in the case of other material, and which frequently causes a loss to the contractor of some 20 or 25 per cent. on the supply." In order to test their strength, two of these bituminous paper pipes of 5-inch bore and half-an-inch thick were subjected to hydraulic power, and they are said to have sustained, without breaking or bursting, a pressure of 220lbs. to the square inch, or equivalent to 506 feet head of water. The cost of the pipes is understood to be about one-half the cost of iron. Specimens of pipes employed in the transmission of gas at the Palace des Invalides during the last eighteen months were exhibited by Messrs. Joske & Young, the proprietors.

**PUBLIC IMPROVEMENTS.**—A bill has been brought into Parliament by Mr. Slaney, and read a first time, the object being to enable a majority of two-thirds of the ratepayers of any parish or district, duly assembled, to rate their general district in aid of public improvements for general benefit within their district, a certain proportion being before raised by donations and inscriptions. The bill would be permissive and enabling, and only where two-thirds of the inhabitants thought a particular object desirable, and half the calculated expense was subscribed.

**DANGERS OF ARTISTS.**—It may be as well to say, with reference to Mr. Papworth's observations, that the narrow escape of an artist alluded to in the paper, headed "An Eminent Architect," referred to Sir James Thornhill, some time Sergeant Painter to the King, and father-in-law to Hogarth. The same escape has been attributed to the same painter while employed in decorating the dome of St. Paul's Cathedral: it would equally illustrate the position taken in the article. The statement of the frequent loss of life from false steps on a scaffold is corroborated in the paper read by Mr. Barry, on Monday evening, at the Royal Institute of British Architects, and which we print elsewhere.

**THE NORWICH SURVEYORSHIP.**—Mr. E. E. Benest having tendered his resignation, which has been accepted, the town council have resolved to advertise for a new surveyor and architect, according to a recommendation of their city committee, "that the person to be appointed to such office should be required to perform the entire work of the corporation, including that connected with the Board of Health and Burials Board, and he alone responsible for the due performance of all such work. That the salary should be 350*l.* per annum, and that the person receiving the appointment should not be restricted from taking private practice, provided the same does not interfere with the duties of his office under the corporation, or prevent such duties from being efficiently performed."

**THE CHELMSFORD TOWN SEWAGE.**—The surveyor to the Local Board of Health reported recently, that the Messrs. Marriage had expressed their willingness to take the sewage, the board laying down all the pipes, sluices, &c., and pumping the sewage to any spot required, to a height of not less than 55 feet or 60 feet; Messrs Marriage to pay 5 per cent. on the outlay, and such annual rent as should be agreed upon; the lessees to take up the pipes in the event of their quitting their occupation, in which case the rent was to cease. The sanitary committee had decided that this proposition could not be entertained, but directed the surveyor to intimate to Messrs. Marriage that they would be willing to entertain any reasonable proposition which did not require them to pump to a greater height than at present. Messrs. Marriage had declined to treat with the Board under that limitation, but the surveyor had since had another proposal from these gentlemen, who were willing to pay 11 per cent. on the outlay, and 5*l.* per annum towards the expense of pumping, in addition to a rent of 30*l.* The surveyor added, that for this arrangement they would require a second engine, but not a second establishment. He suggested that the matter be referred to the sanitary committee, which was agreed to.

**PROVISION FORCING.**—In the "good old days," which some like to talk about, and compare with the present, there was but a very limited supply of vegetables, and even fruits. In those times, in some measure in consequence of the scarcity of those supplies, leprosy, and some other diseases, prevailed. Each year improved skill caused the early and late production of these edibles. To these accustomed to the old fashion of gardening, a visit to some of the nursery-grounds which skirt London surprises. Here, in the midst of the winter snow, rhubarb and other plants may be seen struggling towards perfection by the aid of varietal glass-frames and the extensive use of various kinds of manure. In the same scientific manner, geese, turkeys, and chickens, are raised for the markets. In such establishments these feathered tribes are not permitted to roam in the stubble-fields and meadows, but are lodged together in crowds, and supplied by a regular system with food. By this means, in a short space of time, the birds grow to a large size. Poultry, in fact, is manufactured, so much corn or other food being allowed to produce so many pounds of goose or turkey, and allow profit. Large as is the increase of the quantity of provisions and vegetables by this system of forcing, it is a question if the flavour and quality are improved by the process.

**ROMAN ANTIQUITIES DISCOVERED IN FRANCE.**—At Vienne (Isère), a fine Roman mosaic has just been found. It is in a dining-saloon or triclinium, about 20 feet wide by nearly 35 feet long, forming part of a Roman habitation recently discovered. The whole is divided into compartments, some octagon and some square, separated by coloured bands. The whole mosaic, which is surrounded by a white and black border, is decorated with figures representing Orpheus charming animals with his lyre; a design of which there are several examples in this country.

**METROPOLITAN BOARD OF WORKS: TENDERS FOR SOUTHERN SEWER.**—At a meeting of the Board, on the 3rd instant, it was ordered that, in consequence of Mr. Rowland Brotherhood having declined to proceed with his tender for the southern outfall sewer, fresh tenders for the work should be invited, to be received in a month. Mr. Leslie gave notice of his intention, on an early day, to call attention to the section of the Metropolis Local Management Act which related to members of the Board interested in any contract executed for the Board, or who should act as a member of the Board after ceasing to be such member. A notice respecting the widening of the upper end of Chancery-lane was given.

**NEW SCHOOLS AT HASLINGTON, NEAR CREWE, CHESHIRE.**—On Wednesday, February 1st, St. Matthew's Schools, Haslington, near Crewe, were opened after Divine service in the church. Three hundred and fifty persons, chiefly parishioners, took tea in the new schools, and the meeting was addressed by the Rev. J. Bardsley and other clergymen. The Rev. Charles White is the incumbent of Haslington, to whom the greatest thanks are due for his strenuous exertions in founding and establishing the schools, which are so greatly needed. Mr. James K. Colling, of London, was the architect, and Mr. John Buckley, of Davenham, Cheshire, the builder. The amount of the contract was 1,080*l.*

**THE HOLME RESERVOIRS AT HOLMFIRTH.**—In his yearly report, Mr. Bateman, the engineer employed by the directors of these reservoirs, says,—"At the Holme Styes Reservoir I am sorry to say that the repairs which were alluded to in my last report have not been as effective as was anticipated. There is evidently still some defect in the puddle lining, and the water must be again drawn down for repairs. It was expected for examination in June. The puddle lining was found to have failed in several places. It was made good as was supposed, and the reservoir filled, being full and overflowing by November. It is not yet, however, perfect. The Bilberry reservoir remains in the same state, gradually getting better, but occasionally failing and requiring repair."

**THE DRINKING-FOUNTAIN MOVEMENT.**—At Pontypool, a fountain has been erected, near the Town-hill, and thrown open for the use of the public. The design was by Mr. R. G. Thomas, architect, Newport, and executed by Messrs. A. & J. James, of that town. The base is composed of Forest of Dean stone, decorated with rusticated work; the buttresses of serpentine marble, forming pillars, the caps carved, and the termination of the buttresses consist of Bath stone, carved on angles. The basin of light marble into which the water flows is carved as a shell, and supported by an ornamental corbel. The water runs from a bunch of flowers, and passes through a water lily of statuary marble. This is surrounded by a niche of birds and foliage, geranium leaves and blossoms, the termination of the label over the niche representing maple and oak, a dog being entwined in the former, and a stag in the latter. The urns, crest, and motto of C. H. Leigh, esq., are also carved in statuary marble, surmounted by a hand with the inscription,—"Presented by Mrs. C. H. Leigh, 1850." The hood mould is made of Bath stone, the top forming a *fleur-de-lis*. The drinking cups are of iron, enamelled, and chained. The water passes into a stone trough, accessible to canine and other quadrupeds.—"There has risen up in Newcastle, says the *Gateshead Observer*, in the square of St. Nicholas, a drinking-fountain, summit of that a monster lamp, crested by a Grecian temple! As a work of art, it is a most absurd production, and may well justify a stranger in asking, "Is there no School of Design in Newcastle?" Surely, if a site between the old church of St. Nicholas and the new town-hall was to be occupied by a lamp and fountain, care should have been taken to secure, from some architect or artist, a suitable design. The present "composite candlestick" excites the amazement of passers-by. Cannot the water of the fountain be made to play over the temple, and veil the incongruous superstructure?"

**VALUE OF LAND: CROYDON.**—When arrangements were being made last year between the London, Brighton, and South Coast Railway Company and the Mid Kent Railway Company, and the former agreed to erect a junction station at Norwood for the reception of the Kent traffic, the Brighton Company, through their surveyor, Mr. F. Fuller, purchased the land for the purpose, and having no Act of Parliament to compel the landowners to sell, were in a great measure at their mercy, and as a consequence had to purchase seven acres more land than the Company required, at the rate of 500*l.* per acre. These seven acres were sold by auction, by Messrs Fuller, on the 26th of January last, at the Mart and realised no less a price than 830*l.* 10*s.* per acre.

**NEWSPAPER ADDRESSING MACHINE.**—An American invention, patented by the Rev. James Spencer, editor of the Toronto *Christian Guardian*, for the facilitation of the tedious process of addressing newspapers at the publishing offices, is described in the Cincinnati *Scientific Artisan*. It is called a "mailing machine." By means of this invention, it is said, a youth of fourteen or fifteen can address 5,000 papers in two hours and a half whereas, to address so many by hand, it is said one clerk would take forty hours, or four clerks ten hours. By the machine, the addresses are printed directly on the newspaper, or on the wrapper.

**GLASS, Newport (Isle of Wight).**—Two sections, forming part of the great window proposed to be placed in St. Thomas's Church have been forwarded to the churchwardens for inspection, and have been placed in one of the chambers of the Town-hall. They consist of two designs, completed in stained glass, from the original plans of the artist, Mr. Holland, of Warwick. The first, having an arched top, represents the angel appearing to the Virgin Mary, with the Holy Ghost descending on her in the shape of a dove. Underneath the design are the words, "Blessed art thou among women." The subject of the other section, a square one, is "Christ's Entry into Jerusalem on an Ass."

**BUILDING PROGRESS IN LIVERPOOL.**—The annual report of Mr. Rishton, the building surveyor, states that the number of dwellings erected, or in course of erection, during the past year, was 1,758, or 41 more than in the previous year,—considerably more than in any other similar period for the last twelve years, and about four times as many as were erected in 1849 and 1850 respectively. Many of these houses do not exceed the means of the working classes, and are constructed so as to accommodate lodgers without interfering with domestic privacy. In some instances houses have been built with two street-doors to each, on the level of the ground; one door leading to the apartments on the ground-floor, the other by a flight of steps to the apartments above; each having its own separate yard, privy, or water-closet. The tenants who occupy such houses have good accommodation at less cost than those who occupy the old, badly-built houses, destitute of every sanitary requirement. The evils arising from reckless and incompetent persons building houses on refuse deposited on excavated land still continues. The probable cost of the building operations within the borough during the year amounts to a sum exceeding 528,000*l.*, irrespective of the value of the land. Taking the new houses for the year 1858 in all, as accommodating six persons each, and taking the separate cellar dwellings, 110 in all, as accommodating four persons each, they would represent an additional population of nearly 11,000, whilst the houses pulled down in the same period are less than 120.

TENDERS

For two houses at the corner of the Minorities and Aldgate, for Mr. Isaac Moses. Mr. D. A. Cobbett, architect.

Jay	£2,859 0 0
Rivett	2,823 0 0
Lawley	2,749 0 0
King	2,740 0 0
Hill & Son	2,590 0 0

# The Builder.

VOL. XVIII.—No. 589.

The Royal Mint, Tower Hill.

ATELY we gave a few particulars of the mode adopted in "milling" money, and, as these seem to have interested some of our readers, we are led to enlarge a little on the arrangements of the national money-making establishment generally.

A squalid part of London must be threaded to reach the Mint. It is but a short distance from the Tower, and formerly was within the Tower walls, where "Mint-street" serves as a record. The present building, plain and substantial, was commenced from the designs of Mr. Johnson, and completed under Sir Robert Smirke. Soldiers and policemen guard the entrance to the court-yard in front,

and these defences are readily passed on the production of an order of admission from the "master."

After crossing the court-yard, the visitor is introduced into a large unadorned hall, and hence passes to an open quadrangle of considerable area, paved and laid with several lines of railway, which are used to convey the precious metals to and from the various offices. In the buildings which surround this square are the various apartments wherein the processes of coining are carried forward. The noise and whirl of steam machinery and a heavy, rapid, thumping noise attract attention, and the visitor is taken under intelligent guidance to the melting-room, where a range of furnaces glow with a clear, bright light. Into some of these stalwart workmen are placing crucibles, charged, some with bars of gold, others with scraps of thin plates, perforated with circular holes: other furnaces are already charged, and the gold-melting is going actively forward. With great accuracy the metal has been made of the proper standard, so that a portion of a certain size and thickness may, when coined, have its right value and exact gauge and weight. Attached to the furnaces are lifts, which enable the casters to convey the molten gold from the glowing and roaring furnaces to the iron mould in which the precious material is cast into bars of about 2 feet in length, about 1 inch in thickness, and 2 inches broad. The mould, as it stands ready for the operation of casting, consists of several upright frames, which have somewhat the appearance of the smaller barrels of church organs: these are so constructed that when the metal has been poured into the proper space and cooled, the mould can be made to fall to pieces, and the bars be readily taken out. The mould can then be fixed together again for further use.

By long experience the casters judge when the gold has become of a proper heat and consistency. And by means of a peculiar instrument a moulded ueek is then taken from the crucible. This has been placed there for the purpose of allowing the fire to be piled to a certain height above the crucibles, which are made with very great care, of plumbago and clay. With great nicety the crucible, which is not bigger than a man's head, is brought and

emptied into the moulds. The gold sparkles and hisses, and with rapidity aperture after aperture is filled. One of these crucibles, when properly charged, although not full, and small as it is in size, contains 5,000 pounds worth of the metal.

The gold bar, when released from the mould, is of a dull dead yellow colour, and each bar of the size above mentioned is worth, say 2,000*l.* each; for there is a little variation in weight. In order to make it certain that the quality of the gold is of the standard value, each bar is marked and numbered; and then four or five portions are cut from various parts of the bar, each of which is sent to a different assayer, who, after testing the purity of the gold in the usual way, reports upon the matter. If all the reports agree, and provided the metal is up to the standard, the bar is passed for use.

It is then conveyed to the rolling-room, in which are a number of machines: with these the gold bars are gradually thinned and lengthened. This process has also the effect of making the metal more solid, and preventing cracks or flaws. With the greatest precision, very slowly but surely, the bars are brought to the exact thickness of a sovereign or half-sovereign, and of such a width as will allow of the diameter of two sovereigns being struck out. These long bars of gold are trimmed and adjusted by steam machinery. One instrument, which works slowly but with a terribly strong mouth, trims and shears: another cuts out the unstamped sovereigns in rapid succession, as the bar is passed along.

It is now seen that the shavings of gold which we had noticed in the melting-room for the purpose of fresh melting, are the remains of the bars after the circles for coining have been stamped out. After the "blanks" are cut out, by means of a machine of rare quality and power, the edge of each is raised. Before this the sovereigns are singularly like the bright brass buttons formerly worn on men's coats. The golden circles are, as regards form, ready now for the finishing process of milling and stamping. There is, however, much to be attended to before this is done. The future sovereigns have to be put into the annealing furnace; and, in order to effect this, they are placed in rows on their edge between thick metal plates, which are fastened together, and then all openings are fastened with clay. These cases, which contain gold to the value of 12,000*l.* or 13,000*l.*, are then placed in furnaces, which are highly heated. After remaining here from thirty to forty minutes, according to the heat of the furnace, the hot gold is dashed into cold water; thence it is removed to a vessel containing diluted sulphuric acid; then it is dashed into hot water; then it is dried in a large heated iron trough, partly filled with dry hot sawdust; next they are put into a perforated cylinder, which is caused to revolve in a heated oven: and by these various processes the gold is properly tempered, and all impurity is removed from the surface.

Now the gold is taken to an apartment in which each piece is weighed and sounded for the purpose of detecting any cracked or imperfect specimens. In this room, and in some of the others here, there is an unceasing ring of falling gold. In one place the workmen are throwing with great rapidity the metal upon small steel anvils; the least defect is readily heard, and those displaying it are sent again to the melting-pot. All the golden circles which pass this last examination are weighed by eight machines, so delicate and beautiful that it is difficult without the aid of illustrations to give an idea of their construction. It must therefore suffice to mention that long rows of sovereigns are placed edgeways in a groove, which is arranged at such a gradient that it allows one piece at a time to fall on a balance. Here it remains an instant, as if to give the machine time to consider of its quality. Then the piece of gold is dropped into one of three drawers placed below, one marked *heavy*, another *medium*, and a third *light*. With the most certain exactness each of these instruments weighs and disposes of the intended coins, at the rate of about twenty a minute. The *medium* and *heavy* gold is next

passed to the coining-room, and the light is sent back to the furnace. One hundred and fifty thousand sovereigns can be prepared and coined in one day at the Royal Mint. Before going to the coining-room, it is worth while to see the department in which the dies are prepared.

All the dies for gold, silver, or copper are cut within the walls of the Mint, and these are required not only for Great Britain, but also for India, Australia, and other colonies. It may be necessary to mention that the original die for each description of money is cut in steel, which for the convenience of the artist is tempered to a certain degree of softness. When the work is done, it is hardened, and is used to transfer the impression by means of great pressure on to softened steel, and thus to obtain the requisite number of dies. For this purpose there is a press of tremendous power. In front of this a circular piece of steel, of about the size and something of the shape of a little boy's whipping-top, is fixed. The original hardened die is brought into use, and after five or six heavy blows, the required impression is made. Several of these are needed, for sometimes this important part of the coining process gets unfit for use in a very short time. After leaving the press just referred to, the impressions are cleaned and touched where necessary; then the die-turner polishes them off, and cuts away all superfluity; and after hardening, the die is fit for its position in the coining apparatus. Here we saw dies for gold, and silver, and copper money; dies for Calcutta and other distant places, to be used at the mints established there; \* little dies for marking the Queen's "Maundy money," which consists of 1, 2, 3, and 4 penny pieces. Wonderful order reigns in every part, as it need do, remembering the vast quantities of bullion which are passed through the various departments and courses of manufacture, in order that no loss may take place nor mistakes be made. We proceed through carefully-locked doors towards the coining-presses. At each step onward the sound becomes more deafening. In the coining-room are eight presses, which, by the force of a blow of 40 tons weight, impress the well-loved face of the Queen, the reverse of the coin, and, at the same time, mill the edge of the coin in the way previously described. From each press, the perfect sovereigns are thrown off at the rate of sixty-four in the minute. At this rate, supposing that all the presses could be kept working, a stream of 30,720 sovereigns would run out in an hour. Each batch of coins is assayed by the Queen's assayer. One coin of each kind is then placed in a pix or basket, secured with three locks and three seals, and this is given to a jury to compare with the trial-plates, preserved in the Chamber of the Pix at Westminster, of which our readers have heard.

Returning by some of the streets behind the Minories, the wretched abodes of half-starved inmates come into contrast with the running stream of gold we have left behind, and suggest matter for reflection.

## THE METROPOLITAN MAIN-DRAINAGE: THE DEPTFORD PUMPING STATION AND MACHINERY.

THE progress of the metropolitan sewerage has been met by obstacles of a character almost impossible to be provided against: it is, however, much greater than is commonly supposed. Certain opinions at one time, as to the effects of the strike in the building trades on the progress of the Northern High-level Sewer, obtained credence; but the issue at present is not what was apprehended; and, although difficulties have occurred in letting works on the south side of the Thames, which in the case of the Outfall Sewer have been thought to render necessary a fresh call for tenders, there is every prospect that within a period much earlier than was predicted by some persons, the system devised as a whole, for London, will be undergoing partially the best of use. Let us hope that whatever fears may have been expressed, whether as to results of the subtraction of water from the volume of the Thames above bridge, the substitution merely of other channels and vomitories

\* The chief part of the copper coin is made at Birmingham, but the dies are supplied from Tower-hill.

of misance for the present outfalls and the river, or other imputed errors in the scheme, may be discovered to have been without reason. We have already spoken of the intention which there is, of trying the efficacy of the furnace system of ventilation at the pumping stations. We have not yet the means of judging how far this method, which is said to have succeeded in the provinces, and has, on the other hand, been considered inapplicable where there are numerous inlets, will answer for sewers several miles in length; but we may shortly have it in our power to give particulars of arrangements intended to be subservient to the object, in addition to some which will fall within the scope of the machinery and contrivances of which we are now about to offer information.

Whatever the progress of the sewerage, assiduity and care on the part of the engineering staff, in the preparation of the drawings and specifications, and in superintendence of the works, are not wanting, and we have, therefore, been able to give our readers the detailed particulars of the intended course and construction of the principal sewers, north and south of the Thames, including some which have not yet been tendered for. In these particulars, as well as in the general account of the whole scheme at the beginning of our last volume, it will have been made sufficiently clear how much of the success of the general undertaking must be dependent upon the design and execution of the pumping machinery needed for the elevation of the sewage of the extensive low-lying districts, each side of the Thames,—and for that indeed of the whole sewage of the south side, at least at the point of outfall below Woolwich. With the exception of the ease last alluded to, the pumping machinery at the station on the Lea, north side, and by Deptford Creek, south side, is simply for the elevation of the low-level sewage to the high-level, or that of the outfall sewers. In these cases, however, the volume of liquid to be raised is enormous, even considering that the high-level lines will intercept the great body of water now finding its way to the Thames across these low-levels, or which has been, on occasion of storms concurrent with the time of high-water, stored up for some hours in the sewers, to the inconvenience and injury of the residents in those districts. The construction of the high-level sewers, prior to that of the low-level sewers, was necessary or desirable in an engineering point of view; and, being itself calculated to afford great relief to the residents in the low-levels, the clamour at one time against the postponement of the low-level sewers, raised on the ground that these last were most wanted, was not justified.

The liquid to be raised from these low levels, is not merely to be considered as large in quantity; but it may be, from the character of those districts, sewage in the most concentrated form,—and of course more so after the upland waters have been intercepted, than at present. The existing sewers and outlets, however, will be available, it is expected, in most cases, for dilution or flushing with water from the river. Even anticipating that there will be such dilution, before deciding upon the description of contrivance at the pumping stations, it is not altogether unnecessary to take into account the habits of the people who reside in many parts of the districts, the indescribable "rotton and jetsam" which have to float or be deposited, and the liability which ensues, of obstructions to the working of pumps. Considerations of this latter nature, drawn from the known condition, as at present, of sewers which appear to be not unfavourably situated, have, as we shall see in the sequel, led to predictions of the failure of all machinery in which there are valves. We can scarcely suppose that these risks have not been very carefully estimated by Mr. Bazalgette, and disposed of, in his mind, in favour of the ordinary principle of the "lift-and-force" pump which he intends adopting; indeed, he has, by designing the foot or base of each of his pump-cylinders, as a fender-plate, provided the means of stopping access to the valves of such obstructive matters in the sewage, as could not pass through an orifice of about 2 feet 10 inches by 9 inches,—an area, however, which is larger than that of each of his valves: but considering the immense importance of the question, we shall do right to allude to views which have been held by others. First of all, we will describe the arrangements as they appear from drawings and a specification which have been prepared for the Deptford pumping machinery, and from information which we have been able to gather in various ways.

The drawings are not, to ourselves, quite so ex-

planatory as those which we have had previously to examine,—partly because we here anticipate the completion of the specification for one portion of the work,—that which is structural, or not belonging to the department of mechanical engineering, and consisting of the engine-houses themselves, and the boiler-house, the chimney, and the sewers in their course joining to the machinery,—and partly, perhaps, because in the details of the machinery there is much alluded to only, for which the contractors are to submit drawings. The drawings now before us, show the buildings as well as the machinery in them; but the specification refers to the machinery only. Besides the omissions last alluded to in details of the machinery, there are others which might not have been noticeable had the specifications for the whole of the work been before us, or written explanation upon the drawings been less sparingly given than it is. We can gather enough, however, from the various sources of information, to afford matter which may interest our readers. The machinery is to be completed to the satisfaction of the engineer of the Metropolitan Board; and the drawings have doubtless been prepared in great measure under his supervision; but it would not be fair, should defects occur, to impute all those of the steam-engines, or even pumping machinery, should such there be, to a civil engineer, especially as Mr. Bazalgette informed the Board, some time since, that the designing of such machinery was not his "specialty."

The contract for mechanical engineering work of the Deptford pumping station, is to include four steam-engines and ten boilers, eight single-acting force-pumps for the sewage, and two large wrought-iron delivery troughs, four vacuum vessels for the cold pumps, two air-vessels for the feed-pumps, and other articles described. The arrangement of the engines and pumps may be best understood by the aid of a description of the buildings in which the machinery is contained.

The pumping station is intended to be fixed in ground by Deptford-creek, and on the eastern bank, immediately adjoining the Greenwich line of railway. The spot is nearer to the Thames, by perhaps a furlong, than that where, on the opposite side of the Creek, is the temporary outfall, or storm-water outfall, now in course of construction, of the High-level Sewer. It will be recollected that there is a length of the intended Outfall Sewer, amounting to about a quarter of a mile, and extending from the commencement of Church-street, Deptford, to North Pole-lane, which has not yet been made the subject of any contract, or advertisement for tenders; though this length will eventually be required as part of the line of the Outfall Sewer, which last is one with the line of the "high-level," from which, at Church-street, the temporary outfall, as before named, branches off. The pumping station will be close to North Pole-lane, or near to the point of commencement of the length which was the subject of the last tenders, and those last advertised for. At this point, the invert of the Outfall Sewer is shown on the drawings, which we described in our last volume,\* as 13 feet 6 inches below Trinity high-water mark. To that level the low-level sewage has to be raised, or a height of 17 feet from the other. The sewage actually will be raised from two channels divergent from the Low-level Sewer, into sewer-troughs, spoken of as part of the present required contract; and thence the lines will converge into the one line of the Outfall Sewer. The troughs are at the distance of 136 feet 3 inches from centre to centre, apart, as shown on the drawings; each trough being in length 51 feet, somewhat less than the length of the engine-house in which it is placed, and just below the ground-level, in a central position, between sewage pumps, which are two on one side of it and two on the other. Each pair of pumps is worked by an engine above. The low-level sewage having passed under the Creek, will be received into a large space, which may be called the basement story of the engine-house, in which the four pumps are fixed on supports of two iron girders built into the brickwork of the flooring. Each pump will be cast in three pieces, and be single-acting, cast-iron plunger of 7 feet diameter and 4 feet 6 inches stroke; also a short wrought-iron plunger into a socket formed at the lower end of the plunger, and shall be attached at the top to a strong wrought or cast iron (and if the latter, feathered) pump-rod, which pump-rod shall be attached at the head to the cross-gudgeon of the

back-link of the outer and inner end parallel motions respectively,—that is to say, the pump rods will be worked by the beam of the engine, the sewage-pumps occupying the positions of the air-pump, cold-pump, and feed-pump, in most steam-engines; whilst for those latter parts of each engine, space is provided beyond the cylinder and a counter-beam for their working will be provided, tailed to a vibrating pillar fixed in the end wall of the engine-house, and connected at the other end to the cap-gudgeon of the piston-rod, proper parallel motion being attached for the air-pump, guided by radius rods connected to the lower gudgeon of the vibratory pillar.

The machinery is designed to elevate the sewage-water to a total height of 20 feet. The quantity to be raised in twenty-four hours, dry weather, is estimated at 3,400,000 cubic feet; but for six or eight hours of the time, the estimate is that 4,720 cubic feet per minute must be raised, the quantity decreasing gradually to 1,000 cubic feet per minute. The machinery, however, is provided with the view of meeting all emergencies, such as those of excessive rain-fall, when all direct outlets to the river might happen to be closed by the tide; and in these cases the amount calculated to be raised is 10,900 cubic feet per minute. The nominal horse-power of the engines will be that, for each, of 125 horses, or for all, that of 500 horses; and these engines are to be of not less strength than equivalent to at least ten times the maximum pressure (estimated at 35 tons), of the steam on the piston, being intended to work expansively with a pressure on the boilers of about 25 lbs. per square inch above the pressure of the atmosphere. They will be of the kind known as Watt's double-powered rotative expansive horse-engines,\* and will have cylinders of 48 inches diameter, and 9 feet stroke, and beams of not less than 60 inches deep in the centre (where they are supported by an cast-iron column and six iron columns and arches, across the engine-house), the distance from the centre of the beam to the line of the cylinders, and to the centre line of the cranks for the motion of the fly-wheel, being in each case 15 feet 9 inches; whilst the distance to the centre line of each sewage pump is one half, or 7 feet 10½ inches. The fly-wheels of the four engines will be each 27 feet in diameter, and will be of unusual weight, having rims 13 inches deep and 9 inches wide, to provide for the passage of the dead-points with facility when the engines are working at a slow speed. There is a parallel-motion, it will be understood, at each end of the beam, in order to work the sewage pumps. Many details of the engines are specified,—though necessarily, so as to confine much to the contract; but into these we will not enter much further. The air-pumps and condensers are to be respectively, of 32 inches diameter, or thereabout, placed in iron cisterns, and fitted with hot wells and other requisites; the cold pumps are to be each of 18 inches diameter and 27 inches stroke, drawing from a vacuum vessel of 18-inch diameter, and 9½ feet high, to which an 18-inch suction-pipe, of 200 yards long, with hinging valves and wind-bore piece, is to be attached; and the feed-pumps are to have each a solid cast-iron plunger of 6 inches diameter, and 27 inches stroke, each pair of pumps to be united to an air vessel 2 feet diameter, and 5 feet 6 inches high, to which will be attached a 7-inch feed-pipe leading to the boilers, with 3-inch branches entering below the bottoms thereof. In lieu of the feed-pumps, or in addition thereto, the engineer may require for each boiler, one of Giffard's self-acting water-injections.

Each engine-house will measure in the clear of the walls 59 feet 3 inches by 38 feet 9 inches, and will be about 35 feet in height of the walls, from the main floor line. The walls will be 3 feet thick, strengthened at intervals by pillars of half-brick projection. Below the floor line, to the bottom of the footings, which will be a mass of brickwork from 5 to 8 feet in vertical thickness, will be a depth of 43 feet 6 inches; in which the external walls will be 4 feet 11 inch, and there will be cross walls or piers, of 5 or 7 feet thick, where needed for the support of the several parts of the machinery, the cross walls having arched openings in them where required for the flow of the sewage from one part of the basement to another, and for the passage of the iron sewer-trough of the upper level. The two engine-houses will be distant from one another 91 feet 6 inches; the interval being occupied by the boiler-house, appearing as one story in height, with the chimney rising from the ground, a height of 150 feet, at the back of it. The decorative character of the buildings, which are to be brick, with Italian dressings in stone, might certainly be improved.

The chimney, as shown, is an elongated Roman Doric column on a pedestal. A capping which would be more effective at the height, and would not give the resemblance to the column, which is now objectionable, might be designed, so that the result would be something having a distinctive character as a chimney, and one every way agreeable to the eye. The buildings will be covered with light iron roofs, which will be surmounted externally with ventilators; the stone cills and ornices will tail through the full thickness of the wall; and the work in all respects is intended to be of the most durable description. The conductor for the machinery is to fix wrought-iron strengthening beams for raising the machinery. The chimney, 18 feet square at the base in the external dimensions, will be 8 feet 6 inches in the clear at the base of the circular shaft, and 6 feet at the top, the brickwork in the shaft being 1 foot 3 inches, 1 foot 6 inches, and 1 foot 13 inch. The boiler-house will measure in the clear, 1 foot 6 inches by 51 feet; and the internal height from the floor line to the top of the walls which last, or the front and back walls, will be 6 feet 6 inches in thickness, exclusive of the cast-iron plates. The boilers, ten in number, will be cylindrical single-flued boilers, 9 feet in length and 6 feet in diameter—the diameter in diameter. The plates of the shell, the best Staffordshire or other esteemed iron, are to be  $\frac{3}{8}$  inch thick; and the tube and furnace plates, of guaranteed Low Moor iron, are to be, the former,  $\frac{3}{8}$  inch thick, and the latter,  $\frac{1}{2}$  inch thick. Not fewer than seven  $\frac{3}{8}$ -inch rivets are to be placed in a foot of the seams, which are to be soundly caulked. Extending, together, across the whole range of boilers, there are to be two beam chests 3 feet diameter, made of plates  $\frac{3}{8}$  inch thick; and these are to communicate with the boilers by lateral pipes connected to the stop-valve boxes or steam jugs; whilst upon the chests will be fixed two steam-pipes of 18 inches diameter, each dividing into two branches leading to the furnaces. Many details of the boiler-apparatus and fireplaces are merely named in the specification. Attention has, we believe, been given to economizing of fuel; and it is to be hoped that the same attention will be paid to the prevention of smoke nuisance. The double-flued arrangement, sometimes considered advantageous for the object last mentioned, possibly has been considered from recent experience to involve greater chance of accident, than that of single flues which is to be adopted.

To complete the description of the machinery, it is necessary to examine into the arrangement of the valves of the sewage pumps, upon which we have said so much depends. In each pump, the valves of suction and delivery are divided, in each case, into a considerable number of valves, which will work at the same time, but independently of one another. Thus the suction-valves may be between thirty and forty in number, distributed over the area of the cylinder or plunger-case, at the height of 11 feet from the base, where the diameter increases to 9 feet,—the seats of these valves being set in one piece, or as a sort of grating in the appearance on a small scale. Each ordinary opening covered by a valve, will measure 1 foot 6 inches by 9 inches; and the valves will be formed of leather  $\frac{3}{8}$  inch thick (which is to be laid in the tan-pit for two years), screwed between two "valve-irons" or plates; the small portion of the valve which serves as the hinge, however, is necessarily, the leather only. The delivery-valve box, of which the lower part of the circular opening is 9 feet 10 inches above the suction-valves, and measures 9 feet 2 inches in the whole inner width, by 3 feet 10 inches in height, is to be fitted on the plunger-case, and fitted with a face-plate for twenty hanging valves to openings which measure 1 foot 7 inches by 8 inches. Care is to be taken in making the valve seats, to have the centres of bolts and size of the openings to correspond with one another, so that they may take up other's places if required. The sewage will be delivered through these valves of the four pumps, directly into the iron trough which is above the floor of the engine-house; each pair of pumps as before described, being worked by an engine; and each engine-house (distant from the other 91 feet 6 inches) containing on different levels, four pumps, one iron trough, and two engines.

The trough placed in the centre of the engine-house, will be 51 feet long as already mentioned, and headed in the cross-section, and with a dividing down the centre; and will be 8 feet in the width, and 11 feet 6 inches in the whole height. It will be formed of  $\frac{3}{8}$ -inch boiler-plate, with angle and strengthening pieces, and cross-ties. There

will be proper man-boles, and removeable plates, to give access to the pump-valves and to the interior of the iron trough. Whether similarly efficient means will be provided for the prevention of obstruction, beyond what we have named in describing the formation of the feet of the pumps, we cannot be fully aware until the drawings for the sewers themselves of the low level are before us. It will, however, have been noticed, that each opening of the valves is, as we said, less in area than the opening at the feet of the pumps through which the sewage will find admission.\*

ON THE RATIONALE OF GOTHIC ARCHITECTURE.

MR. SCOTT'S SECOND LECTURE AT THE ROYAL ACADEMY.

In my last lecture I traced out the rationale of a number of the leading features, both of Romanesque, as distinguished from Roman architecture, and subsequently of Gothic as distinguished from Romanesque. I will endeavour to avoid wearying you by carrying the inquiry into too great a multiplicity of details, but I must, nevertheless, ask your indulgence while I pursue them somewhat further than I have yet done.

Nothing would, perhaps, do more to show the reasonableness of the various developments in question than to trace out the details of the vaulting system; to show the varieties it exhibited in different countries and provinces and at different periods; the various modes adopted for effecting a given purpose, and the many mechanical and other difficulties to be contended with, and the methods adopted of meeting them. This is, however, so extensive and so intricate a subject, that, if I had devoted these two lectures exclusively to it, I could barely have done it justice. I will therefore at present content myself with referring those of you who are anxious to make themselves acquainted with it, to an admirable and elaborate essay on the subject by Professor Willis, in the Transactions of the Institute of British Architects, and to the article "Construction," in the fourth volume of Viollet le Duc's Dictionary. No one who has not gone carefully and practically into the subject can have any idea of the amount of forethought which it demands; so much so that, as Viollet le Duc says, the design for a vaulted building has to be commenced at the top, and worked downwards; and we may often form a pretty correct idea, from the bases of a thirteenth-century church, of what was the plan and construction of its vaulting.

This principle of designing each part from the first with reference to its ultimate intention, is very strongly marked in French work of the twelfth and thirteenth centuries, and in those of the transitional period in England. The form, not only of the capital but even of the base of each shaft, usually indicates the direction of the arch or rib, or other which it is destined to carry.

This was, however, lost in English works on the introduction of the circular abacus, and I must say that much expression and emphasis was lost with it. Not only, indeed, did the abacus in French work face or point in the direction of the arched rib, but its plan was often made to fit to it in the most direct manner, and even the direction of the principal stalks of the foliage had reference to the supported rib.

The system of moulding again follows out the same laws of reason. An arch-moulding, for instance, is founded on what is supposed to be the original section of the order or rib. Thus, if the normal section of the rib be square, the section of the mouldings is made to fit to that figure; if chamfered or a part of an octagon, the mouldings, again, fit to it; the abacus in each case taking the normal plan of the ribs.

As to æsthetical forms, the mouldings were studiously arranged so as to produce in some parts the greatest contrasts, in others the most elegant gradations of light and shade. The heaviness of large roll mouldings was often relieved by fillets or by raised edges or "keels," by which diversity was gained without loss of mass.

Hollows, again, were relieved by the insertion of sparkling ornaments, such as the toothed ornament, the rosette, the ball-flower, the four-leaved flower, and many others; and in other instances by the introduction of hands of foliage. The sections of moulding differed entirely from those of Roman architecture, being far more free and less mechanical, and at once more delicate in feeling, more carefully studied with reference to light and shade. They resembled Greek mouldings, in fact, far more than Roman.

Enriched mouldings differed from the usual practice in antique work in this respect, that the enrichments were added to instead of being cut out of the original moulding; its practical use being to strengthen the hollows rather than to enrich the rounds. In this respect the practice of the Romanesque builder had been different, and perhaps a union of the two systems would be better than a close adherence to either.

Mouldings which receive much rain, as copings, cills, tops of cornices, &c., were very much more sloped than in Classic work, so as to throw off the wet more rapidly. The custom in modern Classic buildings, where the stone is not very hard, of putting lead on the upper surface, as well as the damage often sustained when this is neglected, show the reasonableness of this increased slope. They had to do with a more rainy climate, and generally with softer stone than the ancients, and they designed their work accordingly. The undersides, again, of projecting mouldings, as string-courses, dripstones, water-tables, cills, &c., were carefully designed so as to prevent the wet from running round them. Base moulding round buildings was designed in such a manner as both really and apparently to give it a substantial footing, and at the same time to add greatly to its beauty; many of them are as noble combinations as could easily be conceived.

In short, it may be asserted, without fear of contradiction, that in no style of architecture has a system of moulding been generated so full of variety and so capable of suiting itself to every position, and not only to provide for the practical demands of each position, but to give to each just that kind of effect which it most demanded.

Let us now proceed to consider the window. In the days of ancient Greece, and in the earlier days of Rome, windows were necessarily kept in a very undeveloped form, through the non-existence of window glass; so much so, that in Classic architecture the window seems a thing shunned as an unhappy necessity; and the imperfect manufacture and dearth of this material, no doubt, influenced, in a considerable degree, the architecture of the later Roman and the immediately succeeding periods. In churches, and other vaulted buildings, another cause would lead to the use, during the last-named (*i.e.*, the Romanesque) period, of as small windows as would just answer the purpose. The unaided thickness and the whole length of the wall being relied on for the shutment of the vaulting, it naturally followed that perforations were as much avoided as possible, as tending to reduce the abutting mass. Accordingly, as buttresses increased in projection, greater and greater openings in the curtain wall were ventured on, simply because there was strength sufficient to admit of them; till, when Pointed architecture received its full development, and the pressure of the vaults was entirely concentrated upon the buttresses, the whole intervening space might, if needful, be converted into windows.

Simultaneously with this change, the increasing use of stained glass necessitated a corresponding increase in the area of window opening, so that we have one development facilitating, and the other rendering necessary, the constant enlargement and multiplication of the windows.

The *primæ facie* mode of obtaining increased window-light would be to widen the openings; but as this, if carried too far, would at once injure the beauty of the window, and cause inconvenience in glazing it, the more usual course adopted was to increase their number. Hence the couplets, triplets, and more numerous groups of the early English windows. These groups, when placed in a side-wall and under a level roof-plate, would naturally assume the form of arcades of equal height; but when under a gable, an arched roof, or a vaulted bay, they increased in height towards the centre,—thus giving us the two most familiar forms of grouping. The sections of the jambs were arranged (as in the earlier period) in the manner best suited to the admission of light,—care being taken externally, to avoid deep shadows upon the glass, and internally, to disperse the light, as readily as possible, through the building.

In domestic buildings, where windows have to serve the double purpose of admitting the light and facilitating external view, they were not usually grouped as above described, but were made wider in their openings, the unpleasant effect which might otherwise arise from it being obviated, and the glazing and opening of the window rendered more easy, by the use of thin mullions or pillars dividing the window into two or more lights. This system offered advantages so obvious that it was very soon adopted for churches also; so that,

\* To be continued.

instead of obtaining increased light, as heretofore, by the indefinite multiplication of comparatively small windows, it became customary now, for the first time in the history of architecture, to make windows of any size which their position or utility might dictate; the whole end of a church and the entire bays of its flanks being occupied, if need be, by single windows.

Now nothing could be more rational than this development. The mode of glazing in use was most conveniently applicable to spaces of moderate width. It is true that the more extended use of iron it was then, as it has often been in modern times, applied to openings of 6, 8, or even 10 feet in width; but narrower spaces were much more convenient. The lights, however, at Westminster Abbey, which is one of the earliest buildings in which this kind of window is systematically used in this country, are  $4\frac{1}{2}$  feet wide, and in France they are generally much more. The prevailing practice of placing a massive pier between each of such lights was obviously imperfect. The concentration of pressure upon the buttresses now allowed of openings of almost any size: what, then, was more reasonable than to make extensive openings, and then to subdivide them by light mullions into compartments at once slightly and convenient? That this practice has sometimes, from caprice, been carried to a vicious excess in no degree militates against its rationale; indeed, with all our modern facilities for glazing and opening our windows, we continually find the same expedient resorted to for convenience, and invariably so when any extraordinary amount of light, and consequent width of window, are needed.

The next question which would arise is, how is the arch to be filled in? This we find done at first by a plate or tympanum of stone as thick as the depth of the mullions, each light being arched, and the tympanum pierced at pleasure with such openings as suited the builder's taste; and, later on, we find these piercings connected together into these systematic groups which we call tracery; thus converting the window into a perfectly novel and most beautiful architectural feature.

As I shall have more to say on the subject of windows when we come to secular architecture, I will limit myself to two remarks. One is this; that in positions in which there is not much height, where there is no great load to be sustained, and where the termination of the wall internally and externally is horizontal, the mediæval architects by no means held themselves bound to the arched form, but reserved perfect liberty to put square heads to their windows: the other is a passing remark on the rationale of stained glass. I do not conceive it to be simply a decoration, or a means of adding rich colouring; but that it also arose from an unconscious feeling that it was necessary to the perfect effect of an architectural interior that it should be self-enclosed. In a living room one wishes not only for admission of light, but for facility of looking out at the windows; and this necessity prevents us from seeing the windows well as architectural features, because the focus of the eye has constantly to be changed in passing from the window itself to the view beyond. In a church, on the contrary, you do wish to look out at the window, and it is better that it should be filled with a medium only semi-transparent, and which, being at about the same distance from the eye with the surrounding architecture, at once does away with the necessity of a change of focus, and supplies a beautiful decoration to the medium by which that object is effected.

I have not yet noticed one of the leading features of the style, and one in which it assumes a character most peculiarly its own: I mean the roof.

All previous styles of architecture with which we are acquainted, having originated in southern countries, had roofs of a low pitch. I have no doubt that in many of these countries there were occasions in which a higher pitch would have answered better; but, as the lower line harmonized better with the generally horizontal lines of their architecture, and was found to answer, they naturally adopted it. The Romanesque architecture of southern Europe had also somewhat low roofs, and when first imported into Germany the roofs were by no means high. Gradually, however, as men forgot its connection with Italy, and viewed it as belonging to themselves, they would naturally use with it the form of roof they had found most serviceable, and were most accustomed to in their ordinary buildings; and thus the high roof of the north became engrafted upon the Romanesque style, and the roof became a conspicuous feature in external architecture. Happily

ply this change harmonized well with its general character. The arch seemed to suggest a higher pitch of roof than did trabeated construction; and, when greater height was generally introduced, and the pointed arch took the place of the round, the pitch of the roof would be increased to harmonize with it.

I view, then, the high roof as partly the result of climate and partly of the æsthetic tendency of the style. But is it to be considered as an essential characteristic of Gothic architecture? By no means. The true characteristic of the style is liberty; and in the roof, as in every other feature, perfect freedom is reserved, so that we find roofs varying from almost perfect flatness to a very high pitch, a preference being given, *cæteris paribus*, to the high roof, where there was not some decided objection to its use.

In internal construction also the roof was founded on rational principles,—good construction being always considered before beauty, but the latter made very generally to result from it.

Gothic timber roofs would form a subject which could hardly be done justice to under one or two lectures, so I will not go further into them now. Modern carpentry has shown us how to construct roofs with less timber than was used in those structures (there was then less necessity for the economy of timber), but we have never done anything to compete with the noble pieces of ornamental carpentering bequeathed to us by our Mediæval forefathers. As to covering of roofs, I may just mention, in passing, that though the Mediæval builders made use of every material which it is customary to use for this purpose, there are several which cannot be made use of with any but a high pitch, and are therefore unuseful with low roofs such as are used in other styles. As for instance, plain tiles, ordinary stone, slate, shingle, and thatch.

The next point in the rationale of Gothic architecture is one which I by no means claim as its peculiar property, inasmuch as it is common to all good architecture, though certainly our style is somewhat pre-eminent in its adoption of it. I refer to that general principle of ornamentation which trusts mainly for beauty to the useful and constructive features of the building, rather than to those which are introduced directly for appearance.

Thus, in a noble Gothic building, the ornamental character arises from a greater or less richness in the doorways, in the windows, the buttresses, the cornices, parapets, or other parts useful for the uses or construction of the building. This belongs to all noble architecture, but is more thoroughly, I think, carried out in Gothic than in other styles, and perhaps less in modern Italian, especially in what is commonly called Palladian, than in any other. I do not lay claim to it as an argument in favour of one style above another, for all ought to possess it alike; but the absence of it in a very great deal of modern architecture is at least a proof that much reformation is needed among ourselves; and the strong degree in which it was adopted as a maxim by the Gothic architects is a great proof of the reasonableness of the principles on which they acted.

There are, of course, in all styles of architecture, decorations of a merely gratuitous kind; and, when largeness of means leads to profusion, they are likely to be carried to excess; but, in Gothic architecture of the best periods, the beauty of a building (after good proportion, outline, &c. are secured), depends not on this deliberate ornamentation, but on the artistic treatment of the necessary features. Whatever parts were dictated by practical necessity were the chief objects on which decoration was expended, and to which the architect trusted for the beauty of his building.

More especially was it, *par excellence*, a window style. Of all the objects provided for, the admission of light was the first and chiefest: accordingly, the window was made, both within and without, the leading source of beauty. It is by the design of the windows that we define the gradations of style. It is chiefly by the windows that we describe a building, and the first question asked about a Gothic building generally relates to its windows. On them, therefore, was expended a large portion of the architectural decoration. How marvellous, then, is the inconsistency which we meet with;—people with one breath objecting to Gothic architecture—the offspring of Northern climes—as not admitting light enough, and urging the use of Southern architecture, to obviate the imagined defect; and then telling you of the beauties of a modern building, the great characteristic of which is, that its principal façade has no windows at all.

Next to the windows the doorways claim the most careful attention. Indeed, in some respects they had the precedence, in as much as of parts of a building the doorway is that which challenges the closest inspection. The decoration consequently, of doorways were those which contain the greatest amount of actual sculptured art. It is a great privilege to place sculpture where it will be best seen; and as every one who enters a building must of necessity obtain a close view of the doorways, they were naturally made the great vehicles for sculpture. In France especially every part of the doorway frequently is sculpture. Take, for example, the western portals of Amiens; the pedestal or basement of the jambs is decorated with medallions, illustrating Biblical history, by bas-reliefs. The central pillar of a great double doorway contains the chief statue; the tympanum is filled with subjects, and the orders of the arch with angelic figures; so that the entire doorways are alive with sculpture.

The buttresses, again,—those naturally uncounted projections, were inert masses, to resist the pressure from within,—are rendered beautiful by their stately proportions and architectural detail; the niches and statues which adorn their receding stages, and the aspiring pinnacles by which they are crowned.

The stone roof-plate, enriched with moulding and foliage, and, perhaps, supported on sculpture, corbels, becomes the crowning horizontal feature of the parapet—the defence of the workmen engaged on the roofs—is pierced into tracery, or forms a miniature arcade, giving delicacy and lightness of effect to the generally-massive structure; while the bell-tower, raised high, to make its voice heard from afar, becomes the culminating ornament of the whole exterior; so completely was it the recognized principle of the architecture to render the useful and constructive parts sources of decoration, that, where any deliberate decoration was made use of, it was often formed of imitations of constructional features,—such as window tracery, arcades, gables, pinnacles, columns, &c.

I am not prepared to say that this is in itself to be applauded; indeed, I think, it ought, at the least, to be kept within moderate limits; but it nevertheless, owed its origin to the firm hold which the principle of rendering construction, the leading source of decoration, had upon the architects. Being accustomed to decorate construction, they got into the habit of using constructional forms as decorations.\*

#### THE AMERICAN MILL-FALL.

The inquest on the bodies of the unfortunate men who were killed by the fall of the Pemberton Mill, at Lawrence, and the fire which followed had been exciting great interest. The verdict had not been given when our letters left. The immediate cause of the fall appears to have been the breaking of one of the iron pillars supporting the floor. The pillars are said to have been badly cast, of bad metal. *The Boston Journal* writes:—

"The pillars on which the mill depended for almost its entire support were much too light, and there were not enough of them. In fact, there were only two-fifths of the number requisite for security, for it is certainly bad construction to leave an area of 20 feet by 5 feet (1,080 square feet) with all the heavy machinery upon and above it dependent for its entire support upon one small and perhaps carelessly cast iron pillar. Architects generally consider that 12 feet between the supports of floors framed like those in the Pemberton Mills is a large space. But here the pillars were 27 feet apart. The only wonder is that the mill could have stood for so many years before the weight and motion together crushed it to the earth. The theory that the weight and force of the machinery were no more than such pillars were capable of sustaining in an exactly perpendicular state was well enough for a theory but not for practice. Allowance should have been made for accidents, and care taken to have had sufficient supports, so that, if any one got out of plumb or failed from some unforeseen cause, it should not have involved the others in a general ruin.

At the time the Pemberton Mill was erected, there appears to have been no architect employed to make the plans and superintend the building. Singular as it may appear, it is almost always the case, that factory buildings, in the construction of which the greatest care should be taken, are

\* To be continued.

planned and superintended by others than architects; or, if an architect is employed, it is simply for the purpose of making an ornamental design for the exterior of the structure, the sizes, heights, and openings being furnished him by the proprietors or engineer, and no voice being given him in the arrangement of any other part.

HARTLEY INSTITUTE COMPETITION.

At the meeting of the Southampton Town Council, held on Wednesday, the 8th, Professor Donaldson's report was read, the pith of which we gave in our last number. The following is a list of all the designs:—

- No. 1.—Fortuna favet au. 23.—Sigma
2.—A device 24.—Perseverance
3.—Nil sine labore 25.—In memoriam (medieval)
4.—Portier 26.—Triton
5.—Quello same 27.—Silva
6.—The Southern Liverpool 28.—Prodesse quam consipit
7.—A shield, a second design, same device as 31 29.—In memoriam (Italian)
8.—Uhlitas Fermitas 30.—Spe
9.—Scientia 31.—Same device as 7
10.—Literature, science, arts 32.—Architecture for 1859
11.—Fit via vi 33.—Labore et honore
12.—Utinam Ii can 34.—Utility
13.—V.R. 35.—Premonstrator
14.—Success to Southampton 36.—Utility
15.—Argonaut 37.—MDCCCLX
16.—Multum in parvo 38.—Omega
17.—Desideratum 39.—Spes
18.—Voluntar 40.—Res non verba
19.—Columba 41.—Within compass
20.—Amor patrie 42.—Ingenium delictice
21.—Spero 43.—In manus
44.—Stella 45.—Stella

The referee selected the following as prominently deserving of notice, and estimated them at the sums attached:—

- No. 15.—Argonaut ..... £12,300
19.—Comme ça ..... 14,000
20.—Amor patrie ..... 30,000
28.—Prodesse quam consipit ..... 15,700
31.—A shield ..... 22,000
33.—Labore et honore ..... 17,700
34.—Utility—an inferior design ..... 16,000
40.—Res non verba ..... 20,000
44.—Stella ..... 8,000

After suggesting that the authors of "Stella" and "Argonaut" might be communicated with, his report thus concluded:—

"The authors of the following designs were high merit, both in the disposition of plan, and treatment of the decorative parts:—Nos. 7, 15, 16, 19, 24, 25, 31, 32, 33, 40, and 41; those with the asterisk attached being either of the highest class, or approximating nearest to the expenditure of 8,000."

The Committee, in their report, said:—

"That with regard to the unmentioned designs, viz.,—

- No. 2.—Winged Circle 21.—Spero
7 & 8.—A Shield 22.—Omnia Spero
9.—Scientia 23.—Sigma
10.—Literature, Science, Arts 24.—Perseverance
11.—Fit via vi 25.—In memoriam (medieval)
15.—Argonaut 27.—Silva
16.—Multum in parvo 33.—Labore et honore
17.—Desideratum 36.—Utility
18.—Voluntar 37.—MDCCCLX
19.—Comme ça 40.—Res non verba
44.—Stella 43.—In manus
45.—Stella 45.—Stella

The committee suggest to the Town Council that the designers should be at liberty to send in several guarantees from competent practical persons, and who will undertake to execute a contract to carry out their designs for an amount not exceeding the total sum of 8,000, according to approved specifications, and that no such guarantee shall be entertained unless it shall be accompanied with the names of two responsible persons willing to be sureties for the performance of such contract."

After a long discussion it was resolved that the report should be printed and circulated, and the subject deferred till the next meeting of Council.

THE SEWAGE FOR THE SOIL.

MR. MECCHI'S LECTURE.\*

It must be a very strong practical conviction by which Mr. Alderman Mechi is actuated in the persevering—we had almost said the pertinacious—persistence of his views as to the vast and national importance of the sewage of our towns to the soil of adjoining country districts. In this conviction, we need not now inform our readers, we heartily concur: the views we have long entertained on this subject are thoroughly well known. It cannot for an instant be supposed by any one who has well considered the whole subject, that our new

sewage system will settle this great question as regards even the metropolis: it will do no such thing; although it appears to be a step in advance, to which the extension of the metropolitan house drainage has driven the public, in their desperate efforts to get rid of the temporary nuisance thereby occasioned in the river and the sewers.

It was a strange and stupid proposal to get rid of that nuisance by reverting to the cesspool system, the permanent evils of which were precisely what forced the public into the extension of house drainage itself, as the half doing, at least, of a work which was essential to the public health. This half-doing, moreover, has had the further merit, we may truly say, of creating such a nuisance, in the meantime, that it has forced into notice the necessity of getting the other half of it done without delay; and the objections to the status quo are about as rational as those objections to "things half done" for which "fools and children" are so notorious in nursery tactics. True, the most long-headed scarcely see their way, as yet, to the full doing of the remaining half of the work, any better than the "fools and children;" but that there is a way, and that it must and will be found, the best informed have the utmost confidence.

Mr. Alderman Mechi's way, like that of his celebrated chymical friend, Baron Liebig, has been for some years before the public; and, so far as regards the mere abstract question of the propriety and advantage of returning the sewage to the soil, who can doubt that they are essentially right? The only question is how to get them together. In the first place "the stable mind" is not yet fully prepared for the advance from the stable to the sewer. "If the money value of the contents of our sewers," as Mr. Mechi remarks, "could be shown to the British farmer in bright and glittering beaps of sovereigns, he would grasp at the enormous wealth, and make great efforts to obtain it;" but, as it is, we "have not seen any practical desire or effort, on the part of British agriculture, to obtain this treasure"—in the dirty shape of sewage—a shape, after all, not so "dirty" as that in which the glittering gold itself not infrequently reaches the pockets of mere money-grubbers.

Then, again, comes the great and important question of liquid versus solid excreta. Mr. Mechi advocates for the liquid form of sewage, but he has not every one with him on that point. Well authenticated instances have occurred, both of late years in England, and for many years, as at Edinburgh, in which the diluted sewage of towns has been found to fertilize the soil to a luxuriant and almost rank extreme. But the most extensive experience is that of China, in which there are either no sewers, or at all events the excreta are removed from towns in the undiluted form, as is the case, too, at Paris. Mr. Mechi, however, states that the Parisian manure has been found too strong and wasteful in this form.

Another question, which we have not seen started, but which assuredly will come up, and perhaps at an inconvenient time, when it might damage the cause of the disposal of town manure over the soil of the country, and which had better therefore at once be started in a friendly spirit towards that end, is the question of the influence of crops reaped from human excreta upon human life and health themselves. It is well known that sheep will not continue to eat of grass produced from their own manure;—not only so, but that certain diseases arise in cases where they have been compelled to do so. It may fairly be asked, therefore, whether grain or other crops reared from town sewage be wholesome as human food; and, at all events, may not a prejudice arise, at a critical time, against the extensive use of town sewage, on the basis of such a question? In considering and discussing it, however, let it not be forgotten that there are divers ways of obviating evil, even though it be liable to occur, from the direct human consumption of grain crops manured by town sewage. Animal produce could be manufactured chiefly from it, and of course crops (besides grasses), to be consumed by such animals. It must also be remembered that in China, which teems with human life, a large proportion of the soil is manured with human excreta for the production of crops which are directly consumed as human food, and that for 3,000 years the land there has been cropped, but never exhausted, either in its own fertility, or in the human life sustained by it. We certainly know much less on this subject as regards China than we ought to know; and it is very desirable that every opportunity should be embraced, of access to the country, in adding to our knowledge of this interesting and important subject.

Another difficulty in the way of returning the

sewage to the soil is, of course, the question of distance: districts in the vicinity of towns may readily be reached, however; and these districts may be found sufficient to absorb the whole of the sewage of the respective towns. But as regards the huge metropolis, still the question remains one of no little difficulty; and we are all well aware that one attempt to make use of its sewage in the vicinity was a failure, probably chiefly on account of this very vicinity itself. On this subject Mr. Mechi remarks:—

"Some years ago a company was formed to pump sewage from the Counter's Creek Sewer to the market gardens at Fulham. This was like 'carrying coals to Newcastle,' for we all know that the soil, naturally very fertile, receives annually, per acre, from 50 to 100 loads of London stable dung, which is brought back free of cost for carriage by the carts that have taken the vegetables to London. It is on the poor soils, beyond this influence, that the water and sewage will be profitable."

In the very interesting and important lecture from which we have in this and previous instances quoted, Mr. Mechi gives, in support of his view, in favour of sewage as it flows from town sewers, in a diluted form, the following reason:—

"Why the Sewage Form of Application is the most Preferable.—Baron Liebig, in his last work, page 267, lays down this great principle, that 'the action of a manuring agent in a given time must increase in proportion as its surface increases.' Now you have, in town sewage, a perfect practical illustration of this principle. The food has been converted into its original elements by mastication and digestion, and it comes to your field dissolved in water and comminuted or separated by frictional action in the sewers. It sinks into the soil and sub-soil in the only condition in which its elements can be seized upon, and condensed on its surface, and each grain of soil cultivated soil. Compare this with the clumsy dung-heap, where unseparated masses inaccessible to the soil show themselves for years, to the farmer's great loss, thus preventing the quick return so essential to farming profit."

These few desultory remarks, suggested by Mr. Mechi's lecture, we may appropriately conclude with two or three disjointed extracts from the lecture itself, chiefly as regards the difficulties connected with farmers and sewage companies:—

"Farmers, as a body, have no faith in liquid manure, and are not, probably, aware that twelve parts out of their own manure, and that of all their animals, is deposited as urine. The sheep-folding, deprived of its liquid, would be almost worthless. It appears to me that the only way to remove, or overcome, this difficulty will be for any company that may undertake the scheme, to show the effects of the town sewage on small plots of ground, in various parts of the country through which their pipes may pass, or otherwise offer such inducements for trials as may tend by their results gradually to remove this unprofitable prejudice. On sloping grounds below the cesspits it might flow over the surface as in ordinary irrigated meadows, thus saving the farmer the expense of subterranean iron pipes. No one can reasonably doubt that the great want of British agriculture is more manure."

"Provided an abundant supply of town sewage were annually used, it would be impossible to exhaust the soil by any cropping; and our farms-leases might be a great deal shorter than they are at present. The generality of farms are now only manured once in four years. Such a system would suit farmers of limited capital. The only excuse for treading our straw under foot, and consuming our hay, straw, and green crops on the farm, is to produce manure to grow the cereals. It is quite clear that, as sewage manure contains all the elements of every crop that can be grown, we need no longer feed out oaks, cut a loss, or pay away our money for guano, bones, blood, and other manures."

"Until a change is effected in the agricultural mind, sewage companies, formed for its general distribution, must be great experiments. As such, they should, in the first instance, be encouraged, and even, probably, subsidized, by the towns, for the first few years, no charge being made to them for the sewage. In course of time, when the operation shall have resulted in good dividends to the shareholders, the sum to be paid to the towns might bear an equitable relation to the per centage of profit realized by the shareholders. Except by such an arrangement, capital will not be advanced for such companies, for it will take some years to convince agriculture that she will be benefited by using and paying for town sewage. If landholders desire to prevent the exhaustion of their soil by the restoration of the sewage, they must give practical evidence of that desire, by taking shares in, or giving other facilities to, any public companies which will devote their capital to such an object. . . . Towns will derive a large revenue from their sewage; but they can only be when agriculturists have tested its value. In order to induce them to do this every temptation and encouragement must be offered to them, and to those companies who propose to supply them."

Last but not least in importance is what Mr. Mechi tells us of the actual practical and money profits of his system:—

"Influence of Sewage Manure on my Farm Profits.—I am much indebted to the sewage system on my farm in this respect—for the last six years my gain, as landlord and tenant, on my little farm of 170 acres, has been nearly 7000. per annum. Even this last year, with wheat at 45s. per quarter, I have gained 6000. after paying every expense. Of course much of this benefit has arisen from steam power, drainage, deep cultivation, and other improvements; but the liquified manure system has greatly contributed to this result."

ROYAL SCOTTISH ACADEMY.—At a general meeting of the academy, held on Friday, Mr. John Ballantyne, one of the Associates, was elected to the degree of Academician.—Edinburgh Courant.

\* On the Sewage of Towns as it affects British Agriculture: read before the Central Farmers' Club, London, February 6th, 1859. By Mr. Alderman Mechi. With a copious Appendix. London: printed by Jones and Casson, 47, Estreep, and 14, Paddington. 1859.

ON THE CONSTRUCTION AND REBUILDING OF THE ITALIAN OPERA HOUSE, COVENT GARDEN.\*

It has been already stated that the works were commenced in the autumn of 1857. The removal of the old foundations was a work of great tediousness and difficulty, and as the day of opening was even then fixed for the 15th of May in the following year, all were most impatient to see the conclusion of the excavation, which, however, was so long delayed, that portions of the foundations were put in to save time long before the whole site was clear. The first brick was laid on the 23rd of September, 1857, but it was not until the end of October, in the same year, that the whole site was available for the energetic prosecution of the works. Almost all the iron-work, however, was ordered before the footings were completed, and the roof was, in consequence, furnished and ready for fixing before the building was more than three parts up.

Considering the unfavourable period of the year, and the risk of interruption to the bricklayers by rain, it was resolved to try to obviate this kind of delay, if possible. Messrs. Lucas, directly the matter was named to them, agreed to furnish all their men with complete suits of waterproof clothing, consisting of coat, leggings, and hood; and the men, while working on the walls in this black-hooded costume, reminded of nothing so much as the story-book pictures of familiaris of the Inquisition. It was soon found, however, that the walls, being built in mortar, could not be prudently carried up during severe rain, and the waterproof contrivances were, therefore, only used very occasionally. It will be seen that the arrangements for the auditory are quite independent of the external walls, and the boxes and corridors are, in fact, a separate structure of iron, stone, and wood, erected inside the chamber formed by the many walls of the building. For reasons already adverted to, it was resolved to use iron for this portion of the work; and it may be remarked that wrought iron has been adopted for almost all portions of the construction exposed to danger from fire and severe tensile strains, in consequence of its presumed advantages over cast iron in such cases. The boxes are supported by wrought-iron cantilevers, formed of two pieces of T iron  $5 \times 5 \times \frac{1}{2}$ . These are connected together with connecting web-plates, so as to form a double T, one piece serving as the upper flange, and half the web and the other constituting a lower flange and the completion of the web. A specimen beam was made before the works commenced, and carefully tested by actual weights before its application was resolved upon. The floor of the corridor is formed of 3-inch York landings, rubbed on both sides, which thereby form at small expense both floor and ceiling. They are supported on rolled iron joists, connecting together the cantilevers, before described, which are strongly let into the wall of the corridors, and have a point of support distant rather more than half their length on cast-iron columns placed at the backs of the boxes. The columns are eighty in number, in sets of four, resting on each other, being carried up to the basement. In consequence of the necessity for the cantilevers to pass through the columns at the points of support, the top of each column is formed into a species of box, through which the cantilevers pass, and to which they are safely secured. It will be seen that as the columns rest on each other they cannot yield to superincumbent weights unless their foundations give way. It was, therefore, felt to be a difficulty that, while the walls would certainly settle (especially when carried up so rapidly), the columns by remaining rigid and unyielding would probably cause serious inconvenience, and might, by altering the levels of the cantilevers and beams, expose them to aggravated cross strains. To obviate this danger, it was resolved not to fix the iron work until the walls were carried up, so as to give as much time as could be afforded to allow them to settle. It was also determined to make the boxes forming the heads of the columns rather deeper than was necessary. The bearing was then brought up to the right height by their filling in pieces of sheet-iron, any number of which might be easily withdrawn in the event of the walls settling, and requiring a corresponding lowering of the beams and cantilevers. It is satisfactory to add that these precautions have never been called into play since the framework was fixed, nor has any settlement occurred, as far as I know, since the completion of the building. The number of bricklayers for some weeks exceeded a hundred, and

the number of workmen of all classes varied from a small body at the commencement to as many as 1,200 during the last few weeks of the works. The joiner's work was prepared at Messrs. Lucas's works, at Lowestoft; and all the principal portions of it were put in hand at the same time that the brickwork was commenced, and all difficult parts were carefully put together on the premises, then and there carefully taken down, marked, and sent to London. Thus the ceiling over the pit, the combined curves of which needed some care to ensure accuracy, was put together and temporarily supported in Messrs. Lucas's yard many weeks before the building was ready to receive it. Owing to the limited space occupied by the building, the site of the Floral Hall being still encumbered by ruins which there had been no time to clear away, much difficulty was experienced in finding room for the large quantities of materials daily required; and when the time came for delivering the great roof girders, 96 feet long, 9 feet deep, and weighing 17 tons each, it became necessary to hire a wharf on which they might be stored until they could be received and fixed. The girders were divided into halves for convenience of transit, and in that form were eventually brought to the works. Considering that the walls, 85 feet high, had been carried up in thirteen weeks, and during an unfavourable time of year, precautions were thought necessary to ensure, as far as possible, an even distribution of weight upon them, which was rendered the more necessary from the fact that, owing to the peculiar construction of the roof before adverted to, the main girders had not only to carry their own weight and the weight of the roof, but were also required to support the ceiling of the auditory, the scenic arrangements over the stage, and a complete story of workshops. In the old theatre Sir R. Suirke had effectually provided for distribution of weight by placing two wall plates of nearly whole timber dimensions along the walls; but with an iron construction this resource was of course unavailable, while the iron girder was not only heavier than the wooden truss, but was also nearly one-half lighter apart from its neighbour, thus adding in every way to the necessity for precaution from the greater concentration of weight on certain points. The mode adopted was, instead of using wall plates of wood, to carry up twelve courses in cement and hoop iron, forming thereby a wall plate of brick and cement. This 3 feet of wall was connected with the external and cross wall by iron ties similar in character to those before described, and from it six more courses, also in cement, were carried up to the underside of the templates which receive the main beams. These are of stone, 4 feet by 3 feet 9 inches, and upon them are fixed cast-iron plates, 2 inches thick, carefully fitted to the shape of the lower flange of the beams. These iron plates were found very useful in fixing the beams in their places, as will be seen presently. The operation of hoisting and fixing the main roof girders was a matter of some difficulty, and several modes of accomplishing it were considered. It may, perhaps, be interesting to describe shortly the manner in which these great metallic principals, each weighing 17 tons, or more than the unfortunate Big Ben of Westminster, were safely fixed in their places. It was felt that, in the absence of cross walls, a sudden blow, from any accident in hoisting the girders, might be attended with very serious consequences. Moreover, the length of the girders being 96 feet, and the space between the walls only 90 feet, it was obvious that they could only be hoisted in an oblique position if raised whole, and such a course would entail great difficulties in getting them into their permanent places, on the top of the building. It was consequently determined to raise them in two pieces, in which condition they came to the works as before stated, and to rivet them together on the top of the building. In a central position, where the Proscenium now stands, a scaffold, about 30 feet by 20 feet, was raised, and floored over at the same level as the top of the walls. The half girders were then raised and placed temporarily, so that the two ends rested on the walls, and the divided centre portions were supported on the scaffold, which resembled a gigantic table. Small portable forges were then supplied on the scaffold, and the half girders were riveted together in the position described, the whole operation taking about three days to effect. The girder then required to be moved to its place, and room made for the others. Great caution was used in moving the girders, in order to avoid exposing them to any severe cross strains, which by deranging

their parts might materially injure them. It was necessary, therefore, that the girders should be moved, evenly and easily, both for their own sakes, and by reason of the state of the walls. To effect this a whole timber was laid upon the walls, longitudinally, and an iron rail fixed on the top of the same. Carriages, with flanged wheels running on the rails, were placed under each end of the girder, and a very moderate force applied to the carriages, caused the great mass to move along the walls with the ease and smoothness required. As soon as a girder was moved from the scaffold another took its place, and before the latter was riveted, a third was hoisted, ready to occupy the scaffold as soon as vacated. Thus the three operations of fixing, riveting, and hoisting, were all pursued together by different gangs of men. We have now accompanied the girder to its place, but we have not yet seen it placed in its permanent resting-place, to do which without a jar to the walls, and with perfect accuracy, was an operation requiring some delicacy. As the whole roof is so connected together, both with floor beams and roof principals, all of which were made at the same time as the girders, and were fitted taken them of the same. Inaccuracy in fixing the girders would have produced serious difficulties. The iron bed-plates under the ends of the girders were therefore fixed in the stone templates with great care; they were provided with a hole through them, under the centre of the girders tapped for a 2-in. screw, and a corresponding hole was drilled through the stone template. Several courses of the brickwork under the stone template were also temporarily left out. The screw was then introduced from below, and passed through the carriage under the end of the girder, which was carefully adjusted, directly over the screw. The carriages were then removed, and the girders left resting upon the screws, which were then slowly withdrawn from below, and the girder finally lowered to its resting-place. The omitted brickwork was then made good, and the fixing was complete as far as the main girders were concerned. Care was taken not to surround the ends of the girders with brickwork, but to have them free and susceptible of being painted from time to time. The small intermediate roofs, having been all prepared before, were next fixed with great rapidity, and the roofs at the ends of the building were slated and covered in before the girders for the middle portion were even hoisted.—The whole operation of hoisting and fixing the girders having taken only three weeks. The floor-beams between the girders over the auditory were likewise soon in their places: they are made of wrought-iron, and carry the floor of the workshops and the ceiling of the theatre. The chandelier is supported by two iron beams supported at each end by the main trallis girders. It is worked by a crab, and can be raised partially into the workshops, or lowered to the floor of the pit. As soon as the floor was completed, as described, the internal works of the building were pushed forward as much as possible, and the interior of the auditory, which was at present only in carcass, began soon to assume its present shape. It being naturally of the greatest importance to employ as many hands as possible, it was decided not to allow any scaffold to be erected from the ground, but to construct the beams of the roof and the floor in the same. The platform was constructed in the following manner:—Rods of wrought-iron, 1 inch in diameter, were hung down from the beams above, where the aperture, in the centre of the ceiling, would ultimately be formed. From this point, timber beams, or joists, radiated like the spokes of a wheel, each beam or spoke being supported at one end by one of the iron rods above alluded to, and the other end being carried by a rope strongly fixed to the beams of the floor above. These radiating beams, thus constructed, formed the supports of a platform on which the necessary scaffold was erected for the fixing and completion of the ceiling. The latter is covered with Bielefeld's fibrous shib, which has been extensively used at the British Museum. It was fixed in large slabs, about 12 feet by 6 feet, and is  $\frac{1}{4}$  inch thick. Of course, in covering the ceiling, it became necessary to slant the ropes supporting the scaffold to such positions as would not interfere with the decoration, or cause unsightly holes to be made through the slabs. Provision was accordingly made for the existence of some holes in the ceiling, through which the ropes might pass, not only during the progress of the work, but also at any future time when repairs or redecoration might be necessary. The holes, twenty-four in number, are placed at

\* By Mr. E. M. Barry. See page 85.

the joints of the fibrous slabs, and are concealed in the finished ceiling by plugs let down and removable from the floor above, so that ropes may be at any time lowered through them, and a scaffold formed with facility, and at slight expense, whenever required. The form of the ceiling is as follows:—Over the pit is a flat dome, 65 feet 1 inch diameter, and 7 feet 2 inches high: this rests upon four elliptical arches, 63 feet 7 inches span, with pendentives. The ceiling over the main gallery is flat, and the two side galleries or steps are covered with arched ceilings, following the shape of the elliptical arches supporting the dome. The dome is formed of pulvius in two thicknesses, circular in plan, and hung down from the floor above by wrought-iron rods. The pulvius carry ceiling joists in the ordinary manner. The arch nearest to the stage is 10 feet from the curtain, to allow of the formation of a sound reflector over the foot-lights and the projecting piece of the stage from which the principal *artistes* commonly sing. The reflector is curved, and follows the form of a parabola. It displays for its ornamentation a bas-relief, designed by Signor Monti, representing the ancient and modern drama, with a likeness of her Majesty in profile between the two subjects. The box-fronts were also designed by the same artist, and are executed in the new combination of canvas and plaster, which Mr. Owen Jones has largely used, and has lately introduced to the notice of this Institute.

The decorations of the interior were for the most part carried out under the personal directions of Mr. Gye, assisted by Signor Monti, only a small portion of the original designs for this portion of the work having been carried into effect. The whole of the operations connected with the ceiling, such as fixing the carpenters' work, fixing and painting the fibrous slab, and fastening the enrichments in their places, were carried on from the suspended scaffold, and during this time the works below were being pushed on with all despatch. The foundation walls under the pit were built, the iron columns and cantilevers for the boxes were fixed, and carpenters, masons, smiths, painters, decorators, and gilders, jostled each other. Indeed, the interior of the theatre at this time presented an epitome of the building trade, almost every handicraft having its numerous representatives, while the placards in the streets, announcing in large letters the 15th of May as the day of opening, were calculated to cause all concerned the greatest anxiety. In designing the construction of the floor to the pit, a question arose which determined its general character. With a view to render the theatre applicable to all possible purposes, it appeared to be an advantage to possess the power of raising or lowering the floor if required. On such occasions as public dinners, *bals masqués*, &c., it is obvious that such a facility might prove very advantageous. It was accordingly resolved to support the floor on trussed timber beams, 2 feet 3 inches deep, resting on cast-iron columns. These columns have split heads, resembling a musician's tuning-fork. By the adoption of this form, the trussed floor-beams can be lowered into the columns their own depth, whenever required, a number of packing-pieces filling up the cavity in the top of the column if it be desired to retain the beams at any particular height. An instance of the convenience of being able to alter the position of the pit floor was shown soon after the opening of the house. From some misconception, the stage had been fixed 9 inches too high, and the occupants of the front rows of stalls had an impaired view of the performers in consequence. During the recess, the front portion of the pit floor was raised 9 inches, so as to occupy its proper relative position to the stage, and the inconvenience was at once obviated. While the works above described were in progress the stage was in active preparation. Mr. Beverley, the distinguished artist, was consulted as to its general arrangement and mode of working, and the practical realization of his views was confided to the experienced hands of Mr. Sloman, who has been so long connected with the theatre, and whose reputation in such matters is so well established. The procession columns are arranged to slide on wheels, so as to expand or contract the opening when desired. The grooves so commonly used for the support of the scenes are entirely done away with, it being considered that their undoubted convenience is more than counterbalanced by their attendant disadvantages, and more particularly by the obstacles they afford to the formation of a grand open scene embracing the whole extent of the stage. The back scenes are of single sheets of canvas, lowered from the top, and secured to rollers resting ultimately upon the main beams of

the roof. The side scenes and set pieces are fixed to the wing ladders behind which the side gas-lights for lighting the stage are placed. The wing ladders being unattached to anything above, the artist is enabled to place large set-pieces, such as trees, rocks, houses, &c., against them and still preserve the total height of the stage, while they are so constructed that they may be moved completely across the stage. The upper pieces of scenery, known technically as *horders*, are of somewhat novel construction. Owing to the great size of the stage, it was desired to possess the power of using it to its greatest width, especially for out-door scenes, and I may perhaps mention some of the scenery in "Dinorah" as instances of how admirably Mr. Beverley can use his opportunities; but borders to suit such extended scenes would be useless for those of a more limited description, and to avoid the necessity for a double set of scenes, it was resolved to make the borders in three pieces—a centre and two wings; the latter being so arranged as to slide forward and back, so as to form an arch of any required diameter. There are two sets of flies, each 8 feet wide, from which the machinery is worked, and there are recesses on each side of the stage to receive the scenery not in use. One of these recesses is occupied by a powerful organ, often used as an auxiliary in operatic performances.

The painting-room occupies the ordinary position at the back of the stage; but as the floor is carried by a trellis girder of the same description as those supporting the roof, the stage is enabled to extend entirely under the painting-room without interruption from walls or columns. The painting-room is 90 feet long by 30 feet wide, and 50 feet high in its highest part. It contains several painting frames of different sizes, hung in pulleys, fixed to the walls, and furnished with counter-balance weights. The frames are contrived to slide downwards through the floor, so that the artist can readily gain access to any part of the canvas he may desire, without leaving the floor of the painting-room. There is a large skylight in the roof, and the floor is furnished with traps to admit of moving scenery to or from the stage below. The scenes being necessarily often of very large size, owing to the great dimensions of the stage, slits are provided in the stage floor under those already described in the floor of the painting-room, so that the scenes may be lowered even as far as the basement, if required. Under the floor of the painting-room are fixed the contrivances for simulating the noise of thunder, rain, and the like; and the great bell, whose mournful notes have sounded the knell of so many a disconsolate tenor, is fixed in the same position. The new theatre being intended to be used principally in summer, it was not considered necessary to do much in the way of warming, as far as the opera season was concerned; but with a view to its occupation in the winter, as is now, in fact, the case, some artificial means of warmth were, nevertheless, required. A chamber is consequently placed under the pit, sufficiently low to admit of the lowering operation before described, in which hot-water pipes, heated from an apparatus under the grand staircase, are fixed: an air-grating round the pit, allows the heated air to escape into the house. The principal exit for the heated and vitiated air is through the aperture, 10 feet wide, over the chandelier; above which there are openings into the external atmosphere. There are air-valves to the boxes over the doors, and a number of small holes are drilled in the risers of the gallery seats, giving a passage for the air from the halls and corridors to the chandelier, but not in sufficient quantities at any one place to create a draught. There are also air-flues in the corridors and in the crush-room, to carry off the products of combustion from the numerous gas-lights; and there are outlets into the roof from the side galleries. None but these simple expedients for ventilation are adopted, experience having, I think, shown that most elaborate systems of ventilation are liable to failures, more or less complete, in proportion to their greater or less elaboration. A copious supply of water is of course one of the first essentials in a theatre, as a precaution against fire; for it is clear that, if a fire is to be resisted successfully, it must be so within the first quarter of an hour, as after that time the body of flame would be so vast as to defy all control. The precautions sometimes provided of iron curtains, and the like, are of questionable value, as when most wanted they are seldom available, or in order; and the only valid precaution appears to be to provide plenty of cocks, with a high pressure water supply, in all parts of the building. At Covent-garden there are twenty-five of these

cocks, supplied from cisterns in the roof, capable of containing 12,000 gallons. The main cistern is placed over the stage stair, in the north-west corner, towards Hart-street; and, in order to secure a constant supply in case of fire, the cistern is divided into two unequal parts, the smaller of which supplies the closets, sinks, and taps, of the house, while the larger is entirely reserved for the supply of the fire-cocks, at high pressure. The supply to the cistern is so arranged that not a drop of water can find its way into the smaller compartment until the larger is full to overflowing. As long, therefore, as there is any water in the closets, &c., it is certain that the fire-cocks are charged; and if by any chance the supply should run short, the inconveniences would be at once felt and remedied. It may possibly be remembered, that when the theatre was opened to the public on the 15th May, 1858, the tympanum of the portico was not built, and the removal of the scaffold at this part of the building was not completed until the afternoon of the opening day. It had been intended not to have attempted the erection of the portico until the next year, but considering the inconvenience and interruption to the business of the theatre that might be expected by a renewal of the works at the principal entrance, Messrs. Lucas were asked, as late as March, 1858, whether they would then undertake to erect the portico, the columns of which are 36 feet high, and 38 inches diameter, before the 15th May, leaving the tympanum only to be added afterwards. This they consented to do; and on the 27th March the order was given to proceed. On the 22nd April the last capital was set, and the last stone of the architrave was fixed complete on the 8th May, just one week before the opening of the theatre, although the ground at the theatre was now so crowded that every stone had to be worked at the wharf in Lambeth.

The satisfaction, however, of all concerned in the erection of this work was damped by a very sad occurrence. The mason (Mr. Gaiger) in charge of the work under the contractor's principal foreman of masons (Mr. Hatfield) met with his death on the very day of the completion of his work. He had been promised a present contingent upon his exertions being crowned with success, and after setting the last stone with natural satisfaction, when he took one step beyond the scaffold, from which he fell in an instant and met his death on the spot. Looking to the unavoidable dangers of building and other peaceful occupations, I am not sure that we always do justice to the courage and determination so eminently displayed by our artisans, or always sufficiently remember the sacrifices and sufferings by which the battles of science are won.

After the portico was completed, iron beams were fixed over the space between the front wall and the colonnade, a beam being placed across each column. At the close of the season a platform of scaffolding was formed upon the iron beams, and the tympanum carried up entirely from the same; the space thus formed being converted into a practising room, 7 1/2 feet by 14 feet, over the portico, and entered from the back of the theatre gallery.

In fitting up the interior of the auditory it was resolved to allow to each spectator a more liberal share of room than had formerly been the case, and the consequence of course is that the actual number of persons accommodated suffers a corresponding diminution. When the theatre is used for the opera, the number of spectators, comfortably seated, amounts to 2,300; but when otherwise fitted, 3,000 or more visitors can be easily accommodated.

There were many sub-contractors employed by Messrs. Lucas for various parts of the work, and all exhibited the most praiseworthy anxiety to complete their work, and enable faith to be kept with the public by opening the theatre on the day named from the commencement. Where all did well, I feel a selection might seem invidious, and as the names of all concerned were published in the *Builder*, I shall not do more here than allude to the clerks of works, Messrs. Allen and Miller, and the foreman of Messrs. Lucas in charge of the works, Mr. Clemence, whose zeal and ability, evinced under most trying circumstances, deserve special recognition. With this I propose to close my description, and hope the Institute will excuse me, if I have trespassed too long upon their attention.

WEYMOUTH TOWN SURVEYOR.—We have received some animadversions on the town council of Weymouth, in respect of their views as to this appointment, but we cannot deal with men's motives on mere assertion.

## THE BUDGET.

The proposed treaty with France, and alteration in home taxes, if confirmed, will give a great stimulus to many branches of trade. Our iron masters, machine-makers, and makers of pottery, will at once find new markets of the most extensive kind. Many will remember the anxiety that was shown in France on the occasion of the international exhibition to obtain the cheap wares of Minton, Copeland, and others.

The reduction of the timber duties will promote activity. The duties it is proposed shall stand:—

Timber, or wood, not being deals, battens, boards, staves, handspikes, oars, latwood, or other timber, or wood sawn, split, or otherwise dressed, except hewn, and not being timber, or wood otherwise charged with duty, the load of 50 cubic feet	0 1 0
Of and from British possessions	0 1 0
Of and from foreign possessions	0 1 0
Deals, battens, boards, or other timber, or wood sawn, or split, and not otherwise charged with duty, the load of 50 cubic feet	0 2 0
Of and from British possessions	0 2 0
Of and from foreign possessions	0 2 0
Planed, or otherwise dressed, or prepared for use, and not particularly enumerated, or otherwise charged with duty, for every 100ft. value	5 0 0
Of and from British possessions	5 0 0
Of and from foreign possessions	5 0 0

A more important change still, however, will be worked by the proposal made in the following words:—

"That on and after the 1st of July, 1859, all duties of excise on paper, button-board, mill-board, paste-board, and scale-board, made in the United Kingdom, and all drawbacks and allowances in respect thereof, shall cease and be repealed."

This tax has long been a blot on our intelligence. We have taxed ourselves, on one hand, to assist the spread of education, and we imposed a tax, on the other, to cramp these endeavours and limit the extension.

## ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

We have already classified the 505 photographs now in the Couduit-street Gallery as waiting selection on the part of the members of the association, the object of which is, as set forth by the committee:—

1. To procure and supply to subscribers photographs of architectural works of all countries.
2. To form a collection of such photographs for the association.
3. And in any other manner to render the art of photography serviceable to the promotion of the knowledge of architecture and to the requirements of the profession."

The specimens are marked with a numerical value as on previous occasions, and subscribers are able to select any subjects, of which the values, added together, shall not exceed 50; and for every 5 beyond, a small sum is payable in addition. Thus, of Mr. Fenton's English views, and these are amongst the best, the uncial value of each, mounted, being 18, three may be had for each guinea's subscription. The "West Porch of Lichfield Cathedral" (303) is an admirable specimen. Many of the English views are exceedingly good. Mr. Melbush's, for example, "The West End of Tintern Abbey" (319), and "The West Doorway of Rochester Cathedral" (325), in particular. Mr. Bedford, too, has several capital photographs. Amongst these we must point to one which is very remarkable if examined with a strong glass (175), the photograph of the celebrated monumental brass of Bishop Burchardus De Serken" (1817), and "John de Mil" (1350) in the Cathedral at Lubek, made from a rubbing by Mr. John Christopher. The original is 12 ft. long by 6 ft. 1 1/2 in. wide. Amongst Mr. Cooke's specimens (366) should be looked at, "Darham, from the River," for, being by the instantaneous process, the ripple is exhibited in a way we have never before seen.

Going to France, Bissou has an admirable set; notice for example (50) "The Western Portal of Rouen Cathedral."

The views of Jerusalem, by Robertson and Bents, appear to be new, and this cannot be said of all the collection. 115, "Part of Old Walls of the Temple," the "Wailing Place" of the Jews; and (116) "A general view from Mount Scopus," are particularly interesting. Professor Donaldson has already given sufficient praise to the specimens from Rome, indeed so much so that one correspondent "E. R." has addressed a communication to us, accusing the Professor, good-temperedly, of making his lecture on photography a cover to an attack on medieval in favour of classical styles.

The photographs by Ponti, from North Italy, although of very interesting subjects, are neither so good in colour, nor so true in focus, as they might be. We need not tell those who have read

the observations we have made at different times on the subject, that the Architectural Photographic Association is not yet thoroughly carrying out what we believe to be its mission; but we may, nevertheless, safely commend the present exhibition to notice as an interesting collection, offering for selection, at a small cost, some valuable subjects.

Mr. Lightly, who is acting as honorary secretary, or Mr. Moody, the curator, will give any information that may be desired.

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

## THE GOLD MEDAL.

A SPECIAL general meeting of the members was held on Monday evening, the 13th instant, Mr. C. R. Cockerell, R.A., president, in the chair, to take into consideration the recommendation of the council with respect to the award of the Royal Medal, the silver medals, and other prizes of the Institute for the year 1859; and their recommendation with reference to the medals for the year 1860.

The council recommended that the Royal Gold Medal be presented (provided the sanction of her Majesty be obtained) to Mr. Sydney Smirke, R.A. The recommendation of the council was unanimously adopted.

The report of the council stated that two essays and one set of drawings had been received in competition for the Medal of the Institute and the Soane Medallion. One of the essays, signed "Hope," was on the genius of Vanbrugh; the second, inscribed, "He that hewed wood afore, out of the thick trees, was known to bring it to an excellent work" (Ps. lxxiv., 6), on woodwork of the Mediaeval period. The latter was accompanied by a remarkable series of pen-and-ink sketches. While admitting the excellence of the sketches, the council expressed regret that the incompleteness of the essay, apparently from want of time, prevented them from recommending the award of the Institute Medal to the author of it, and suggested some honorary acknowledgment. After considerable discussion, and an amendment to the effect that the Institute Medal be awarded to the author of the essay (which was lost), a Medal of Merit was voted.

On opening the letter accompanying the essay it was found to be by Mr. G. E. Street.

For the other essay and the design no award was made.

The subjects for which essays and drawings are to be invited were settled, and will be duly advertised.

Mr. C. Fowler, Mr. Kerr, Mr. Godwin, Mr. Papworth, Mr. Rowe, Mr. John Billings, Mr. Jennings, Mr. Mylne, Mr. Morris, Mr. Williams, Mr. Roumieu, Mr. C. C. Nelson, Mr. Sancton Wood, Mr. Haywood, Mr. Marrable, and others, took part in the discussion.

## CERAMIC WOOD.

Mr. J. C. MARTIN, of Barnes, has patented a plastic material, resembling wood in its finished state. It may readily be moulded by pressure into moulds of any form: it admits of carving or cutting to any extent required; may with facility be glass-papered; and will receive the highest French polish.

The material is in great part composed of fibrous pulp of as long a description as possible (to which it owes its strength), which is worked together with resinous and gelatinous gums, acted upon chemically, and as nearly to imitate the nature of wood as possible.

The inventor says,—"It is unlike all the ordinary descriptions of moulded papier maché or carton pierre, as it contains no earthy or non-fibrous substance in order that it may be made to take a fine impression, and to this it in a great measure owes its strength and the facility with which it may be carved and finished, and renders it suitable for the manufacture of many articles to which other descriptions of plastic materials could not be applied, and, at the same time, from articles made from it being homogeneous throughout, they do not chip with a blow, as is the case with ordinary moulded ornamented papier maché articles, which are faced over with a weak, readily-moulded material, in order to take an impression."

It was while engaged in experimenting with various woods, with a view to their conversion into pulp for the manufacture of paper, that it occurred to Mr. Martin to replace the pulp and the gums of which the wood had been deprived, varying the proportions to meet the circumstances, and upon this the invention is based.

When the duty is taken off paper, as it probably

will be shortly, we shall hope to see some fresh material for its manufacture hit upon, or the consumer will probably benefit less than should be the case.

## ENAMELLED PIPES AND UTENSILS.

The improvement of the sanitary condition of large towns, and the best and most economical means for effecting so desirable an object as the preservation of the public health, are questions for the grave attention of those to whom the interests and social comfort of the rate-paying public are delegated. Various plans for conveying pure water from reservoirs through towns and into dwellings have been tried with more or less success. As bearing on this, we notice an invention, which has been patented by Mr. Paris, for the purpose of avoiding the evils arising from poison in water conducted through lead pipes, and the impurities which are constantly accumulating in iron ones; and also the breakages to which earthenware tubes, otherwise desirable for this purpose, are liable. The invention consists in the preparation of a fused glass, or enamel, applied to the surface (externally and internally) of iron tubes, which are thus encased. The enamel is incorporated with the iron while it is in a nearly white heat. Messrs. Alcock & Sons, the brewers, we are informed, have adopted these enamelled tubes for conveying their water, for brewing, throughout the whole of their new premises at Burton-on-Trent. The invention is also applied as a coating for the surface of vessels used for culinary and other domestic purposes. As a substitute for earthenware for the use of prisons, public asylums, and workhouses, it is urged that it has advantages. The works for the manufacture of this article are carried on by the Patent Enamel Company at Birmingham.

## THE MORNING-ROOM AT ASHRIDGE PARK.

ASHRIDGE PARK, in Buckinghamshire, near Great Berkhamstead, the principal seat of the Right Hon. the Earl Brownlow, has engaged the best talents of three generations of architectural Wyatts. The mansion, originally built by James Wyatt (the Surveyor General), for the Earl of Bridgewater, was probably (after Fonthill) the most imposing, both for extent and elaboration, of all the series of florid Gothic houses on which that active artist was engaged. In common with almost all his other works, the original structure evidences that vivid perception of picturesque effect, both internally and externally, in which James Wyatt was generally regarded as excelling all his contemporaries. Nor, indeed, are the details by any means so poor and frittered as those he introduced in Mr. Barrett's "Priory" at Lee, in Kent,—the building on which the most prosperous change in the current of his fortunes was based.

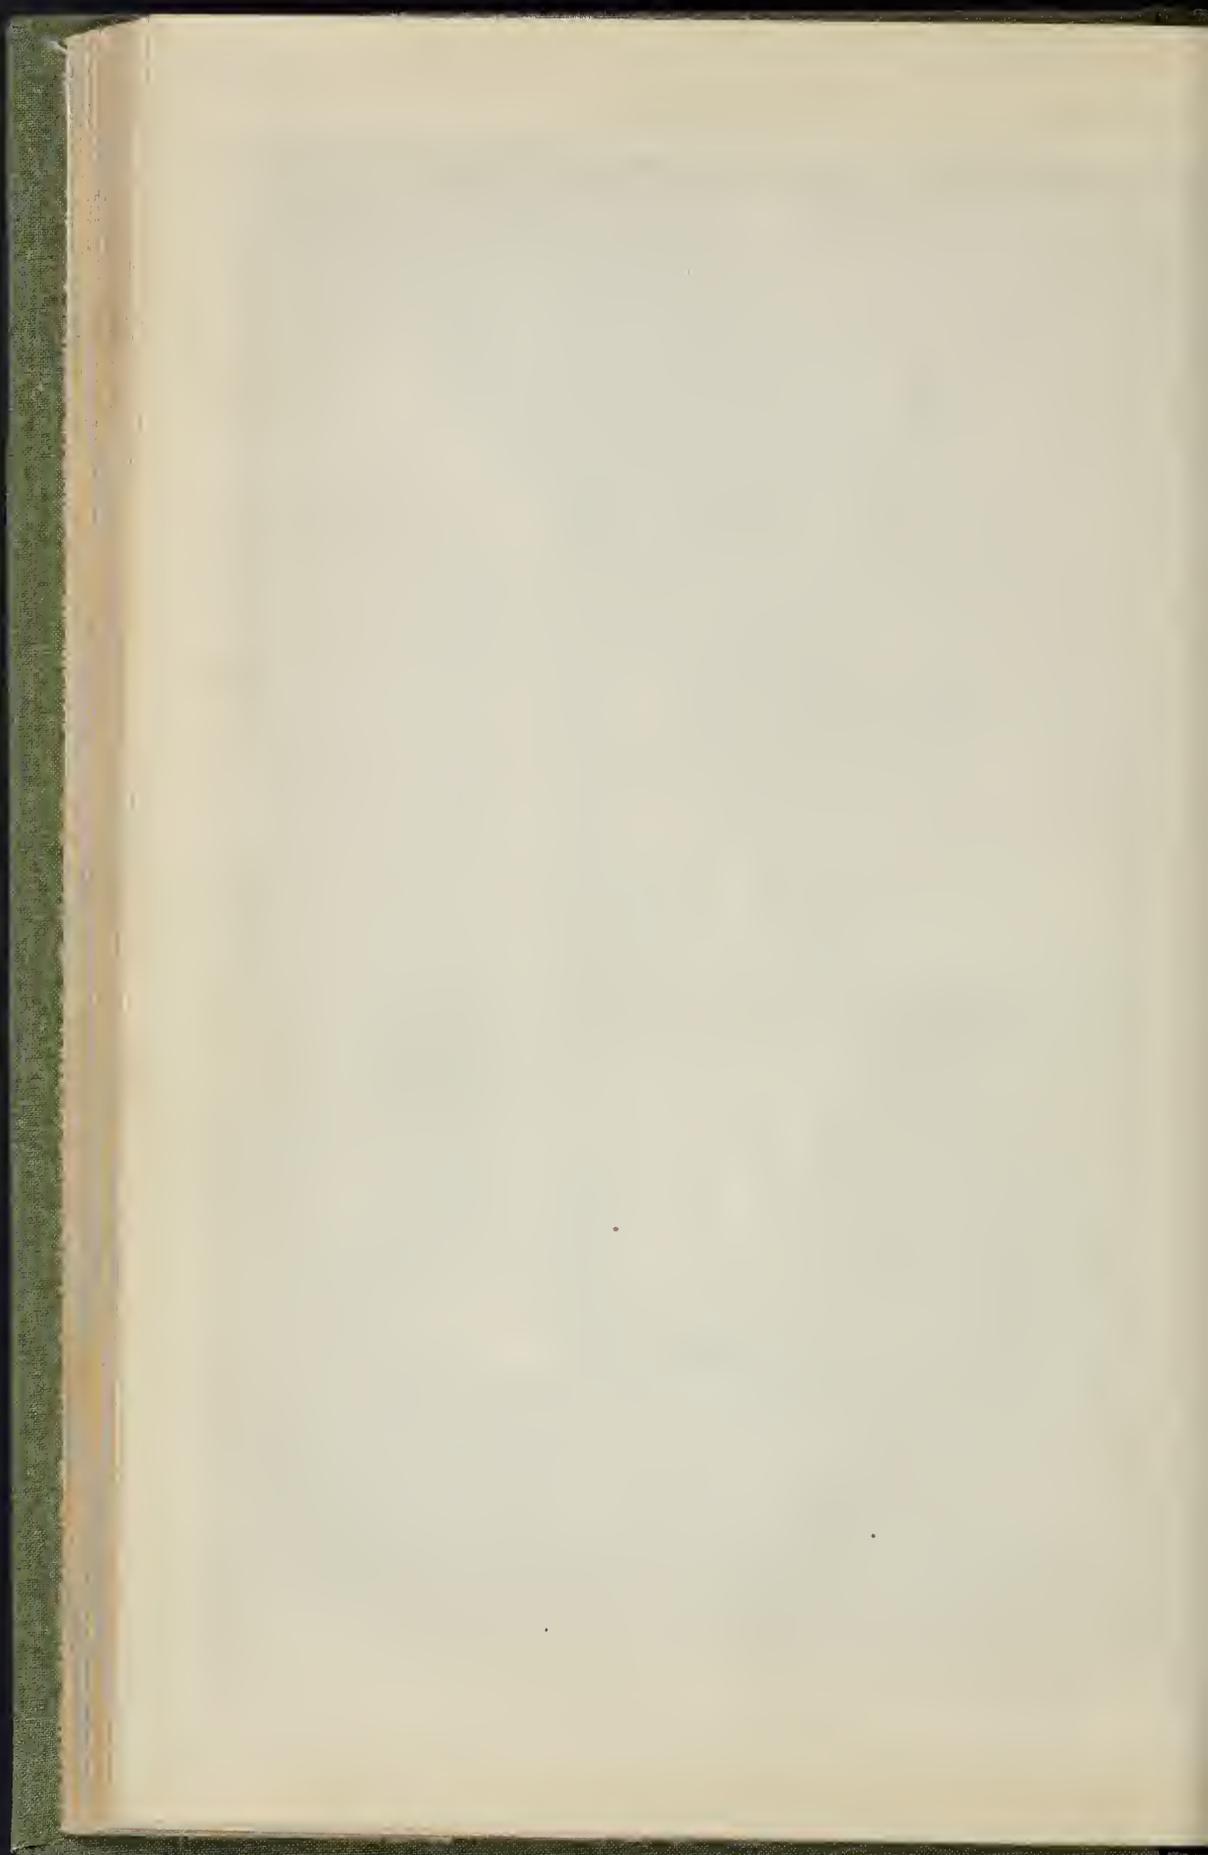

Jeffrey Wyatt, the nephew, was called in to make various additions to his uncle's work, and has not failed to vindicate his superior knowledge, and to exhibit, at the same time, his inferior imagination.

Their descendant, Mr. Digby Wyatt, in the elaborate apartment which forms the subject of our engraving, has proved himself a not unworthy scion of the house. The Renaissance style was no doubt selected, in this instance, in preference to that in which the rest of the house is built, from the circumstance of the apartments being especially destined to receive and display many very beautiful and interesting works of art of the Cinque-cento period, collected in Italy by the Lady Marian Alford—the mother of Lord Brownlow, and the accomplished daughter of one of the most accomplished noblemen (the late Marquis of Northampton) who has ever graced the English peerage. Herself a highly cultivated artist, she has brought the control of a refined and highly critical judgment to the aid of Mr. Digby Wyatt in the successful carrying out of his design, and the result has been the production of the work of art of which we now place a representation before our readers.

The whole of the working and full-size drawings, for the elaborate details which give animation to this composition, were made by the architect himself: the modelling was executed in Paris, by Mr. Deschamps and his assistants; and the reproduction at Ashridge, by Mr. Parsons, of Acton-street, Gray's Inn-road. The work was superintended with great zeal and care, by Mr. Shelbourn, Clerk of the Works to the magnificent estates, which, it may be remembered, formed the great prize in the celebrated law-suit between the Custs and the Egertons, of Totton.

THE MORNING-ROOM AT ASHRIDGE PARK, BUCKINGHAMSHIRE.—MR. DIGBY WYATT, ARCHITECT.

western or lateral towers, equal and similar, and corresponding in position, rising on either side of a noble nave. Two towers, or even minarets, placed in such a position, appear to stand in "supporters" to some other more important, though less conspicuous, member of the fabric. A single tower proclaims, as it were, its own dignity and its own purpose with less direct reference to the relative importance of the rest of the building. I am far from arguing that a single isolated and independent feature may not be so treated as fairly to fulfil the requirement of high art; and it is possible that the same expenditure upon a single tower would often give greater effect than if divided into two. Neither would I pass by the fact, that some of the most imposing and magnificent examples consist in single towers, upon which the architect's whole energy appears to have been concentrated. But commonly, if there are two towers, they ought to be similar in outline and general treatment.

In good work of the best periods we often do find a great dissimilarity between them. This dissimilarity, however, is rarely, if ever, found in the case of two exactly equal towers, or of two side western portals, or other similarly corresponding features, which can be taken in by the sight at the same time. In many, perhaps in the majority, of those towers that are thus counterpoised and otherwise similar, there is a slight difference in the treatment of detail; and this again shows the more forcibly the care taken to assimilate the outlines, subordinating the detail to the general effect. In case of transepts, aisles, or porches, however, which being on opposite sides of the fabric, cannot be seen at the same time, the diversity is allowable, giving scope for a pleasing variety and the display of individuality of treatment. That such diversity is justifiable in the case of two western or otherwise corresponding towers is not an evident, for in a large building each tower may be considered of sufficient importance to be taken almost as a separate whole by itself, thus affording scope for a separate treatment, and, in very many instances of early examples, the diversity cannot be for an instant regretted. Two noble works of art, emanating each other in richness or in grace, standing as sentinels on either side of the same building, of either of which we should perhaps equally deplore the loss,—two such towers add to general effect almost more by their pleasantness of outline than they lose by the lack of uniformity. Our hearts are told us that each one is grand and true, and we do not—ought not to pause and inquire whether two towers alike might not possibly have been, in some respects, better or more imposing. Each tower, perhaps, is sufficient to stand upon its own merits as a separate design, and we must not be too critical as to what would or might have been the effect of a different arrangement. Neither can we accept them as precedents for our modern practice; for, when found in good old work, the diversity arises from their having been built at two different periods—it may be not a few years apart,—by different founders, and by different architects. The case, therefore, does not apply, and still less will it appear applicable as a precedent when we consider that in those days there was a strongly marked uniformity of character, resulting from the development of a systematized and conventional mode of treatment, that gave to the architects of those days a vigour and power upon which individuality, originality and originality might be brought to bear with the certainty of ensuring the greatest success.

We now bring our subject to a close. I have not troubled you with abstractions, and with definitions, but have dwelt upon the practical and self-evident, rather than attempted to force upon you a theory or a special rule. Not because theory is of no interest or of little value, but because theory is a matter for close, earnest, and laborious study, rather than for popular and general discussion. It is with the results, and with the means of producing these results, rather than with the cause of such results, that most men are concerned. Moreover, it is much more to extend the proper appreciation of art than to propound rules and methods of improving or facilitating design, that all efforts raise the condition of art must be primarily directed. Proper appreciation is, indeed, within the reach of most men; but power of design, or to be an artist, can never be taught by rules or methods, and rules and methods are all unavailing, excepting in the hands of the true artist, who gives himself up to his work with life-long labour and devotion. But let us not rest content with the mere external or superficial view which will satisfy many. Let us, each select before us, not passing over apparently trivial minutiae, but reaching them to some tangible shape and position in taking in the subject as a whole; and let us all labour as though we really and truly did appreciate the supremacy of mind over matter, and of the discriminating taste, when refined and educated by cultivation, over mere natural instinct.

#### ELECTRO-TELEGRAPHIC PROGRESS.

A new telegraphic company has been established for the purpose of supplying communications between various parts of the metropolis. Already there have been opened thirty stations, the central one in Thredneedle-street, and nearly 100 other stations, including the various railway termini, are shortly to be opened. The tariff of charges (delivery inclusive) is 4d. for ten words; message and reply, 6d.; message of twenty words, 6d. Messages can be sent from the district stations to and from every telegraph station included in the international telegraphic communion. It is to be hoped the fourpenny telegram is destined to initiate a new system, not restricted within merely metropolitan limits. Why should there not even be a uniform charge of 4d., like the penny postage system, over all the country, if not a rival penny system itself, as the *Western Morning News* has recently urged? As this paper justly remarks,—“No invention offers such great facilities at a small cost as the electric telegraph. The erection of the wires and batteries requires but a small outlay; and, when the communication is complete, messages can be transmitted from one end of the line to the other, at the rate of fifty words per

minute. The cost of working the telegraph in the Grand Trunk Railway of Canada, for the last twelve months, was less than 1,500l., and the number of messages transmitted during that time was over three and a half millions. The expense was, therefore, less than one farthing per message; yet, while messages can be conveyed as cheaply as letters, we are called upon to pay twenty to fifty times as much for the former as for the latter.”

The Liverpool Dock Board have resolved, it appears, to give the marine telegraph system of Mr. Lindsay, of Dundee (without crossing wires), a trial across the Mersey, in consequence of the breakage of the wires of the line already laid. A suggestion made to them by a Mr. T. Craig, of Douglas, Isle of Man, to suspend the wires from lofty poles, instead of sinking them to be dragged and broken by anchors, was laughed at by some of the members present; but, as the *Engineer* points out, there was little to laugh at in such a suggestion, considering that “in Paris five or six wires are suspended, with a very moderate deflection, at a distance of nearly half-a-mile, from the residence of the Minister of Marine to the Tuilleries; at Kowloon, in Russia, the telegraph wires have a clear span of 1,700 feet across the Niemann; in the United States, a telegraph wire is carried, in two spans of 2,400 and 3,750 feet respectively, across the Ohio river, at Paducah; whilst between Turin and Genoa there is one span of three-quarters of a mile (or about that required for crossing the Mersey), between the summits of two ridges of the Hochstaeth chain.”

The Mediterranean Telegraph Company have adopted the report of their directors, which states that the idea of repairing the line from Malta to Cagliari has been abandoned, but that the Malta end of the cable had been taken to Marsala, thus forming a second line to Sicily, in case of any accident happening to the other wires. The report also states that the Government have agreed to divide their guarantee into two parts, so that, should the line between Malta and Corfu, or that between Malta and the Continent, be out of order, one-half of the guarantee will still be received on the half in working order.

#### STREET TRAMWAYS FOR HORSE OMBIBUSES, &c.

For many years, as a very cursory reference to our columns will show, we have advocated the importance and advantages of street tramways, especially in the metropolis, where orderly procedure and smooth progression are so requisite and desirable. We are glad, therefore, to observe that there appears to be a prospect of a fair trial of the system in the City.

The expediency of laying tramways along the principal traffic routes having been frequently brought under the consideration of the Commissioners of Sewers, Mr. Haywood, their engineer and surveyor, was directed to report on the subject generally, but more particularly with reference to a proposal submitted by Mr. John B. Redman. Mr. Haywood has accordingly presented an able report, in the course of which he says that the great towns the advantages of tramways may be thus stated. First, the diminution of friction, the consequent facilitation of the draught of vehicles, and reduction of the strain of horses; secondly, the diminution of noise and vibration, and the increased comfort, both to travellers and inhabitants, consequent thereupon; thirdly, an increased duration of surface, the consequent diminution in the frequency of surface repairs, with the inconveniences attending reparations. In addition to the foregoing, they are very useful in streets having much pedestrian traffic, where the footway space is small; they prevent to a large extent the splashing from the wheels of vehicles; are always cleaner and drier than ordinary pavements; and are more readily kept clean by the scavengers. For many reasons, therefore, the adoption of tramways, where practicable, in large crowded cities is desirable.

Mr. Haywood thus concludes his report:—

“Under all circumstances, I beg to recommend that about from 1,200 to 1,500 feet of Mr. Redman's cast-iron tramway be laid experimentally in Fenchurch-street, or Leutenants-street, in single lines next the kerbs, those being placed where repairment must be made in the approaching spring, and where, from the severe nature of the traffic, the several heads of severity, duration, or cost, can be advantageously tested and studied. This loss, and I believe with positive gain, and information will be obtained which in no other body in the metropolis is so much interested in acquiring as your honourable commission.”

In America street tramways have for some years been in actual use, and their advantages are so highly appreciated that there is not the least

probability of a withdrawal of them. There are five lines in the city of New York. In 1858 they carried upwards of 27,000,000 of passengers, being an increase of 17 per cent. over 1856; and only twelve accidents occurred among 35,000,000 passengers in Brooklyn and New York together. The shares are at 40 premium, and paying dividends from 10 to 14 per cent. “So popular have the roads become,” says a recent letter from New York, “that daily applications are made to our authorities for new grants, in many cases filibustering on those laid down.” The growth of New York has been greatly aided by these facilities of travel. In the United States they are laid in New York, Brooklyn, Philadelphia, Boston, Cincinnati, and other cities, and all pay large dividends. Why should the metropolis, as well as Glasgow, Dublin, Manchester, Liverpool, and other great towns, be without them?

We may refer those of our readers who feel an interest on the subject to a pamphlet by Mr. G. P. Truin, just published, by Low, of 47, Ludgate-hill, in the form of a letter, addressed to the Right Hon. Milner Gibson, M.P., President of the Board of Trade, and titled “Observations on Horse Railways,” in which the American experience in such tramways is fully treated of.

The *Times*, in opposition to Mr. Grantley Berkeley's prejudiced view of this question, advocates the absolute necessity of some such system in London; but says that “the rail should be laid in the middle of the street, with stations at the chief crossings, while the lighter traffic, and all that had to stop in the intervals, would naturally take the side.” For omnibus tramways, however, the sides, next the pavements, would surely be the most fitting, while the common highway would best occupy the middle of the street between the two lines, at least in thoroughfares admitting of three distinct wheel ways, whether trammed or not. One line of tramway only, we may fear, be worse than useless, as meeting vehicles would perpetually obstruct each other, and better have two such lines without any untrammed way between them, than one line with two untrammed side-ways.

#### PROGRESS OF DOCK WALLS AT LIVERPOOL AND BIRKENHEAD.

Dock masonry is progressing at Liverpool and Birkenhead. The dock and river walls are, for the most part, rubble, or irregular masonry set in engine-ground hydraulic mortar. The walls are about one fourth mortar. At the several establishments, not much less than a hundred mortar-pans are at work, grinding with a power of some three hundred horses. If we take ten hours as a working-day, and each pan grinding one cubic yard per hour, this will give 1,000 cubic yards of mortar, or 4,000 cubic yards of masonry, per day; and taking 300 working days per year, gives 300,000 cubic yards of dock masonry per annum. The mortar is made from Alkin mountain lime, and costs, ground, about 10s. per cubic yard. The masonry set in the work costs, with all expenses, staving, &c., about 15s. per cubic yard. Dock and river walls are set to a slope of 3 inches to each foot vertical, or 4 to one on face; 6 feet thick at the coping; 12 feet thick at 30 feet depth and in like proportion for extra depth.

#### THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held at the house in Curditt-street, on Friday evening, the 3rd, Mr. J. W. Penfold, president, in the chair.

The minutes of the last meeting having been read and confirmed, Mr. Arthur Smith, of 15, Great Castle-street, Cavendish-square, was unanimously elected a member.

Mr. Druce then brought forward the resolution of which he had given notice at the meeting of the 6th of last month, that a class be formed for the purpose of learning and practising wood-carving and modelling, to be held at seven o'clock in the evening of the Class of Design. Mr. Druce explained that the only expense attending the matter would be payment of a skilled instructor, to meet which he would propose that a small subscription be raised among the members of the practical class. He should like to hear the opinions of the members on the subject before the proposition was laid before a general meeting. With regard to the actual expense to be entailed by its adoption, he had hoped to be supplied with full information, but was prevented in consequence of the illness of the gentleman from whom he expected to have obtained it.

Mr. Roger Smith seconded the resolution, ob-

serving that a practical knowledge of wood-carving and of modelling was extremely desirable for the proper discharge of their professional duties.

The Chairman, before putting the resolution to the meeting, stated that he was desirous that the studies in connection with the School of Design should be practical, and of a constructive nature. He approved of wood-carving as likely to conduce to that object, but he hoped that drawing and sketching, as now carried on, would not be interfered with.

The resolution was then put, and carried unanimously.

Mr. Blashill then read a paper "On the Application of Iron-work to Architecture."

At the conclusion, On the suggestion of the Chairman, the discussion was adjourned until the next night of meeting (Feb. 17), and the proceedings terminated with a vote of thanks to Mr. Blashill for his communication.

OXFORD ARCHITECTURAL SOCIETY.

The first meeting in Lent Term was held on February 1st; the Rev. the Master of University, in the chair.

The subject proposed for discussion was "The use of coloured materials in the construction of buildings." The President, after calling attention to the existence of alternate courses of stone in the vaulting of the cloisters of Westminster Abbey, proceeded to remark on the good effect produced by a variety of colour in constructional materials, whether brick or stone, provided there was not too great a display attempted. The use of colour in constructional materials had not, he thought, been sufficiently studied, as yet, to justify any very decided statements as to what rules should be observed in its employment; but he considered it important not to make too strong a contrast, nor to attempt too much brilliancy. He also called attention to the fact that great care should be taken that the materials should not be of so porous a nature as to lose their colour easily.

Mr. Parker advocated the use of coloured materials of construction, as being likely to improve greatly the effect of buildings; observing, at the same time, that red stone was much more liable to lose its colour than others, and hence that its effect was much sooner lost.

Mr. Buckridge objected to the restricting of architects in their choice of materials. He observed that coloured materials must be used in courses, and hence that they must frequently be employed to form horizontal lines, which he maintained were not inconsistent with the principles of Gothic architecture.

The President, in conclusion, called the attention of the meeting to a church now building at Highbridge, near Bristol, and stated that, in his opinion, we had yet to feel our way in reference to this subject, and that experience would eventually decide much that was now uncertain as to the most advantageous manner of employing coloured materials.

NORTHERN ARCHITECTURAL ASSOCIATION.

COMPETITION, BISHOP AUCKLAND.

A MEETING of the Committee of this Association was held on the 8th instant, when resolutions were unanimously come to, in reference to an advertisement issued by the directors of the Bishop Auckland Town Hall and Market Company, for the best plan for a Town Hall and Market, to cost 3,500*l.* for which a premium of 20*l.* would be given; the directors, however, not binding themselves to employ the architect of the prize design; and also reserving to themselves the right of purchasing any unsuccessful design for the sum of 5*l.* if not objected to before February the 11th.

It appeared that Bishop Auckland Town Hall and Market Company had returned no reply to the communications addressed to them by the secretary of the Association on the subject.

The following are the resolutions:— "This Association begs to submit that the premium offered of 20*l.* is not a sufficient reimbursement for the services rendered in preparing the required design, unless the architect of the successful design be employed to carry out the work on the usual terms. The Association wishes to draw the attention of the directors to the fact that a commission of 14 per cent. on the estimated outlay is the usually required charge for such drawings as are required by the directors.

The opinion of this Association, moreover, is, that services cannot be done to the building by any architect other than the author of such design. After what has been stated, as to the value of the drawings required, the Association does not consider it

necessary to dwell upon the utter inadequacy of the offer of 5*l.* as a remuneration for the copyright of any unsuccessful design.

The Northern Architectural Association respectfully begs that the directors of the Bishop Auckland Town Hall and Market Company will take these resolutions into their consideration, in justice to their own constituents, and to the architectural profession.

- (Signed) JOHN DONSON, President.  
 " THOMAS ARSTY, Hon. Treasurer.  
 " THOMAS OLIVER, Hon. Secretary.  
 " J. E. WATSON,  
 " M. GREENBER,  
 " F. R. N. HASWELL,  
 " A. M. DUNN, } Committee."

GRAVING DOCK, DUBLIN.

THE new graving dock for some time in progress of construction at the North Wall Point, Dublin, has been opened. It will accommodate the largest vessels that can enter Dublin, and is at the north-east side of Halpin's Pool. The dock is 400 feet in length, 80 feet wide at top, and 35 feet at bottom, with an entrance 70 feet wide. An engine, 40 horse-power, and constructed by Easton & Amos, of London, with an Appold's centrifugal pump, are used for the emptying of the dock when the gates are closed. Mr. Dargan was contractor for the masonry, which is granite, and Messrs. Wilde & Mallet constructed the gates, which are on a cellular principle, patented by them. Various buildings are in connection with the dock, viz., engine-houses, workshops, timber-steaming apparatus, &c., &c. The first vessel admitted into the dock was the *Agnes Anderson*, 200 feet in length, and the property of Messrs. Martin & Sons. It is in contemplation to construct a basin, 1,100 feet in length, close by, and to prolong the present quay considerably beyond the lighthouse.

DINNER OF THE BUILDERS' SOCIETY.

THE twenty-sixth anniversary of this society was celebrated on the 9th instant, at the Freemasons' Tavern, Great Queen-street, Mr. James C. Lawrence in the chair, and was attended more numerously than usual in consequence of recent proceedings, above sixty sitting down. Amongst them were Mr. Henry Lee, Mr. Thomas Piper, Mr. Charles Lucas, Mr. George Mair, architect, Mr. Dunmore, G. of Bird, Mr. James Bird, Mr. Myers, Mr. Plucknett, Mr. Watts, Mr. Hill, Alderman Lawrence, &c.

Mr. Lawrence discharged the duties of his office very ably. In proposing "The Society," he said it had served to turn ruinous rivalry into honourable competition. He dwelt on the importance of maintaining a high standard of character, and hoped every builder would entitle himself to be spoken of as the carpenters were described on the walls of one of the old Halls of London, where it is said the money was not counted that was handed to the carpenters, because they were faithful to their engagements.

Alderman Cullitt was elected president for the ensuing year; and Mr. Lee, in replying for him and for himself, said the society was founded by seventeen builders, who being asked to tender on a specification they did not contain the arbitration clause, had all declined, and this was still the rule of members of the society. Mr. Plucknett replied for the vice-presidents; and Mr. Thomas Piper, as honorary secretary, made, as usual, a very good speech.

A song by Mr. Cole, let us say, in passing, combining feeling with humour, was much more satisfactory than the music of the professionals engaged.

FEMALE SCHOOL OF ART, GOWER STREET.

A MEETING has been held to prevent if possible the dismemberment of this school. It was attended by about a dozen gentlemen, who at its conclusion formed themselves into a Provisional Committee.

They first took into consideration the merit and value of the school, and unanimously resolved that there could be no doubt as to its importance and claim to continued support. Next came the question as to whether, with a fair start given to it, by the purchase of premises and other help, it could eventually become self-supporting, and this they also came to the conclusion would be the case after a certain time.

They then drew up a brief statement to be laid before the public, concluding with an appeal for funds to enable them to purchase premises, and establish the school on a firm self-supporting basis independent of the annual Government grants hitherto accorded.

We quite agree with the Committee, that the instructions given in this school are eminently

useful, and may be received and eventually turned to profit, without necessarily taking them out of their proper sphere. To throw away the ground won by many years of patient industry would be mortifying, if not foolish; and it is hoped that this appeal on behalf of a school hitherto so ably conducted, and so conveniently situated for the North and West of London, as well as the City, may be liberally responded to, not only by the residents in the immediate neighbourhood, but also by the inhabitants of the Metropolis at large.

STAINED GLASS.

Gloucester.—The restoration of the interior of the west end of the cathedral, according to the *Chronicle*, is now nearly completed, and the memorial brass to the late bishop has been erected. In order to carry out the restoration, the monument of Bishop Martin Benson, which stood on the north side of the doorway, has been removed.

Tettenhall (Staffordshire).—A window of stained glass, executed by Messrs. Hardman & Powell, has been placed at the west end of Tettenhall Church, by the family of the late Mr. William Ward, to the memory of their deceased parents. The subjects, eight in number, are, "Missions of Angels to the Earth." The tracery in the head of the window is filled with a choir of angels. Beneath is a brass plate, bearing the inscription.

Glasgow.—A committee has been appointed for the purpose of erecting a decorated window in the crypt of the cathedral, as a memorial of the late astronomer, Professor Nichol. The committee were empowered to collect subscriptions, which it was agreed to limit to 1*l.* each. Mr. James MacKenzie, of Auchenghlish, according to the *Glasgow Gazette*, has kindly consented to place the window adjoining his vault at the disposal of the friends of Professor Nichol.

PROVINCIAL NEWS.

Seer Green, near Beaconsfield (Bucks).—Schools have been completed at Seer Green from the designs of Mr. L. G. Butcher. The group consists of residence for mistress on the ground-floor, and bed-rooms on the first floor; a school-room 30 feet in length, 16 feet in width; by a height of 16 feet to the collar of the roof, at which level the roof is ceiled in, forming a chamber for the extraction of the vitiated air. The school-room is planned in accordance with the requirements of the Committee of Council on Education, to accommodate fifty children, having separate entrances for the boys and girls. Each of the entrances has an open-framed timber porch. The material of the buildings is brick, made in the neighbourhood, a few black bricks being introduced in the arches over the windows, and in a band running round the walls both of the school and residence. The roofs are covered with tiles, with bands of ornamental tiles introduced, and finished with a plain tile cresting. The funds were raised mainly by the Rev. H. Herbert, the incumbent of the district, aided by a grant of 144*l.* from the Council on Education. The works have been executed by Mr. Jessup, of Maidenhead, at a cost of 465*l.*, exclusive of fences and fittings.

Moccas (Herefordshire).—A rectory house has just been built here for the Rev. G. H. Cornwell. It consists of drawing-room, dining-room, library, and kitchen department, on the ground floor, with eight bedrooms on the first floor. It is built of red bricks, with stone bands. The joinery is varnished, neither painted nor stained. The principal rooms have fireplaces, lined with Poole tiles, and have dog grates. The building looks large from the high road, from being in the form of an L, set with corner towards the road. The total cost is 1,000*l.* Mr. George Truefit is the architect. Messrs. Evans are the builders.

Manchester.—The Manchester and Salford Banking Company have resolved to erect a new building, for which the plans have been prepared, and operations have been commenced for clearing the ground. The site selected is a central one, at the junction of Mosley-street and York-street. The frontage to Mosley-street is 112 feet, and the depth to Back Mosley-street is 80 feet. Mr. E. Walters, who designed the Free-trade Hall and many warehouses at Manchester, is the architect; and the style he has adopted is the Italian. The building will be of three stories; the lower stage being rusticated, and the windows resting upon some 9 feet of solid masonry, marked only by the simplest lines. The height from the ground to the top of the balustrade will be fully 86 feet. The entrance will be from Mosley-street; there being a broad entrance porch which will be carried

only to the height of the lines of the ground-floor. By a flight of steps, and an outer and an inner lobby, access will be gained to the banking room, which will be 84 feet long, 50 feet wide, and nearly 27 feet high. The floor and the ceiling will be fireproof; and there will be special arrangements for "the treasury." The building will be of Yorkshire stone.

**Liverpool.**—Messrs. Phillip & Son's new premises, South John street, are finished. The building is about 70 feet by 40 feet, and 60 feet in height, consisting of four stories above the ground, besides the basement, which is half its height above the street, and is intended for superior printing machinery. The front is built with patent pressed brick, and all the doors and windows finished with Welsh stone dressings. The entrance to the saloon is flanked with red Aberdeen granite columns. Messrs. J. W. & J. Hay are the architects; Messrs. Holme & Nicol the contractors for the brickwork and carpenter and joiner's work; Messrs. Parker & Son for the mason work; Mr. Holt for the plumbing, painting, and glazing; and Mr. Thomas Jones for the slater and plasterer's work.

**Hull.**—It is proposed to provide a public park at Hull, and the town council have appointed a committee to further the project.

#### THE "BUILDER'S" FIRE.

SOME time ago the *Builder* drew attention to a method of laying and lighting house-fires, known as "the *Builder's* fire." One part of the plan consists in closing the bottom of the grate with a plate of sheet-iron, and this alone will effect a considerable saving in coals. Have a piece of thin sheet iron cut to the form of the bottom of the grate, and make the fire above it: the sheet-iron prevents the ashes falling through, and produces a more equal combustion: it does not "dead" the fire, which will burn as brightly and as warmly, indeed warmer, than with open bottom bars. A saving of a fraction of the coal consumed in the metropolis, and a reduction of smoke, are desirable results. The *Builder's* fire will, most undoubtedly, accomplish these: the bottom plate alone will effect considerable saving. I have continued the plan at office and house for some three years, and, therefore, have had this length of experience. Dr. Farr, of the Registrar General's Office, Dr. Southwood Smith, Mr. Graham, of East-ledge, Enfield, and many others, have also adopted the plan, and are satisfied as to the benefit and saving. I only give these names, and my own, as guarantees of the facts stated. Amidst so much trade advertising, and puffing, a disinterested puff, this cold weather, to make the *Builder's* cheap and improved fires burn more extensively, may be allowable.

ROBERT RAWLINSON.

#### MONSIEUR MAZois AND PROFESSOR COCKERELL.

A FRESH edition of the elegant volume of Mazois, "Le Palais de Scarus," has just appeared. This important work, in the form of letters from a German prince, supposed to be residing at Rome, gives, most of our readers are aware, a description of a Roman palace in all the detail of its structural arrangements, embellishments, and furniture, and alludes with minute accuracy to the domestic manners and customs of the ancients, illustrated by numerous plans and views of the parts of a Roman house. This reprint is prefaced by a biographical notice of the author by Monsieur Vauclerc, enriched by original materials found among Mazois' papers. A letter to Monsieur de Clame, dated June, 1815, is of peculiar interest to us Englishmen, and will therefore not be unacceptable, we trust, to our readers, from the tribute it bears to the character of so eminent an architect as Professor Cockerell, when a young man abroad, on his studies, and the moral worth of both these eminent architects, realized in after-life.

"The storm [alluding to the expulsion of Murat and the return of the Bourbons to Naples], has just fallen upon Naples. It has struck down my protectors and dispersed my friends; but there still remain to me my courage, my intelligence, and my love for you. These are more than enough to surmount the new obstacles with which my onward way is so thickly beset. I have no money, which in truth renders my position very critical; and at the same time I am deprived of my pension and of my firmest supporters. Well, let us hope that Heaven will raise up others. Does it ever abandon those who, like me, only entertain legitimate hopes? In the meantime I must have assistance, and endeavour to procure me funds

without contracting new debts. There is but one means to effect that, which is to sell the little house which still is left to us. My work, the ultimate success of which is ensured to me, will be of greater good than this precarious possession. Besides, the least delay in the publication of my work may be productive of serious consequences.

There is a young English architect here, Robert Cockerell, who has just made a long journey in the East. After having traversed Asia Minor and Greece in every direction, he visited, with the zeal of a clever artist and well-educated man, Sicily, and the Kingdom of Naples, and has collected much valuable information. Having heard of the book in which I was engaged, he called upon me; and, finding that our tastes were congenial, we were drawn to each other, and soon became the best friends in the world. The intercourse with such men is not only very precious, but is also very advantageous, as you will see. Mr. Cockerell, with infinite kindness, has offered his services with respect to the introduction of my work into England on his return thither. In the meantime a happy opportunity has arisen, which enables him to render me a still greater benefit. His master, a rich and influential man, in London, as architect to the court, has written to him, saying, that, having formed the project to make drawings and measurements of the ruins of Pompeii, with a view to publication, he begs him to organize this work, and to accept the editorship. Ah! my good friends, what an unexpected blow was hanging over us! Cockerell, with all his loyalty and goodness, hastened to reply that the ruins of Pompeii, drawn, measured, and explained, with as much talent as care, had begun to be published two years before,—that it was matter for regret that England should not know of the work when France and Italy already appreciated its merits. Besides which he, of all men in the world, could take no part in a rival work, for he had too great an esteem and respect for the author; and, as disaster and ruin would be the consequence of the competition, it was only consistent with his honour frankly to state the truth, and to decline contributing to the proposed work.

For me the result has been doubly advantageous,—the abandonment of the English project, and the subscription of the English architect. So that, after this providential occurrence, and although I have 10 feet of water in the hold, I am not at all disposed to abandon the helm or the pump. I have all faith in the future.

MAZOIS."

#### THE WAR OFFICE AND CONTAGION.

Will you permit me to say a few brief words in reply to "X." I ask this favour, because one does not like to seem inaccurate or unjust; and Mr. Herbert is the very last man towards whom a sanitarian—as I presume, in a modest way, to call myself—could wish to be unjust or inappreciative; besides that, as it happens, I, and others of my cloth, owe him a special and heavy debt of gratitude. When I sent you the note on Camp Hospitals, the War Office circular was lying before me, so that I knew quite well what names were at the top and bottom of it, but I never dreamt of imputing any knowledge of it to General Peel or Mr. Herbert, any more than to the greater War Minister than either about whose time I was guessing. The term "Secretary for War" was seemed a convenient mode of saying from what office the order had proceeded. Besides, have we not heard something of a "Sanitary Councillor" who was to be responsible for these things?

"X." thinks that in strict grammar the second order annuls the first. But the War Department is, like the French king, *super grammaticum*, above grammar. If logic and Lindley Murray are against it, why, *tant pis* for logic and Lindley Murray. It never cancels an order. It only contradicts itself. On looking carefully into the matter, I fear that "X." is mistaken. "Contagious" and "epidemic" are not convertible terms. The first order provides for the fumigation of rooms (page 3) as well as of foul linen and bedding. The second speaks only of the latter. I suspect, therefore, that if, in any instance, "X." were to assert the common sense of the latter, and seek to ignore the antique absurdity of the former order, the War Department might say, with the lady in the "Merry Wives of Windsor,"—"Why, were best meddle with buck-washing."

The order being still in force then, let us pause for a moment and consider the extent of its meaning. Never, surely, has authority laid a ruder hand on opinion, since the Pope, one morning, commanded a hundred and fifty millions to believe

the dogma of the Immaculate Conception. For nearly seventy years, ever since the good ship "Hanky," Cox's, Master, sailed southward, he for the island of Balaña, the world has been fighting about the contagiousness or non-contagiousness of yellow fever. Such another angry controversy has never been known in socio-medical polemics. It has almost raised municipal war in some colonies, as at Gibraltar. It has estranged fast friends. It has made fat sinucures and has unmade them. It has made enthusiasts swallow black vomit, and sleep in beds in which men had just died of the disease. I myself have seen a letter from New Orleans advocating non-contagion, and written with the black vomit for ink, handed round to a hundred medical students, the writer thinking that he had thus proved his case. Ducks have been fought about it. It is said that in one tour of West Indian service, an impatient Irishman fought three duels about it, and killed his man in the last, without convicting anybody. One really fancied that Lord Shaftesbury's board (1832) had finally laid the ghost of yellow fever contagion, but, with a stroke of Sir Benjamin Hawes's pen, here it is alive and active again. Not boldly asserted, but gently implied by a conjunction, here is a formal resurrection of Dr. Chisholm and Sir William Pym. Sir Benjamin Hawes writes the little word *or* between "yellow fever" and "other contagious disease," and, forthwith, all the old discarded properties must be furnished up, and put on the stage again; all the obsolete absurdities must be revived: yellow flags, the *quarante jours* of "expurgation and infestation," tobacco-smoked letter-bags, meat steeped in vinegar, oilskin dresses, restricted commerce, broken hearts, and a cordon of sentries, to shoot even a rat if he tries to pass from one house to another. Look again at another result. I, for one, had read myself into a belief in the "localizing causes" theory. Need I say that since Waterloo-day, 1859, I have abandoned that foolish modern innovation, and have dutifully returned to "the wisdom of our ancestors."

Now, seeing that we have, just at present, a Secretary for War who is not only an enlightened sanitarian, but also a man of great and acknowledged taste, what I would like to say to Mr. Herbert, if I could approach him, is this—and I hope that "X." would agree with me.—If *we must* have the closed doors, the closed windows, and the stinking cauldron, let us also have something aesthetic,—the appropriate trio from Verdi's "Macbeth," for instance. Unluckily, so many "departments" are to be concerned in the process that the music would surely be out of all time. CWX.

#### THE RIGHT OF COUNTY SURVEYORS TO RETAIN THEIR DRAWINGS.

THE question on this subject between the county magistrates of Norfolk and Mr. Brown, their late surveyor, has been arranged. It will be remembered that the Court of Quarter Sessions held on the 5th of January refused to accept either of the offers made by Mr. Brown. The first proposition was moved by the Deputy, "To allow the clerk of the peace, or any of the persons appointed by them, to make, for the use of the present and future surveyor, copies or tracings of all the plans and specifications prepared by the late surveyor for the works executed under his superintendence as county surveyor, or to furnish copies upon being remunerated." Mr. Brown's other proposal was, "That the matter in dispute should be referred to two eminent metropolitan architects, with power to call in a barrister as umpire." And they finally determined to instruct the committee who had reported the matter to enforce their claim by legal proceedings if they could not effect an amicable arrangement. On the 11th of January, the clerk of the peace served Mr. Brown with a formal notice and demand for delivery of the plans, to which Mr. Brown's solicitor made the following reply.—"Sir: I have conferred with my client on the resolutions of the magistrates, together with the proceedings (as reported in the Norwich papers) of the court at which they were passed, and we see no reason for altering either our views or our position. The demand is, at least, an unusual one; and I find that no plans were delivered to my client when he entered on the duties of his office. I need not repeat here his views and reasons, which have been already explained to you, except by stating that his claim to retain the plans in question is based on the broad ground that they are his own property, by the recognized usage of his profession, and the proper construction of the terms of his late engagement. I may observe that the opinions entertained by some of the magistrates

themselves, and the manner in which the question has been since taken up by the Royal Institute of British Architects, justify the course taken by my client;" and he concluded by again offering to submit the matter to arbitration on the terms previously offered, or to adopt the amendment moved by the Dean. On the 28th, the clerk of the peace, instructed by the Castle committee, consented to accept the proposition moved by the dean, and nearly unanimously rejected at the sessions. Arrangements have since been made to carry this into effect, and the drawings are being copied by Mr. Phipson, the present surveyor, Mr. Brown retaining the original plans, his property in which is thus admitted by the magistrates.

Books Received.

VARIORUM.

THE American "Annual of Scientific Discovery; or Year-Book of Facts in Science and Art," for 1860, edited by Mr. D. A. Wells, A.M. (Gould & Lincoln, Boston, U.S., and Trubner & Co., London), has been published. It appears to be as worthy of commendation as ever it was, and forms a very interesting volume, in which many of the facts of the year are treated of at considerable length. The whole is prefaced by some twenty pages of notes by the editor on the progress of science for the year 1859.—A pamphlet, titled, "The Invasion of England rendered impossible, by a simple and practical mode of defence," by a "Member of the Naval and Military Institution" (Hardwicke, Piccadilly), suggests that from Edinburgh, southwards, round the east coasts, and northwards, round the west coasts to Glasgow, all open beaches, mouths of rivers, sea-coast towns, &c., should be protected by long 32-pounder guns, 30 yards apart, the whole series comprising some 60,000 guns, costing, say, 6,000,000*l.*, and to be manned, and sand-bag batteries thrown up in time of war, by coast-guard gunners, aided by crews invited from the respective neighbourhoods, under certain pecuniary and other regulations. The pamphlet also contains an interesting account of eight attempts at invasion. The author is of opinion that the object to be mainly kept in view is to prevent a hostile landing, rather than to provide armaments against invaders already landed.—Mr. E. F. Merrill, C.E., has had published (by Wilson, Royal Exchange) "A Letter to Col. A. Cotton, upon the introduction of Railways in India upon the English Plan," in which India stands greatly in need of a few thousand miles of railway; but the enormous cost of many English lines, it is to be hoped, will not be incurred in providing these.—Among other books received we may here note "A Manual of Interest and Annuities, including Fifty-four rates of Interest; the Value of Life Annuities, by the English Life-table; and Suggestions for the more equitable Assessment of the Income-tax," by E. E. Smyth (Routledge & Co.); and "Vacher's Parliamentary Companion," published monthly, during the session, at 29, Parliament-street, Westminster.

Miscellaneous.

"PRIVATE" COMMUNICATIONS.—We are requested to express Mr. Falkener's regret that the observations made by him in last week's *Builder* were printed in inadvertence, in consequence of his having omitted to mark them "private."

THE CRIMEAN MEMORIAL AT CHATHAM.—The excavations for the foundation of the Crimean memorial to the Royal Engineers, to be erected at the eastern entrance to Brompton Barracks, Chatham, have been commenced by Messrs. Mansfield & Son, the builders; but, in consequence of the character of the proposed structure, it is probable that six months will be occupied in its erection. The site selected by the Government is the piece of ground between the Hut Barracks and the Brompton Barracks. The architect is Mr. Digby Wyatt. The design, which have received the approval of the Government, include a large central arch between 20 and 30 feet in height, on each side of which will be a smaller arch, upwards of 12 feet in height and of proportionate width. The general form of the structure will be that of a parallelipedon, nearly 40 feet in height, 44 feet in width, and 10 feet in depth. The whole will be surmounted by an attic, with carvings in relief. It will be built from Portland stone, with white marble tablets and facings.

THE LOMAS-SQUARE NUISANCE AT CHATHAM.—We are glad to hear that the horrors of Lomas-square, Holborn-lane, Chatham, which the *Chatham News* lately dragged into light, are now in a fair way of being removed; the Local Board of Health and Watts's Charity Trustees having come to an understanding as to the nuisance, which the trustees have promised to abate by the erection of various conveniences and other means. At the expiry of the lease in 1861, moreover, the character of the property will be altogether changed.

ST. MARTIN-IN-THE-FIELDS LIBRARY FOR THE WORKING CLASSES.—The Rev. H. Mackenzie, vicar of the parish from 1848 to 1855, when he resigned, reappeared among his former parishioners on February 13th, and entertained them with a lecture on the subject of "The Young Chevalier and the Battle of Gulloden." The reverend gentleman was warmly received by his audience, and a cordial vote of thanks was passed to him at the conclusion of his interesting lecture.

CAMBRIDGE ARCHITECTURAL SOCIETY.—On February 9th, a meeting of the Cambridge Architectural Society was held at the Philosophical Society's rooms, when the Very Rev. the Dean of Ely made a communication concerning the lantern at Ely. He showed by a model the original construction by Alan de Walsingham, pointing out the alterations which it has undergone, so far as can be ascertained. He showed that it was originally a campanile, for there exist documents giving a detailed account of the bells. He explained the several questions which are being discussed concerning the present restoration. In conclusion, he stated that they are still in want of funds for carrying this out. They have under 3,500*l.*, whereas the sum required is 5,000*l.* They intend to commence work in the spring.

GAS.—At a meeting of the Ware Gas Consumers' Company, recently held, it was resolved that 3,500*l.* should be offered to Mr. Holcombe for the present works. He has refused to accept this sum, and has since sold the works to a company in London for 4,000*l.* It is not unlikely, it is said, that the Local Consumers' Company will establish independent works.—The Worcester Gas Company have declared a dividend at the rate of 7 per cent. per annum.—A correspondent of the *Bradford Observer*, asks "How is it that while in Huddersfield the price of gas is 3s. 6d. per thousand feet, and at Saltaire the same price is charged, we in Bradford should be charged 4s. per thousand?" and adds: "It is high time that a Gas Consumers' Association were formed here, to take in hand the whole subject connected with gas supply, with a view to the reduction of the price charged under the present monopoly."—The convenience of a good steady light, it appears, has been obtained in some of the first-class carriages on the East Lancashire Railway, by the use of gas. The meter from which the gas is supplied is contained in the guard's van. It is conveyed to the roofs of the carriages and through the usual lamp holes. There is one light in each carriage, which is sufficient to illuminate the compartment thoroughly, so that the smallest print can be read. The taps are on the roof. The junction between the carriages is effected by means of a flexible tube, with a little slack.

DISEASES.—Is it not living in a continual mistake to look upon diseases, as we do now, as separate entities, which *must* exist, like cats and dogs; instead of looking upon them as conditions, like a dirty and a clean condition, and just as much under our own control; or rather as the reactions of kindly nature against the conditions in which we have placed ourselves? I was brought up, both by scientific men and ignorant women, distinctly to believe that small-pox, for instance, was a thing of which there was once a first specimen in the world, which went on propagating itself, in a perpetual chain of descent, just as much as that there was a first dog (or a first pair of dogs), and that small-pox would not begin itself any more than a new dog would begin without there having been a parent dog. Since then I have seen with my eyes and smelt with my nose small-pox growing up in first specimens, either in close rooms or in over-crowded wards, where it could not by any possibility have been "caught," but must have begun. Nay, more, I have seen diseases begin, grow up, and pass into one another. Now, dogs do not pass into cats. I have seen, for instance, with a little over-crowding, continued fever grow up; and with a little more, typhoid fever; and with a little more, typhus, and all in the same ward or but. Would it not be far better, truer, and more practical, if we looked upon disease in this light? For diseases, as all experience shows, are adjectives, not noun substantives.—*Notes on Nursing, by Florence Nightingale.*

EASTBOURNE DRAINAGE COMPETITION.—The local Board of Health for this town some time since advertised for plans for the drainage of the neighbourhood, to include Eastbourne, South-street, and the sea-side houses. There were fourteen competitors; and the board, at their meeting on Monday last, awarded the premium of 50*l.* to Messrs. Morpew & Green. It appears that the Duke of Devonshire has thrown open a quantity of land for building purposes, which will render a system of drainage absolutely necessary.

"TRAVELLERS' RESTS."—Dr. Kendrick, of Warrington, who has erected a number of "Travellers' Rests" on the highways in that locality, has published an engraving in the *Harrington Guardian*, exhibiting the form and size of these public conveniences, as an inducement to others to do likewise. The "rest" is of stone, slightly rounded on the upper surface to throw off the rain. The dimensions are 5 feet 3 inches long, 22 inches wide, and 16 inches high; and at each end of the centre of the seat, and forming part of it, is one 10 inches high for children, and which likewise forms a convenient footstool for a mother with a child at her breast. The lowness of the seat enables the occupant to bend the body forward, and to rest the elbows upon the knees.

THE DRINKING FOUNTAIN MOVEMENT.—At Yarmouth the fountain presented by the late mayor, Mr. R. Steward, to the town, and placed on the north side of the Town-hall, has just been completed. The water flows from a piece of rough unpolished rock into a red granite basin.—At the Edinburgh Council last week, a communication was read from Professor Balfour as to the erection of a drinking fountain in the quadrangle of the college, which Councillor Hope proposed to be erected at his sole expense. The matter was remitted to the college committee, with powers.—A drinking fountain is to be erected in Elgin, at the west end of the Plainstones, on the High-street. It is to be of cast iron, with four taps and ladles, a trough for horses, a basin for dogs, and is to have a gas-lamp on top. The council have given their sanction to the erection.

THE ELECTRIC LIGHT: APPLICATION TO SURGERY.—One of the greatest obstacles to the success of a surgical operation is the scanty and imperfect light which, in some cases, is the surgeon's only guide, and is fraught with danger to the patient. Thus, the extirpation of a naso-pharyngeal polypus is almost performed in absolute darkness, it being impossible to bring a common light near enough to the patient without scorching him. The problem, therefore, of finding a light which might be introduced into a cavity with impunity, remained still to be solved; and from a communication to the Academy of Sciences at Paris, by MM. Th. Dumonceau, Fossagrives, and Rulnikoff, it would appear that this desirable object has at length been attained by means of the electric light. A glass tube, having a very small bore, is bent into the form of a bell or screw, and by this means a kind of luminous cylinder is formed, which is sufficiently small to be conveniently introduced even into a narrow cavity. The apparatus has been successfully tried in various dental and other operations.

THE PROPOSED FINE ARTS GALLERY FOR MANCHESTER.—We have already mentioned the scheme proposed by Mr. Thomas Fairbairn, for the foundation here of a permanent and free art gallery and museum on a grand scale. In the letter which he addressed to the local papers, Mr. Fairbairn proposes to erect, in a convenient and central situation, a palace, to be devoted to the arts, at a cost of not less than 100,000*l.* Under one roof he would collect, not only what the city already possesses in its various museums and art institutions, but would construct "rooms or saloons, with a floor area of 3,000 square yards, which would give ample space for the proper arrangement of the largest collections of pictures and drawings of the ancient and modern schools, and would permit, also, if desired, a chronological arrangement of the works of the several masters. In addition there should be corridors for works in sculpture, both original marbles and copies of the famous statues and groups which adorn the various capitals and cities of Europe. It might further be found exceedingly advantageous and interesting to devote one extensive hall to the portraiture of Lancashire worthies and local benefactors,—a hall of fame, where aspiring youth might muse upon the features of the mighty dead, where one could claim a kind of acquaintance with the men whose genius and inventions had not only created industries, but built up empires; and with the illustrious men and women who, as authors or artists, philosophers or philanthropists, had shed a lustre upon the places of their birth."

**WASTE IN BRICKMAKING.**—Mr. C. E. Bernard was summoned before the Cardiff Police Court, by James Stockbridge, for refusing to pay him two days' wages. Stockbridge said he was a brick-maker, and engaged by Mr. Bernard last spring at 5s. 6d. per day. On the 17th of December he left work and was paid up to the 15th. He summoned Mr. Bernard for 11s. due to him for the two days. He was engaged by the day. Mr. Bernard said he had an account from plaintiff of bricks on the ground, burnt, unburnt, and waste: in order to check it, he sent a person to measure them, and he made the number 23,000 less. The bricks on the ground, of all descriptions, and those sold, ought to tally with those made and paid for. He had paid for 200,000 which were deficient on the year.—*Plaintiff:* There was a frost last spring which spoiled 30,000. I have not charged for a brick that is not made. You promised to make me a handsome present: have you done so? No; but you sack me in the middle of winter.—*Mr. W. H. Hawkins,* in the employ of defendant, said he measured the bricks, and made them 23,083 less than plaintiff. There was a number of bats measured. Case dismissed. Plaintiff said he should apply to the County Court.

**EXCLUSION OF DAMP FROM BRICKWORK.**—As we are continually asked to state some mode of preventing moisture from penetrating through the surface of brickwork, we may here, in reply to "A Constant Reader," restate one method which has been already more than once described in our columns; at the same time not committing ourselves to any inference or assertion as to its being the best, or even an effectual process. It is said, then, that the evil alluded to may be obviated by the following simple remedy:—Three quarters of a pound of mottled soap are to be dissolved in one gallon of boiling water, and the hot solution spread steadily with a flat brush over the outer surface of the brickwork, taking care that it does not lather: this is to be allowed to dry for twenty-four hours, when a solution formed of a quarter of a pound of alum dissolved in two gallons of water is to be applied in a similar manner over the coating of soap. The operation should be performed in dry, settled weather. The soap and alum mutually decompose each other, and form an insoluble varnish which the rain is unable to penetrate, and this cause of dampness is thus said to be effectually removed. Another method was some time since described (as, by the way, the previous one was) at the Royal Institute of Architects. It consists of sulphurized oil as a varnish or paint, and is said to improve the colour of brick and stone, as well as preserve them. It is prepared by subjecting eight parts of linseed oil and one part of sulphur to a temperature of 275 degrees in an iron vessel. It is said to keep out both air and moisture, and prevent deposits of soot and dirt, when applied with a brush to the surface of a building of brick or stone, or even of woodwork.

**BAKESWELL HALL, LONDON, VULGARLY CALLED BLACKWELL HALL.**—This edifice has been employed for ages as a market for all broadcloths brought to London. *The City Press* says.—Its original name was Basing's Haugh, or Hall, from the family of Basing, who originally raised the fabric, and have given their name to Basinghall-street, and to Basing's Haug (corruptly Bassishaw), Ward. Basing's Haugh, in process of time, descended to a proprietor named Thomas Bakewell, in the thirty-sixth year of the reign of Edward III, and from him it took the name of Bakewell Hall. It afterwards fell to the Crown, and Richard II. sold it, with its garden and appurtenances, to the City, for 50*l*. The old hall, after having been rebuilt in 1558, was destroyed by the Great Fire, and again constructed, in its present form, in the year 1672. The building is square, with two courts, surrounded by warehouses, with two spacious entrances—one from Basinghall-street, the other from Guildhall-yard, which is the principal front. The door-case of this front is adorned with two columns of the Doric order, entablature, and pediment, in which are the king's arms, and underneath, the City arms, Cupids, and other ornaments. Within this building, which also has an entrance on the west side, from Catantou-street, there are divers apartments or warehouses, called by the names of the different cloths. They obtained the names of the Devonshire, the Gloucestershire, the Worcestershire, the Kentish, the Medley, the Spanish, and the Blauket halls, in which each piece of cloth pays one penny for pitching, and a halfpenny per week resting; by which means there arises a large annual revenue, which, by the generosity of the citizens, is applied to the support of Christ's Hospital, and the governors have the sole management of these warehouses.

**THE WESTMINSTER PALACE HOTEL.**—It is stated, and we believe, correctly, that Government has taken a portion of the great hotel near the Houses of Parliament for three years at 6,000*l*. per annum; and that about May the whole staff at the East-India House will be removed there. Further, that so soon as the records can be removed (probably by December), the whole property in Leadenhall-street will be sold.

**REMOVAL OF THE METROPOLITAN EVENING CLASSES FROM CROSBY HALL TO SUSSEX HALL.**—On Thursday, the 9th inst., the final lecture at Crosby Hall was given by the Rev. T. H. Dullock, the subject being "Wise Saws and Modern Instances." After a vote of thanks to the lecturer, the whole of the audience, headed by the two hon. secretaries, the Revs. Charles Mackenzie and Richard Whittington, accompanied by a few ladies, proceeded to Sussex Hall, and took possession of their new premises. Mr. Mackenzie was called to the chair, and a resolution was passed of confidence in those who had the management of the classes.

**STRIKES.**—For some time great dissatisfaction has prevailed among the nail makers of Sedgley, Cosely, Gornal, and neighbourhoods, at the reduction of remuneration for their work. On Saturday week every man refused to take any iron away from the warehouses, and the workmen have determined not to go to work until they get an advance of 6*l*. per cwt. The masters manifest a determination not to yield to their wishes, and there is every probability that the strike will last for some time.—Eighty-seven of the Glasgow furnaces have been damped, owing to the demands of the miners for an advance. Neither masters nor miners appear to be inclined to give way, and it is considered probable that the furnaces will remain out of blast during this month at least.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The usual fortnightly meeting of this society was held on Wednesday night, the 7th inst. in the Royal Institution. Mr. Horner, the president, occupied the chair. Touching the memorial to the town council, adopted at the special meeting of the society, as to by-laws, Mr. John Hay proposed the formation of a committee of the society, to consider the new by-laws, and to report thereon to a subsequent meeting. Mr. Barry seconded the motion, and the following committee was named and agreed to.—Messrs. Horner, Barry, Pictou, Kilpin, Ellison, Hughes, Goodall, Hay, Sherlock, Waightman, Huggins, Gee, and Stables. Mr. Barry then read the paper of the evening, upon the system of drainage now being carried out for the metropolis. The lecture was illustrated by a map and numerous diagrams.

**NINEVEH.**—At a recent meeting of the Asiatic Society, Lord Strangford read a translation of an inscription of Sennacherib, found on a clay cylinder in the British Museum, which was printed by the Museum authorities. The translation was made by Mr. Fox Talbot. This inscription contains the annals of the two years commencing the reign of the monarch. In it he details the improvements effected by him in his capital of Nineveh. The building of a splendid palace is fully described; the re-establishment of the ancient canals for supplying the city with water, "for the health and comfort of the citizens," and the construction of such new works as were necessary for the same purpose; also the widening of streets and squares, the erection of gates and other embellishments, until the city became "as brilliant as the sun." The inscription concludes by invoking blessings on the restorer of his palace when time shall have caused it to decay.

**MASTERS AND OPERATIVES.**—The bill brought in by Mr. Mackinnon, Mr. Ingham, and Mr. Slaney contains the following provisions:—Power to form councils of conciliation; powers to her Majesty or Secretary of State to issue councils of conciliation; councils to consist of not less than two masters and two workmen, or more than six masters and six workmen, and chairmen; petitioners for council to elect the first council; council to be elected for one year; householders and part occupiers may demand to be registered, and have a vote for the council, and may be elected thereto; register of voters to be kept; meetings of masters and workmen to elect the council; voting-papers to be delivered in case a poll is demanded; no voter to give a greater number of votes than the number to be elected; altering or effacing voting paper to be a misdemeanour; election to be declared within seven days of nomination; council to appoint the chairman; appointment of clerk; and penalties on referees, &c., for refusing or neglecting to attend cases of dispute.

TENDERS

For new warehouse, Wood-street, Silver-street, City. Mr. James Murray, of London and Coventry, architect:—

Longacre & Burge.....	£5,725 0 0
Hedges.....	5,164 0 0
Jackson & Shaw.....	4,905 0 0
Asby & Horner.....	4,712 0 0
J. & C. Hanson.....	4,679 0 0
Piper & Son.....	4,650 0 0
Lucas, Brothers.....	4,617 0 0
Brett.....	4,602 0 0
Jay.....	4,570 0 0
Myers.....	4,461 0 0

For the erection of a warehouse in Major-street, Manchester, for Messrs. Rhomer (Brothers), Messrs. Speckman and Charlesworth, architects. Quantities supplied by Mr. Thomas Taylor:—

Southern & Co.....	£4,720 0 0
Hay, Cochran, & Co.....	3,615 0 0
S. Bramall.....	4,599 0 0
Bowdon, Edwards, & Forsler (accepted).....	4,503 0 0

For gasholder tank, 100 feet in diameter, and fences, in Southth, near Dewsbury, Yorkshire, for the Dewsbury and Batley Gas Company. Mr. Michael Sheard, Jan., architect. Bailey:—

Whitworth & Topham.....	£2,560 12 0
J. Brooke & Co.....	1,870 18 3d
James Brier.....	1,652 0 0
George Simpson (accepted).....	1,563 0 0
Henry Smith.....	1,456 0 0

For alterations and repairs at the Lord Tyravet Tavern, High-street, Marylebone. Messrs. Finch Hill & Paraire, architects. Quantities supplied:—

Hill.....	£1,255 0 0
Turner & Sons.....	1,247 0 0
Elston & Son.....	1,221 0 0
Patrick & Sons.....	1,188 0 0
Brown.....	1,180 0 0
Selleck.....	1,036 0 0

For erecting new premises for Mr. William Royou, No. 33, Essex-street, City. Messrs. John Young & Son, Architects. Quantities furnished by Mr. Shoppee:—

Knight.....	£1,737 0 0
Mansfield & Son.....	1,560 0 0
Little & Son.....	1,527 0 0
Carter.....	1,489 0 0
Lawrence & Son.....	1,430 0 0
Conder.....	1,410 0 0
Axford.....	1,372 0 0
Coleman.....	1,359 0 0
Hart.....	1,330 0 0

For the re-building of house situate in Great Tower-street, for the Corporation of the City of London. Mr. Bauning, architect. Quantities supplied by Mr. Meakin:—

	Amount for the Re-building.	Separate amount for the Molety of East Party-Wall.
McClumont.....	£1,850	£23 0
Garnon.....	1,849	27 10
Jay.....	1,643	27 10
Piper & Son.....	1,621	25 0
Nutt.....	1,630	34 10
Browne & Robinson.....	1,592	31 0
Sewell.....	1,591	34 0
Axford.....	1,515	29 0
Westcott (accepted).....	1,497	40 0

For the supply of glazed stoneware pipes and other articles, and also for the excavation and laying of the main sewers, and the formation and construction of the several streets and passages in the Balfour Estate, for the Burslem and Turstal Freehold Land Society. Mr. Ralph Hailes, engineer:—

Downes & Mc Dougal.....	£280 4 0
Lockett & Pearce.....	812 0 0
Tomlinson & Hargup.....	730 0 0
James Frayne.....	679 0 0
Jos. Smith (accepted).....	615 0 0

For alterations to the Crown and Anchor Tavern, Woolwich, for Messrs. Reid:—

Pritchard.....	£216 0 0
Patman & Potheringham.....	770 0 0
Wagstaff & Son.....	775 0 0
Elston.....	749 0 0

For erecting stabling, &c., for Cranmer Villas, West-end, Aidersholt. Mr. C. Marshall, architect

All materials except bricks:—

Suelling.....	£297 0 0
Goddard.....	260 0 0
F. Birch.....	264 0 0
W. Duke.....	258 13 0

# The Builder.

VOL. XVIII.—No. 890.

The New Marine Infirmary: Woolwich.

We are now able to respond to an appeal which was made to us some time since, for particulars of the new hospital at Woolwich. The carcass of the building is at present completed. The structure has been generally spoken of as an example of the "pavilion principle" of arrangement which was particularly referred to by us last year, when we were noticing the designs for the Ashton Infirmary, and the new building at Blackburn, and gave a plan of the hospital of Lariboisière, at Paris; and

which principle, as those interested in the subject are aware, had been explained, and illustrated (as by a plan of the hospital at Bordeaux), and prominently urged on previous occasions in the *Builder*, and contrasted with the arrangement of plan followed in the hospital at Netley. As the

building at Woolwich has several times, in Parliament or elsewhere, similarly been contrasted with the building at Netley, on the assumption that the former represents the principle spoken of, we shall be careful to explain in the course of this article, to what extent it does so represent it, and is therefore a step, as it is a considerable one, in improvement of hospitals; and what features of the principle (either form or portion of the design, or must be considered as impaired by what is the actual disposition of the particular structure.) By this course we shall best do justice to the merit of the work, and prevent any misconception of its exact value as an experiment or a precedent.

The new building occupies the site formerly that of the reservoir of the Kent Waterworks, not far from the dockyard, and close adjoining, on the north, the Marines Barracks. It is not sufficiently removed from populous districts to satisfy one of the demands, and that the most important of all, in hospitals regarded generally; but perhaps there are reasons, such as have been alluded to by a correspondent, which necessitate the selection for such hospitals, of sites contiguous to the other quarters of the military or naval service. The present building is for the marines; but may be used for invalid seamen on emergency. The site in question, however, has a considerable elevation; and fine prospects of the country and the river's course are obtained from the building, the roof of which has a promenade 14 feet in width, and about 400 feet in length, over the corridors. The soil is sand and gravel. The longitudinal axis of the building, or main corridor, runs north-east and south-west. From the windows of the wards, and indeed those of the corridors, the prospect is interfered with, through the particular arrangement of the ward-blocks, and on one side also by the barracks. The plan more resembles that of the Blackburn Infirmary, than that of other such buildings as the hospital of Lariboisière, where alone is fulfilled in its entirety the "pavilion principle;" though the arrangement, both at Woolwich and Blackburn, has the wards so far detached from one another, and in separate blocks, as is required in the condition of lighting by windows on two of their sides, and has the like system of lighting and ventilation to the corridor. In the hospital of Lariboisière, as we have been careful to point out, the blocks containing wards are to be regarded as separate buildings joined by a

covered way; in the infirmaries at Blackburn and Woolwich, on the other hand, the open arcade is replaced by a walled corridor, though one, as we have just said, otherwise well lighted and ventilated; and there is not as in the French examples, a staircase to each block; whilst at Blackburn there is not even a lobby intervening between the corridor and the ward, though one occurs in an equally important place, at the farther end of the ward, with advantages which we shall again advert to. The entire plan, whether at Woolwich or Blackburn, consists mainly of a long corridor with the ward-buildings at right angles at regular intervals. Here, however, unless in certain of the features of the separate wards, the parallel would end; and the advantages, except as to the lobby which in a perfect plan would separate the ward from the corridor, and number of the sick intended to be accommodated in a ward, must be said to be on the side of the building in Lancashire. The ward-blocks at Woolwich are not only much too close, but the wards themselves are in some important details of planning other than those we have named, and in their cubical capacity for the number of patients, much inferior to those at Blackburn. The contrast will be shown approximately, from the printer's diagram which we subjoin, of the form on the ground, of the building at Blackburn:—

compared with the form of that at Woolwich, which here follows:—

each figure indicating the plan as intended to be completed, in the corresponding case. The distance of blocks which are on the same side of the corridor, at Blackburn, is 65 feet, the short intermediate projection being here deemed not worthy of notice; whilst the distance of those at Woolwich is only 44 feet 5½ inches; or, in two cases, 45 feet 11 inches; that is to say, since the walls are upwards of 50 feet in height, not half what it should be, if we had the least foundation for saying last year, that the distance should be equal to double the height of walls. The distance at the hospital of Lariboisière, however, seems to be only about 65 feet, for buildings the same number of stories, three, in height. The defect in the light to the wards, at Woolwich, is increased by the omission of windows in two of the ordinary spaces for them, each side; and may be still greater by the existence of small intermediate pavilions, for staircases and lifts, two of these (indicated in the diagram above) only, being completed on the side of the corridor opposite to that on which ward-blocks are at present built. Both at Ashton and Blackburn, the fire-places are at the ends of the wards, instead of the sides; and if the intermediate lobby to the bath-room, scullery, and conveniences in those cases, at the further end of the wards, and the provision for a current of air through that lobby, so that ventilation can be maintained independently of the ward, be correct, the arrangement at Woolwich, wanting this provision, is not an advisable one.

The general disposition of the plan at Woolwich, together with some of the merits and the defects, being now understood, we proceed to give the dimensions, and to fill up the outline of the description. The extreme length of the building on the line of the corridor, or including a bow at one end, and the central feature of the front at the other, is 456 feet 8½ inches; and the width, or length of two opposite ward-blocks, finished,—measuring in, and transversely to, the corridor,—will be ultimately 182 feet 10 inches. The end buildings, one of which is that of the principal front, may be 4 or 6 feet longer. Each ward-block projects from the wall of the corridor about 83 feet.

Except the building which comprises the main front and its wings, and the correspond-

ing feature of the plan at the opposite end of the corridor, the transverse blocks (four) are built only on the north side of the corridor,—the four ward-blocks corresponding southward, and intermediate between the completed wings of the east and west ends, being left for future erection. The meritorious feature of the building is the disposition of the corridor with the ample width of 14 feet, and with windows opening down to the floor, having balconies.

The wards, as already noticed, are in three stories, the upper floors being reached by four large staircases, two next one end of the corridor, and two at the other; and by the two staircases at the south side, to which, when the wards southward are completed, it may be intended to add others north, in similar positions. In these smaller staircases, winders should have been omitted. The small pavilions containing these stairs and the lifts, are carried up slightly above the general height, to provide space for water-tanks,—which thus are two in number. Together the tanks would contain by our estimate, 4,540 gallons, a quantity which would not afford so much as seventeen gallons per patient per day; and although the forty gallons per patient, of lunatic asylums, may not be required, the sixteen or seventeen are manifestly insufficient for the purposes of an ordinary hospital—without considering the future enlargement in the present case. Some use might have been made of the rain-water before allowing it to flow into the drains. The main front, west, will be appropriated, as regards the ground-floor, to the dispensary in the north wing, and to the rooms for the surgeons, in the south, with the entrance-hall between; and the floors above will contain separate rooms for officers who are patients. A portico on the level of the two upper stories forms the centre of the front. The corresponding portion of the plan, at the east end, contains, in the north wing, wards for infectious cases; and in the south wing, on the ground-floor, rooms for the matron and for officers. There are officers' rooms also above in this wing. These two wings are separated by the chapel, over which is the operating-room, having a low-fronted projection and recess, 10 feet radius, glazed at the top for light to the operating-table. The infection wards are repeated in each of the stories; the wing being divided into rooms, 26 feet 6¾ inches, by 13 feet 10½ inches, in the clear of the brickwork; and others' 22 feet by 13 feet 2½ inches, opening from a corridor of 4 feet 8½ inches width,—a square compartment of the plan, at one of the angles, which is made a feature of the design externally, and has its counterpart at each of three similar positions in the building, being appropriated to a scullery on each floor and closets. It is no doubt after some consideration that these wards have been planned, not as a detached building, itself on the pavilion principle. The wing has its own staircase; and the only communication intended with the body of the building is by a single opening (with double doors) for the surgeon's use. It is true that the pavilion principle for hospitals does not recognize the need of separate buildings for fever cases; but the plan at Woolwich is, as we have shown, a departure to a certain extent therefrom; whilst, for fever cases at all events, as we approach, the full measure of the principle is required; and it will be noted that the plan of small rooms opening from a corridor, is that arrangement which it was the object in the general plan to avoid. The basement will be appropriated chiefly to the kitchen and offices; but we are told that wards may also be placed in that situation.

We proceed to notice the internal arrangement of the wards, some defects in which have already been adverted to. Each ward, exclusive of its adjuncts, measures 60 feet 2 inches by 24 feet 2 inches, in the clear of the brickwork, and is 15 feet 3 inches in height, except in the top story, which is 17 feet; and each ward is intended to accommodate fourteen patients. It will be seen that in the ordinary wards, the space per patient cannot amount to more than 1,583 cubic feet—a quantity below that which has been considered desirable, 2,000 feet, and also below what has been provided in the other cases we have named. This is not quite satis-

factory; but equally questionable is the deficiency of window-space. There are only three windows in each side wall. They have 4-foot openings, are 3 feet 6 inches from the floor, and the crown of the arch is about 2 feet 3 inches from the ceiling. The fireplaces in these external side-walls are not opposite one another; and the corresponding piers or breasts were at first intended to receive a hot-water heating apparatus, chases for pipes being left along the face of the wall. This proposal, however, may have been abandoned. The chimney openings are not of sufficient height from the floor. Ventilation has been provided for by the use of Jennings's patent "air-chamber smoke-flues" and "ventilating chimney blocks," the former of these being circular flues for the smoke, with cavities at the angles-as air-channels, and the latter hollow tubes to be built in as wishes. Difficulty was found in working these in, in some of the flues; and expense may have been incurred accordingly, but not greater than the object justifies. The ventilating flues are continued from valved apertures near the ceilings, and terminate in openings at the sides of the chimney-stacks. Like apparatus for ventilation is connected with the closets.

Between the hither end of the ward and the corridor are two rooms, separated by the lobby, each 15 feet 3 inches by 10 feet. One is a nurse's room, having an inspection window to the ward; and the other, at first designed for a scullery, is now intended for a separate sick-room. The fireplace in each case is beneath the window. At the other end of the ward there are a lavatory, a room which is part scullery and part bath-room, and two closets,—the lavatory being in the middle. The closets are to be fitted with Jennings's india-rubber valves.

The walls will, we believe, be finished in trowelled stucco, and the ceilings in plaster, and the floors boarded; but these parts of the work had to be completed at the time of our visit. There is nothing in the window-sashes different from ordinary double-hung sashes, with circular head, except that there is an inner segmental arch, behind the semi-circular one of the brickwork, to allow the lower sash to be pushed up when required to the full height. The floors are framed and laid on Fox and Barrett's principle of rolled-iron joists and concrete, throughout the wards and corridors, and most other portions of the building. Some of the narrow passages are arched, and the floors of the nurse's-room and sick-room next each ward, have half-brick arches and girders. The sleeper joists of the wooden flooring are supported on tiles at intervals on the concrete, so as to leave space for circulation of air. The officers' sick-rooms, in the wings of the end blocks, are the smallest of them about 13 feet square: they are arranged in each wing in which they occur, with a central passage. We should be glad to know whether this arrangement, which as in the fever wards, seems, even where there is but one patient in a room, open to objections that do not pertain to the plan of wards with opposite windows, has been decided upon as fitted for a model, or whether with some other features of the plan, it is the result of inadequate extent of ground.

The portion of the building at present in progress, as we should have said ere this, is intended to provide for 273 patients. Of these it will be perceived that only 168 patients could be accommodated under the more favourable circumstances in the ordinary wards, leaving 105 to be divided amongst single rooms attached to wards, the officers' quarters, and the infection wards. The outlay for this amount of accommodation, as we learn from the Navy Estimates presented the other day, will be probably 65,300*l.*, but inclusive of land, as well as of fittings, boundary-wall, and other items. The gas-fittings and mains, however, would add 750*l.* or more; and there may be some other amounts. The cost of the building, exclusive of moveable furniture, may be set down as about 50,000*l.* At a further cost of 18,000*l.*, making the cost of the entire plan 68,000*l.*, the south ward-blocks could be built, and accommodation provided for 180 more patients, making the whole number 453; whilst it is thought, in cases of emergency, the corridors

could be used (though this would be fatal to the principle), and the number would then be raised to 660 patients. The works were commenced upon the signing of the contract, which bears date September 14th, 1858; and the first portion of the building will be completed about September next.

The bricks used in the building are the Suffolk bricks, grey and red, the latter, with which the fronts are chiefly faced, being from Ballingdon. The stone is Bath. The terrace promenade of the roof is covered with asphalt, laid on the concrete. The contract is one for prices. "Conditions of contract" were drawn up, which set forth that each party tendering was to price the items of a schedule attached to the specification, he undertaking to proceed on acceptance of his tender, to enter into a bond if required, to furnish materials of the proper quality; to give due notice whenever work was about to be covered up, that the measurement might be taken; to incur a forfeiture of 20*l.* per week for delay, and to accept other duties and liabilities. Payments were to be made in the proportion of 900*l.* to each thousand pounds of work as done, or of materials delivered. By the specification, the contractor was to suspend work if called upon to do so, as in time of frost; to observe certain defined methods of execution of the brickwork, masonry, and slating, as that the sand should be sifted through a screen of approved gauge, the lime be kept under an enclosed shed, and no mortar be mixed more than sufficient for a day's consumption; that the slates should have not less than 3 inches lap; and that the iron-work should have the bearing surfaces accurately fitted by chipping and filing. In masons' work, the cube quantity of stone only, as found in the work, was to be measured and paid for, except that no deductions were to be made for sinkings and rebates. Labour on masonry was to be measured nett; and no stoppings, mitres to mouldings, or sinkings were to be allowed, and no extra hoisting. Half a bed only was to be allowed upon stones in connection with brickwork. There was little other matter of any kind in the specification and conditions; but the drawings were sufficiently explicit. The structure contains a large quantity of brickwork; nearly all the internal and cross partitions or walls are of this material, and these are seldom less than one brick and a half thick, and are often more. But lathed quarter-partitions, at the further end of the wards, are needlessly used, and objectionably so. A course of asphalt was laid in the walls to keep down damp.

The plan allows of a small portion of unoccupied ground at the north and west, where there is a retaining-wall next the roadway; and the gates and lodges are being treated decoratively in character with the building. The space unoccupied is, having regard to the site, a good feature of the design; and the same may be said of the terrace-promenade on the roof,—though, we apprehend, the chimneys should be raised to prevent annoyance from their smoke. Where ground is not wanting, the plan of the Blackburn Infirmary would be better, from capability of extension without detriment to previously erected ward-blocks, and from the central position of its offices.

In decorative character, the design has somewhat the same sort of detail as the back of the Admiralty, with the addition of the four small pavilions, at angles, with high curved lead-covered roofs, and the portico in the principal front. The portico is a tetrastyle Italian Ionic, between square piers or ante. It has a pediment, ranges with the two upper floors, and stands on a rusticated basement. The first-floor windows in the portico-recess have enriched console heads, and there are also three medallions charged with the emblems, the rose, the shamrock, and the thistle. The wings, in red brick, have rusticated plaster-like projections in the grey Suffolk brick. The windows of the corridor, both sides, have stone balustrades to the balconies.

The site and the dimensions, the portico and apse, and the tall roof coverings of the pavilions, cause the building to be a conspicuous, and, otherwise, a not ineffective object from the river and other points of view; but good pro-

portion of the stories and other main divisions of the design, and invention and study in the details, are, on nearer approach, somewhat wanting.

We cannot, however, agree with Lord Clarence Paget, in the applicability of certain phrases he used while referring to this structure, the other night, in the House of Commons, in the course of the generally able and excellent address which he delivered, on bringing forward the Navy Estimates. "Architectural magnificence" and "stately colonnades" are phrases not in any degree justified by the character or the details of the new Marine Infirmary at Woolwich. But it is a mistake on the part of men officially responsible for expenditure, to regard such an amount of decoration as there may be in this building, as useless, and to take pride in having elsewhere rejected "remarkably tasteful designs." Lord Clarence, and men of his stamp, may get a cheer from the House, but do not the less misunderstand what true economy is, what art can accomplish, and what the public mind desires; what is the positive duty of individuals and authorities having it in their power to block out a portion of the face of nature with that which may be an eyesore, or may, on the other hand, give a new interest to the scenery that remains; and, in fine, do not understand that, without bating one particle of the useful, the *use*, in any sense taken, requires also what is decorative, and that the beautiful, on its own account, is an end worthy to be sought, and presented to public view. Without speaking now in favour or disfavour of extraordinary embellishment, we take leave to repeat that architectural beauty requires not necessarily anything of the kind: the error, in expression of opinion, which is made, arises from misconception of what is ornament and what is purely structural; and we suggest, as a lesson very useful to the economically-minded members of the House of Commons, who are ever thinking of the sum total of the Palace at Westminster, that one of them should move for a return of that portion of an outlay, in the case of such a building as the Infirmary, to be set down to mouldings and enrichment; and, probably then there would be some surprise at the small per centage, or insignificant fraction of cost, that could be rightly held due to that "too much attention" to "architectural design" and "scope to taste" which, Lord Clarence Paget thinks, are compatible only with "magnificence," and must comprise "unnecessary expenditure." Probably then, works being confided to qualified hands, and the scope being given, we should have works of taste, in architecture, more worthy of admiration than those which official management has produced with all the aid of the money and the ornament.

We may add that the building at Woolwich was designed by Mr. Wm. Scamp, under the general supervision of Colonel Greene, Director of Architectural and Engineering Works to the Admiralty, and with the approval of the Medical Inspector of Hospitals,—Mr. John Haite being the Admiralty Clerk of the Works,—and that the builder was Mr. Wm. Higgs, of Lambeth.

#### ON THE SUPERINTENDENTS OF ENGLISH BUILDINGS IN THE MIDDLE AGES; WITH AN ESPECIAL REFERENCE TO WILLIAM OF WYKEHAM.\*

SINCE the time of Walpole and Dallaway, little has been done to compile any notice of the early practitioners of our art, or to ascertain who were really the persons entitled to the credit of designing the works erected during the Middle Ages. That credit, especially with respect to ecclesiastical buildings, is generally assigned to certain men of high rank in the Church,—while the claims of a body of working men, called Freemasons, to have devised and directed the operations necessary to the development of their employers' wishes, have also been put forward. Searching into the numerous printed as well as MS. authorities whence these respective deductions have been drawn, I have been induced to form a collection of notes

\* By Mr. Wyatt Papworth, architect. Read at the Royal Institute of British Architects, January 23rd, 1860.

which enable me to have the satisfaction of now bringing before you the first classified account of the official situations of persons upon buildings erected during the Middle Ages, with some general idea of their duties. Wherever practicable, I have chosen the words of the original document, or the apparently best translation; a course which has led me to discard some of the hitherto received quotations.

My observations will include the terms architect, ingeniator, supervisor, surveyor, overseer, the employment of William of Wykeham, his master mason, the master of the works, the keeper of the works, the keeper of the fabric, the director, the clerk of the works, and the devizer, reserving for some future occasion all notice of the master mason and of the Freemasons.

Of the term "architect," I find no use within the period to which I propose to limit my remarks. Walpole, in "Anecdotes," &c., 1762, recites a writ, dated 1199 (10th Richard I.), wherein one Elyns, ingeniator, was allowed ten marks by the Sheriffs of London and Middlesex for the repairs of the king's houses at Westminster. This word has been translated "engineer or architect," and Walpole stating that Elyns was certainly an architect, mentions this writ, with another, a few years later, as being the earliest evidences of art in our records. This memorandum is valuable as far as it goes; but it is the only one to which I shall refer in respect of that title, as we may be more inclined to translate the original term in the writ by the single word "engineer."

A term used several years after the Conquest was "supervisor," and this word has generally been translated "surveyor," or perhaps "overseer." The earliest mention of a surveyor or supervisor of the works (even the term "architect" has been applied in the translations), is in the case of the erection of a bridge at Hereford, between the years 1100 and 1135, when Aldun de Malverne is said to have held such an office. Passing some uncertain cases of the term, we are told that in 1349 Edward III. appointed John Peyntour to the office of Surveyor of the Works at Windsor Castle. I am inclined, however, to believe that if the original document were inspected, the word translated would prove to be "supervisor." I lay no stress on this point, because my endeavour is to show that "supervisor," although changed to "surveyor" in later times, never meant the surveyor of the present day. In the following year, Richard de Rocheley (or Richard de Rochelle) appears to have held the same office. He is also recorded to have held it once before. Subsequently, but in the same year, William de Hurlle and William de Herland also received the appointment. The following year, 1351, Robert de Bernham held the office; "and," as is recorded, "to the end that this great undertaking might be honestly and substantially performed, the king (Edward III.) assigned John Brocas, Oliver de Burden, and Thomas de Foxle, jointly and severally, with all care and diligence (at least once a month) to survey the workmen and their works, and to encourage such as did their duty competently well, until he should obtain ecclesiastical preferment." Bernham still held office in 1353; and it was on the 30th October, 1356, that William of Wykeham was appointed to the post of "supervisor of the king's works at the castle and in the park of Windsor," having the like powers with those surveyors first named; the payment was also the same as that enjoyed by his predecessors, namely, one shilling per day while resident at the works; two shillings a day while travelling; and three shillings per week for his clerk. The following year his salary was enlarged to two shillings per day, "until he should obtain ecclesiastical preferment." I have been thus particular in the remuneration, because the clerk of the works at the castle, a few years earlier, was paid, according to the authority I follow, "twopence" per day, but this is clearly a mistake for two shillings, the usual payment for the "clerics operationum regis." This difference would lead us to consider that the supervisor ranked lower than the clerk of the works. Moreover, it is recorded, that in 1358, William de Mulsho was appointed supervisor at the castle; where then was Wykeham? And again, on the 10th July, 1359, a writ testifies that Wykeham was "capitalem custodem et supervisorium castrorum regis," of Windsor, Ledes, Dover, Hatfield, and other places, which included something more than mere works in progress. In 1361, William de Mulsho was appointed clerk of the works; and in the following year, when Wykeham resigned his appointment, he was succeeded by Mulsho, who appears to have held the appointments of both clerk and supervisor until 1364, when Nicholas Dernard took the post of

"surveyor" (as he is called in the translation), for life; and in 1366, Adam de Hertynadon became clerk of the works in place of Mulsho. As these transactions may be regarded as genuine evidence, it is clear that the supervisor, if promotion and remuneration be taken into the account, was of inferior rank. I have also found a notice of this office as late as the time of James I., when Sir John Trevor is called "surveyor and receiver of his honour and castle of Windsor." For the present, however, I must quit Windsor, and see what information other records afford towards clearing up the point. The next in my list, after that of 1366, is dated 1370; in this, Thomas Staple, called the king's squire-at-arms, is granted a shilling a day for good service rendered; in the same year he is termed by the translator "surveyor," and also "overseer," of the works of the lord the king at Queenborough Castle. He had upwards of 153l. (about 1,850*l.* of our money) paid to him for the works then being executed or completed. Was he an architect? In the same year also, 1370, the prior of Rochester Cathedral was paid a somewhat larger sum for works at the castle in that city, while acting as "surveyor" or as "overseer." John Boyfield had been supervisor of the works under the two abbots of Gloucester preceding himself; he is one of the proofs of the supposed system of electing monks, acquainted with building and other operations, to the higher and responsible positions of prior and abbot.

Dated 1417 and 1422, are two orders, written in a mixture of old French and English, giving about the earliest uses of the word "surveyor;" thus, in the first of them is mentioned, "Notre aunc Esquier Robert Rodyngton, survoeur de la construction de nos Tourres a Portesmouth;" in the other, "une survoeure de les oveignes do devf, chastell et villes deing Northgales." But how shall we regard another order, dated 1417, in fairer English, requiring "sum gud, true, suffesaint mon, to be survour of vitel and werkes in North Wales?" This curious union of appointments appears again in 1338, when Edward III. made his clerk of the works at Perth, in Scotland, "receiver of the pennies and of victuals;" and in 1384, Richard II. made his chamberlain of Berwick the clerk of the works there, and also "keeper of the victuals and artillery;" in the same year he was also constituted the "chancellor and chamberlain." During the erection of King's College Chapel, at Cambridge, we find recorded, that in 1441, there was an overseer and manager; in 1451, a clerk of the works; 1479, an overseer; 1484, an overseer; 1513 to 1527, a surveyor, in the person of Thomas Larke, termed "Mr." in the first year, but "Clerke, Archdeacon of Norwiche," in the latter year. All Souls' College, at Oxford, was erected under the supervision or inspection first of John Dymell, 1377-82, and subsequently of Roger Keys, 1423-44. They kept the accounts which were in existence at the end of the last century. Roger Keys had previously (in the words of the grant) rendered such "acceptable and laudable services, and in many and divers ways renders, and will in future render to us, as well in our operations connected with the building of our Royal College of St. Mary of Eton, as in other respects,"—that the monarch, Henry VI., ennobled him by a grant of a coat of arms. He had acted as master of the works, an office to which I will refer hereafter; Robert Kente, William Lynde, and William Waryn were to be the overseers, William Lynde being also Clerk of the Works; and John Hampton, esquire, an attendant upon the king's person, being surveyor.

In 1461, to John Keudale was granted the office of "supervisor of all the king's works" throughout the realm. In 1474, Richard Beauchamp, Bishop of Salisbury, was "master and supervisor of the works at St. George's Chapel, Windsor," then being rebuilt; he was succeeded by Sir Reginald Bray with the same titles. The tower of Magdalen College, Oxford, was added in 1491-95, during which time Magister Gosmore had the supervision, which included keeping the accounts of it. To Jobu Aleock, successively Bishop of Rochester, Worcester, and Ely, and Lord Chancellor, many works in architecture have been attributed, probably because he held the office of comptroller of the Royal works and buildings under Henry VII., which monarch, in making John Islip, Abbot of Westminster, receiver of the money for his chapel at the Abbey there, gave him the supervisorship, and thus, chiefly, has Islip also had the title of architect attached to him.

So late as 1514 William Mavern, supervisor of the works at the Abbey of Gloucester, was elevated to the abbacy. In 1520 the king granted to Thomas Vachell the office of supervisor of all and singular the honours, castles, &c., which had be-

longed to the monastery of Reading and to the late priory of Leominster, for his life, and to receive out of the issues and profits of the same twenty marks annually (13*l.* 6*s.* 8*d.*). He is again called "supervisor or inspector." From this period the term surveyor becomes very common, and it shortly appears to be used in the modern sense of the word. Thus, James Nedsam, carpenter, was, in 1531, appointed carpenter to the king, and in 1539 or 1541 he is named surveyor-general of the king's works, and had the same salary as his successor, Lawrence Bradshaw, also carpenter, viz., 2*s.* per day, the payment, as I have before noticed, of the king's clerk of the works. There was a surveyor at the Tower of London, in 1542, at the same salary, which was increased forty years after by an augmentation of an allowance of 70*l.* for diet, and 25*l.* 13*s.* 4*d.* for riding charges and boat hire. As another use of the word "surveyor," we find in a late period (about 1510) that the endowment of St. Paul's Schools, London, was given to the Mercers' Company, to whom was intrusted its care, charge, rule, and governance; and they were to elect eleven persons annually, free of their company, as "surveyors of the scole." These persons were to receive the rents of the endowments, and to transact all affairs relating to them and to the school; to pay the different salaries quarterly; and when the annual accounts were audited, an assembly should be appointed, and "a littell dinner ordeyued by the surveyors not exceeding the price of four noles." These surveyors were to have 1*l.*s. each for their labour for one year, and the same sum if they rode to visit the estates. A similar sense of the word is to be found in a legal document of 1680, stating that Sir C. Wren, with the parson of the parish and another person, had been appointed "supervisors" of the building to be erected, and which had been designed by that architect. During the reigns of Elizabeth and of James I., the head of the Royal establishment of Works loses the title of "Clerk of the Works" (to be mentioned presently), and becomes "Surveyor and Paymaster;" and in 1628 "Mr. Jones" is surveyor alone. From that period we are well acquainted with the duties of that officer, as now understood. The duty of the Surveyor-General at the Tower of London, in 1756, was chiefly to inspect the stores and provisions of war; to see they were preserved with care; to allow bills of debt; to keep a check upon all labourers' and artificers' work; as well as to see that all provisions were good and serviceable, and that they were marked with the king's mark.

It is only occasionally that we find any mention of the duties of the supervisor. In the case, however, of Wykeham, the first patent, as recorded by Ashmole, states that he was empowered to impress all sorts of artificers, and to provide stone, timber, and all other materials and carriages. The second patent was an extension of his powers, as besides the appointment and disposition of all workmen, providing necessaries for reparations, he was to provide carpenters, masons, and other artificers, stone, timber, &c.; also to hold leet and other courts, pleas of trespass and misdemeanour, and to inquire of the king's liberties, rights, and all things appertaining thereto. Would not our word "steward" be a more appropriate interpretation of the word "supervisor," when used in the old records? In support of this view I would mention that Shakespeare, in his play of Henry VIII., act 1, sc. 2, gives the term "surveyor" to the Duke of Buckingham's steward of the household (as I read the passage),—thus recalling the old term "supervisor." And Shakespeare (to judge from Henry IV., 2nd part, act 1, sc. 3), may perhaps have understood the difference between such an officer and an architect or surveyor of buildings; but this last use of the term might be interpreted both ways.

There is one other employment of the term supervisor, and, as it is found in the words of Wykeham himself, the meaning is of great importance. In his will he directs that the works of the cathedral at Winchester are to be continued under the care of William Winford; of Simon Membury,\* now supervisor of the said work, and also paymaster, who is to be paymaster and supervisor during the continuance of the above-named work; and of John Wayte, the comptroller on the part of the convent. It will be observed that he does not state the exact position which Winford held or was to hold; but as I shall have again to refer to him, I will leave further remarks for that occasion.

Now, so far as we have pursued the inquiry, shall we not be rather inclined to deny that

\* Nunc dii iis operis supervisor non nec solutor, sit etiam solutor et supervisor in futuram, durante opere supradictio.

William of Wykeham is entitled to the name of "architect," in our sense of the word? Tradition, warping the meaning of early historians, has assigned to him wonderful powers of design in architecture. Is tradition always to be relied upon? Allan Cunningham, in his *Life of Wykeham*, states that "under whose auspices he attained his knowledge in architecture has not been told, nor have we any notice of any of his designs before his twenty-third year." We know how to estimate the real value of tradition in the case of Van Eyck, the reputed discoverer, in 1410, of oil painting (he was born just after Wykeham was made bishop, and he died about forty years after him); and also in the case of Sir Richard Whittington, four times Lord Mayor of London, who also flourished during the last years of Wykeham's life. Not only is the origin of the story of the cat placed about a century after its supposed master's death, but it has been discovered that the penniless Richard was the son of a riev man of title. Within the last few years, an enlightened French author has ascribed to the English of the traditional crime of roasting the Maid of Orleans, and shown that she lived a married life for years after the date assigned to the event; while recently, the sorrowful catastrophe of the interesting Amy Robsart has been reduced and vulgarised into a case of *felo de se*. The term "rising Wykeham's" must be, I think, retained for the benefit of young ecclesiastics, rather than of aspirants in our profession, unless, indeed, the time shall come when an architect may again be considered eligible for a bishopric, as some slight return for the usurpation of the title of architect by so many bishops.

It is said that it was partly Wykeham's knowledge of architecture which induced Edward III. to employ him. But examine the authorities, and there is nothing but tradition to support the argument. It was by the advice and persuasion of Wykeham (in 1359 says at least one author) that the king was induced to pull down a great part of the Castle of Windsor, and to rebuild it in a magnificent manner. But works there had been commenced by that king some ten years previously. Moreover, it is said, that it was at the suggestion of the kings of France and Scotland, who were prisoners together at Windsor, that Edward III. was induced to extend the Castle, and he did so at the expense of his captive advisers. Another support of my argument is this: Wykeham was made supervisor of the works in 1356. Mulsho took his place (apparently *pro tem*) in 1358, and Wykeham was appointed constable in 1359; the alterations proceeded slowly until 1363, 1364, 1365, and 1366, when the masons are highest. Now Wykeham resigned his appointment to Mulsho in 1362, the year before the heavy payments began, and at the time when Mulsho was acting as clerk of the works. The traditional account of the words "Hoc fecit Wykeham," attached to the walls of Winchester Tower, is put aside by some of his biographers; and Lowth commenting on his early life observes that all the particulars relating to his name, birth, parentage [education, and early employment], rest either upon tradition or upon accounts penned many years after his death; that is, at least, above fourscore years after the times of which they treat: we have nothing concerning him authenticated by contemporary evidence before the year 1352, when Bishop Elyngdon constituted him his attorney to take possession of certain lands; at that time he was twenty-eight years of age.

It may be in the recollection of many that even the chevron in the coat of arms adopted by Wykeham, was said to be commemorative of his architectural attainments, because the learned herald Upton has written that it was one of those bearings which were carried "per carpentarios et donorum factores," by carpenters and builders of houses. But another herald, equally learned, states that the chevron was usually taken by the head of a new house or family when arms were granted to him (the chevron or raftor being at the top of the house), and it was enlarged by one or two more chevrons, as the wealth of himself or of his heirs increased. The number of coats having chevrons amongst the ecclesiastics, presents a good elucidation of the fact, as well as the number appertaining to those to whom it has never been attempted to affix the title of architect or of carpenter.

In 1360, Wykeham had been appointed Dean of St. Martin's-le-Grand, and continued so until some time in 1363, having been busy "rebuilding the cloister of the Chapter-house and the body of the Church" in a very handsome manner and at a very great expense. He also held from 1361 to 1368 the co-wardenship of the forests on this side of Trent. Although so early as 1319 the king

had conferred the first benefice upon him, it appears that he could not take possession of the living, not being in orders; it was only in December, 1361, twelve years later, that he was admitted to the degree of an acolyte; it is therefore, most probable, that the king gave him the office of clerk of the works at Hereford and Yeshampstead, with that of supervisor in the same and in the following years, in order to afford him an income; indeed, this appears to be the true reason, from the patent of November, 1357, which doubled his salary until he could obtain ecclesiastical preferment. In all the patents of appointments granted to Wykeham he is styled "Clericus," hence many have presumed him then entitled to be considered a churchman. It was "a title addressed to academical students," says Walcott, one of his biographers; but this may be doubted, though it probably was applied to all educated persons, especially those who could write. Thus it is affirmed, that the word "Clericus, often affixed to the names of witnesses in an early period, does not always signify a clergyman, for this was expressed by persona, or if he was not benefited, by capellanus; clerics seems commonly the person who wrote the instrument." This is, however, rather a digression, but yet it was necessary to explain away the seeming force of the epithet.

From the often quoted year, 1361, Wykeham, however, was making rapid progress in the church, until he obtained, within the short period of six years, the bishopric of Winchester, on the 17th September, 1367. During these years, Queenborough Castle was erected (1631, and finished in seven years, as generally stated), and is traditionally ascribed to Wykeham as its designer; yet one author has named Henry Yevele as the supervisor of it. As such works would necessarily, in those days, entail the personal supervision of the designer, I cannot but be strongly of opinion that Wykeham's thoughts and presence were of more importance (to himself) elsewhere, and, therefore, that he did not act as architect at its erection. He is also said to have been the originator of the Perpendicular style of Medieval architecture, but as this assertion rests on the assumption of his having been an architect, the further consideration of this claim for Wykeham may be deferred to the time at which the origin of styles shall be settled. The college at Oxford, founded by Wykeham, was not commenced until the end of the year 1379, twelve years after Wykeham had been installed in the episcopal dignity; the college at Winchester was commenced eight years later still; and it was not until another seven years, namely 1394, that he decided to commence the reconstructions at Winchester cathedral; in 1403 he made his will,—a few months before his death in 1406. Now, supposing that he was the architect of these buildings, we must also suppose that he was a freemason, and acquainted with that important secret of design which we are all so anxious to rediscover; otherwise, much that has been maintained, as to the wonderful attainments of that band of skilful designers and workers, falls to the ground. But I cannot suppose that he was one of the craft. He has, too, the *quasi* honour of being twice mentioned in that very questionable list of grand-masters of the fraternity, under the dates of 1357 and of 1377; the first, the year after he had been appointed supervisor; the second, before he had commenced his colleges. But we yet require some evidence that any bishops were ever made acquainted with the secret; the contrary even might be judged to be the case, by those who have considered all that has been written respecting the celebrated statute of Henry VI., which was passed for putting down the assemblies of masons. We must not forget, either, the fate of a German bishop, who was killed by a master mason, because his son had been beguiled, or had unwittingly betrayed the secret to the bishop. I am of opinion that Wykeham was not one of those initiated in the masonic mysteries, and, consequently, in this light, could not have been the designer of his colleges. Who then was the talented person? This portion of the subject led me into a more extended field of research than I had at all anticipated, and the result is satisfactory only to a certain extent. It leads me, however, to believe that the master masons were generally the architects during the Medieval period in England. The steps of the inquiry will be best understood if explained upwards in this account. Wykeham, in his most carefully-drawn will, declares that "the disposition and ordination" whatever those words may truly mean, "of the works at the cathedral, he made by Master William Winford (I have mentioned his name before), and others sufficient, discreet, and approved persons in the art, as may be depicted

by any executors." But this is the first time Winford is mentioned by him, it may be said. Fortunately, he is almost the only exception I have found to a recurrence of a name; and, furthermore, his portrait exists. In the stained glass of the college at Winchester may be seen the representations of three personages: first, the carpenter, whose name unfortunately is lost to fame, unless it can be recovered from the books of accounts; the second, our already known Willielmus Wynfor, labtonius (or mason, a term to be explained on another occasion); and the third, Dns. Simon Membrury, who has not any office appended, but whom I need scarcely remind you, is also named in Wykeham's will as the supervisor and paymaster of the cathedral works. I conceived that in William Wynfor we thus obtain the architect of the college at Winchester, as well as of the works at Winchester Cathedral. Now for that at Oxford. This, however, is not so easy of proof; I must beg leave for a little conjecture. The college was commenced, as before stated, in 1379. In a roll of expenses of the 44th year of King Edward III., under the date of 22nd April, 1370, it is recorded that William do Wynneford, plasterer (as the original word is translated, which, no doubt, is eumentarius, or mason as it should be rendered), was sent to various parts to retain divers plasterers [Le. masons], to be sent over in the retinue of the late king beyond sea, by command of the chancellor. It is not a little in my favour that the chancellor of this period was William of Wykeham himself. This Winford then was a mason of some position; an equal with Yevele, who was employed for the same purpose, and we know he was a mason by his works at Westminster Hall. We may suppose him to have been about thirty years of age, or more, when entrusted with this command, so that at the end of thirty-three years, when mentioned in Wykeham's will, he would be at least sixty-three years of age, not too old to carry out the wishes of his patron. I should even venture to presume that both he and Yevele had been in the employ of the monarch at Windsor Castle; but as the records of the period, and especially the accounts of the castle are scarce, no other mention occurs of his name; this early date of his employment, however, permits me to conjecture that Wykeham, appreciating his excellence, might have employed him at New College, Oxford. Some further research into the fabric accounts of the buildings may elucidate this point; as no doubt the name of the master mason will be found recorded, as usual, in those documents. Lastly, as respects this part of my subject, a friend has reminded me of the observation made by Wicklife in one of his sermons, probably written between the years 1366 and that of his death in 1354, entitled, "Why poor Priests have no Benefices." It is only by inference, however, that the expression I used was applied to Wykeham, and considering all that I have brought forward, I am not disposed to believe that the epifits his head.

The "magister operum," or master of the works, was an important one in monastic establishments. At Crolynd, he was the first of six greater officers. It was the sacristan, or sometimes the treasurer, who held this post, and it was his duty to receive all the legacies and donations that were made for the support and ornament of the buildings and utensils; to his superintendence was submitted the construction, reparation, beautifying, and enlarging the churches and various buildings of the monastery, particularly those of the abbot below the court, except some houses near the garden. John of Wheatlamsted, Abbot of St. Albans, "who in architecture was the Wykeham of his time," is specially recorded to have instituted in his abbey a new officer called the master of the works. The sacristan was also sometimes the secretary, auditor, and chancellor of the convent, therefore necessarily a very important personage. With this extensive employment it is remarkable how few names of sacristians have come down to us. William Stove, of the Abbey of Evesham, erected about 1319 the new steeple or belfry. Paulinus, of Rochester Cathedral, built between 1125 and 1137 the church at Frenshurst, in the same county. In 1237 died Elias de Lidford, the sacristan of the Abbey of Gloucester, who rebuilt the tower and constructed the stalls of the

\* See Journal of the Archaeological Institute, Winchester Proceedings, 8vo., 1848.

† Lowth, in his "Life of Wykeham," edit. 1777, p. 195, states he employed William Winford as architect; Simon Membrury was appointed supervisor; and John Wayne, controller, &c.

‡ I have traced this application of the observation to Warton, who appears to have first used it in "History of English Poetry," first edit. 1774-81.

two illustrations on the contrary side of the question. I believe that the normal state of the atmosphere is the best, but I do not thereby admit that a large class of diseases attributed to foul air are really attributable to it. If we were to carry out that theory—if we lived in pure air we should live for ever, or die of pure old age, which I believe no man ever died of yet. It will be in the recollection of many gentlemen that in 1832, when the cholera ravaged Paris, there was a large manufactory at one of the *barrières*, at which all the waters of Paris were discharged. At that place there worked a thousand men, women, and children, and they were the only persons in Paris who were exempt from an attack of cholera. I might also go to the men who work in the sewers, and say that they have a strange immunity from those diseases attributed to foul smells. I believe that is undoubted. I should like to see some statistics as to the health of different classes of the community, with the men separated into classes of avocations. I think that would help us. But even that might be fallacious. The generalization of figures is fallacious. One word now as to malaria. I know that I have to run counter to a dogma that is extensively received at this moment. I only hope, indeed, that I shall not be ostracized for it in a leading article. With regard to malaria, does anybody know what it is at all? Dr. Parkin attributes it to volcanic origin. I am not quite sure that anybody knows what malaria is. That a peculiar condition of the atmosphere is the cause of specific illness there can be no doubt; but how that arises I believe nobody knows. As to the epidemics that have passed over the earth, it is very likely that they have died out through simple cosmical changes; and so it will be with regard to the cholera, not because we drain the Thames, but the disease has had its course under some fixed law. We have no more chance of controlling that than we have to fly. I will venture to address myself to the real question that we have under discussion, that is, as to the means of prevention by altering the standard of the houses. We know that we have little control in that respect. Unfortunately you are obliged to indulge the whims of your clients. With regard to epidemics, there is one point that medical men always ignore, and that is the empty stomach. Now, if the disease has power at all, it is, undoubtedly, on the empty stomach. In the next epidemic, take a thousand poor people out of London with 9s. or 10s. a week, a quarter of which is spent in gin; whitewash them, and then place them in one of the royal palaces, and there cholera, or the epidemic, or whatever it is, will appear. The reason is, that the empty stomach is the absorbent of the system; therefore the best remedy you can possibly have is to get a law passed by which every man shall have 1*l*. a week and plenty of butchers' meat. I am no advocate of dirt or filth, but I like to trim this subject in a perfectly practical way.

Mr. H. H. Burnell read an extract from Erasmus, to show that statements which are now made were made in his time.

The Chairman.—I must confess that I have heard with extreme pain, if I may use that word, the statements of the two able speakers who have appeared before us to night. I cannot see what possible good result can be looked for from them; but on the contrary, fear much evil. Both those gentlemen admit, as it seems to me, that bad air is bad, that bad drainage is most undesirable, and yet their ingenuity has been lavished in throwing discredit, as it seems to me—I hope I am mistaken—on those who are desiring to impress those facts on the public mind—to lead to that repeated state which Mr. Burnell very properly said can alone produce a remedy. As it seems to me, they are putting themselves in the way of the progress of those improvements which unquestionably have shown themselves in every town where sanitary measures have been applied as likely to produce an admirable result. We find that in one part of the country thirty persons in every thousand are dying annually, while in another only seventeen per thousand die; and surely these gentlemen cannot deny, with this and other facts staring them in the face, that some of this difference results from circumstances within the control of man, and that those circumstances being discovered, and proper remedies applied, we may hope to save some of those thirteen extra in every thousand who die every year. I have visited many parts of this and other towns, and have given long and painful attention to the subject. I have seen many a house where good health is impossible; where every person who lives in the house loses health. I once went into a house where, on the table, stood three coffins of three

children of one family. Well, it was shown to be as certain that those three children died because the foul drain had become stopped under the house, as that if you were to put your hand into the fire it would be burnt. The cause of the result was as distinctly shown as that heat comes from the fire. In that same family two other deaths under precisely the same circumstances had occurred some years before. It seems to me insulting your common sense to say to you—that if a man lives in a house where no ventilation is, or the ventilation is bad, his health will unquestionably suffer; that if the air he inhaled by foul gases from the sewers, his health will suffer; if his house be put down in swampy ground, undrained and uncovered, he will suffer. Then I do ask you, instead of throwing any obstacle in the way of medical men and others who would point out these evils, to aid them and honour them; for I do say that immense advantages must result from their labours. I know that there are one or two gentlemen who desire to speak, and I must content myself with a strong protest against the tendency of observations that have been made.

Mr. Edwin Nash paid a high compliment to Dr. Drnitt, and urged upon all architects to adopt the suggestion with regard to permeable pipes round dwellings.

Mr. J. W. Papworth said he agreed with Mr. Burnell, but Dr. Drnitt had, nevertheless, done great service in coming forward as he had done. Much of the fault complained of lay with the better classes. He surveyed a house not long ago, and, on going downstairs, he found a passage leading from the back-kitchen into the yard. Out of that passage was a kind of closet which had been made into a bedroom for two servants. The cement was tumbling off the walls, and the mistress said that was the general condition of the place; and yet for fifteen years the servants had slept in that place, and the mistress said they had always some complaint. In another house, he found that the butler slept under the stairs. One of the most active of our leading philanthropists had erected a school-room, but he positively refused to allow of proper ventilation; and yet he acknowledged that, after the children had been there a certain time, he always discovered a disagreeable odour. He then always sent in a chest of oranges, which he said got rid of it. The hon. gentleman concluded by moving a vote of thanks to Dr. Drnitt.

Mr. Ferrey seconded the proposition, which was unanimously carried.

Dr. Drnitt briefly replied to some of the observations made, and the meeting adjourned to the 5th of March.

Messrs. R. Barris, of Wollingham-place, Lambeth; H. H. Burnell, associate, of Bouverie-street; C. Ainslie, associate, of Old Jewry-chambers; and Louis G. Butcher, of Guildford-street, were elected fellows; and Mr. John Young, of Lincoln's-inn-fields, was elected associate.

At the previous meeting Messrs. E. A. Graving, of Grove-house, Highbury-grove; John W. Penfold, of Charlotte-row, Munition-house; E. R. Robson, of Adam-street, and Durham; and Herbert Winstanley, of Great Jaimes-street, Bedford-row, were elected associates.

#### CIVIL ARCHITECTURE.

ON Wednesday evening last, Mr. E. B. Denison, Q.C., delivered a lecture at the South Kensington Museum, on Civil Architecture.

The chair was taken by Mr. Eeresford-Hope, who introduced the learned gentleman as "a devoted student of architecture and expounder of Gothic art."

Mr. Denison commenced by observing that the title which he had selected for his lecture was quite clear to those who heard him. They had Greek architecture, and Gothic architecture, and architecture, and of the fine arts of Gothic, but not of Civil architecture as a style of architecture. They might likewise have heard of Secular architecture and of Ecclesiastical architecture, but not perhaps of that which he ventured to call Civil architecture. The term might, like some things, be logically or historically wrong, but he ventured to think that it was justifiable, and had a meaning. He apprehended that the short and intelligible definition of "style" meant a mode of ornamental building that flourished at a particular time in a particular place. Until a recent period the various styles of architecture were successive. There was the Grecian, the Roman, the Gothic, and so on; but since the fall of Gothic architecture in the fifteenth or sixteenth century,

what was commonly supposed to be a conflict of styles arose; though in reality there was no such conflict until a very recent time. Gothic architecture was supposed to have died out in the country. Then came the style of Sir Christopher Wren and of Inigo Jones, which is now called the Renaissance, or Classic, style. In early times there was no conflict of styles, although in the lapse of ages they might, so to speak, have once lapped each other; but still, distinct traces were preserved of the Norman, the pointed, and the English; there was no conflict. In the time of Wren there was no conflict, for Gothic was dead; Wren was too great a man and too profound a thinker to regard the Gothic with feelings other than those of respect, although his son, who might appropriately be termed the "Little Wren," subsequently spoke of it in a very different manner. The elder Wren instituted a style of his own, expanded the old classical models, and made up a style which was in a great measure his own, although he was not its founder, but merely its introducer—that style which was termed the "domed." While upon this subject he might remark that the dome which we were all most familiar—that of St. Paul's Cathedral—was not a dome, but a cone. Sir Christopher Wren was not only a great architect but a great mechanic and astronomer, and if he had not been famous as an architect, his name would have come down to posterity as a great mechanic. He built the dome of St. Paul's in the shape of a cone, and he was quite right; for, the only way to build a dome to carry a great weight upon it was not to build a dome at all, but a cone, tying the bottom, as Sir Christopher Wren did at St. Paul's, with a strong chain. This skillful treatment in respect to domes ought to be remembered in his credit. He was an inventor and expounder; he invented the Italian steeple, such as St. Bride's Church, Fleet-street, which, however, he (Mr. Denison) considered inferior to the Gothic steeple; but that was only a private opinion. Up to Sir Christopher Wren's time nothing was known in England, of copying styles, or of a conflict of styles. After him came men of little note—Vanbrugh and Chambers, of the former of whom a wit of his day had penned the epigram—

"Lie heavy on him, Earth, for he  
Laid many a heavy load on thee."

Chambers was immortalized in that particularly lively-looking building, Somerset-house, in which the architect intended to construct a model classical building, the windows of which were to be all large, and the corridors full of light! Leaping over another gap, we come to the end of the eighteenth century and beginning of the nineteenth, when there were no architects who would be long remembered in the annals of fame, although their works might stand for many centuries. This was the copying period—the Greek Temple style,—an era of nothing but copies, and many of them bad copies too. How often, for instance, the Parthenon had been copied, upon all scales and in all materials, be would not pretend to guess. This was the epoch in which the London churches began to spring up in the form of Greek temples. The portico of Marylebone church was a portico by Act of Parliament, and as such was entitled to be regarded with respect by all beholders. Then there was the Great Extinguisher church in Langham-place, with a round portico; the church of St. Mary, Bryanston-square, with a semicircular portico at the side (!); and the new church of St. Pancras, distinguished for the money which it cost, and for its close resemblance to some heathen temple, the name of which he had forgotten. St. Pancras was built on the model of a pagan temple; it cost 100,000*l*., and was to be remembered as a distinguished specimen of the church ecclesiastical style of the nineteenth century. But to thoroughly appreciate the utter badness of the copying style, it would be necessary to descend to modern times. In later times architecture seemed to have been set adrift. There was the Greek Temple style, the Wren style, and that of his followers and copyists. At that time no one had any idea that the Gothic style would be revived. At the beginning of the present century, for the first time in this country, there was no style of architecture, because there were so many styles. Gothic was supposed to have died out; the public had become tired of Greek temples; Wren had disappeared from the scene, and mankind were left to choose an architecture for themselves. Time was when the Gothic was spoken of in terms of disparagement, not by a prime minister who had set his face against it, but by a man of recognized authority and taste. In the latter part of the reigns of the Stuarts, the last Catholic kings who sat upon the English throne, Evelyn described Gothic art as "fantastic and licentious"—as ex-

hibiting "great industry in carving, but without heavy, dark, heavy, melancholy, and monkish." Then came the "Little Wren," who styled it, not indeed, "fantastic and licentious," but as "mountains of stone, not worthy of the name of architecture." Now, considering that the metropolitan cathedral occupied a larger area than any other building in the empire, a mountain of stone was about the last thing the son of Wren should have called a Gothic building. The dawn of the revival made its appearance in a shape bordering upon the ludicrous: Horace Walpole's house at Strawberry-hill was the first specimen of Gothic revival. It was scarcely deserving the name of sham; in fact, it was such a sham that, compared to it the worst modern sham, became a respectable reality. Having made a commencement at Strawberry-hill, it gradually crept into churches, and thus got on with quite as much success as the Greek or other ancient styles that came to be revived. There was now a choice of styles between the revived Greek and the revived Gothic. Then came the question—How was the choice to be made? One person said he liked this, and another that, which was fair enough, for the estimate of art was gauged by taste, and not by reason. The object of temples, whether Christian or Pagan, it must be admitted, was the same, although the purpose to which they were dedicated was very different. That object was worship; and in order to worship it was deemed necessary to see and hear. The Greek temples were built to ensure those objects as much as possible; and referring to that circumstance, Mr. Pergusson had pointed out a similarity which he had observed between Greek and Gothic models, in the manner in which the architects of each had endeavoured to obtain their light. If we were to choose the models of our churches upon logical grounds only, he saw no reason why we should not choose Greek temples. The houses of the ancient Greeks we could not, however, copy: first, because there were none of them left to copy; and, secondly, because they were unfit to the climate in which we live. The Greek houses were built for a population living in 32 degrees of latitude, while we lived in 52; and, while the Greeks required but little fire, such was our climate that we required fire and protection from the weather during the major portion of the year. Yet what was the fact; we did not copy Greek temples, and we did try to copy Greek houses. There was another peculiarity of southern buildings, and that was that they had porticos while we had cloisters—not cloisters for monks to read in, but cloisters to keep out the wind and the rain. Now, if we were in reality the practical people that we wished to be deemed, we would have copied cloisters and not porticos. Having briefly referred to the aspect of architecture under the reign of the Stuarts, which he contended was the style of any that partook of a pagan type, because coming from Rome, Mr. Denison referred to town-halls, which, after churches, were growing into importance in proportion with the wealth and enterprise of the age. There were no town-halls in Greece or Rome, but on the Continent they had been carried out in the Gothic style with great success. Among the principal town-halls built in England of late years were those of Liverpool, Leeds, and Halifax. These vied with each other in the costliness of their construction—a proof that even municipal bodies were not free from the vulgar crime of vanity. As municipal bodies were not the sort of communities likely to run into extravagancies of style, and as the town halls of the continent were known to answer their purpose remarkably well, it might be supposed that they would be copied in this country. But they had not been. The Donatist style had not been adopted, of course; but the municipal mind had run into an entirely opposite direction. There was no doubt some reason for this, and if they looked into history the mystery would be solved at once. Gothic churches were first badly copied, but we improved as we went on, and we might now choose our own building—either the church in St. Margaret-street, or the Oxford Museum, or the Chapel of Exeter College, at Oxford. Gothic architecture had now been applied to churches in great perfection. That it had succeeded was conceded, and it was now admitted that it ought to be extended to eleemosynary buildings, to colleges and hospitals, and even to workhouses, for which it had been found to be peculiarly adapted, both as regards the convenience of the inmates and the cost of construction. A writer upon architecture, into whose book he had lately dipped, but whose name he would not disclose, had occasioned him some amusement by contending that Gothic architecture ought to be tolerated notwithstanding it had a

character of its own—an arabic character, just as the Bible was continued, notwithstanding the archaicism of the language—the archaicism of the Bible and the Prayer Book! This was extremely good, as it was an admitted fact that the special prayers composed by hishops of the Church for particular occasions were infinitely superior to those in the book of Common Prayer. But the Gothic was not the only style which had been badly copied. The Italian had been sinned against almost as much, and Downing College, and the University Library, at Cambridge, were about the worst specimens of the Italian style which it had been his lot to behold. The Taylor building at Oxford was also a good specimen of bad Italian. It reminded him of a cherub, all head and wings—or rather, a small head, large wings, and no body. Of Gothic, however, it might be said that although there were many bad illustrations, it was working its way up. But he asked how it happened that in the matter of town-halls the Gothic models of the continent had been wilfully rejected? The same Evelyn to whom he had referred when speaking of what he termed "the great and noble buildings of the Greeks and Romans" had characterized their style as "pompos." Mr. Ruskin had also described it in similar terms, and he (Mr. Denison) was inclined to believe that the pomposity of the Italian style was in accordance with the modern spirit of the age and of the municipal bodies who built town halls. At Liverpool, where there were town dues from which the funds were drawn, 100,000l. had been expended upon the town-hall, and the gates alone had cost 5,000l., including the luxury of a lawsuit; and yet, although the site was spacious and magnificent, the architect had not found it possible to put windows at both sides of his building. The town-hall at Leeds had cost a third of that at Liverpool, and yet nothing could be contrived to relieve the monotony of the skyline but the superimposition of a wonderful tower—a tower which, he ventured to say, would evoke the wonder of Sir Christopher Wren, or of the builder of Canterbury Cathedral. At Halifax, where a town-hall was necessary because Leeds had got one, Gothic and Grecian plans were submitted for approval. The Gothic was rejected, and, to the astonishment and horror of mankind, the corporation resolved to employ their own surveyor to build the town-hall. However, in the end wiser counsels prevailed; the surveyor was set aside, and the building was placed in the hands of an architect of great fame, whose name he would not mention. An engraving of it had appeared in that very useful publication the *Builder*, and in the comments appended the editor had very properly stated that vertically was chiefly aimed at. Singularly enough, however, the town-hall of Halifax was a building in the style supposed to be that in which *horizontally* prevailed. It was, he presumed, what was called a Gothic building with Italian details. But, notwithstanding the failures in public buildings, he thought it was gratifying to find that the taste for Gothic design was becoming every day more generalised, as evidenced by the improved taste exhibited in the Gothic villas in the neighbourhood of London. The Museum of Oxford was also an indication of a revival of Gothic architecture, for there, in his opinion, there was a great deal to admire (as, for instance, the cloistered square, if the roof would fall in once more) and a good deal to blame; but still the portions that were good were very fine, and showed a hopeful tendency in the right direction. Another indication of the spirit of the age was to be traced in the Gothic roofs introduced so frequently in the designs for the new public offices, lately exhibited in Westminster Hall,—these "abominable" high roofs [Mr. Denison drew a section of what he meant] were now forcing their way into Italian buildings. Carving was also extensively introduced, and many of the Gothic realities, including something more emphatic in the shape of towers. These latter were making their way into classic buildings. Mr. Denison next dwelt upon the necessity of paying attention to acoustics in the design of buildings. Town halls were for the most part intended for music and public meetings. It was therefore desirable that the science of acoustics should be applied to their construction; and yet the great halls at Liverpool and Leeds turned out lamentable failures in this respect. At Leeds there were under the same roof four smaller halls or courts, for the administration of justice; and so lamentably had the acoustic properties been neglected, that you could scarcely hear yourself speak in them—the speaker was, in fact, bewildered with the echo of his own voice. Other buildings in Yorkshire were, however, more fortunate. Mr. Lockwood had built several which

were most successful for the purposes intended. As a proof that the great hall at Liverpool was a failure as far as acoustics were concerned, he might mention that Mr. Cunningham had built another hall in the same town, because St. George's Hall was partially useless for the purpose for which it had been built. The chapel at Whitehall, which was cited as being so successful outside, was also sadly deficient in acoustic properties, although so much had been done to cure the defect. Having glanced at the prevailing notions with regard to uniformity and symmetry, and pointed to the case of Cumberland-terrace, Regent's-park, as a mistaken example, Mr. Denison inquired whether a Greek, in designing the approach to a gentleman's park, would have built two models of the Parthenon, in one of which the old woman was to wash, and in the other to bake. Next, with regard to the choice of materials, he thought they ought to consider how buildings would look in ten years hence, or in a hundred years hence, and not how they would look the day they were finished. In his opinion, the only material that would look well, and at the same time bear the vicissitudes of our climate, was red brick, and not stone. He was also quite sure that it was a universal mistake to suppose that any style of architecture would be inaugurated in our day. His impression was that we would go on improving Classic, Gothic, and, in fact, all styles, and that no Victoria style or any universal style would meet with general acceptance.

Mr. HOPE, in moving that the thanks of the meeting be awarded to Mr. Denison for his address, observed that, although he might not be able to agree with him in all the views he had expounded on the subject of architecture, he quite agreed with him that brick, or some material consisting of burnt earth, was the proper implement to wage war against the deleterious climate with which we had to contend. The hon. gentleman announced that there would not be any lecture on Wednesday, March 7, but that he hoped there would be a large attendance of the public to witness the presentation of prizes to art workmen.

Mr. Denison, in acknowledging the compliment, called attention to the Architectural Museum, which, he said, was now nearly out of debt, and afforded an admirable opportunity for the self-improvement of art workmen.

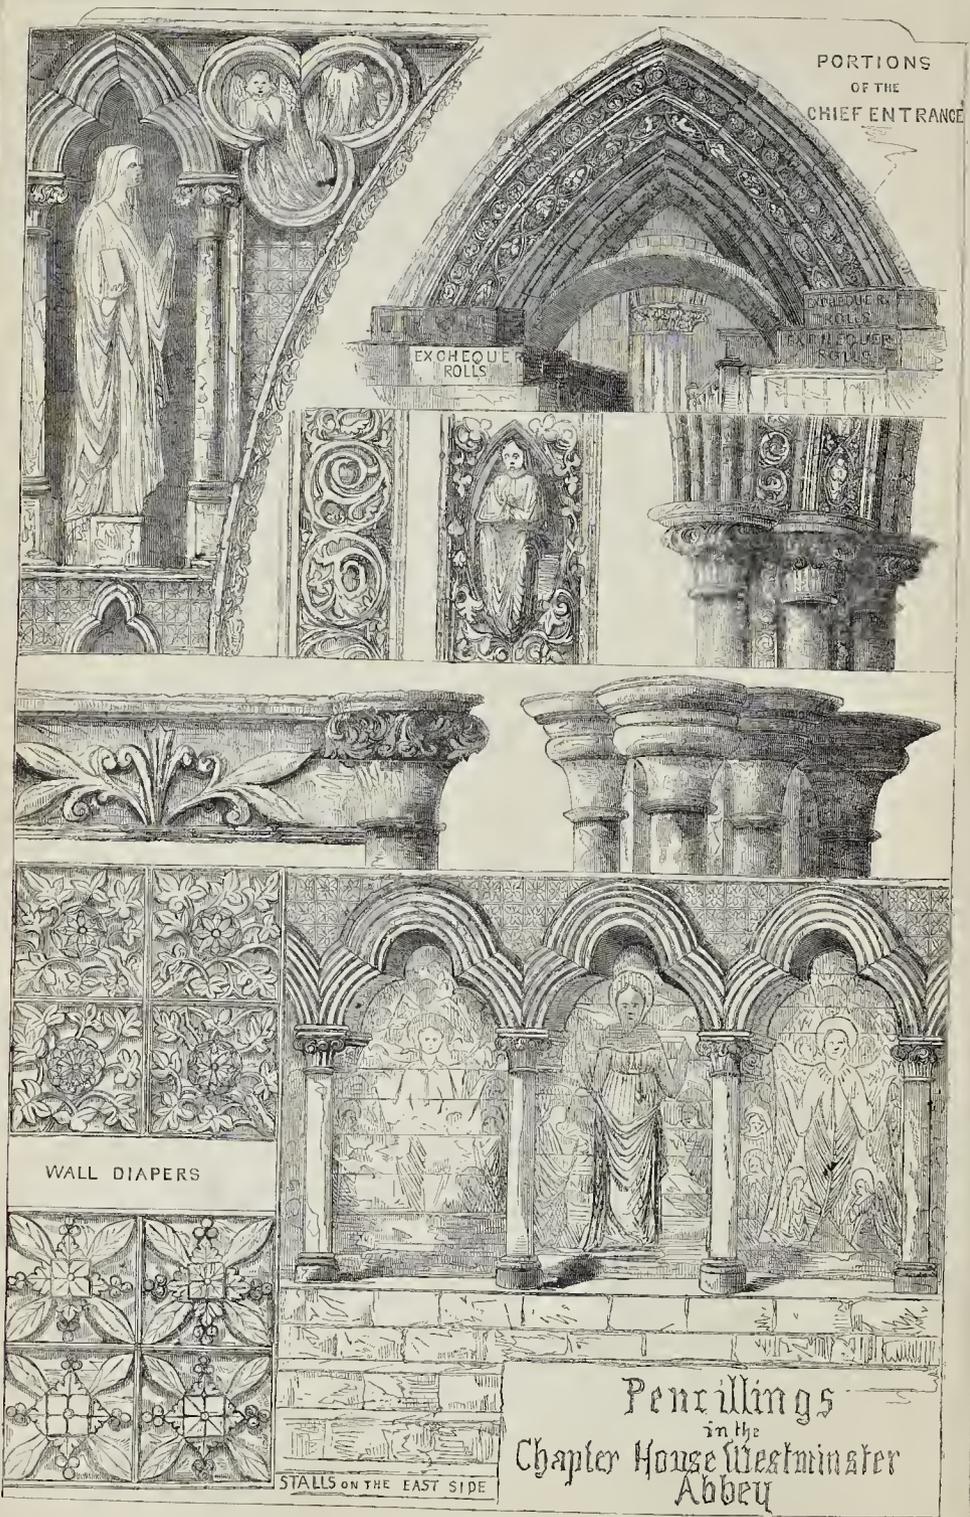

#### PROPOSED CAMBRIDGE GUILDHALL.

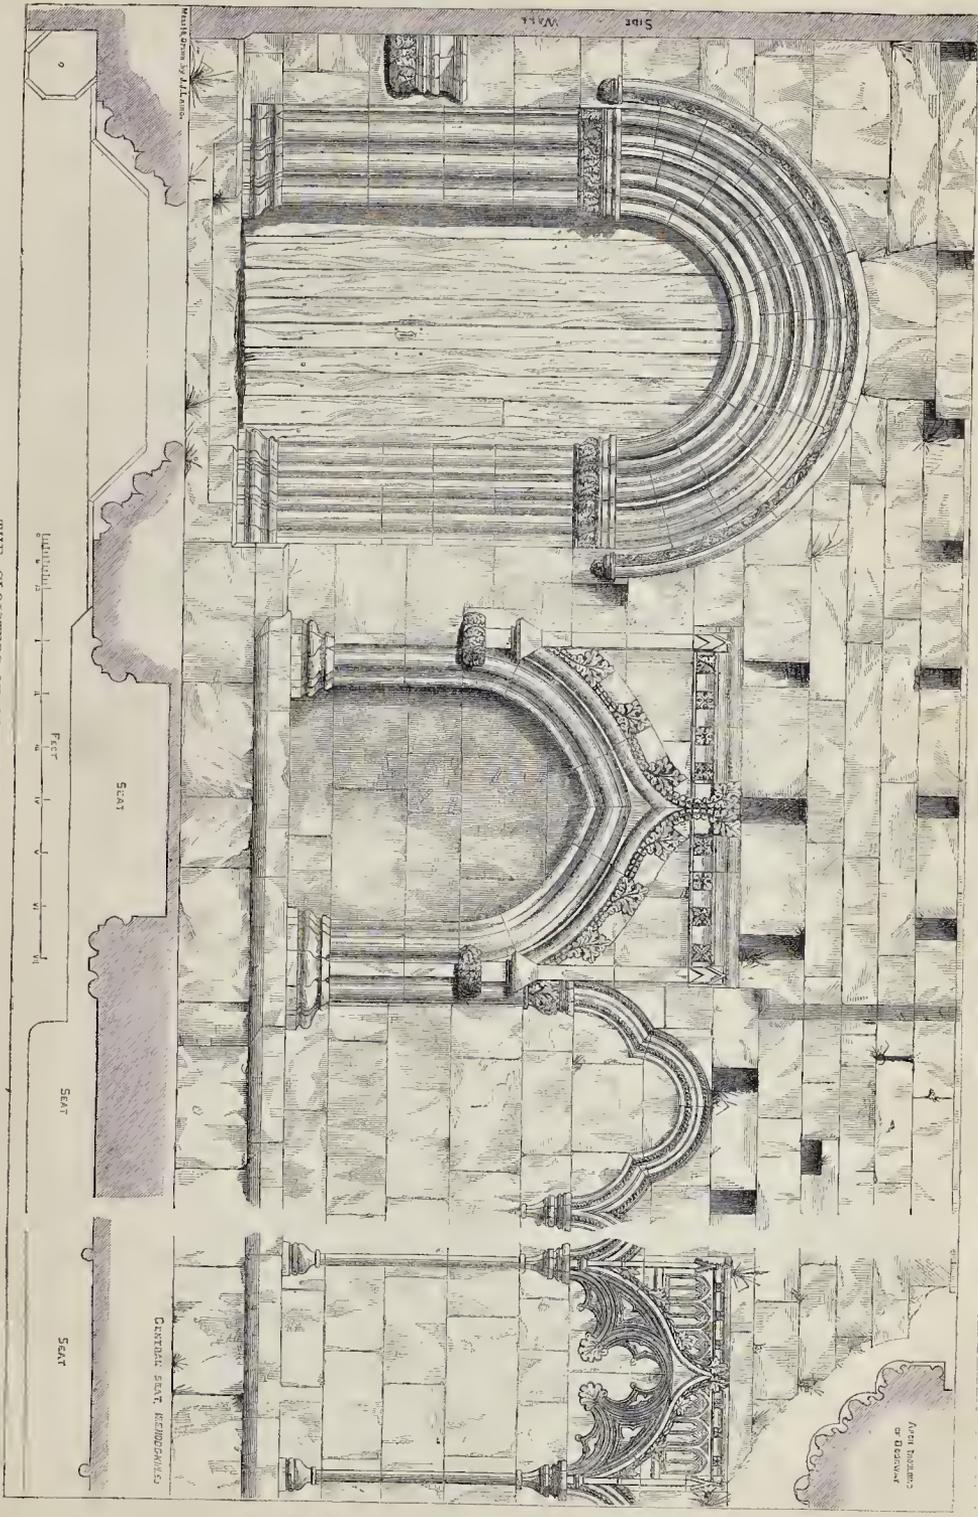

The committee have purchased an additional site for 400l., and have employed the authors of the first-prize design in the late competition, to prepare an entirely new design, with the condition that the lowest tender shall not exceed the stipulated sum of 6,000l.

Should this condition not be complied with, the authors of the second-prize design, it is said, will be employed to carry out their plan with additions.

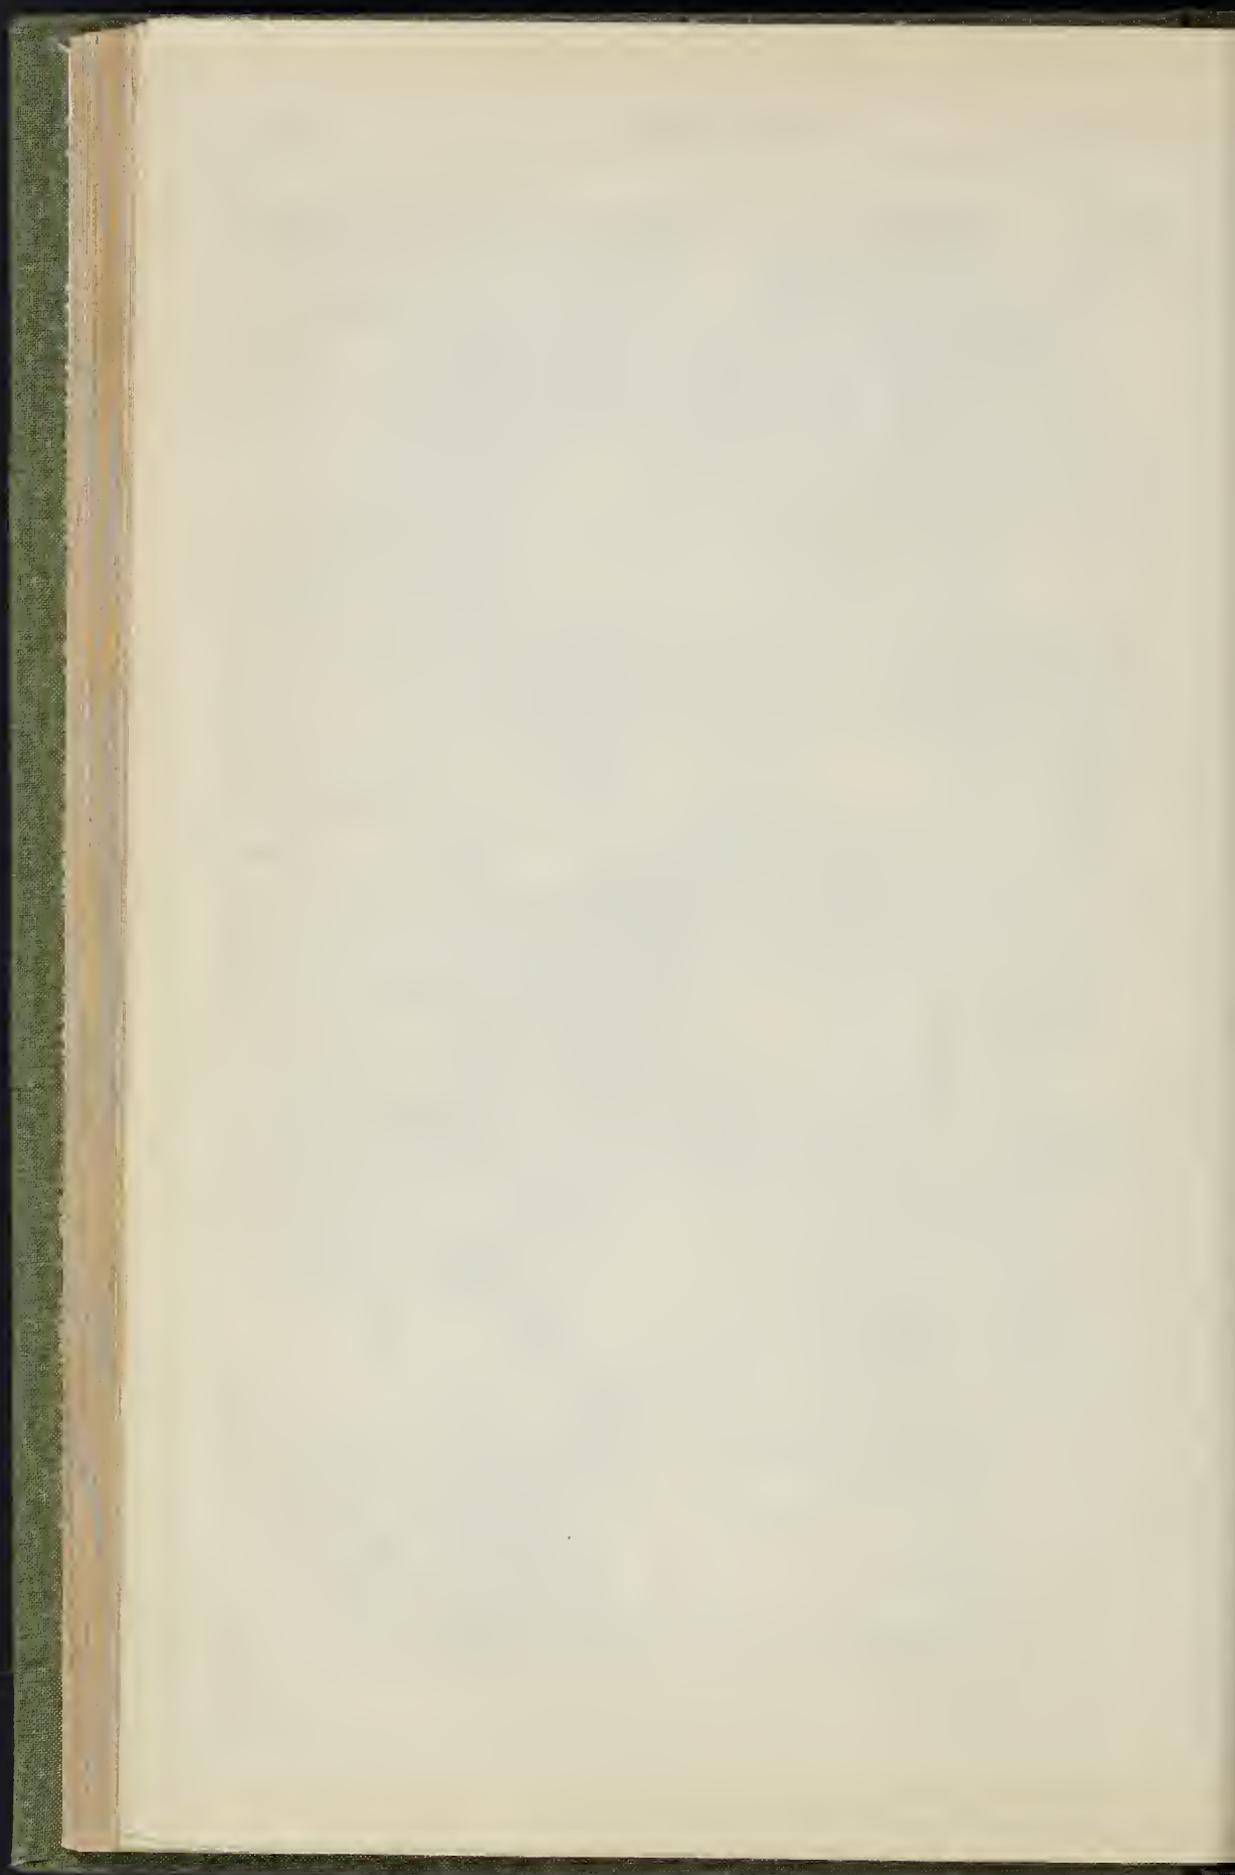

#### THE CHAPTER-HOUSE, WESTMINSTER ABBEY.

We have spoken on various occasions of the beauties of the Chapter-House, at Westminster, and its present miserable condition, and have often urged the desirability of restoring it to a proper state. Full particulars of the structure will be found in Mr. Scott's papers on the Abbey, which we printed not long ago. We now give a number of free sketches, including portions of the chief entrance to the Chapter-House, the mural arcading and wall piers. It will be remembered that an entry was found under the date of 1253, of the purchase of canvas, to fill the windows of the Chapter-House, pending the completion of the works—a valuable fact, as settling the age of the structure. Within the church work is going on quietly in the north transept; and in the lantern men are busily at work, suspended, clearing away the accumulation of black dust which has been collecting for centuries, restoring the gilding, and repairing other parts. The Purbeck pillars are being cleared of impurities. When this portion of Westminster Abbey has been renovated, the stained glass of the principal window there will look very objectionable. At the time this window was thus decorated, it was thought a successful attempt to revive an art which was considered lost, and probably the admission of it gave a stimulus to this important art in connection with church architecture. Since then, however, great improvements in glass-staining have been made, and it would be well to remove this very inferior glass, and refill the window with a better kind, restoring the tracery to its original condition.

THE CLOISTERS OF MELROSE ABBEY, SCOTLAND.

MELROSE ABBEY.

MELROSE ABBEY was founded by King David of Scotland, in the year 1136, for the order of the Cistercian monks. Amongst its famous abbots was St. Waltheof, of whom mention is made in Fordun's "Scottichronicle," where it is stated that he was the second abbot. The abbey is finely situated at the base of the Eldon hills, in the valley of the noble Tweed, from which it is distant but about two hundred yards; and in ancient times was surrounded by rich forests, and with the river and tributary streams, afforded ample opportunities for sport and provision. This district is so great in such resources, that a cluster of abbeyes arose from time to time, such as Dryburgh, which is but a short distance from Melrose, Kelso Abbey, and Jedburgh. In and around these, are the remains of the massive towers or peels, so much needed in self-defence, and security against the invasions of the English. It forms altogether one of the loveliest districts in Scotland to which every tourist is attracted, principally through the writings of Sir Walter Scott; whose seat at Abbotsford is close to Melrose, and near to the romantic glen of Thomas the Rhymer, whose grave is pointed out at the little country church of Earlstone, near to Dryburgh.

The abbey of Melrose is built of red soft stone, easily cut, and capable of the most delicate carving, still seen throughout the whole ruin in its niches, pinnacles, capitals, and elsewhere. It is, in its material and construction, not unlike Strasbourg Cathedral; there being a similarity, especially in its masses of masonry, enriched with light open decorations, which seem to hang like lace-work. In some features it is not unlike Antwerp Cathedral, as in its picturesque turrets, and machicolations in its tower; parts which Scott adapted to his mansion at Abbotsford.

There is a strange mixture of the Early English and Perpendicular styles, with occasional modifications of Continental work, all put together in a peculiar manner, as if in haste, yet in a trim and massive construction peculiar to the Scotch, which may be owing to their continual warfare and struggles, especially when near the Border, whence we see so much of that heavy, often clumsy, and castellated work even in sacred edifices, designed for security against not only English aggression, but against marauders from the neighbouring districts. In 1322, the brotherhood made a decisive stand, with the Douglases at their head, against an invasion by Edward, whose troops suffered so severely from Douglases, that in revenge he destroyed the abbey and slew the brothers, and carried off the communion plate. The soldiers of Richard II., after receiving the shelter and hospitality of the monks, rudely burned it; at which Richard was so conscience-stricken that he made over certain privileges to the abbey, but soon withdrew them.

Greater part of the existing building has been repaired and restored subsequently to these events. In the reign of Henry VIII. it again suffered, under the Reformation and the cannonading of Oliver Cromwell, from Gattonside, on the other bank of the Tweed, made it almost a complete ruin. An attempt was made to obtain the restoration of the nave of the abbey, some years ago, as the parish church of Melrose, but the Duke of Buccleuch, on building a large plain edifice instead, from the hill to the west, became proprietor of the abbey, and preserves it with great care.

Of all parts of the abbey most scrupulously guarded, are the cloisters,—the subject of the accompanying illustration,—which excite the liveliest admiration from the exquisite of the carving, and rich diversity shown in what still remains of them. The cloisters are situated in the north-west angle of the abbey, and probably have been quadrangular in plan; but all that exists, extends from the transept wall on our left westwards 273 feet to the seat shown on our right in the illustration, which is evidently a central or principal nave, there being thirteen of the trefoiled arches, and next the doorway. Extending northwards, along the exterior of the west transept wall, there remains only about 46 feet, containing six deeply-recessed seats similar to that near the doorway. The carving throughout all these is somewhat similar to that shown in the illustration; of some of it is most delicately undercut, through which it is the custom of the Scotch guide (who is a good specimen of the old covenant) to stick straws to show the skill of these ancient workmen. By close examination it will be found that the little square rosettes, as in one cornice over the deeply-recessed seat (some sixty in number), are all different, and most carefully designed and sharply cut.

These cloisters are evidently about the only thirteenth-century part remaining of the abbey, together with the massive columns and their exquisitely carved capitals. The greater portion is perpendicular, particularly the great east window, which Scott calls an oriel. Scott, if he had not ideas on Gothic similar in some respects to that of Sir James Hall, at any rate recognizes the *resemblance* of the theory, when he says in his stanza, in the "Lay of the Last Minstrel,"—

"The moon on the east oriel shone  
Through slender shafts of shapely stone,  
By foliage tracery combined;  
Thou wouldst have thought some fairy hand  
'Twixt poplars straight the ozier wand,  
In many a freakish knot, had twined;  
Then framed a spell when the work was done,  
And changed the willow wreath to stone."

The body of Michael Scott, the wizard, is said to be buried in the chancel of the abbey; and beneath the high altar is said to be buried the heart of King Robert the Bruce, brought from Palestine where it was in charge of the noble Douglas during the Crusades.

Amongst the numerous curiously carved corbels, gargoyles, and grotesque subjects, is a tablet, evidently of the end of the fifteenth century, inserted in the south transept wall probably during some repairs, bearing the following record:—

"John Murdo some time capitall was I,  
And born in Paris certainly,  
And had in kepung all mason work  
Of Sanct-Andreys, ye hie kirk  
Of Sanct-Mercol, Melrose and Galay,  
Of Nyddysdall and of Galway,  
Pray to God and Mary both,  
And sweet Sanct John, to keep  
This haly kirk fra skaithe."

Our engraving is from drawings made expressly on the spot by Mr. J. J. Laing.

ON THE CONSTRUCTION AND MANAGEMENT OF HUMAN HABITATIONS, CONSIDERED IN RELATION TO THE PUBLIC HEALTH.\*

I propose to bring before you some considerations on the manner in which human life is affected by the construction and management of dwellings; and I do so with the belief that the demolition and reconstruction of a large part of London, and the better management of the remainder, is the means through which we may hope to be delivered from some of our common domestic pestilences. Besides it is evident that, when the Legislature confided to your institute the duty of examining into the professional acquirements of district surveyors, it placed in your hands likewise the power of exacting a knowledge of the conditions under which houses are healthy, or the reverse; so that, whilst on the one hand we may be secured against accidents arising from insufficient solidity, we may also be secured against those slow and silent, but a thousand times more destructive, accidents which arise from want of sunlight and fresh air.

It is evident that your calling and mine meet at a certain line. I spend my life in the prevention and treatment of disease, you are the constituted heads of a profession employed in the construction of houses. I shall not apologize, therefore, for endeavouring to present a sketch of the natural history of such diseases as may be presumed to arise from misconstruction or mismanagement of houses; and I will not apologize for treating the question in its medical aspects; any practical inferences will be best supplied by yourselves.

Now, in seeking to display the facts of the case, it is evident how masked and complicated they are as they exist amongst ourselves, and how desirable it is to bring forward some experiments which shall show them in the form of simple analysis. Such experiments are made whenever a body of men go and take possession of a country, and encamp in the open field, as in the common operations of warfare. Then four sets of consequences follow as a matter of certainty, and there is no campaign of which we have any record, from that of the Greeks before Troy to that of our own troops in the Eastern campaign, or that of the Spaniards now in Morocco, in which we do not find distinct evidences of them.

Let me, as a fair specimen, turn to the pages of Sir John Fringie, the historian of the medical events of the various campaigns in the reign of George II.; and I choose him because it delights me to give an incidental mark of respect to one of the earliest and most honest observers of these matters, whose opinions, if acted upon, would have rendered Miss Nightingale's labours unnecessary.

Let us accompany then 16,000 British troops, who, in June, 1742, disembarked in Flanders. Their first autumn and winter were not very eventful. They were quartered in various towns in Flanders, and it was noticed that those who had barracks in high and dry situations were healthy, whilst those in low and damp ones, where their shoes and hats rotted, were unwell. Their diseases were various fevers and dysentery, which lasted through the autumn, but ceased with the first frosts of November, and, during the winter, colds, coughs, stitiches, and rheumatism. But there was one malady observed during this winter which attracted some attention; and this was a peculiarly malignant and fatal fever, confined to the hospital, and seeming to have originated in the foul air of a ward where lay a man with a mortified limb.

So the winter passed, and in the spring the troops marched out, and on the 17th May, 1743, found themselves encamped in an open and healthy country, at Heelst, on the Meuse.

Then began a regular cycle. During the first three weeks various inflammatory diseases from cold prevailed,—pleuritis, coughs, and the like. By the end of June the weather had become very hot: the men fought the battle of

Dettingen on the 27th, and encamped on the spot, on wet ground, without straw, for two or three days afterwards. The dysentery broke out, and Sir J. Fringie takes the opportunity of denouncing the vulgar error that such maladies arise from eating fruit. It continued all July and August, and did not abate till the army marched onwards, leaving the foul, filth-saturated spot of earth behind them.

But mark this. The village of Peckenheim, a league from the camp, was taken up for an hospital, into which besides the wounded, about 1,500 men were sent, sick with the dysentery. By this means the air was vitiated to such a degree, that not only the rest of the patients were infected, but also the nurses and apothecaries, and other attendants of the hospital, with most of the inhabitants of the village. To this acceded a still more formidable disease, namely, the hospital or malignant fever, an inseparable attendant of foul air from crowds and animal corruption. These diseases combined, caused a great mortality in the village, while such as were seized with dysentery, and not removed from the camp, escaped the fever, and generally did well.

Now with regard to the army, when they removed to fresh ground, the dysentery ceased; but the intermittent and remittent fevers of the country broke out, and lasted till the first frost, when the men became healthy again, till from increased severity of cold, again came round the winter crop of stitiches, coughs, and rheumatism.

But no such good fortune awaited the inmates of the hospital. There, no matter what the original malady, they caught the fever, which acquired all the characters of pest plague—spots, blotches, and abscesses of the face and glands. Of the hospital attendants, all were sick, and third died; of the patients, half died; and of the poor inhabitants of the village, between the fever and dysentery, almost all were destroyed.

And now for the last phase. When the survivors from Peckenheim were removed, they were first taken to another hospital, which they infected with their own fever; and then were sent a tedious voyage down the river, in some country barges, to Ghent. Then, it is said, and there seems no doubt of it, that a parcel of old tents, used as bedding on the voyage, were put into the bands of a tradesman to be repaired, and that they conveyed the virus to his workmen, seventeen of whom, out of twenty-three, died.

Here I must leave Sir John Fringie. But without following him in the Scottish campaign of 1745, I draw sufficiently from him to show how four classes of effects follow in definite sequence. 1. Fevers arising from the condition of the surface of the earth, including intermittent and other malarious fevers, 2. Colic, and other catarrhs, arising from insufficient protection; 3. Diarrhoea and dysentery, from insufficient drainage; and lastly, under certain conditions of filth and crowding, fevers of new type, destroying all within their reach, and invested with an intensity which enables them to spread amongst persons not within the original focus.

Now it is these four classes of maladies, of which we have seen the origin in the definite experiment of a campaign, which in a greater or less degree affect us, and which it is the province of the scientific constructor of houses to guard us against specifically.

In fact, there are these four questions, which should be asked concerning every house. Is it protected from malaria, or emanations from the soil? Is it adequate as a protection against cold, and does it supply such an amount of fresh air and sunlight as shall be a protection against scrofula, and other diseases of decay? Is it so drained that the inmates shall not suffer from diarrhoea and other sewer diseases? And lastly, is it so arranged that it shall not be a breeding place for pestilence, nor yet a lurking-place, if it happen to enter from without?

I would more particularly urge the necessity of looking at these things always in their relation of cause and effect. If defective construction and defective drainage cause such and such evils, then where those evils exist let us look for the causes. If, for instance, a fall of the thermometer be followed by a rise in the death-rate from any disease, let us consider whether the habitations of the people are such as to afford them adequate protection from cold.

These, then, are the four points to which I shall direct your attention, although it is the first and last only that time will allow me to notice at length.

First, then, under the term malaria, we may comprehend emanations from the earth generally. And in considering houses, we should never forget the large extent in some countries, the increasing portion of the earth's surface, which is rendered unfit for human habitation by the emanations from the soil. Well, does this fact bear out the divine admonition to *subdue* the earth, as well as to replenish it; and the other divine announcement, that bounds have been set to the habitations of tribes of men? But we cannot wonder at it if we think of the myriads of generations of which the earth's surface has been the graveyard; and that, speak as we may of pure and virgin soils, the whole earth, down to the bare rocks, is full of organic *débris*, and that our valleys, meadows, and marshes, and even some of our hills, are little more than the elevated mud of rivers and estuaries.

I will not dwell on the standard facts respecting malaria; that it affects white races in preference to the black; that it is lost about fifty-five degrees north of the equator; that it is intense in proportion to the heat; that it requires moisture, and yet is destroyed by actual drouth, and is most dangerous after long drouths, when land previously wetted is acutely dry; and that heat and stagnant water undergoing evaporation, above or under ground, are the efficient elements in its production.

Of the effects of malaria, the most specific in this country are agues, which in hotter climates and more marshy soils passes by degrees into the pestiferous fever of Wächleren, the remittent of Spain, the Yellow Jack of the West-Indies, and the fever which secures the annual apothosis of an Anglican Bishop at Sierra Leone.

Ague is now seldom fatal in London; the Registrar General gives only 178 as the average mortality of all England for ague during the seven years '48-54.

In Sydenham's time, the reign of Charles II., the case was different; he speaks of its doing fearful mischief in July and August, 1661, whose families falling victims to it. He speaks of it further as raging in 1668. But the few cases of ague met with now attract little attention, so that terrestrial emanations are virtually disregarded,—whether with perfect prudence is another question.

For it must be remembered that ague, although the specific, is not the only product of malaria. There is, besides, in the first place, that brood of most painful illnesses, called rheumatic neuralgia, of which brood, in face ague, is the commonest type. This flourishes in

\* By Dr. Druiitt, elsewhere referred to.

marsh districts, and can be caught to perfection at Herne Bay (let me say, by way of parenthesis, that the myriads of snails which infest this place are a sure sign of a swampy situation, and that abundance of the signs always indicates the presence of neglected leucoglycogenic matter); but the brown ague is present every year in London; and in practice, one knows that it affects certain houses or streets by preference.

In the next place, it is a property of malaria that it produces the same class of illness which more usually arises from defective house-drainage. Witness, the cholera which broke out amongst our troops in the beautiful but potential valley of Alady, near Varna, and on board the ships of the Black Sea fleet, and amongst the Spaniards now in their Moorish campaign. Witness, too, that love of a low level which is a constant feature in the cholera, and which seems to show its alliance with marsh miasma. Dr. Farr tells us, that taking the mean of the cholera epidemics of 1818 and 1819 in London, nearly 15 per 1,000 of those living under 10 feet of elevation died; 1 per 1,000 of those at the highest elevation; and that if London be divided into terraces of different degrees of elevation, the mortality from an epidemic of cholera is, in round numbers, inversely as the elevation.

Another property of malaria is its power of producing fevers of the continued or ardent type, like our typhus fever. And here let me observe, that any one who reads the works of the physicians of classical antiquity, or even of our own Sydenham, may well be surprised and thankful at the accounts of fevers which were then called, stationary fever, or fevers of the country, of which we have no practical knowledge in our happier times.

Another point to be remarked in malaria, is the remarkable way in which it enhances all diseases of degeneration. The tan-bellies, crooked limbs, pale lips, and glandular swellings of the chest, the scurvy which appeared of the adults at Walcheren, were remarkable.

Again, another point is the power it has of giving intensity to almost any disease; of which the following may serve for an example:—

In the years 1805 and 1806, certain regiments which they had previously contracted the disease, were removed to Dover, and other places, without getting rid of it; and on May 9, 1806, were sent to Riding-street barracks, twenty miles from Dover, to the Marsh. Dr. Vetch, who wrote a description of the disease, called attention to these emphatic facts; it was generated amongst the debased inhabitants of the marshy soil of Egypt, when brought first to the Marsh, and then to violence at Hythe, at the edge of Romney Marsh. At Riding-street, in the centre of the Marsh, it broke out with tenfold violence; it assumed a remarkably mild form when the men were removed to twenty-four miles from Riding-street to Maidstone; and an equally remarkably severe form on the return to Riding-street, when the assizes compelled the men to remove from Maidstone.

Now if we consider these facts with regard to malaria, I can remember that London like ancient Rome, as the regi-tran-general says, built upon low hills, in the midst of an imperfect drainage; and that it was once severely scourged by it; that even now there are occasional indications of its presence; and that it contains in itself the essence of all such diseases as can be produced by muddiness and damp, besides the fact that it is once to itself, and that it aggravates all; the practical question arises, it is not worth while to take even superfluous precaution to get rid of every trace of the evil, and to avoid every thing which would create it anew?

Now it will be well worth asking, are there any present indications of the presence of malaria in London? I believe that it does exist, though generally in a masked form, and undistinguishable from other prevailing sources of illness. Let me give the following instance:—

My attention was called to a small cluster of houses, inhabited by respectable tradespeople, and with no want of drainage or ventilation. In the first place a healthy girl of 18 years of age died of fever at No. 12. Two cases of fever then occurred at No. 11. A year afterwards, another case of anomalous fever occurred at No. 10. I then saw some people from No. 10; the children suffering from diseases of degeneration; the mother told me that last year she had a regular tertian ague, though she had never been out of London. I have long known of these houses, that they stand on the side of a hill, on the very edge of a bank of clay, parallel with Piccadilly, which banks up the water in the great conduits behind; and that these houses are always wet, sometimes flooded; and just the place where theoretically ague might be expected.

A friend of mine lived at Kilburn for some years, with nothing worse than occasional rheumatism; and never anything like fever or ague; moreover, ague was unknown, and fever very rare indeed in the place, till in the winter of 57-58, a railway was constructed, and an embankment of red high made off from under Lord's Hill, at Hampstead. The first effect was to cut off ventilation, and render my friend's garden damp; but so soon as the hot sun acted on this bank, it produced emanations which poisoned every member of the family, more or less. The eldest son had a continued fever, preceded by great depression, sighing, and ocular spectra; two of the daughters had severe tertian ague; another, mumps and slighter ague; the servants and wife were similarly affected, and several other cases of ague in Kilburn.

It must be remarked, too, that there are ague years, as 1801 and 1828, and in our time, 1827 and 1828, when it prevailed unusually in London.

Moreover, there are many instances of the spread of disease, which, in the absence of personal contagion or other common source, can scarcely be being attributed to malaria; and there is no reason to doubt that organic emanations from an undrained soil are similar to those from sewers.

It seems physically certain that malaria may be got rid of by deep drainage. I do not mean merely the closed pipes and impervious channels by which house drainage and surface water are carried away, but the system employed by the scientific farmer. The philosophy of the thing is obvious. A constantly descending capillary current through a porous soil, provides for the oxidation of noxious matters; but this oxidation is conditional on free access of air, which the displacement of absorbed water causes. If this were attended to, probably we should bear less of the fevers which prevail in new suburbs on the outskirts of London, on a clay soil; but as things are, you may see houses erected on a clay soil, covered with stagnant water, which, in just concealed by a little made ground. Last summer, I saw at Weymouth, a whole row of new houses standing in a

swamp. Moreover, in many parts of town, a fetidous elevation is created by means of made earth and rubbish, which charged with offensive organic matter. I can point to examples of this kind in many parts of the town, and Gloucester-road, South Kensington. I may conclude this part of my subject by submitting to your judgment the opinion of the eminent chemist, that the most important point, and the first point to be grounded in the scientific construction of houses.

On the second and third divisions of my subject, viz., diseases which arise from imperfect protection of the system of house drainage, I have not time to treat; but whilst dismissing malaria, let me say one word on the kindred subject of damp. I have many cases collected from various parts of this parish, in which mere dampness by itself produced a most singular and uniform train of symptoms, consisting of extreme mental despondency, and accompanied with anæmia and bodily feebleness, and with a tendency to drink or to suicide.

Passing over these matters, I now wish to direct your attention to a matter in which none of us can help being personally interested. I allude to the origin and propagation of the common domestic pestilences, small-pox, scarlet fever, and others of the group.

Consider, in the first place, the number of them. There are small-pox, measles, scarlet fever with diphtheria, and whooping cough, each of which is, so to say, the centre star of a host of satellites in the guise of chicken-pox, eruptions on the skin, mumps, and others; which, being taken together, form a host of no less than 115, or 116, though they often cause most distressing illness. Now, it is worth remarking, that the average annual mortality from these four diseases, in the seven years 1818-24, was 102,158, or 27.166. The total loss of our army in the Crimean war was under 22,000.

Now, in respect of these four diseases, it is too often taught, both by members of my own profession, and by others, that they arise from a miasmatic cause, or contagia, that is to say, that they never arise de novo, or *ab initio*, out of itself and growing; but that they absolutely originate in their development a germ derived from some preceding case.

Of course, it will be seen at a glance, that belief, in such a case, has some very practical bearings; for if a man be infected with scarlet fever, he may not only contract it from without, derived from pre-existing case, he will carefully look to his front door; he will exclude suspicious friends, and perhaps tamper his letters, and the clothes which come from the laundress; and so desire to be shut out well. But he possibly may neglect to see where it is that the air of the house comes from by night, when his front door is fast, and his window aperture rendered as impervious as possible, which is a clear error; he will enter; and he may neither know nor care that the air of his bedroom enters through an ill-fitting door in the basement, where it has received contributions from a dust-bin, from a cellar full of mouldering old hampers and straw, and from a damp coal-cellar and servants' water-closet in the area.

Now, partly under the influence of this doctrine of specific contagion, and partly from the fact that these four maladies and their satellites for the most part attack us but once in our lives, the public mind has attained to a wonderful degree of credence, in the notion, inasmuch as we are accustomed to look upon them as necessary and unavoidable evils, and to think that the annual loss of 100,000 may be lamented, but cannot be helped.

If I can succeed in dislodging this doctrine, by endeavouring to prove to you that they do arise from the same class of exsues as did the malignant fever in the hospital at Leeds, it will be a venture to hope that our time will not have been quite wasted.

Now, in the first place, let me remark that the above four domestic pestilences are members of a very large family of zymotic diseases, so called, because they, likewise, were once regarded as *specific*, but which now are admitted, on all hands, to be capable of being created under the necessary conditions are combined.

Take, for example, typhus, or continued fever, which destroys 17,841 persons on an average per annum. I was reading the other night an essay by a venerable friend, in which he says that amongst troops in Jersey, in 1806, and he says of the cases of fever, that they are utterly unknown, and looked up in the bosom of the Delly. When, too, I received my medical education at King's College, the professor of medicine, who was all as a most sagacious and benevolent physician, laid particular stress on the doctrine that fever must come by contagion, and that although dirt might create the soil, it could not create the seed. But that resolved typhus into typhus. In one we recognize a fever generated by the vapour of sewers; in another, the product of overcrowding, and so on,—so that no one doubts now that by putting the proper elements together, a fever poison can be bred, as certainly as prussic acid can be formed in the laboratory of the chemist.

Let me, in the second place, allude to that group of zymotic diseases which are generated in hospitals, and I do so for the purpose not merely of showing that they, in their degree, serve amongst ourselves for laboratories of new diseases, as surely as did the hospitals of which, them, but likewise of paying a tribute to your President, whose papers on hospitals are not the least of his services to humanity.

Begin, if you please, with the well-known story, a "Light for the Line," by the authoress of "Hedley Vicars." Thomas Ward, a young navigator, has his arm torn off, and he lost his life because his blood was poisoned while in the hospital, that it was unable to furnish material for healing the severed arteries. He was advised to leave, in order to escape the hospital fever, and went home and died. In the place of the hospital, the patient would bleed to death unless they got out of the hospital air.

It is curious, indeed, are the varieties of effect of hospital miasma. You may have erysipelas, or a form of pyæmia, a condition in which a patient perishes with universal abscesses, or you may have low inflammation, and a purulent suppuration; each of which can be propagated from one patient to another, either by direct contact, or more particularly if the native miasma of the hospital be aided by a blast of sewer air.

Some of the most remarkable and successful operations in the history of surgery, have been performed by one of the leading metropolitan hospitals. The works of the surgeon were remarkable, but the patient died of low inflammation. I heard one of the young men attached to the hospital, say that a patient was held in, which gets all the faces of the *resolventes*; every

patient in that bed lies under a operation. I entered the surgeon not to put this one there; but he does not believe in sanitary measures."

If it could be proved, as we sink into insignificance in all other respects, when we consider the relation which they have to the death of women by purpural fever, at every time when they are most the objects of solicitude and affection, the fever may be cured.

No one not in the medical profession can have an idea of the painful series of facts which have forced accounts, which guard women in childbirth from every source of putrid miasma, and which show that the putrid water-closet, or the ordinary cause of fever, or scarlet fever, may soon rob a house of the mother, and that wherever originated the fever may return.

Still more fully may the source of this domestic pestilence be found in that mistaken and unimproving institution, the Lying-in Hospital. For whole generations has it been known that what is death to the wounded soldier in the Military Hospital is equally death to the poor woman in the Lying-in Hospital. My friend, Dr. Robert Ferguson, some years physician to the General Lying-in Hospital and professor of Midwifery, King's College, writing in 1839, says,—"We have abundant evidence of the disease being most fatal in hospitals. Neither the skill, nursing, nor diet diminishes the mortality to a level with that of the out-door population. It is, in some instances, and is generally better placed with regard to ventilation than in most hospitals, and in no malarial is pure air, quickly changed, so to speak, by the frequent stirring of it, by the chief prophylactic. A lying-in hospital may consist either of a series of cottages, or its spacious wards should contain very few patients. When fever prevails the mortality is high. In the Lying-in Hospital, Dr. Ferguson in 1838. But General Routh, the oldest commander in the British army, regius omnipotens elsewhere; and in 1858 the medical periodicals are furnished with fresh accounts of the mortality in the Lying-in Hospital. Dr. Rigby, senior physician to the hospital, showed that, from January, 1837, to August, 1841, the mortality of women in childbed was 70 per cent. The mortality was high wherever the mother was being obstinately missed by the nurses whilst the old open windows were in abeyance, the death-rate during the period of the epidemic was 100 per cent. The mortality at the rate of 90 per 1,000. Then for a period of seven years of perfect ventilation the deaths were reduced to 4 per 1,000. Again, in April, 1849, the committee determined to experiment with the opening of the windows to time May, 1845, thirty women died, or at the rate of 26.77 per 1,000. No evidence can be clearer than that the purpural fever is an artificial disease, made out of putrid miasma, and that it is a disease which is not to be cured in private life, at least, have received the contagion from hospitals. I must not quit this disease without noting that there is a now almost obsolete disease—the erysipelas of infants, which is a disease which wherever the mother is of purpural fever; and that one disease—look-jaw of infants—is now scarcely met with, even in Ireland."

It is possible that contagion of kind of mortification, attended with exudation of a leathery putrescent material, which is constantly generated in crowded military hospitals, is occasionally the cause of cases in which a capital experiment recorded by Professor Brugmans, of Leyden. In 1798 hospital gangrene prevailed in a lower ward of a hospital to that city. A surgeon, in order to ventilate the ward, had the opening through the ceiling in the ward above, and in thirty hours the disease attacked the three patients in the upper ward who lay nearest the opening. Hospital gangrene of a wound and diphtheria in the throat present the same characters.

Next, glancing in passing at the diseases which ensue more emphatically, although not all exclusively, from the sewer poison, that is, the typhoid fever, rheumatism, dysentery, cholera, and the severer cases of typhus, and bunette—all of which, if severe, are communicable—let me allude to the vast number of diseases of external surface, such as erysipelas, erythema, and others, which are produced, viz. that they may be engendered under certain conditions, and then spread to the healthy. Amongst such maladies are many known to us only by name, although vestiges of them are to be seen in the most advanced stages of the polio, the button scurf, scyosis menti, and the leprosy of the Middle Ages; amongst them, too, are those maladies which are the appointed scourge of incontinence, such as the erysipelas of the face, and the erysipelas of the nose, expresses his belief, that wherever foul and promiscuous immorality prevails there will spring up. Let me not quit this subject without alluding to the fact, which the object of so much dread and controversy in the last generation. Never absent from the debased peasantry who occupy the crowded bays in the towns in the marshy soil of Egypt, it was brought home from that country by our troops in 1805, and was propagated and flourished wherever it met with a congenial habitat; was often noticed to disappear during a march; was aggravated by close, damp air; but always has been, and is now certain to appear in Yorkshire schools, workhouses, and barns, wherever the eyes are irritated and exposed to an atmosphere tainted with human exhalations. But nowhere was this more palpable than in the case of slave ships, and there is an absolute truth in the tale sometimes told by poets, of a ship rolling about at the mercy of winds and waves, and the crew perishing by the inability of the captain and the ship's crew to be blown by the wind.

Equally true is this with regard to the air passages. Let one or two persons ill with common catarrh, shut themselves up in a room, and the atmosphere, and the air, visitors will, to my knowledge, run the great risk of "catching cold."

Another disease, which at times creates an awful interest, is that which is called the plague, and which is the glanders, a well-known disease of the horse. But although the effects of the glander poison are as regular and specific as possible, yet veterinarians have always maintained that it can only be generated *in situ*, under the combined influence of *low condition and bad air*. The constancy with which it breaks out when horses are sent long voyages is worth noticing.

Let me now touch in passing some of the diseases of bygone days, at the Hungarian fever, for example, which was said to have been introduced by troops in the reign of Louis the Great, either by direct contact, or from one end to the other, and still better at the plague, of which Sir W. Petty, writing in 1683, declares that a variation of it occurs once in twenty years, and that it is introduced from the East Indies, and that it is the cause of the plague, says they are "matters, like many others, upon which vain and arrogant philosophy speculates to no purpose," and proceeds to "thank the mercy and goodness of the supreme God," because He

redolent in bloom. The border next Piccadilly was certainly not so favourable for flowers; still they blossomed, despite the incessant thunder of omnibuses; and the various shrubs, laburnums, thorns, and lilacs, whilst they offered a pleasing screen from within, flourished, ay, even under the trees, as in mockery of their denaturalized and civic position. Let those who saw it last summer compare the open iron railing and the view of Buckingham Palace with its aspect when the hawthorn bloomed. All this, however, is to be restored, perhaps only at the cost of 1,000*l.* and the loss of a year's growth.

So much for the management of the "terra firma." There was, however, a question about the water, which agitated the public mind. It was found that the Serpentine had become polluted and fetid; that it was dangerous both to the health of the crowds habitually bathing there, and even to the lives of many. Numerous suggestions were made by the *Builder* and by the *Times* for the correction of these sad disadvantages, and correspondences with the late Chief Commissioner were published, clearly showing that a largely increased supply of water was requisite for its purification. In these reports estimates and figures were given of the expense, and one in particular, sent in by the engineers of St. James's "Canal" improvements, and of the Trafalgar fountains, proposed to supply two million gallons daily during the summer, and one million during the winter months, for 16,000*l.*, and to give distinct supplies of fresh spring water to St. James's Park, Buckingham Palace-gardens, and the Serpentine, for a total annual cost of 1,000*l.* a-year, so as at the same time to effectively change the whole body of the Serpentine once a month, and to gratify the public with a real and incessant cascade at the Knightsbridge pond head!

These propositions were made on the 5th of August, 1859, and rejected by "my lords" on the following day.

At the same time, the same firm offered, for the Serpentine alone, to supply one million gallons daily to Kensington Palace-gardens, and thence to the Serpentine, for 11,500*l.*, and to work it at the charge of 700*l.* a year. This proposal the secretary also rejected on the 11th August, 1859, "by order of the Chief Commissioner."

These data are given from published documents, in apprehension that the works now in operation, whatever may be the cost thereof, will turn out wholly insufficient for the objects so much needed by the public in securing either pure water or a quantity sufficient to meet even the waste by evaporation, not to speak of all of the ornamental or landscape effect.

Now, a contract has been actually concluded at a much larger sum, for not only pumping back the natural supply of the Serpentine into a filtering bed at the Westbourne end, whence it is to be under constant process of filtration, and return to feed the whole expanse of a mile in length.

At this moment, about an acre and a half of the water-bed is dammed off; the slush or mud is being cleared out; tunnels are being built, and iron pipes laid, to withdraw the same identical bath suds of two thousand washers daily, and to return it gradually into this Lake of Acheron by way of purification. But this is not all; for a steam-engine, and, of course, a house, is to be placed on an insulated tongue, close to the bridge at the Victoria-gate entrance.

There is an apprehension, not a little excited by recent speculations, that unwise men may seek to win laurels by short cuts, or not by daring raids against good taste or common sense; no mean skill in diplomacy has been exercised to shield wrong-doers already; and the fear is that politicians, and not engineers, are at the head of the *Improvement Commission*.

Save us, oh! save us, the little of nature that remains in the metropolis; or, if violence is done to simplicity,—if we are bereft of the ornamental and beautiful,—substitute what is really effective and useful.

It is not only the needless waste of large sums of money that is dreaded, but the failure of people plans (that of a table fountain-*toy*), the adoption whereof would be a national disgrace.

QUONDAM.

FALMOUTH DOCKS.—Messrs. William and John Freeman have received the formal acceptance of their tender for the supply of granite for the construction of these works. The half-yearly meeting of the Docks Company is appointed to be held on Tuesday, the 28th instant, and Lord Falmouth has accepted the invitation of the directors to lay the foundation-stone of the breakwater on the day of the meeting.

BALL FOR THE BUILDERS' BENEVOLENT INSTITUTION.

The newly-decorated Willis's Rooms, St. James's, received, on the 16th inst., the friends of the Builders' Benevolent Institution, to the number of about 520, and the ball passed off with great satisfaction to those who were present, and the gain of more than 100*l.* to the excellent charity in whose cause they had assembled. Mr. Joseph Bird officiated, as he has heretofore done, honorary secretary, and with Mr. A. G. Harris, the acting secretary of the institution, exerted himself to ensure the comfort of the visitors.

The rooms look bright and pleasant with their new face, and, if we consider the haste in which the works were executed, are creditable to Mr. Kneekuck's skill as a decorator.

PLEYL LAND COMPETITION.

The committee have awarded the first premium of twenty guineas to Mr. George Felton, architect, Llandudno; and the second of ten guineas, to Messrs. Williams and Underwood, architects, Denhigh. And, inasmuch as many of the plans possessed considerable merit, the committee awarded a third premium of five guineas, to Mr. George Toussaint, of Deva-terrace, Chester.

A MISCREANT IN THE BRITISH MUSEUM.

It is with very great regret we notice that the authorities of the British Museum connected with the library, have felt it necessary to exhibit certain mutilated books in the reading-room, with a note directing attention to the circumstance that portions have been torn out by some person or persons who have visited the room. In one of these, Haydn's Dictionary of Dates, several leaves have been wilfully abstracted, and from an atlas a large map has been torn.

The principal librarian, in directing attention to this most disgraceful act, expresses a hope, in which we cordially join, that the readers will endeavour to discover and put a stop to such proceedings in future. We are sure that no one, except those concerned in this infamous act, can fail to regret this most unpleasant occurrence, and hope that the delinquent or delinquents will be brought to justice. An offence such as this cannot be too severely reprobated. Every reader has an interest in discovering and punishing the scoundrel.

CAMBRIDGE RIFLE BUTT.

The committee of the rifle club have purchased a piece of ground about 450 yards by 50 yards, and erected at the end a brick wall, plated with iron. Several persons interested in property within the line of fire, have threatened legal proceedings on the ground that the wall afforded insufficient security to them. The committee have lately had the butt inspected by a Government official from Hythe, who has reported against it. He requires additional work to the extent of about 350*l.*, to be executed before he can allow it to be used.

The butt was erected by a builder who furnished his own design,—we presume under the common but mistaken notion, that such an arrangement would save an architect's commission.

There are other rifle corps who appear to be at sea in this respect: they are unable to use their barrel because they can't get their butt.

COTTAGE IMPROVEMENT.

MISS MARTINEAU gives, in *Once a Week*, the particulars of such a cottage as can be built in Westmoreland for 60*l.* "By the plan," says the lady, "it will be seen that there is a fair-sized front room [13 feet by 10 feet], a kitchen [12 feet by 10 feet 6 inches], and two bed-rooms above, all having fire-places, by the chimney running up the middle of the house. The walls are two feet thick, the windows large, and the ventilation ample. There is, however, no out-door accommodation; and a pump and sink cannot be afforded for the money. The items of cost are these, 'walling' comprehending the entire building, and paving, and all the stones of the walls:—

Walling .....	£23 0 0
Plastering .....	7 0 0
Slatting .....	10 0 0
Carpenter's work, which includes the entire fitting up of the interior .....	20 0 0
	£60 0 0"

It is to be regretted that Miss Martineau should

lend countenance to any extent to the construction of labourers' cottages with only two bedrooms: there should always be three; so that the male and female children may be separated.

We take the opportunity of mentioning again "The Cottage Improvement Society," Adam-street, Adelphi. The cottages, with three bed-rooms, of which they have circulated plans, can be erected for 160 guineas the pair. Cottages for families with only two bed-rooms lead to an incredible amount of vice.

THE ARCHITECTURAL EXHIBITION.

We must remind our readers that the tenth exhibition will be opened to the public on the 11th of April next, and will remain open till the 30th day of June. All drawings and models must be delivered on the 20th of March. It is suggested that the description sent with each drawing should contain an account of materials, cost *after completion*, object, &c., of the building or design.

Plans and sections intended only to illustrate arrangement, should be drawn to a *small scale*. Inattention to these points, it is mentioned, will, in many cases, cause plans and sections to be left unlung.

There will be a department for models, carvings, decorations, specimens of manufactures, and inventions connected with building, as heretofore.

TREATMENT OF TENDERS FROM BUILDERS.

STR.—Will you please insert the following in your next paper, as we most strongly protest against the system adopted in the decision of this court.

We are informed by the architect that his client "avails himself of the privilege of a clause" in the advertisement for tenders, viz., "lowest nor any tender necessarily accepted," as it appears to us to enable him to get an idea of the cost at the expense of two and trouble of the five or six builders who estimate. If parties about to build have not sufficient confidence in their architect and builder, why not pursue a straightforward and upright course, and employ a disinterested surveyor to go through the bidding estimate, and pay the surveyor for it?

ONE OF THE FIVE.

Villa Residence, Atherstone.—The contract for this work was this day (February 16th) let to Messrs. J. G. & John Fox, for the sum of 2,900*l.*, subject to a reasonable reduction on the price of timber in case the duty should be reduced.

The following tenders were received:—

Pooley .....	£3,620 0 0
Hudson & Meredith .....	3,100 0 0
Spencer .....	2,978 0 0
Harrod .....	2,850 0 0
Potter .....	2,837 0 0

R. JENNINGS, Architect.

THE MORNING ROOM AT ASHRIDGE.

STR.—At the same time that I thank you for exhibiting to me such a choice and unusual subject as the "Morning Room at Ashridge," I must say that it would have been all the more valuable and interesting had Mr. Digby Wyatt volunteered, or had you extorted from him, some particulars that would enable us to understand what cannot possibly be made out from the partial view of the room. To the best of my power of computation, it would not have taken many columns to state the actual dimensions of the room, that of height included. What one is most of all at a loss to understand is, whether there be a corresponding loggia or pillared recess on the side opposite to the one shown in the drawing.

Craving permission to do so, I would further remark that the room does not at all answer to the character of a morning one, the style of its decoration being so exceedingly ornate: this, however, partakes of hypercriticism. A very positive objection, on the contrary, may be urged against the fireplace and chimney-piece, as being not only a decidedly unwholesome feature, but one quite at variance with nearly all the rest of the design. I desist from further observations, or I should protest against the gratuitous offensiveness, to my eye at least, occasioned by the top of the curtain, before the book-shelves being lower than that of the hooks on the uppermost shelf; yet nothing was easier than to avoid such defect, and, at the same time, consult architectural consistency, by merely continuing the entire entablature correspondingly with that over the two projecting columns. It will very likely be said, in excuse for it, that, after all, such irregularity is a very trifling offence,—one scarcely worth animadvert-

upon. But then "the smallest speck is seen on snow;" we are therefore warranted in looking for and demanding the most conscientious observance of synthesis and symmetry in architectural design; notwithstanding that, a new school of architectural antinomianism has now come up, and preaches up the disregard of architectural rhythm as a certain and safe short-cut to architectural eloquence. My pen itches to say a great deal more on this abominable heresy. But the safer course may be to add no more than yours, &c.—  
ZETA.

**BISHOP AUCKLAND COMPETITION.**

Sir,—I really am of opinion that the profession are much indebted to the Northern Architectural Association for the resolutions they passed and addressed to the directors of the Bishop Auckland Town-hall and Market, and it is to be hoped that those gentlemen will not only be induced to revise their decision by being guided by the opinion of those who are capable of forming a correct judgment on the labours of the architect in preparing a design for such a building, but that they may, with others, be able to establish the idea of paying a value of £1, on any set of drawings they may choose to select. It is time that such a course was put a stop to, and the Northern Architectural Association merit the thanks of the profession.  
A SCANDINAVIAN.

**LYNCOMBE CEMETERY CHAPELS COMPETITION.**

Some time since an advertisement appeared in the columns of the *Builder*, offering the munificent premium of £100, for plans of chapels, &c. for Lyncombe. Some forty architects responded to this advertisement. The Board, by advertising in the *Builder*, had thrown the matter open to the whole profession, yet, as I am informed, one of the first resolutions proposed was, that designs not sent in by Bath architects should be at once excluded. Although this resolution was rejected by a small majority, yet there have been selected, had it been carried by local architects. The Board allowed the names of competitors to appear. The Board limited architects to an expenditure of £500. The Board invited designs from a local man, the lowest responsible tender for which is, as I am informed, £2,300.  
A COMPETITOR.

**ARCHITECTS' RESPONSIBILITIES.**

GAY B. DICKSON AND OTHERS.—COURT OF COMMON PLEAS.

Mr. Lush, Q.C., and Mr. Barnard appeared for the plaintiff, and Mr. M. Chambers, Q.C., Mr. Hawkins, Q.C., and Mr. Dowdeswell, for the defendants.  
The declaration stated that the defendants were employed by the plaintiff as surveyors to value the beneficial interest of one Benjamin Parker, in the lease of certain premises at Millwall, together with the plant and machinery thereon, and required to report whether the interest of Parker in the said premises, plant, &c., was of sufficient value to warrant an advance to Parker upon mortgage by the plaintiff of £2,000, upon the security of the said premises, plant, &c. The defendants reported that the said interest was of sufficient value to secure such advance; that the plaintiff had thereupon advanced to Parker the sum of £2,000; that the interest of Parker was not, in fact, of sufficient value to secure such advance, whereby the plaintiff was damaged, &c.

The circumstances of the case were that in November, 1857, Parker, who was the lessee of the premises in question, being then under peculiar embarrassment, and a prisoner in the Queen's Bench Prison, made applications for a loan of £2,000, to an attorney named Marsden, who, acting conjointly with an attorney's clerk named Brady, the plaintiff having then undertaken to find the money, the plaintiff having then undertaken to find the money, the defendants, Messrs. Dickson & Davenport, who carry on business as surveyors, valuers, &c., in Bucklersbury, Messrs. Dickson & Davenport, who carry on business as surveyors, plant, machinery, &c., and state their opinion whether Parker's interest therein (the lease had at that time only two years and a half to run, but it was represented to defendants that there would be no difficulty in procuring its extension) was of sufficient value to cover the advance of £2,000, to be made by the plaintiff. Nothing was said either to the plaintiff or to the defendants of the precariousness of Parker, then a prisoner, and who had already been three or four times a bankrupt; and Messrs. Dickson & Davenport, under the impression that Parker, who was represented as the patentee of a certain invention connected with railway sleepers, was a substantial person, who would be able to carry on his business successfully, in connection with Marsden, an engineer carrying on business in Old-street, St. Luke's, the third defendant, pronounced that Parker's interest in the premises was sufficiently valuable to warrant the proposed advance. In doing so, they acted upon a belief of Parker's ability to continue his business, there being no material respect to his machinery and similar property a material difference between the value as between outgoing and incoming tenant and the "paling down" or sale by circumstances.  
Mr. Chambers having addressed the jury for the defendants, proceeded to call the defendant Davenport.  
The jury, however, without hearing his evidence, in the present case, declared their opinion that the defendants in their valuation had exercised all reasonable skill and care, and returned a verdict accordingly.

(CHESTER ARCHITECTURAL SOCIETY.—The monthly meeting of this society was held on Monday evening last. The Rev. T. N. Hutchinson read a paper on "Gothic Windows and Window Tracery," after which a conversation followed.

**TRADES' UNIONS AND STRIKES.**

A PAMPHLET of fifty-two pages, entitled, "Trades' Unions and Strikes: their Philosophy and Intention" has been published by T. J. Dunning, secretary to the London Consolidated Society of Bookbinders. It is a partisan production on the side of the men, ignores some unquestionable facts, and restates assertions that have been denied. Nevertheless it is temperate and reasonable in its tone, cleverly put together, and we see no reason why all the respectable publishers who were applied to refused (according to the advertisement) to publish it. The writer does not deny that a "trades' union may be so worked as to be pernicious;" what he urges, is that such is not its natural and proper use. He contends, notwithstanding all that has occurred, that the state of employer and employed is for the most part that of amity. "Under no other circumstances," says he, "could the trade and manufactures of the country have so greatly prospered and extended. It should, therefore, be the duty of both to prevent this harmony being interrupted. Each should consider this state their true relation, and consider its interruption the greatest of calamities." This advice cannot be too often reiterated.

In the "Working Men's College Magazine," a history of trades' unions and strikes has been commenced by Mr. Bennett, M.A. of Christ Church. It is not at present sufficiently advanced to enable us to form an opinion of its usefulness. The Magazine is threatened with dissolution for want of funds, but it is to be hoped that this will be averted. It forms an excellent means of communication between the colleges, and appears to be exceedingly well conducted.

A committee, dating from 269, Strand, are circulating a handbill urging the establishment of Councils of Conciliation and Arbitration. After giving some instances of the losses occasioned by strikes, it says,—

"The moderation of demands, the justice and equity of a cause, will always command respect and sympathy, and the friendly advice of the press and the public, more particularly when the proceedings do not interfere with public right or public policy.

We therefore appeal to all to give their earnest support to establish a legal tribunal, believing as we do that great public advantage would be derived therefrom, that numerous causes of dispute arise from the want of confidence and sympathy between masters and men; and that the separation of feeling might be changed into a much kinder sentiment by a more intimate acquaintance of each others' views.  
We leave it with you to decide, whether reason is better than force; conciliation and arbitration better than strikes; peace and piety better than strife and starvation.

We therefore most urgently request that each society will without delay petition the House of Commons to pass a bill to enable masters and operatives to establish equitable councils of conciliation and arbitration."

**Books Received.**

*A Practical Treatise on Sewerage and Drainage.*  
By Lewis H. Isaacs, A.R.I.B.A., &c. London: Printed for the author (2, Verulam-buildings, Gray's-inn), 1859.

This treatise has been specially written for the use of members of vestries, district boards of works, and local boards of health, and is intended to initiate them into the leading principles that should regulate the disposal of the sewage of towns and buildings, and the forms, sizes, and best means of constructing the sewers and drains designed to effect that purpose. The book is illustrated by explanatory plates. It seems to be well adapted to the purpose in view. The author disclaims any attempt to introduce novel theories or views.

With reference to the utilization of town sewage, a few of his observations on which, we may quote, the author remarks,—

"It must be admitted to be a subject of deep regret, that after all the care and trouble bestowed in arranging a system of drainage whereby the removal and collection of feculent matter may be most satisfactorily effected, we have not discovered the means, up to the present time, of employing the result of our labours to profitable account."

It is almost incredible, that at a time when the means of restoring fertility to the exhausted soil are sought in all the kingdoms of nature, and by the help of all the sciences which minister to the wants of man on earth, an immense mass of fruiting material, lying, so to speak, at our doors, should be cast into the sea and wasted. The Chinese maintain, that in this particular their civilization is not much older than ours, but of a higher quality; and they listen with contempt to the methods to which we resort to rid ourselves by pouring into the ocean as a nuisance what they most carefully collect and preserve, and regard as no more wealth. And indeed, town sewage, if rightly treated by chemistry, contains matters which may be turned into veritable gold, and constitutes, in fact, a perfect mine of wealth."

Science, he thinks, cannot fail to solve this

\* At 5, Raquet-court, Fleet-street.

most important problem, so that at no distant day poison shall be transmuted into food, malaria into health, stench into fragrance, and the most loathsome substances into the freshest flowers and most delicious fruits. He is of opinion that "the utilization of the sewage of a town will be best effected, as far as the non-production of nuisance is concerned, by the process of precipitation at the outlet, and it remains for our chemists to discover the means whereby this great desideratum may be most effectually and profitably accomplished."

The recommendation of the use of perchloride of iron, as distinguished from all other modes of defecation or deodorization in the report of Drs. Hofman and Franklaud, to the Metropolitan Board of Works, is, he rightly thinks, a step in advance towards the solution of the chemical problem."

**VARIORUM.**

In "Observations on the Report of the Royal Commissioners of the Refuge Harbours Enquiry," the author "G. Beaulere, esq." speaks of the said commissioners as "illogical," "unthinking detractors," "influenced by personal motives," and "perpetrators of a 40-horse power job," because of the way in which they treat the claims of Ardglass Bay. The writer may be very right in his views, but he does not advocate them with either good temper or good grammar.—In "A Letter" to Lord Palmerston "on Stoppages from the Wages of the Framework-Knitters," by Mr. T. Winters (Truman, Nottingham, publisher), the writer urges a grievous and but too true cause of complaint against the abominable framework-system, by means of which the poor framework-knitters of Nottingham, Leicester, &c., are ground to the dust by unscrupulous master frame-proprietors.—a complaint, many of our readers may remember, as to which we have more than once allowed writers on the subject and correspondents of the *Builder* interested in these hard-used operatives, the use of our columns, in aid of their endeavours to excite the attention of the public and the Legislature. Mr. Winters has our best wishes for the success of his "Plea for Parliament," as he calls his little tract or letter on this subject.—"The Friend of the People" is a weekly journal of Social Science, which deals sensibly with the numerous subjects included in that term. If wide circulation, however, be desired for it, it must be made a little more lively

**Miscellaneous.**

CHATHAM.—Great activity prevails in the dockyard among the contractors and others employed on the several works in progress for enlarging and improving that establishment. In addition to the works completed and those in progress, the Admiralty have decided on an extension and improvement of the dockyard by means of convict labour. The improvements contemplated will involve an outlay of 160,000*l.*, a portion of which has been already expended, leaving 127,000*l.* still required to complete the works. The total estimated amount required for the works to be performed at this dockyard for the ensuing year is nearly 30,000*l.*

IRON MINIMUM.—Lead minium, or red-lead, has been considered till now, in England, as the best opaque colour to cover wood and metals. Doubts, however, have arisen as to its solidity and power of preserving iron vessels from oxidation. Steam navigation companies have had their attention attracted by the injuries caused on their steam-vessels painted with red-lead, after one single voyage to the East Indies. Engineers and chemists have observed histers on the minium cover, and the iron hull brought to light. They have ascribed this awkward effect to the superposition of the lead colour on the iron, and supposed the injury to be unavoidable as long as there would be any lead in the colour. An invention, however, has been made in Belgium, called *iron minium*, which penetrates the objects painted with it, gives them, it is said, an indestructible varnish, and effectually prevents them from oxidizing. This iron minium is used on the Continent, by Belgian and several other railway companies, by ship-builders at Antwerp and elsewhere, by military and civil engineers; and the engineers of the Dutch War Office are said to have declared that the painting with iron minium costs only a fourth part of the painting with oxide of lead. The basis of the newly-discovered colour is *peroxide of iron*; it contains *no acid at all*, and is regarded as a cheap and good paint for bridges, railings, fronts of houses, hulls of vessels, &c.

A HINT TO BUILDERS.—A correspondent expresses regret, and with some reason, that, in constructing houses for the working classes, the juvenile portion of the family are not properly provided for in one of the offices.

A CORPORATION IN A FIX.—The Corporation of Gravesend having mortgaged the whole of its property to Mr. Wells for the sum of 12,721*l.*, notice has been given that the mortgage will be foreclosed on the 20th March next. At the last meeting of the corporation the subject was discussed; and the town clerk stated that there were no means of obtaining the required sum. The Town-hall and the whole of the corporation estates will therefore become the property of Mr. Wells on the day named.

USELESS REDUCTIONS.—Unless the pruning-knife can be applied, not merely to a year's estimates for our larger public expenditure, but unless an economical administration for the future can be secured, you do nothing to the purpose. We built floating batteries at the beginning of the Russian war, then we built harbours at the end of it. After that, last year, we gave all our energies to building great ships, and gunboats were pool-pooled. This year steam-runs are to be constructed; and, with a fleet of 70,000 men, we are subsidizing a naval reserve besides. All the while our administration is a by-word! Sir R. Walker is still allowed the privilege of spending millions with less control than is thought necessary where a few hundreds have to be applied in any other department.—*The Piccadilly Papers*, No. 1. (A good idea.)

THE TIMBER TRADE AT LEEDS.—A meeting of timber merchants was held at the White Horse Hotel, Leeds, on Wednesday, Mr. R. Harrison, of Leeds, in the chair, and the following resolutions were unanimously agreed to:—"1. That this meeting, while it approves of the proposed reduction of duties on foreign timber and deals, as announced in the budget of the Chancellor of the Exchequer, yet deems it but an act of simple justice to the inland timber merchants, who have, as usual at this period of the year, just laid in large stocks for the spring trade, that a drawback should be allowed by government on their duty-paid timber and deals. 2. That it is necessary to obtain an interview with the Chancellor of the Exchequer at the earliest possible period, in order to place before him the anomalous position of the inland timber merchants, and to point out the great loss to which they will be subjected should the proposed reduction be made regardless of their interests. 3. That it is desirable there should be a meeting of the inland timber merchants in London, and that invitations, therefore, be immediately sent to the merchants of other inland towns, to send representatives to meet at Peacock's Hotel, New Palace-yard, Westminster, on Saturday next, at the 18th inst., at twelve o'clock at noon, to determine upon further proceedings." Other resolutions were also adopted to further the wishes of the meeting, and Mr. Harrison and Mr. Illingworth were appointed as a deputation from Leeds to attend the proposed general meeting of the trade in London.

INAUGURATION OF STEPHENSON MEMORIAL.—The School and Institute buildings on the site of the cottage at Willington-quay, where George Stephenson resided, and where his son Robert was born, has been inaugurated. Dr. Bruce, of Newcastle, opened the proceedings, and Lord Ravensworth delivered an address. The corporation of Newcastle erected the plot of ground for the purpose of granting the schools. The building, with its appurtenances, occupies about a quarter of an acre. The erection is from architectural designs by Mr. A. Dunn, the contractors being Messrs. Gibson and Stewart. It embraces three separate school-houses; a boys' school, capable of containing 150; a girls' and an infant school, each adapted for about 100 children. A dwelling for the master and mistress is attached, besides a reading-room for the inhabitants of the neighbourhood. The style of the building is Gothic. It is of brick, with stone facings. The girls' school has been used as such for some time, and the boys' school has just been opened. The old Mechanics' Institute of the village will resume its operations in the hall assigned to it; the books and other property belonging to the Institute being handed over to the trustees of the new building for that purpose. Once more we must express our regret that the cottage of the Stephensons was pulled down, in contradiction to the assertion made to us at the time; and we scarcely think there was much delicacy of feeling in consulting the late Mr. Robert Stephenson on the subject, or in trusting forward his opinion in favour of its demolition as a ground for sweeping it away.

GAS.—The town council of Ross have resolved to reduce the price of the gas supplied by their gas committee to the inhabitants, from 8*s.* to 6*s.* 6*d.* per 1,000 cubic feet, and to charge the public lamps to the rates at 2*l.* each per annum.

—The Leeds old and new gas companies have resolved to lower the price of their gas from 4*s.* 6*d.* to 4*s.*, subject to the usual conditions. The gas company of Marsden, near Huddersfield, have declared a dividend of ten per cent. for the last year.

DISCOVERY OF ROMAN REMAINS IN WILTS.—An interesting discovery of Roman buildings has just been made, it appears, in the parish of North Wraxall, Wilts. The workmen have already cleared the foundation walls of one entire building, measuring about 130 feet by 36 feet, and containing more than sixteen separate rooms, or courts, and traced out several other walls extending over an area of two or three acres. Among other articles met with, were numerous iron cramps, a large iron key with complicated wards, several iron chisels, bronze style, coins, &c. Mr. Ponlett Serpice is superintending the excavations. North Wraxall is on the "Fosseway," or "Acman Street," between Bath and Cirencester.

HENRY IV. AND HIS DRAINAGE SCHEME.—In the year 1599 Henry IV. published an edict enforcing the draining of marshes throughout France, and it was mainly instrumental in causing the "grands dessèchemens de marais pendant plus d'un siècle." On this is based the new project of drainage in France, submitted to the Emperor a few days ago by the Ministers of Public Works, of the Interior, and of Finance. The total marshes to be drained is 185,460 hectares, of which 5,061 belong to the state, 58,383 to communes, and 122,015 to private persons. The lands and uncultivated grounds belonging to communes are 2,706,672 hectares. All the reclaimable ground is to be valued by a state decree, and the works are to be executed at the expense of the communes. If the latter have not the means, or are unwilling to carry out the designs, the Government will cause the works to be done, and look for reimbursement with interest. In cases where the communes are unable to effect the reimbursement, they will be exonerated from any claims from the crown on ceding to the state one-half of such land reclaimed. Ten million francs are proposed to be advanced by Government for the present.

ZEOIDELITE.—Such is the name which has been given to a new composition which has recently been patented by Mr. Joseph Simon, of Paris, and intended as a substitute for lead. According to the *Mining Journal*, he mixes, with about 19 lbs. of sulphur, 42 lbs. of broken jars or glass finely pulverised; he exposes the mixture to a gentle heat, which melts the sulphur, and then stirs the mass until it becomes thoroughly homogeneous, when he runs it into suitable moulds, and allows it to cool. This preparation is proof against acids in general. To unite it in slabs no solder is required; a portion of the molten zeoideite being run in between the slabs placed 1 inch apart, when the heat being 200° cent., the edges of the slabs will be melted, and a uniform surface will be obtained, the whole forming but one piece.

FRIGHTFUL ACCIDENT AT THAMES-BANK.—On Saturday afternoon, Mr. Bedford, the coroner for Westminster, held a lengthened inquiry at the King William the Fourth Tavern, Thames-bank, into the death of Oliver William Thompson, aged twenty-three years, who lost his life by the fall of an iron platform on the premises of Messrs. Simpson, engineers, Thames-bank, on Tuesday before last. The platform was about 40 feet long and 10 feet high. It was constructed to hold coke for feeding the furnaces, and there were about 48 tons upon it. The construction was of iron, and was supported by iron girders, 21 feet long by 12 inches deep. These girders were imbedded in the wall, and the distance between the bearings was 18 feet 6 inches. While a number of men were at work underneath and about the place the greater portion of it came down, completely burying the deceased and others who were at work under the stage. An examination of the broken girders showed that in one of them there was a flaw, consisting of dross or scum, in the middle of the iron of one of the girders. The stage was supposed to be capable of holding 100 tons, but 70 or 80 were the most ever placed upon it. The jury returned a verdict of accidental death, from the breaking of the scaffold. In answer to a juror, the court was informed that the Messrs. Simpson had done everything for the family of the deceased, two members of which were in the employ of the firm.

HIGHEST TIDE FOR A CENTURY.—M. Babinet, the successor of Arago, says, in the *Journal des Debats*, that there will be the highest tide on the 8th of March next that there has been in Europe for a century. Let those who are concerned look out.

TENDERS

For building new offices at 29, Fleet-street, for the directors of the Promoter Life Assurance Company. Mr. William G. Bartlett, architect. Quantities prepared by Mr. D. Campbell:—  
Lee & Son ..... £4,147 0 0  
Mansfield ..... 3,573 0 0  
Ashby & Son ..... 3,540 0 0  
Rider ..... 3,533 0 0  
Piper & Son ..... 3,409 0 0  
Macey ..... 3,285 0 0  
J. Wilson (accepted) ..... 3,265 0 0

For National Orphan House, Ham Common, Surrey. Quantities supplied. Messrs. Waring & Blake, architects:—  
Lucas, Brothers ..... £5,158 0 0  
Turner & Sons ..... 4,799 0 0  
Holland ..... 4,734 0 0  
Hibcock ..... 4,469 0 0  
Gannon ..... 4,129 0 0

For a villa residence, Atherstone. The contract for these works has been let to Messrs. George J. & John Fox, for the sum of £2,000 subject to a reasonable reduction on the timber, in case the duty should be reduced. Mr. Robert Jennings is the architect. The following tenders were received:—  
Pooley ..... £3,600 0 0  
Haddon & Merideth ..... 3,140 0 0  
Spencer ..... 2,978 0 0  
Elston ..... 2,560 0 0  
Potter ..... 2,837 0 0

For new schools, Holy Trinity district, Burton-on-Trent. Mr. George Edmund Street, architect:—  
Wilmam ..... £2,974 7 0  
Revelley ..... 2,961 0 0  
Pooley ..... 2,470 0 0  
Low ..... 2,250 0 0  
Broadbent ..... 2,212 0 0  
Lilley & Elliott ..... 1,233 0 0  
Thompson & Fryer (accepted) ..... 1,140 0 0

For new warehouse, Allen-street, Clecklenwell, for Messrs. Frost. Quantities not supplied. Mr. W. P. Griffin, architect:—  
Brass ..... £1,370 0 0  
Ebbage ..... 1,274 4 0  
Fowler ..... 1,247 0 0  
Elston ..... 1,233 0 0  
Hunt ..... 1,237 0 0  
Brake (accepted) ..... 1,212 0 0

For new warehouse in Windsor-street, Bishopgate-street, City. Messrs. Trench Hill & Paraire, architects. Quantities supplied:—  
Myers ..... £1,583 0 0  
Cobea ..... 1,515 0 0  
Holland ..... 1,409 0 0  
Hill ..... 1,388 0 0  
Piper & Sons ..... 1,345 0 0  
Turner and Sons ..... 1,349 0 0  
Lang ..... 1,299 0 0  
Patrick & Son ..... 1,271 0 0  
Brass ..... 1,233 0 0  
Elston ..... 1,192 0 0

For rectory house, Orwell, Cambridgeshire. First Tenders:—  
Quinise & Attack, Cambridge ..... £1,445 0 0  
Gray & Son, Cambridge ..... 1,295 0 0  
Second Tenders, after the foregoing were opened and the amount of the same ascertained:—  
Gimson, Royston ..... £1,360 0 0  
Wilmam, St. Neots ..... 1,169 0 0  
Third Tenders after a deduction of work to the value of 7*l.* was made:—  
French, Melbourn, ..... £1,338 0 0  
Wilmam, St. Neots ..... 1,235 10 0  
Gray & Son, Cambridge ..... 1,225 0 0  
Quinise & Attack, Cambridge, (accepted) ..... 1,190 0 0

For new infant school and teacher's residence, St. Mary's district, St. Marylebone. Mr. Eales, architect:—  
L'Anson ..... £1,444 0 0  
Morris & Phillips ..... 998 0 0  
Keyes & Head ..... 993 0 0  
Longmire & Burge ..... 877 0 0  
William Carr ..... 870 0 0

For plumber's work of two houses at Spring Grove, Isleworth:—  
Thornbury Houses. Mr. Tufnell's.  
Lovegrove ..... £220 0 0 ..... 100 0 0  
Bacon ..... 152 0 0 ..... 75 0 0  
Oiler ..... 154 0 0 ..... 85 0 0  
Howell ..... 150 0 0 ..... 74 8 0  
Roband ..... 135 10 0 ..... 75 10 0  
Curtis ..... 121 2 4 ..... 65 13 10  
Eastham ..... 126 10 0 ..... 63 6 9  
Crupper ..... 125 0 0 ..... 72 13 0  
Godson ..... 118 9 5 ..... 69 9 10  
Mason's work, same houses:—  
Late ..... 213 10 0 ..... 84 15 0  
Welber ..... 179 0 0 ..... 58 10 0  
Beaver ..... 169 0 0 ..... 59 0 0  
Mitchell ..... 160 0 0 ..... 65 0 0  
Keley ..... 155 0 0 ..... 58 0 0  
Dorcy ..... 153 0 0 ..... 53 0 0

For alterations & additions to Holy Lodge, Richmond. Mr. William G. Bartlett, architect:—  
Penfold ..... 690 10 0  
E. & F. J. Wood (accepted) ..... 550 0 0

# The Builder.

VOL. XVIII.—No. 891.

Incentives to Study in  
London.

I ME was, when our country consins, reaching London by tedious stages of some days' duration, considered themselves recompensed for their fatigue by a sight of the lions and other wild beasts then kept in the Tower. Seventy years ago there was not a very

marked improvement in the class of entertainment provided for their edification. Sir Joshua Reynolds was president of the infant Royal Academy; the British Museum was located in a nobleman's deserted house, and so little visited that, as the books show, in a whole month there were sometimes but five readers in the library; Miss Burney, penning her sketches of London life, as seen from that central rendezvous of wits, her father's house, in St. Martin's-lane, makes her country-bred heroine, Evelina, visit Ranelagh, as the most absorbing of metropolitan attractions. But in those days our country consins are better provided for. They may now speed up to town, stageless, with steam steeds, and find intellectual feasts of the highest order spread for them in every direction. On all sides they may see around them incentives to greatness, which can scarcely fail to produce an effect upon every mind, however unimpressible. Evelina could now visit educational collections from which she might return, if she had eyes to see with, and ears to hear with, a beautiful blue-socking. At two extreme points of the metropolis two magnificent establishments have arisen within the last half-dozen years, vying with each other in the vitality of their efforts at industrial and art teaching—the Crystal Palace and the "South Kensington" Museum, both marvels our ancestors would have been accounted mad or dreaming to mention. Within little more than the same space of time, Montagu House has been razed to the ground, and the present noble and substantial Museum built on its site; the National Gallery has been removed from Pall-mall to Trafalgar-square; the Geological Museum built; and similar improvements made to public property of an educational description in numerous other instances. The new reading-room at the British Museum contains twenty-five miles of book-shelves and upwards of half a million books, whose number annually increases to an extent of 20,000.

No eye can look with apathy upon the price-less literary treasures carefully preserved in this library. In one case is a half-finished sonnet to a lady, written in Italian, by Michelangelo, on the reverse of a rough chalk sketch of a man's face and leg; in another, an order from Peter the Great to his shipbuilder in St. Petersburg, to put the ship, *La Ferme*, in the same order and repair as that in which it arrived from England. In another case, among the avenues of table and screens spread out with missals and autographs of the first interest, is a letter from Lady Jane Grey, calling on the Marquis of Northampton for his assistance in the defence

of her title against the "fayned and untrewed" claim of the Lady Marye, bastard daughter to our great uncle Henry the eighth, of famous memory," signed, "Jane the Queene." And not far from this is the small manual of prayers, margined with her handwriting, the poor lady used on the scaffold. King George II. gave to the Museum all the old royal libraries accumulated from the time of Henry VII. Among these regal relics is a duodecimo volume, whose silken cover is embroidered with silver, in the handwriting of Queen Elizabeth, when princess. It consists of a translation of English prayers or meditations, composed by Queen Katharine Parr, into Latin, French, and Italian, with a dedication to the king, her father, to whom it was presented. There is also a crimson book, with gold clasps and corner pieces, entirely written by King James I. for the instruction of his son, Prince Henry; and a quarto volume in the handwriting of Charles I., when prince, consisting of a selection of passages from the Latin poets, presented to his royal father, to show his progress in his studies. This old regal treasure is rife with glimpses of court occupation 300 years ago. In a book of Hours, preserving the autograph of Henry VII. and his Queen Elizabeth, Henry VIII. and Queen Catharine of Aragon, is contained a prayer translated from the Latin by the Princess Mary, when only eleven years of age. With these tangible hits of history before his eyes, who would not be an historian? Nor can the enthusiasm of the visitor be unmoved when he finds himself before the original Book of Indentures made between Henry VII. and John Islippe, Abbot of Westminster, for the foundation of the King's Chamber in the Abbey, enhanced in interest as it is with the enamelling on its crimson velvet cover; or before the famous Durham Book, cast out of the *Season*, after shipwreck, uninjured, "through the miraculous agency of St. Cuthbert;" or before the Psalter of the Nuns of St. Clare, whose slender figures wrought the intricate needlework on the cover; or before the Psalter of Jerusalem, in a cover of carved ivory, set with turquoises. All these things address themselves to the students of the past, as do the contents of the Roman, Anglo-Roman, Greco-Roman, Lycian, and Assyrian galleries under the same roof. View the veritable fragments from ancient Greece, caryatides, columns, friezes, architraves, cornices, and coffers! Think of the sun-laked bas-reliefs from the overthrown cities of Assyria, representing hull hunts, lion hunts, sieges—showing architectural effects—serrated parapets and arched gateways, capitulations, the triumphal returns from battles,—kings, soldiers, priests, musicians, horses, and grooms; bronze bowls, ornaments, weapons, vases, ivory carvings, fragments of beautifully coloured glass, and, more curious still, the two odd eyes intended for statues, one of which has an iris as deeply blue as an Assyrian pool. Then contemplate the sand-bidden remains of Egyptian magnificence, the sculptures, the obelisks, sarcophagi, and paintings; the ebony chairs inlaid with ivory, the lamps, the bronze mirrors, the vessels in alabaster, serpentine, glazed steatite, porcelain, glass, and terra cotta; the tools, musical instruments, and writing implements, till you can trace the manners and customs of an ancient Egyptian to the dread day when he was made a bugle-decked mummy.

The South Kensington collections may be more especially considered Young England's Museum. There are arranged educational apparatus of every description, from the approved forms on which scholars should sit, to the well-chosen books and maps from which they should learn; so that any country clergyman coming to town for, perhaps, a rare holiday, may take home to his village school information he could scarcely have hoped otherwise to acquire. This boon is so new, that we are not able to estimate the incalculable effect it is certain to produce upon the educational developments of the rising generation. The horn-book, already a thing "not generally known" (*vide* Mr. Timbs), will, by its influence, be looked back upon as a leaf from the Middle Ages. The scheme of this section

of the collection is assisted by the others; in the first degree, perhaps, by the illustrations of food and animal productions. Under this head we can see creations, almost, at a glance; the cereals and fruits of every clime, every thing that can be either eaten or worn, furs, feathers, woollens, silk in every form, in cocoons, wound, dyed, and woven; in fine, everything the ingenuity and enterprise of man could collect is here displayed. These, however, and the architectural illustrations and materials have been too often mentioned in these pages to require now more than an enumeration, to show the immense educational advantages the Future will enjoy over the Past. There is scarcely an object of note on the Continent that cannot be seen now nearly as well in London, either by facsimile, model, or photograph. The decorations of Raffiello's Loggia in the Vatican are faithfully represented in the Kensington Museum. Casts of the finest statues in Rome are there, too; bits of mosaic, cameos,—in short, the particular individuality of Rome is now within a fourpenny ride of the Bank. No passports required; no sea voyage. Open free of charge on Mondays, Tuesdays, and Saturdays! And then the glorious old furniture! What art-workman, countryman or Londoner, could view the rich carvings of the cabinets, the jewelling of the reliquaries, the paintings on porcelain, the enamelling, engraving, or other art-work, unmoved by a determination to go and do likewise? Let him but spend a couple of hours under the influence of the feelings conjured up by these master-pieces, and he must be conscious of an inward and ennobled change in his sympathies and aspirations.

Of the Geological Museum we have already spoken at some length in a former number: on its usefulness as an incentive and assistance to the attainment of scientific greatness, we need not again enlarge; but will remark, instead, upon the great pleasure and varied information just now afforded there by the lectures of Professor Owen. Sculptors would do well to hear these, for the professor boldly points out conventional errors in the anatomical details of their zoological subjects.

Passing on to Sydenham, we see Streatham in the distance, famous as being the residence of the Thrales and their distinguished guest, Dr. Johnson. Here came Miss Burney, flushed and encouraged with the success of "Evelina," which Johnson praised, and Reynolds and Burke sat up all night to read; by the side of which the popularity of "Jane Eyre" pales, and that of "Adam Bede" appears clouded. It is worth while to read afresh a book that the fashionable world feasted on with so much relish, to note, as a phase of our subject, the great improvement that has taken place in the quality of the intellectual food provided for the public.

The contents of the Palace are all that its magic-suggestive name promises. For picturesque effects we have fountains and fishpools, flowers and plants; for art-teaching purposes we have statues and paintings, with uooks of Spain, Pompeii, Nineveh, and Egypt; for examples of industrial arts, manufactures from all the civilized nations. In this building we can again take art from its cradle in Assyria or Egypt, and trace, after its long sojourn on the banks of the Nile, its progress through Greece and Rome, and during the Middle Ages, to the Renaissance. No need to draw upon the imagination. Here are casts and faithful representations of the most important objects that modern research has discovered. The English artisan, with little time for study, and less hope of travel, is, by this means, made acquainted with the works of races whose names were unknown to his forefathers, and familiar with antediluvian monsters, whose pre-Adamite existence was but faintly shadowed out in the griffins and dragons of romance. The Crystal Palace has, like Kew Gardens, especial value for Londoners, for there they may be sure of a real holiday—a day's life in the sweet country air, with "medicine for the mind."

The mention of Kew Gardens brings us to a consideration of the advantages the botanist, and, stranger still, the zoographer enjoy in London. It is all very well for our country cousins to write of their moors and mountains,

and to tramp thirty miles a day after specimens, with their trousers tucked up, and their tin-cases slung at their backs. Let them resort to Kew Gardens as well, and view the Luriant exotics, the hardy plants of the North, the palm-trees of the East, and the firs of Siberia, all thriving within sight of each other, and they will find the instruction they receive equal to the enjoyment.

For the zoographer and zoologist have been gathered together the matchless collections of birds, beasts, and fishes, in the Regent's-park. Visitors, once content with the sagacious elephant and aged camel, and aiming at nothing more than to get the bear up the pole with promissory buns, and see the lions feed, may now study individuals of nearly every known species of quadrupeds. The collection of birds has been increased in the same proportion; while numerous reptiles, and a house-full of zoophiles have been newly added.

Another museum that furnishes incentives to improvement and fame, is that of the United Service Club. Here may be seen weapons of every age, chronologically arranged; the different uniforms of the European armies; models of the successive improvement in fighting ships, of harbours; plans of battles, soldiers' beds, Chinese junks, canoes, and other curiosities from foreign seas; and it is most especially interesting and stimulating, now, as being the repository of the heart-rendering relics of the Franklin expedition.

Enough, however, has been said to re-direct attention to the great opportunities London affords for self-culture in every branch of science and art. People are sometimes known to live at the foot of a mountain all their lives, and never to take the trouble to ascend it. In the same way we may be apt to overlook our metropolitan advantages, if not occasionally reminded of their importance.

#### THE METROPOLITAN MAIN-DRAINAGE: THE DEPTFORD PUMPING STATION AND MACHINERY.\*

THAT doubts might be expressed by some authorities as to the sufficiency of valved-pumps for sewage, is shown by the statements made to the Government Commission of 1857, by Mr. W. Husband, who superintended the erection of the machinery for drainage of the Haarlem Lake, and is well acquainted with results of experience in Holland, where the difficulties would not seem to be as great as with the London sewage. Mr. Husband truly says, it is necessary to consider that this sewage "consists of every refuse that can be got into the sewers by an immense population; indeed, in some of the city sewers it is difficult for a man to walk, his legs becoming entangled by *ropy-like stuff*; there are also *bricks, wood, and other substances*." Mr. Lindley, we may add, in his evidence before the same commission, says of the Iamburgh sewers, which are not likely to be worse than those of London, that substances got in, that it "was impossible to account for, such as brick-bats, pieces of granite, stone, &c., which were too large to pass through the gratings in the streets;" and though this evidence, with more, is given to show that heavy substances, or weighing as much as 15 cwt., could be moved even through a siphon-dip, and "washed out by the force of the water," it equally points to the tendency which must be apprehended, for valves to become choked by any "ropy-like stuff," "wood," or "other substances."

Mr. Husband said in continuation of his previous statements—

"It is evident, therefore, that pumps are unsuited for the work; wherever there are valves they must become choked; and the pumps would not be lifting water half the time: there would also be frequent breakage."

By the pumping machinery for drainage of the Haarlem Lake, they were enabled to pump 500,000,000 gallons of water in twenty-four hours; but, he says—

"Although these pumps eventually accomplished the work, yet there was considerable detention, on account of the pump-valves breaking, although the water was comparatively free from drift wood, &c."

Also that—

"In the London water-works great care is found necessary to prevent floating substances getting into the pumps; a small piece of wood sometimes occasioning considerable damage."

And he—

"Was certain that pumps could never effectually be

\* Concluded from page 99.

used for the lifting the London sewage, on account of the grit which would be sure to find its way into and obstruct the action of the pumps."

He therefore recommended an entirely different contrivance.

Of two alternatives, he, in the first instance, preferred scoop-wheels to screws, as being less likely to be obstructed. A reason for preferring wheels to pumps was that—

"... In case of accident one of the former could be thrown out of gear, and the engine continue its work with another wheel; while with a pump, the engine is so intimately connected, that when the former is stopped, the latter must be stopped also."

We have given some means of judging whether or not these objections pertain to the machinery proposed for the Deptford pumping-station; and it must be allowed that some of those last mentioned are got over by the provision of several engines, and several channels for sewage; so that the question left, irrespective of one of annual outlay, may be whether the engine-power and the troughs and pumps are provided in excess, and sufficiently so, of the demands as they may arise on some ten or twelve days of a year.

The doubt of the sufficiency of pumps with valves is, we need not say, not confined to Mr. Husband. In the same Appendix (of the Report), in which appears the evidence we have spoken of, is to be found a design by Mr. Archibald Slate for an elevating wheel, of which the author says—

"It is constructed of wrought-iron, on a cast-iron centre, and combines the powers of the ancient Persian wheel and modern dredging-machine, so that whatever comes down the sewer, whether bricks or silt, carcases, or baskets of goods, shall inevitably be lifted with the sewage, and pitched into the upper level."

The delivery would be from the centre of the wheel; and it was proposed to place the contrivance in a building hermetically sealed, and to pass the driving-shaft through a water stuffing-box, so as to prevent escape of effluvia from the agitated sewage. One wheel such as he proposed, the author considered would be equal to several pumps, whilst in cases of emergency, the efficacy might be further increased by increase of power; and he thought that the contrivance, if adopted, would allow of lines and levels for sewers in low districts, which would entail much less cost than the raised aqueducts that otherwise might be required.

The difficulties apprehended in the use of valved pumps, need not be less regarded from the fact that the opinion on what should be substituted for them, given by out-of-the-way witnesses, becomes modified on consideration. At first Mr. Husband advised scoop-wheels, on account both of facility and economy of working, and thought them preferable to screws, as being less likely to be obstructed. He said:—

"The velocity in scoop-wheels would be quite sufficient to prevent any deposit at the foot of the wheel, while the case with screws would be very different."

The water raised from the Haarlem Lake by pumps, was lifted a second time into the "Y" by scoop-wheels. One 200 horse-power engine at "Spierdam," drove ten wheels, 18 feet diameter; and at "Halfweg," a 100 horse-power engine was erected for driving six scoop-wheels, 20 feet diameter. These wheels "lifted from 2 to 5 feet, were rarely out of repair, and have accomplished the work in a satisfactory manner." But Mr. Husband said:—

"Gratings were, however, used to keep out the drift-wood; and it appears that as the water way diminishes from the entrance of the water to its eventual discharge, the water should be cleared from substances liable to choke."

Whether from this latter-mentioned experience, or on general grounds, he then proceeds to say that,—

"The machine which, under all the circumstances, seems best adapted for lifting the sewage, is a modification of the open screw, as used in Holland for drainage purposes."

This proposition was explained by a drawing and model, of which the former appears with the Appendix. "The course of the water through the machine being in a line with the sewer," he says there would be but little friction in passing large substances through it; or, the machine being open throughout the length, anything not passing freely could be easily removed. Each screw (laid in the direction of an inclined plane) would be "constructed taper," and with the pitch of the screw increasing towards the top or point of discharge, so that every substance that could enter at the bottom would pass through a channel of gradually increased dimensions until discharged at the top. This arrangement, the expanding channel, Mr. Husband said, "should form an important feature in any machine adapted for lifting sewage." The reverse, as our description at least shows, is characteristic of the particular valved pumping machinery now proposed for the Deptford station.

The taper screw, it is considered, would readily pass up large substances, irrespective of specific gravity.

There is much in the Appendix from which we have quoted, in commendation by Mr. Husband of the advantages of his proposed screw, and the screw in general, over the scoop-wheel,—the advantages of either screw or wheel over the valved pump, being considered demonstrated; and it must be admitted that on the engineering question, and that of economy, the statements made from the experience in Holland are worthy of some attention. We may add that scoop-wheels have been used with great success in the fen districts of England.

Besides the objections which there may be to valves for the particular case of sewage, it should not be forgotten that in pumps usually an enormous proportion of the power applied is lost in the passage of the water through the pump. The experiments of General Morin have shown that this loss in some pumps amounts to eighty per cent., whilst there are machines which will raise, with the same power applied, twice the amount of water from a given depth, as the common pump. It is true that part of this loss of power, it is calculated, may be saved by increasing the area of valves, and this increase seems to characterize the pumps shown in the drawings before us. Indeed, we have not thought it necessary to question the propriety of the decision in the present case, though we have considered it necessary to adduce some facts, and to quote the opinions of others.

With reference to the nature and quality of the materials, the specification for the Deptford pumping machinery says of castings, that they "shall be clean and sound, both externally and internally, and shall be carefully fitted and smoothed;" the cylinders, air-pumps, sewage-pumps, and plungers being of "mottled grey and white iron, as hard as can be worked," and bored and turned parallel and cylindrical throughout, "no stopping or plugging being on any account permitted" in case of holes or flaws; "nor shall any portion of the castings be made in open sand." Minute directions also are given for the finishing of the wrought-iron work. Parts of the engines, above the floor, to be finished bright, are, after being "properly drawn-off in the direction of the strain," to be "smoothed with fine emery, and finished in the best style of dead polish." "The brasses" it is said, "shall be made of a strong and durable mixture of pure copper and tin, no lead, zinc, or antimony being used therewith," &c.

The contractor is to complete his undertaking on or before the 30th of June, 1861, or forfeit as liquidated damages a deduction of 250*l.* per week from the amount of contract; and he is to provide four foremen, and have charge of the engines for twelve months after the time of their starting. The payments are to be made by instalments; and as regards disputes, the decision of the engineer to the Board as to what is the true intent and meaning of the specification and drawings (whether or not matters or things he particularly mentioned and described) is to be binding on both parties, to which intent this submission shall be without power of revocation by either party, and may be made a rule of any of Her Majesty's superior courts at Westminster on the application of either party.

The drawings of the machinery and buildings, fill thirteen large sheets; and the specification of the machinery comprises thirteen pages. These last end with a form of tender which is to be filled up, and signed, and delivered with the specification attached, to the clerk to the Metropolitan Board, on the 1st of March next. Somewhere about that time the specification for the buildings will be ready, in order that these may be proceeded with for the reception of the boilers and parts of the engines to be first placed or delivered. One reason why the works for the pumping machinery are to be put in hand at once, or before the drawings for the Low-level Sewer are ready, is that the machinery may be available at the time that sewer is in construction, for removal of the water expected to be met with. As regards the low-level district, it should be stated that the present outlets into the river, which may be made available for flushing the new sewer as mentioned, may also be used for the discharge of storm-water, should the necessity be concurrent with time of low-water; so that really the full demand upon the power of the machinery might not arise, perhaps, a single day in a year, though necessary to be provided for as a possible and a sudden occurrence.

Information of the progress of works in course of execution, which are part of the general scheme of metropolitan sewerage, will be given hereafter.

date. It is, however, beyond all question, inherent upon that form of revived Classic art with which we are surrounded.

The same may in fact be said of truthfulness in minor things. It would be unjust to father the contemptible and endless fallacies of our own day upon Classic architecture. It is true that they pervade and saturate many of the modern productions of the style, and that the revival of Gothic architecture has somehow led to their exposure; but the truthfulness which we are proud to claim as one of its great and leading stars, we freely yield as the property out of one style but of all noble architecture.

Did time permit, I might follow up the *raisonne* of the style under consideration as evinced in the judicious employment and treatment of, and the mode of workmanship applied to, different materials as well as different branches of artistic decoration. The Medieval architect adopted the material he could most readily obtain, and adapted his design to suit the peculiar qualities.

If he used block stone throughout his work, or united it with rough walling-stone or rubble; or if his building were of brick or flint or pebbles, he studied to use them so as to look well and to aid the effect by their variety. As instances of this I will refer to the exquisite stone and flint structures in the Eastern Counties, and the interstratification of freestone with the thinnest rubble in some of the coltic districts; to the brick domestic architecture of Norfolk, of Northern Germany, and of Lombardy; and to the timber structures of innumerable districts and cities; to the variously coloured stones in the buildings in Auvergne; and, last, but not least, to the magnificent marble structures, with their inlayings and mosaics, which delight the eye in the most perfect principle was how best to utilize the materials which nature had provided: where nature had been chary in her gifts, even external plaster was not despised, but truthfully made use of; where she had been lavish, even precious stones were used as building materials, as at Prague, where there is a chapel whose interior is faced with a kind of rubble work, polished amethyst, the stones being cut through, but otherwise unaltered, and irregular joints being covered with embossed gilding.

In metal work, each metal was treated on its own merits and its own natural characteristics. I give an extract.\*

In decoration, frescoes, mosaics, tapestry, needlework, enamels, &c., were profusely used when means permitted. Indeed nothing was neglected, and the absence of homeliness or expense, provided it suited the work in hand and the means at command.

But what, I may be asked, is the utility of tracing out evidences of a fact so probable on the face of it, as that our forefathers acted upon reason when engaged on so practical a thing as architecture? I would reply that its utility is twofold. In the first place, we have too much the last sight of the *raisonne* of architecture, and of the necessity of acting upon it. I do not wish to rip open old sores, or to object against others, errors of which we are all of us guilty. Let us each examine ourselves, and ask ourselves how far we act upon truth and reason in our designs; and, if compelled to admit our delinquencies, a review like that on which we have been engaged may be more likewise than useful, quite apart from any question about what style we are working in.

In the second place, it is an undoubted fact, as my able coadjutor said the other day, that we are at a transitional period of our art—that we are dissatisfied with the present, and aiming at an altered future; and that some of us are following up that aim on the basis of a revival of the style of which I have been treating; while, as he also truly says, there is a *vis inertia* in art which is not easily overcome, but yields reluctantly to change. How important, then, is it to us to know that the style we are reviving was itself based, at all good architecture must be, on the firm rock of common sense; and how essential to our success that we should place our revival on the same basis! Shall we, then, secure this object by doing only what our forefathers did? By no means. Rather, as I have urged in a former lecture, let us do as they did; that is, *act upon reason*. They thoroughly suited all their works to their varied objects and requirements; they made their houses comfortable to the extent of their habits. Let us make ours so to the greatly increased extent of our own habits. They welcomed every invention as it arose. Let us do the same, by the invention of our own prolific age. They utilized every material which modern science or ingenuity has placed at our command,—only let us do all this truthfully and consistently with reason. For example, if we meet with an invention suited to the surface decoration of rooms, but devoid of constructive strength, let us use it as a surface decoration, and not, as is too commonly done, make troughs and pipes of it, and pass them off for beams and columns. If we admire a vaulted construction, by all means let us use it; but do not let us emulate the vault-

\* In a letter which I have received from a high practical authority—Mr. Skidmore, of Coventry—on the subject of the practical reasonableness of the modes of workmanship applied to metals by the Medieval artists, he shows most clearly, and expresses a very strong opinion on, the superior *raisonne* which guided them in their work, to that which is now, for the most part, practiced upon. He shows that the true measure by which to judge of such a *raisonne* is the degree in which the artist judges of his material; that in modern work this is very much neglected, and that designs for metal-work qualities of the metal to be used; indeed, an modelled in clay just as if they were to be executed in marble or alabaster, so that, if the "piece of plate" were panned over, no one would be able to guess of what material it was formed; that even when any regard is paid to the matter, it is usually to one only of the qualities of a metal, and inasmuch as metals possess it only in common with many other materials,—I mean its susceptibility, with cast in a mould; whereas the Medieval artist, without neglecting this, gave greater prominence to the qualities of malleability, ductility, the faculty for receiving engravings, inlayings (such as niello, &c.), enamelling, and filigreeing in different metals, so that, on the whole, their mode of treating metals was far more rational than those which, in these peculiar cases, prevail amongst ourselves, in and more or less acted, though of course well known and neglected.

ing of Diocletian's Baths, and Westminster, or the domes of the Pantheon of St. Sophia, in lath and plaster! If we want plaster casts of ancient monuments, let us place them in our museums; but, for goodness sake, let our buildings themselves be real!

The conditions to be demanded of our future architecture, whether destined to be based upon the Classic or the Gothic Renaissance, or whether the lines to continue ever, as now, to assert, side by side, their rival claims, are a perfect and unshattering fulfilment of practical demands, whether of construction, convenience, or comfort; equally unshattering adoption of the materials, inventions, and mechanical and constructive appliances of the age; a capability of reasonable economy or of judicious magnificence, in all degrees and proportions; a character at once noble and in harmony with the country and climate and with national associations; a perfect freedom of treatment, united with perfect truthfulness; and a free admission of the sister arts in their highest and most perfected forms. How happy would it be for art if we could proclaim an armistice between rival styles, while the advocates of each devote heart and soul to the realization of those conditions so obviously demanded of reason and common sense!

That Gothic architecture is in its spirit well fitted to unite these conditions, I think, may be judged by much that I have shown you in this and the preceding lecture. It lays claim in a pre-eminent degree to the character of freedom. Free in its use of arched or trebled construction, in its use of the square, in its use of the form of its arches, which, in addition to those used in other styles, assumes other and excellent forms which enable them to assume all possible proportions of height to span; free in its use of the vault, which has power and facility for adapting itself to every possible space and plan; free in its proportions, as well as infinite in the varieties of its columns; free as air in the sculpture it applies to their capitals, as well as to other architectural uses; free in the pitch of its roofs; in the size, number, form, and grouping of its windows; and, above all, absolutely free in its planning, in which the practical requirements of the interior have undisturbed sway irrespective of external design. It seems as if it could not be otherwise than suited to an age in which freedom is the great point to be aimed at in all our undertakings, and in which, in every case, let us devote ourselves, hand and heart, to the task: let us bring all our energies to rendering the style we select as our groundwork, really, and absolutely subservient to the wants and to the spirit (so far as it is a healthful and a fruitful spirit) of our age; let us apply to the work all our reasoning powers, and found all we do upon common sense; but let me not be mistaken—this cannot be done by mere abstract considerations. Let me, therefore, urge upon you who are students, to exercise your reason and common sense in another way? and to be assured of this, that you cannot succeed in the practice of an art, unless, in addition to the practical considerations I have had occasion to allude to, you make yourselves, in the strictest sense of the word,—artists.

#### ON BUILDING STONES—THE CAUSES OF THEIR DECAY, AND THE MEANS OF PREVENTING IT.\*

In a district of so peculiar a nature as the environs of London (where clay of a highly plastic description occurs in great abundance), the style of construction adopted is so markedly characterized by the use of the local material, bricks, that we, inhabitants of London, are apt to forget that other districts are, as it were, compelled by analogous circumstances to adopt a style which is diametrically opposed to our own. In London, and, indeed, we may add, in a large majority of our centres of population, bricks are habitually cheap and good; stone is rare and expensive; and it thus happens that stone becomes to us an object of luxury, only to be employed in monumental structures, or in the decorative parts of ordinary houses. In France the contrary rule prevails, as it does likewise in some of the cities of Yorkshire and of Scotland; and there stone is the common material used in building, and brickwork is the exceptional ornament. It has always seemed to me a matter of regret that this should be the case, for, beyond question, the taste of the London builders has been injuriously affected by the small and unbending character of the material they habitually employ; whilst the grander and more monumental appearance of such towns as Edinburgh, Bradford, Paris, &c., may, to a great extent, be attributed to the fact that in them large ashlar stone is habitually employed. But in addition to this æsthetic inconvenience arising from the absence of building-stone as an ordinary material of construction, the builders of such towns as London labour under the more serious one of being less acquainted with the nature and properties of stone than are the builders of more favoured localities; and we, therefore, find that even when the former do resort to the more costly materials, they frequently employ them under such circumstances, and in such positions, as to expose them unnecessarily to danger and decay. Emphatically this has been the case of late years with many of the London buildings, and it may, under such circumstances, be desirable to dwell for a short time upon the nature of the stones

which usually appear in our market, and upon the various injurious actions to which they are exposed.

The building-stones employed in London are capable of being divided, according to their mechanical properties, into two classes,—namely, those which can only be worked by the pick or by wedges, and those which can be worked by the mallet and chisel,—the latter being known by the name of freestones, in contradistinction to those which do not work freely. These classes, in their turns, are susceptible of numerous subdivisions, such as, in the first class, the granites, porphyries, basalts, whinstones, and the countless varieties of the plutonic and volcanic formations; the quartz rocks, mica schists, gneiss, and the more dense altered quartzose sandstones, the quartzose conglomerates, and the grits or agglutinated sandstones of the secondary and tertiary strata. The slate rocks, perhaps, might be grouped as a subclass of the stones not workable by the mallet and chisel, for they present too decidedly marked cleavage to allow of their being worked freely, though they are susceptible of being sawn, or even worked on the edge, in the same manner as the freestones themselves. In the second class, or the freestones, are comprised the marbles, sandstones, limestones (both carbonates and sulphates), in all their endless modifications. The bituminous rocks furnish materials which may be classed as a subvariety of the freestones, in an analogous manner to the classification of the slate rocks in the preceding division.

Now, of the stones above described as being of the first class, the London market consumes large quantities of granite from the Chamel Islands, Cornwall and Devonshire, Mount Sorel, in Leicestershire, Aberdeen and Peterhead, in Scotland. The Whinstones, basalts, and volcanic tufas are hardly ever seen here—unless in the form of the pouzzalans and trap, which are occasionally imported from Italy and Germany for making artificial hydraulic cements—whilst the quartz rocks and the quartzose sandstones, the mica schists, &c., are never used. The quartzose conglomerates, such as the Bramley Fall stone, are occasionally employed in engineering works, and the tertiary grits, or sandstones, of Windsor forest are used in the neighbourhood of Windsor as paving materials for streets and stables, just as the grits of Fontainebleau, their geological analogues, are used in Paris. The advantages offered by the best of these various materials consist in their extraordinary hardness, their density of texture, their non-absorbent properties, and, generally speaking, their powers of resisting atmospheric influences; but the whole of this class is exposed to the serious objection that the labour upon all its varieties is very costly; and that from the mere fact of their being composed of heterogeneous ingredients in the far greater number of cases, they are also exposed to the action of causes which are able to produce either disintegration or decomposition of their elements.

Thus, for instance, the Cornish and the Devonshire granites, and some of the porphyries and tufas from those counties, frequently contain a notable proportion of felspar; and, when they are exposed to the action of rainwater, containing (as it usually does) carbonic acid in solution, that felspar decomposes, and is then easily removed, leaving the quartz and the mica in relief without any cementing material. Illustrations of this mode of decay may be observed in the granite used in parts of Waterloo or London Bridges, or in the granite piers of the crypt under the hall of Christ's Hospital; but the process is very slow, and it would seem to be subject to some laws not hitherto discovered; for the decay of the felspar does not take place according to any known rules. The more crystalline, in fact, the felspar of any of these bodies may be, the more perfectly does it resist the decomposing action of the atmospheric agents; and we shall have occasion again to allude to the influence of this mechanical state of mineral substances upon their durability. In the meantime it may be added, that in the Bramley Fall and in the analogous stones, the silicious conglomerates, the same phenomena may be observed. The cementing material frequently decomposes, and is washed away from the ingredients it naturally held together, and then the latter, as certainly, fall asunder, or the cementing material decays, and in so doing it produces a dangerous disintegration of the mass. It follows, from these observations, that the smaller and the more uniform in dimensions the materials of these heterogeneous rocks may be, the greater is the probability of their duration, and in the case of granite especially, it is essential to select those descriptions which do not contain large crystals of

\* Read by Mr. G. R. Borell, C.E., at a meeting of the Society of Arts, on Wednesday evening last, Mr. Godwin in the chair. At the close of the paper a discussion ensued, in which Professor Assheton, Mr. Hunt, F.R.S., Mr. C. H. Smith, Mr. Warrington, Professor Tennant, and the chairman, took part, and to which we shall hereafter refer.

felspar. It is singular that some of the granites of Normandy, Brittany, and the north of Spain, present identically the same mineralogical peculiarities as the granites of Devon and Cornwall, and they are equally susceptible of decay. The varieties in the lithological characteristics of the Bramley Fall stone, and in those of the quartzose conglomerates, are still more hard to define than even those of the plutonic rocks: in the same quarry, and even in the same bed, the qualities of these stones will change within a very small distance; and the great irregularities of this description of stone form, in fact, the most serious objection to its use. Nevertheless, when the Bramley Fall or the silicious conglomerates are well selected, they are extremely valuable for engineering purposes, on account of their hardness, and on account of their resisting crushing weights. They yield to atmospheric influence when the silicious cement exists in the soluble silica, and is of an amorphous character: if, on the contrary, the cement assume a crystalline character, it becomes unattackable even by caustic alkaline solutions, and the silicious conglomerates are then as durable as the best descriptions of granite themselves. Of the granites which are used in London, those obtained from Aberdeen, Peterhead, and Mount Sorel are the most valuable, but also, on account of their hardness, the most expensive. They can be obtained of any required dimensions, and are capable of receiving any desired form, and thus are admirably adapted for the construction of buildings of a simple monumental character, designed "not for an age, but for all time;" their colours, moreover, are agreeable, especially those of the rose-tinted granites of Peterhead and Mount Sorel. The best silicious conglomerates used in London for building purposes are extracted from the lower members of the Yorkshire coal-field; their colour, it may be added, is far from being as agreeable as that of the good granite; and at times, when there is much oxide of iron in the cementing material, the colour of the conglomerates becomes unpleasantly fovy.

For the reason above cited, namely, the difficulty of working the first class of stones, the other, or the freestone class, is the one most generally used in building operations, the selection of the variety employed in any locality being too often only regulated by the consideration of its ultimate cost. In London, the freestones commonly used may be stated to be as follows:—amongst the sandstones, the Cragleith, the Dundee and Arbroath, the Yorkshire stones, and the sandstones furnished by the Wealden deposits near Tunbridge Wells, or by the subcretaceous formations of the neighbourhood of Godstone, Maidstone, or Folkestone; amongst the magnesian limestones, the Anston and Bolsover stones; amongst the carbonates of lime, the Portland, Purbeck, Ketton, Barnac, the Caen, Ranville, Aubigny stones, are to be met with in commerce without difficulty, whilst it would be easy to increase their number by the introduction of the remarkably valuable tertiary limestones of the Paris basin. In some localities, even the common chalk becomes so indurated as to allow of its being used as a building stone; less frequently, it is true, in England than in France, for in the valley of the Lower Seine this material is extensively used in the best buildings, as at Rouen, Vernon, Louviers, &c. I dwell a little upon this detail of our subject at present, because I am convinced that a process for the preservation of building-stones, which I shall have the honour to bring before your notice, would enable us to convert to useful purposes of construction the immense stores of chalk with which we are surrounded. I would add that the sulphates of lime are occasionally used for ornamental purposes in interiors, but they are almost invariably so unfit to resist the action of the atmosphere externally, as only to be of value from the fact of their yielding the important material known by the name of the "Plaster of Paris." The argillaceous limestones do not often occur under such conditions as to warrant their use as building materials in other than in the localities where they are found, and this sub-class is only resorted to, for the London market at least, for the purpose of obtaining the hydraulic limes of the blue lias, or the Roman cements, made from the septaria nodules of the Oxford, liassic, or London clays.

The Cragleith stone, of which the majority of the buildings of Edinburgh are constructed, is occasionally used for foundation or basement works in the metropolis, or for the execution of staircases exposed to great traffic; but the hardness (and the consequently high price of labour) of this stone limits its use to such situations. It is ob-

tained from the carboniferous formation, and is composed of minute grains of quartz, with occasional plates of mica, united by a silicious cement, containing usually about 98 per cent. of silica, 1 of carbonate of lime, and one of bituminous and other miscellaneous ingredients. The weight of a foot cube of the Cragleith stone is about 146 lbs., and it is stated to resist a crushing weight of 5,800 on the inch superficial. Generally speaking, the colour is of a greyish white, and, in consequence of the density and the non-absorbent character of the material, it retains a clean appearance for a very long time. The London atmosphere has very little action upon it.

The Dundee and Arbroath stones, obtained from the red sandstone series on the eastern coast of Scotland, are sometimes employed in London; the former as an ordinary building stone, the latter principally as flag pavement. The colour of the Dundee stone hitherto brought to London is rather disagreeable, for it is of a dark purple brown, or a deep oxide of iron tint, but the stone is hard, and resists weather very satisfactorily: in consequence of the colour, however, this material is never used in ornamental buildings. The Arbroath stone is of a denser character than that obtained from Dundee, but it is more decidedly "flaky," to use a workman's phrase, and it is, therefore, almost exclusively used for the purposes above mentioned. Occasionally, however, blocks of the largest dimensions, and of very uniform character, are obtained from the Arbroath quarries. They are hard; they resist weather satisfactorily: the stone is easily worked, and its colour (a light greenish grey) is far from being disagreeable. I am not aware of any observations upon the specific gravity of this stone, or of the crushing weight it would bear; but, judging simply by the eye, I should be disposed to class it in these respects with the Yorkshire sandstones, to be noticed hereafter. As Arbroath lies immediately upon the seaboard, it is strange that the stone from that locality should not be more commonly used in the metropolis.

There are several varieties of the Yorkshire sandstones used in London, of which the most generally known are the flagstones from the neighbourhood of Halifax and Huddersfield, and the compact stones from the neighbourhood of Leeds, commonly called the "Park Springstones." The normal composition of the whole of this series of rocks is that of a fine-grained quartzose sand and decomposed felspar, with an argillaceous cement, and with numerous flakes of mica in the planes of stratification: sometimes the mass is coloured by the presence of the oxide of the silicate of iron, and the colour varies from a decided blueish-green to a light ferruginous-brown. The weight of a foot cube of the paving stone is about 145 lbs.; and the crushing weight it can support may be considered to be nearly equivalent to that of the Cragleith stone, a remark which, by the way, may be extended to the Arbroath stone. It is worthy of especial notice that although the Yorkshire flags absorb water freely, and part with it in as easy a manner, they do not suffer from the action of frost; it may be because their distinct lamination allows the expansion of the water to take place freely in a horizontal direction. But when the Yorkshire stones are used in elevation (that is to say in vertical walls) they are not able to resist the singular destruction which takes place at the extremity of the zone of capillary action in almost all porous stones. They do not, in fact, to use another workman's phrase, "stand well between wind and water," and should not, therefore, be used in the basements, or in plinths, of buildings immediately in contact with damp earth, or in positions to which water has access at irregular intervals.

The Tunbridge sandstone has been occasionally introduced here, but with very satisfactory results. No doubt it would be possible to select stones from the Wealden deposits of Tunbridge or elsewhere, which would resist the action of the atmosphere; but with the exception of the limestones of this series of deposits, to be noticed hereafter, the materials derived from these beds are of far too irregular and too dangerous a character to allow of their being used at any distance from the place where they are obtained.

The sandstones of the subcretaceous rocks are also of a very irregular character, and even when of the best quality they are but ill qualified to resist alternations of wetness and dryness. Nevertheless, the Godstone and Maidstone freestones, as they are called, are of great value in the arts, on account of their powers of resisting the action of fire, through the large quantity of soluble silica they contain, in conjunction with a certain propor-

tion of the carbonate of lime. When these stones are used for ordinary building purposes they require to be kept above the ground, or the influence of capillary attraction upon the moisture it may contain, and also to be protected from rain, by being covered with some impervious material. If these precautions be observed the freestones do not rapidly decay; and in some of the oldest parts of Westminster Abbey, or of the Temple Church, specimens of them may still be seen in a fair state of preservation. For internal elaborate Gothic tracery, the freestones may be advantageously employed, because the ease with which they are worked reduces the cost of labour of such decorations. The colour, a greyish light-green, is far from being unpleasant.

Whilst thus speaking of the subcretaceous building stones, it may be as well, even at the risk of a little departure from the strictly logical classification according to the nature of the materials, to call attention to the Kentish rag, which is now so extensively used in the modern revival of Medieval architecture. This stone is a limestone, with a very small proportion of earthy matters, frequently subcrystalline, but ordinarily of a confused texture, the beds from which it is obtained varying from about 6 inches to 3 feet in thickness, and the colour varying from a lightish green to a deep blue. The stone is, when well chosen, very hard and dense; and indeed the labour upon it is so expensive that it is very rarely that the ragstone is used for anything but rubble masonry, in districts remote from the quarries. It is the custom, at the present day, on account of the expense of working this stone, to execute all the moulded or decorated part of churches, &c., in Caen or Bath stone, and even to carry up the quoins of those materials, whilst the intervening spaces are filled in with the hard rag. In other words, the exposed parts of such fashionable specimens of constructions are executed of soft and yielding materials, whilst the protected parts are executed of hard and durable ones. However, the walling thus produced is certainly picturesque in its effect; and if some of the process for the preservation of the softer stones, to be noticed hereafter, be applied to the Caen and Bath quoins and copings, or weather-tables, there can be no valid objection to the use of the Kentish rag in connection with them, on the score of the durability of the work, at least.

Of late years, in consequence of the report of the commission named for the selection of the building stones for the new Houses of Parliament, the magnesian limestones, from the Anston and Bolsover quarries, have been largely used in the metropolis,—in some cases, as in the Museum of Economic Geology, with tolerable success; in others, as in the Lincoln's-inn Library and the Houses of Parliament, with a precisely opposite result. This discrepancy proves at least that the magnesian limestone is quite as much exposed as any of the formerly used building-stones to great varieties of composition, and, therefore, much attention must be paid to its selection and mode of application. The colour of the best varieties of this stone is of an agreeable light-warm and slightly ferruginous brown; its density is rather greater than that of the oolites; the labour upon it is intermediate between that upon the Yorkshire or the Portland stones, and it can be obtained in blocks of any required dimensions. For many reasons the use of a stone presenting the external characters of the magnesian limestones would be very desirable, and it must be a subject of sincere regret that so little care should have been displayed in the selection of the varieties employed for the important buildings we have above referred to. The decay of the stonework in the Houses of Parliament is really painful to witness,—I had almost said shameful.

With the exception of the Purbeck stone, which is obtained from the local modification of the Wealden deposits found in the Island of Purbeck, the Isle of Wight, and near Petworth, the other freestones, before cited as being used in London, are obtained from the oolitic series. It must not, however, be understood that the oolites are the only valuable sources of supply, for very valuable limestones, adapted for building purposes, are to be found amongst the transition rocks and the mountain limestone districts of Devonshire and of the Midland counties; whilst the blue lias itself is frequently adapted to such uses. But, in the first place, the materials yielded by the transition, and by the mountain limestones are so hard, and so difficult to work, that they are never able to be used beyond the immediate neighbourhood of the quarries; and in the second place, the purer varieties of the limestones from the blue lias series, are so irregular in the thickness of their beds and

in their powers of resistance, that they are equally avoided in general use. The tertiary limestones of the Paris basin might no doubt furnish building materials of a very superior description to those usually employed; but they are, comparatively speaking, unknown in England, and certainly they never appear in the London market. In fact, the only limestones habitually used in the metropolis, are those obtained from the oolitic series, and amongst them the Barnack, Ketton, Ancaster, Portland, Bath, and Caen stones, are those which are most generally known to our architects and builders.

Of these stones, the Barnack stones, obtained from the oolite of Northamptonshire, figure to some extent under a false name, for the real Barnack quarries have long since been abandoned, and in its place the Casterton stone is now commonly employed. Both the original Barnack and the Casterton stones are of a lightish brown colour, and they are composed of a tolerably pure carbonate of lime, of a compact but oolitic character, and containing an infinite number of fragments of pearls and corals. Their specific gravity is about 2.090: the crushing weight (instantaneous) would seem to be about one-fourth of that of the Craghead stone, though there are some marked discrepancies between the results obtained from the respective materials. Nearly all the Medieval structures of Cambridgeshire, the Isle of Ely, and the North of Suffolk, were executed in the Barnack stone, which certainly has resisted atmospheric influences in a very remarkable manner, when care had originally been taken to select for the more dangerously exposed positions the less earthy varieties.

The Ketton oolite, which was largely used in the construction of the numerous beautiful churches in Northamptonshire, and has even of late years appeared with successful practical results even in London itself (as in the tower of St. Dunstan's-in-the-East), is very much like the Barnack stone in colour, but it is more regular in its characters, harder, and more difficult to work, and from the singular apathy of the quarry holders, it seems even to be more costly in the first instance. The colour of the Ketton stone is of a rather warm cream colour: its specific gravity is about the same as that of the Barnack stone, and the crushing weight it will bear is rather greater than that required to destroy the latter. If this material could be brought at a cheap rate to London, there could be little doubt of its being extensively used; for the original colour is decidedly pleasant, and the London atmosphere seems, from the state of the tower of St. Dunstan's, to have very little action upon the Ketton stone, either in producing decay or in changing the colour.

The Ancaster oolite is obtained from Lincolnshire, and is largely used in our midland counties, on account of the beauty of its grain, its pleasant colour, and the ease with which it is worked. Its specific gravity is greater than that of the Barnack stone, and its cohesive force is also greater. This stone is, however, but little known in London, and until it has been exposed for some time to our peculiar atmosphere, it would be dangerous to pass a decided opinion on its merits. In Lincolnshire and the Midland Counties, the Ancaster stone, it may be observed, has resisted the ordinary causes of decay very satisfactorily; and, with proper care, there can be no *prima facie* reason why it should not succeed in London.\*

#### DR. DAUBENY ON THE SEWAGE QUESTION.

DR. DAUBENY, PROFESSOR of Rural Economy in the University of Oxford, recently delivered in Oxford a lecture "On Sewage, with special reference to Baron Liebig's remarks relative to the system of disposing of sewage adopted in the principal cities of this country."

The lecturer remarked that when a man of Baron Liebig's extended European reputation lifted up his warning voice to the British nation on a subject on which he had a right to speak with authority, and staked, as it were, his character as a man of science, by foretelling the ruinous consequences of a system in which the inhabitants of our large cities are embarked, it seemed to be the duty of all who thought they could either directly or indirectly influence public opinion, to secure, if possible, a calm and impartial hearing to the arguments advanced. He proceeded to point out three methods by which it had been attempted to render the sewage of large

cities available for agricultural purposes. The first of these methods was to detain the excrementitious matter in its passage towards its outfall for a sufficient time to allow of the solid matter suspended in it to deposit itself, and then to collect this portion as a manure; the second arrived at the same object by a different expedient, viz., by bringing about a separation of the solid matter from the water, which was its vehicle, through the instrumentality of certain chemical re-agents; and the third was to convey the whole in a liquid state to the very spot where it could be usefully applied, by the aid of pipes and other mechanical contrivances calculated to supersede the necessity for employing cartage and vessels capacious enough to contain so bulky a material. The first of these methods was adopted at Cheltenham, the second at Leicester, and the third at Rugby. It would appear, however, that except in a few small places, like Rugby, which scarcely held out an example which great cities could safely imitate, no successful method had as yet been discovered for combining the sanitary with the economical object sought, and accordingly in London, the public appeared to have acquiesced in a plan which, at a vast expense, was intended to carry off the filth of the city to a distance, and disregarded altogether the agricultural value of the material itself. It was against this procedure that Baron Liebig entered his protest. It might be urged by a practical man, in defence of the metropolitan system, that the valuable constituents of the manure were equally sacrificed under the old *regime* as they will be when the new arrangements are brought into complete operation; that, although cesspools might exist, their contents were rarely made available for the purposes of agriculture, and that no more use was made of the manure, when poured into the Thames in the immediate proximity to the city, than will be the case now, when it is conveyed to a distance of many miles. Thus, the sanitary object, at least, was provided for, whilst the economical question stood upon the same footing as before. The authority of chemists of great eminence might also be appealed to, who reported, as the result of their investigations, that in their opinion no profitable application of the sewage of London to useful purposes that could be adopted on a large scale has up to the present time been suggested. Those and similar reasons, however, although they might serve by way of apology for embarking in the present system in lieu of a better, left untouched the main argument advanced by Baron Liebig, and could not justify us in a blind acquiescence in the system pursued as one intrinsically good. The transport of the sewage matter to a distance from the metropolis had, indeed, become, with the present arrangements, a matter of paramount necessity, but the accomplishment of that end ought by no means to stifle the inquiry as to whether some means ought not to be devised for rendering the same material available for useful purposes. If the citizens of London were as fully impressed as they ought to be with the importance of the subject, if they could realize the enormous pecuniary loss they are at present sustaining by the system pursued, they would not quietly acquiesce in the report of those chemists who have expressed doubts as to the practicability of employing their sewage for agricultural purposes, but would persevere in putting both science and capital into requisition until the difficulties had been surmounted.

#### STRENGTH OF IRON SHIPS.

MANCHESTER PHILOSOPHICAL SOCIETY.

At the ordinary meeting, February 7th, Mr. W. Fairbairn, F.R.S., President, read a communication "On the Strength of Iron Ships." The writer said,—

Recent disasters have recalled to recollection numerous defects in the construction of iron vessels, more especially in their powers of resistance to a transverse strain. When we consider the enormous amount of life and property that is at stake, and dependant upon the security of these vessels, it is assuredly a duty to point out the defects in their construction, and the remedies which it is necessary should be applied.

Vessels of a length equivalent to eight or nine times their breadth of beam are subjected, when pitching in a heavy sea, to two distinct kinds of strain. First, when rising on the crest of a wave, the ship is supported in the middle with the stem and stern partially suspended; and, secondly, when supported at each end and suspended in the middle, as the waves roll under her. In these ever-changing positions it is obvious that her deck, as well as the lower parts of the hull, are subjected

to alternate strains of tension and compression; and the tendency is to tear the ship asunder in the middle. That this does take place is evident from the fact that both wooden and iron vessels have been known to founder by giving way and breaking asunder. Circumstances may at any time arise when the danger from this source becomes greatly increased. The vessel may be cast ashore, and with the receding of the tide may be left suspended partially out of the water, and remain supported at only one or two points in her length, by ledges of rock. Such cases have occurred, and it has become doubtful whether our present construction of iron vessels enables them to withstand the shocks and impacts, to which in such a case they may be subjected.

This is not the first time I have applied myself to the inquiry, for the purpose of ascertaining, in the first place, what is the transverse strength of vessels as now constructed; and, next, whether the builders of iron ships have been guided in their construction by right principles, and have obtained the greatest strength with the smallest quantity of material. In pursuing this investigation, I have come to the conclusion that our present iron vessels are dangerously weak when exposed to strains of the kind I have indicated; and I believe that this defect of construction may be remedied by a more careful attention to correct principles of proportion, without in any great degree increasing the weight of the vessel.

To ascertain the strength of our present ships, I have supposed them to be placed in the extreme position of danger to which they are ever likely to be exposed; that is, supported at the centre of the vessel on some rock with the ends freely suspended. In this position an iron vessel is, in fact, a wrought-iron hollow girder, and we may apply the simple

formula,  $W = \frac{a d c}{l}$ , by which we ascertain the

strength of such constructions.

If we take vessels of the great length of which they are now made, we shall find that they are far too weak along the deck to resist the force of tension, to which, in the position we have assumed, that part is exposed. Taking as an example a vessel of 300 feet in length, built some years ago, I found that she would have given way with four-fifths of the actual displacement of herself and cargo. Taking a vessel constructed according to Lloyd's last rules, and registered A 1 for twelve years, I found her still inadequate to sustain the stress to which she would inevitably be exposed in such a position, the weak part being still the upper deck. I am therefore forced to the conclusion, that a large increase in the sectional area of iron in the upper part of the vessel should be adopted; and the plan I have proposed consists in the introduction of two rectangular and two triangular cells of wrought iron (similar in principle to those in the Britannia and Conway tubular bridges), placed longitudinally under the upper deck of the ship. Cells of this form would increase enormously the strength of that part, and might be adopted without any great modification of the other arrangements of the ship.

In the second place, I am led to recommend the substitution of the new system of chain riveting along the decks and upper and lower portions of the sheathing, in place of the present weak plan of double riveting. This change alone would secure an increase of 30 per cent. in the power to resist tension in those parts; and although there are practical difficulties in the way of its adoption, I believe these may, to a great extent, be overcome.

Now, in looking at the principles on which iron ships have been constructed, it will be found that sufficient attention has not been paid to proportioning every part to the strain it has to bear. As now constructed the iron is distributed almost uniformly throughout the length and uniformly throughout the depth of the vessel, and in this way much material is wasted. In constructions which have to resist transverse strains, economy can only be obtained by collecting the material towards the top and bottom in the transverse vertical section, and towards the centre in the longitudinal section. The longitudinal cells and stringers should be placed as near as possible to the upper deck or the keel, as the case may be, and they should be gradually reduced in thickness from the centre towards the ends of the vessel. With the exception of most of the sheathing plates and ribs, which may be left uniform, no more material should be expended upon the intermediate parts, approaching the neutral line, than is absolutely necessary.

With the adoption of this improved system of construction, and a closer adherence to sound

\* To be continued.

principles of design. I am of opinion that greater security may be obtained, and the fearful accidents which have so frequently occurred be greatly mitigated in severity, if not entirely prevented.

WALL BLOWN DOWN.

The high wind on Monday last, blew down the greater part of the flank wall of a house in Islington, which was ready for the plate of the roof. It happened most fortunately when the men were away to dinner. The work was of a fair description, better than much which stands. Not half an hour previously, the district surveyor had pointed out, with reference to the corresponding wall of a house close by it, the weakness of lofty flank, or party walls, especially where they adjoin the opening left for the staircase. In a house of four stories, there is a wall perhaps 40 feet high, two stories of 14-inch work, and two stories of 9-inch, without any bond in it, and with nothing against the wall in its whole height to steady it. Such a wall, too, is often run up rapidly, and with inferior materials, so that the mortar even at the bottom is quite soft, and yielding. The wonder is not that walls in such a condition do now and then fall, but that any of them stand.

WAR APPLIANCES.

The Armstrong strong arm is not to be left without a rival, although Sir William is confident that when his new cannon is expressly made for the long range, which, it seems, it has not yet been, it will out rival its formidable Whitworth rival. Meantime, like every one else, we may notify and record a few of the experiments recently made with the Whitworth rifle cannon, or cannon rifle. These experiments were made at Southport, before General Sir John Burgoyne and other officers. A three-pounder, loaded with eight ounces of powder, and set at an angle of 35 degrees, was pointed at a mark, which is said to have been far out of sight of the best telescopes; but how it was pointed at an invisible target is not explained: a mariner's compass, one would think, must have been requisite, if even that could have been exactly enough applied to the purpose in view, — or rather not in view. The projectile, it is stated, fell at a distance of 9,688 yards—more than 5½ miles—and only thirty-four yards to the right of the mark; and this deviation was thought to have arisen only from too great an allowance for the strong wind then blowing. At an elevation of 20 degrees the practice, it is said, was the most wonderful that has been witnessed with any artillery in the world. The first shot went four miles, and fell only four yards from the right line of the fire, and the greatest amount of divergence from the true line, at 7,000 yards range, was only 22½ yards. Fired at a regiment in square, or even a picket of a dozen men, every shot would have told! The vault engraven on the old gun at Dover,—

"Load me well, and keep me clean,  
I'll carry a ball to Calais Green."

will be no great promise soon it would appear. Some pamphlets have been forwarded to us in reference to Turner's tents, which we think have been already noticed in the *Builder*. They seem to be a decided improvement on the old close and unsatisfactory field accommodations for our soldiers, which it is the purpose of these new patented tents to supersede. They are covered with Warne's patent mineralized fabrics, or other suitable waterproof material; and the bell tents are ventilated at the apex by a simple arrangement, which also insures safety in reference to fire, the tent-pole being an iron tube or flue connected with a compact and convenient stove of a simple pyramidal form. It fitted to the tent-pole are stays of galvanized wire cord, secured by lanyards to galvanized iron pegs of cork-screw form, screwed into the earth; and over these cords of course the waterproof covering is stretched.

ON THE APPLICATION OF HARMONIC ANGULAR PROPORTION TO GOTHIC ARCHITECTURE.

ATTEMPTS have been made at various times to rediscover the principles and proportions used by the architects of the Middle Ages throughout Europe. One of the most successful, and certainly the most popular of these attempts, is embodied in the rules laid down by Cesarianus in his "Commentary on Vitruvius" (1521). Upon these Mr. J. S. Hawkins, in 1813, founded the part of his interesting "History of the Origin and

Establishment of Gothic Architecture," which treats of this branch of the subject. These rules purported to fix the various proportions of certain Mediaeval churches by means of a kind of angular measurement produced by a system of equilateral triangles; and the plan and sections of the cathedral of Milan were given as illustrations. Nothing more, however, need be said concerning it than that though all the proportions of Milan Cathedral might have been determined by means of equilateral triangles, yet that church is by no means free from the charge of monotony; and the rules of Cesarianus would certainly not be comprehensive enough to account for the more varied and artistic proportions of the churches of the same era in France, Germany, and England.

The equilateral triangle, however, enters largely into, if it does not entirely control, all Mediaeval proportions, particularly in the ground-plans. In Chartres Cathedral (the ground-plan of which will be found in the *Builder* of October 29th of last year), the apices of two equilateral triangles, whose common base is the internal length of the transept measured through the two western piers of the intersection, will give the interior length; one apex extending to the east end of the chancel within the aisles; the other to the original termination of the nave westward, and the present extent of the side aisles in that direction. With slight deviations, most, if not all the ground-plans of the French cathedrals are measurable in this manner, and their choirs may be so measured almost without an exception. Troyes Cathedral is in exact proportion with that of Chartres; and the choirs of Rheims, Beauvais, St. Ouen at Rouen, and others, are equally so. Bourges Cathedral (which has no transept) is exactly three equilateral triangles in length inside, from the east end of the outer aisle to the eastern columns supporting the west towers. Most English cathedrals appear to have been constructed in their original plans upon similar rules. In many cases (as, for instance, at Amiens), it is easy to see the reason for deviating from the original symmetrical plan, but the discussion of this would be foreign to the immediate purpose of the present article.

There is an interesting paper on the above system of proportion, in C. R. Cockerell's memoir of William of Wykeham: Proceedings of the Archaeological Institute, Winchester, 1835.\*

Although the system of equilateral triangles will go far to fix the relative dimensions of many of the Mediaeval buildings, yet it will soon be felt on applying it, that some more comprehensive method is wanted to enable us to account for, and systematize, the ever-varying yet always beautiful proportions of the grander Gothic edifices of Europe. The above, indeed, forms only part of a much higher system of harmonic proportion, of which it is the object of this paper to treat. This system is called by Mr. Hay, the "Harmonic Law of Nature," and it is as applicable to Mediaeval buildings as it is to the Parthenon and the Temple of Theseus, to which Mr. Hay has successfully applied it, as mentioned more than once in the *Builder*.

This law has already been referred to in the *Builder* of May 14, 1859; but it will be necessary to recapitulate the practical part of what is there stated, before testing it by an existing example.

Mr. Hay's mode of constructing a series of harmonic rectangles is shown in Fig. 1, where ABDC is a square, and ACEE a rectangle, having its longest sides equal to the diagonal of ABDC. ACHG is a rectangle, having its longest sides equal to the diagonal of ACEE, and so on. The angles of the rectangles ACEE and ACKI have to be slightly altered or tempered, in order to bring them to a number of degrees having numerical proportions to the others; and this gives the following series:—

45° 36° 30° 27° 24° 22° 30'.

Completing the series by adding 40° (the angle of a rectangle erected on the base, and having its height equal to the vertical of an equilateral triangle, nearly), 33° 45', and 25° 42' 51" (respectively ½, ⅓, and ¼ of a right angle), a series is obtained proportionate to the notes and intervals in the natural scale of C major, with the addition of B♭; and by doubling and bisecting this scale, thereby taking one octave below and one above it, a set of working scales is obtained, as thus:—

\* Mr. W. P. Griffith's researches in this path are well known.—Ed.

	C	D	E	F	G	A	B	H	C
I.	90°	80	72	67½	60	54	51½	48	45
II.	45°	40	36	33½	30	27	27	24	22½
III.	22½°	20	18	16½	15	13½	12½	12	11¼

This series, with four additional octaves, has already been given in *The Builder*.

These angles, with their bisections and complements, will give almost every rectangle used in those Mediaeval buildings on which care and thought were bestowed. All other rectangles appear to be either subordinate to, or inevitable from, some harmonic rectangles of greater importance, or to be derived from proportionably cut polygons.

Figs. 2 and 3 show the application of the above principles to a part of the ground-plan, and a cross section of the eastern part of the Temple Church.

Fig. 2 shows two bays of the choir; one-half contains the angles of construction, the other, the plan of the ribs and groins of the vaulting. The angle ABC is 60°, forming an equilateral triangle to the centre. The angle ADC is 90°, forming two squares of the side aisles. By reference to the other side of the plan, it will be seen that the vaulting ribs of the centre aisle intersect at an angle of 36° (⅓); those of the side aisles at an angle of 48° (⅔). The space between is the thickness of the columns, from which the spring of the vaulting ribs is measured.

Fig. 3 gives the principal angles of the cross section and the points from which they are measured. For the sake of simplicity many have been omitted, as also the east window, the dimensions of which also appear to be fixed by the application of the same principles.

It is to be noticed that the line AB is somewhat above the present level of the floor. It is believed that AB was the original level of the interior of the choir. In the proceedings of the Oxford Society for promoting the study of Gothic Architecture, for Easter and Trinity terms 1815, it is stated that "in the recent restorations of the Temple Church in London, by lowering the level of the floor of the church more than a foot, and leaving the bases of the pillars that much above the present floor (ceasing the part below with marble to correspond with the rest), they are made to appear stilted," &c. In old drawings of the Temple Church, the bases are not shown stilted, and it seems probable that they were not so originally. They are not so in the Lady Chapel at Salisbury, which, in some respects, resembles the choir of the Temple Church.

It will now only be necessary to refer to the angles laid down in Fig. 3, to show the application of the harmonic angular principle to this most exquisitely proportioned church. The rectangle of the whole section has its angle, BAC, 30° (⅓); the angle, BED, which fixes the height of the columns, is 40° (⅔); BEG, which extends to the top of the opening of the side windows, 36° (⅓); BEH, extending to the bottom of the side window opening, 12° (⅒); BEL, 10° (⅒); KLM fixing the point of springing of the side window arches, 5° (⅒); the angle at P, fixing the thickness of wall and buttress, makes an angle of 18° (⅒), with a perpendicular from P (though this angle is correct its originality appears doubtful); BVF, 50°, or the complement of FVS, 40° (⅔); and the angles at O and T, being the angles of the arch sections of the centre and side aisles, 68½ (not harmonic), and 54° (⅔). With regard to the angle O of the centre aisle arch section, its want of proportion appears to have arisen from a desire to have the arch sections of the centre and side aisles of the same radius; and it is evident that the angle of the arch section of the side aisles must have been determined first. The two angles at P are doubtful by reason of the alterations that have taken place at various times—in both buttresses and roof, in the course of the numerous restorations; and from the gradual raising of the ground level outside having concealed the original base mouldings. Probably the angle of the centre roof was originally 60° or 63°.

Enough is here shown to prove the accuracy of the harmonic theory in its application to one of the most beautiful edifices of its age, and on which it is evident great care and thought were bestowed. If its dimensions were determined by any other principle, it is plain that it could not have been that of proportion of lines, for there is scarcely one harmonious combination to be found by those means. It is almost impossible that any two distinct systems could so exactly coincide, the greatest discrepancy between the angular and

HARMONIC ANGULAR PROPORTION AND GOTHIC ARCHITECTURE.

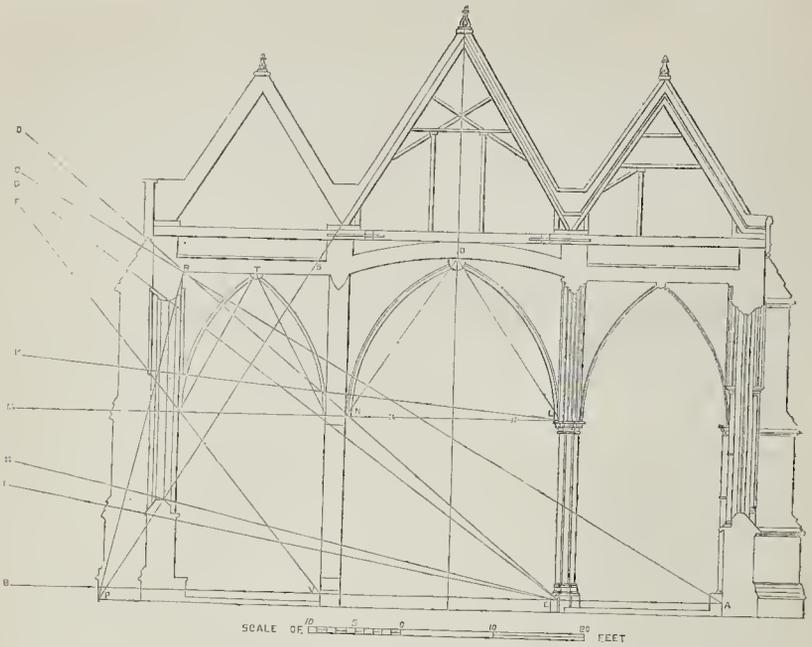

Fig. 3. Section of the Temple Church, London.

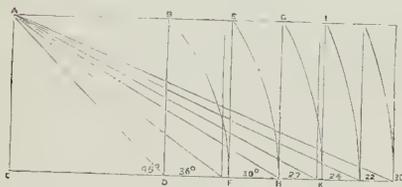

Fig. 1.

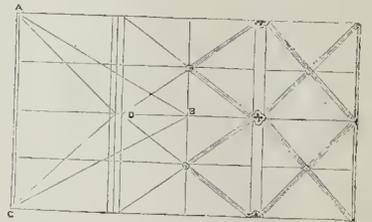

Fig. 2.

actual measurements not exceeding 3 or 4 inches, save in the instances pointed out, being less than those found by Mr. Hay in the Parthenon and Temple of Theseus. It would be easy to show that the whole building is governed by the same principles in the proportions of its longitudinal section, and of the circular portion, the latter being founded on a symmetrical plan; but a full development of their application would require many diagrams, and a pamphlet, if not a volume.

But though the harmonic law is so beautifully developed here, it is not from this building alone that its principles are to be rediscovered. Every application of it to our cathedrals, and more carefully erected buildings, shows plainly how much harmonic angular proportion must have been studied by those who planned them.\* The rules, indeed, were so simple, that they could have been easily learned, and applied by the rudest masons, and such seems to have been the case; the results being, the production of beautiful proportions before which the rules of Palladio and the Renaissance school shrink into insignificance. It is to be hoped that the time will soon arrive, when no architect will allow his designs to be "written in stone" without first carefully testing them by some such principles as those shown in the above simple harmonic law; the proper use of which, to curb and chasten, not to fetter, or clog genius and invention,—can be traced alike in the polished marbles of ancient Greece, and in the coarser stones of Mediæval France and England.

\* Of this, the choir of Lincoln Cathedral is an exquisite illustration.

STANLEY FARM, NEAR BRISTOL.

STANLEY FARM consists of about eighty-four acres, the property of Thomas Proctor, esq., and is worked in connection with Walls' Court Farm adjoining. Of the latter, provided with railway, water supply, school for children, and other appliances, we have given a description, views, and plan in a previous volume.\* Since these were published very considerable additions and improvements have been made.

The house on Stanley Farm, shown in our present view, is occupied by the bailiff; and the buildings erected near it are used as stables, and sheds for carts, waggons, and agricultural implements. There is also a piggery.

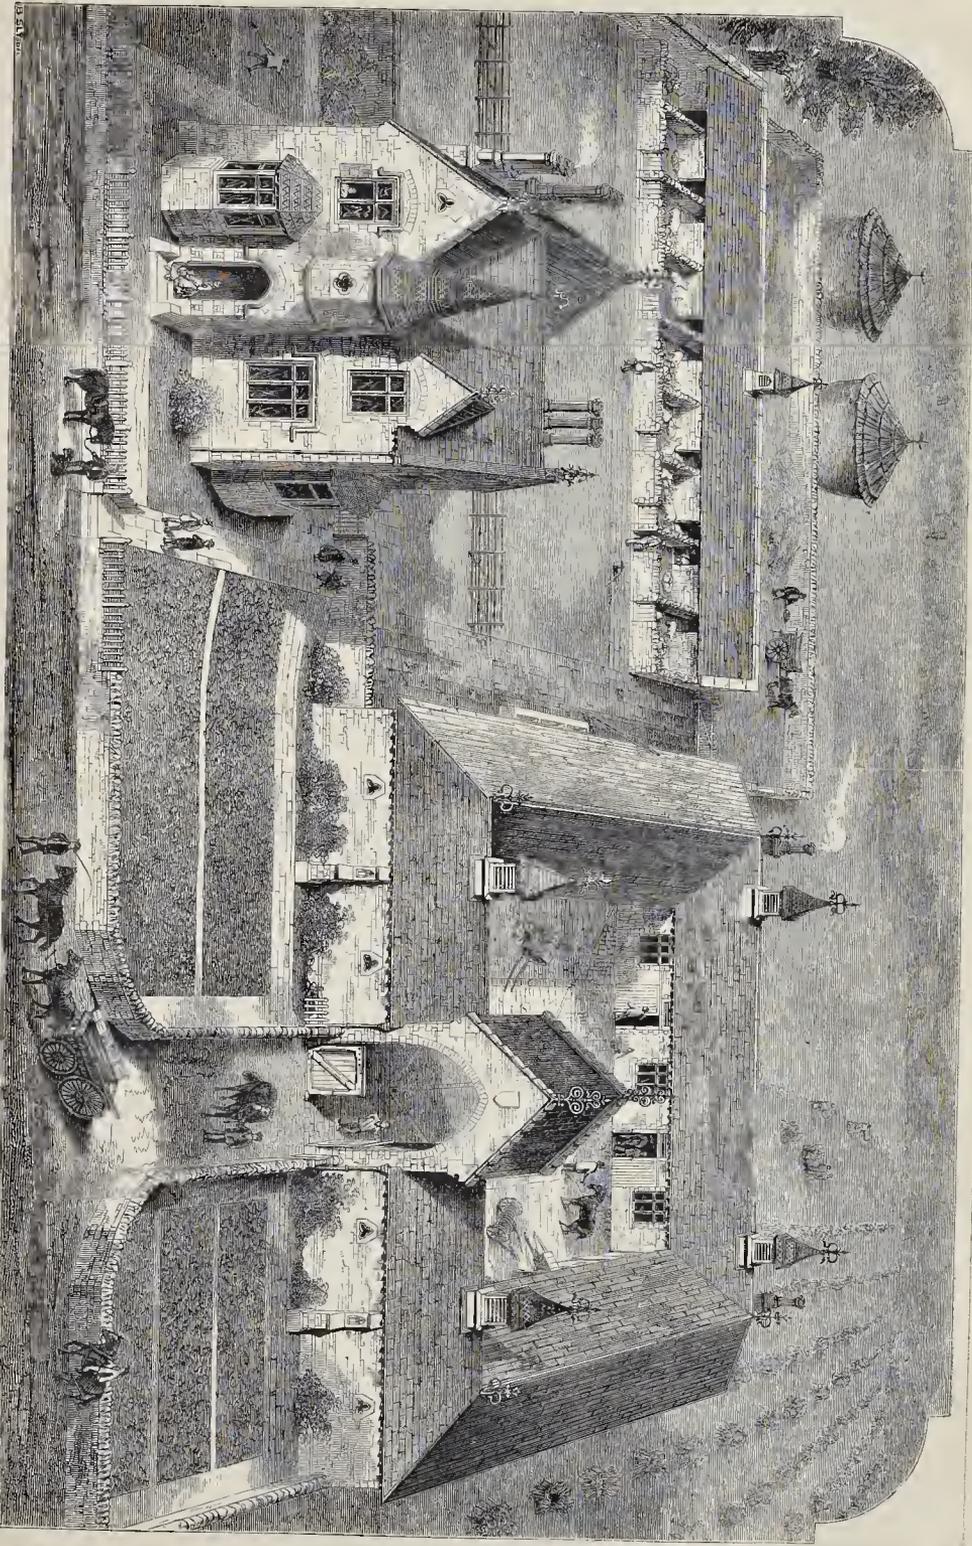

The cattle-sheds at Walls' Court are conveniently situated for the grass land, and Mr. Proctor's residence is near them. The buildings, now shown are about 700 yards from the cattle-sheds, conveniently situated for the arable land; and the proximity of the bailiff's residence gives the opportunity for proper supervision of the horses on the farm. In forming an opinion as to the capabilities of the buildings at Walls' Court, the two views must therefore be taken together. According to the present experience of Mr. Proctor, he finds it work well thus to divide the views with reference to the requirements of the farm, rather than concentrate them all on one spot.

Some years ago, when draining and improving the grass land, Mr. Proctor thought it desirable

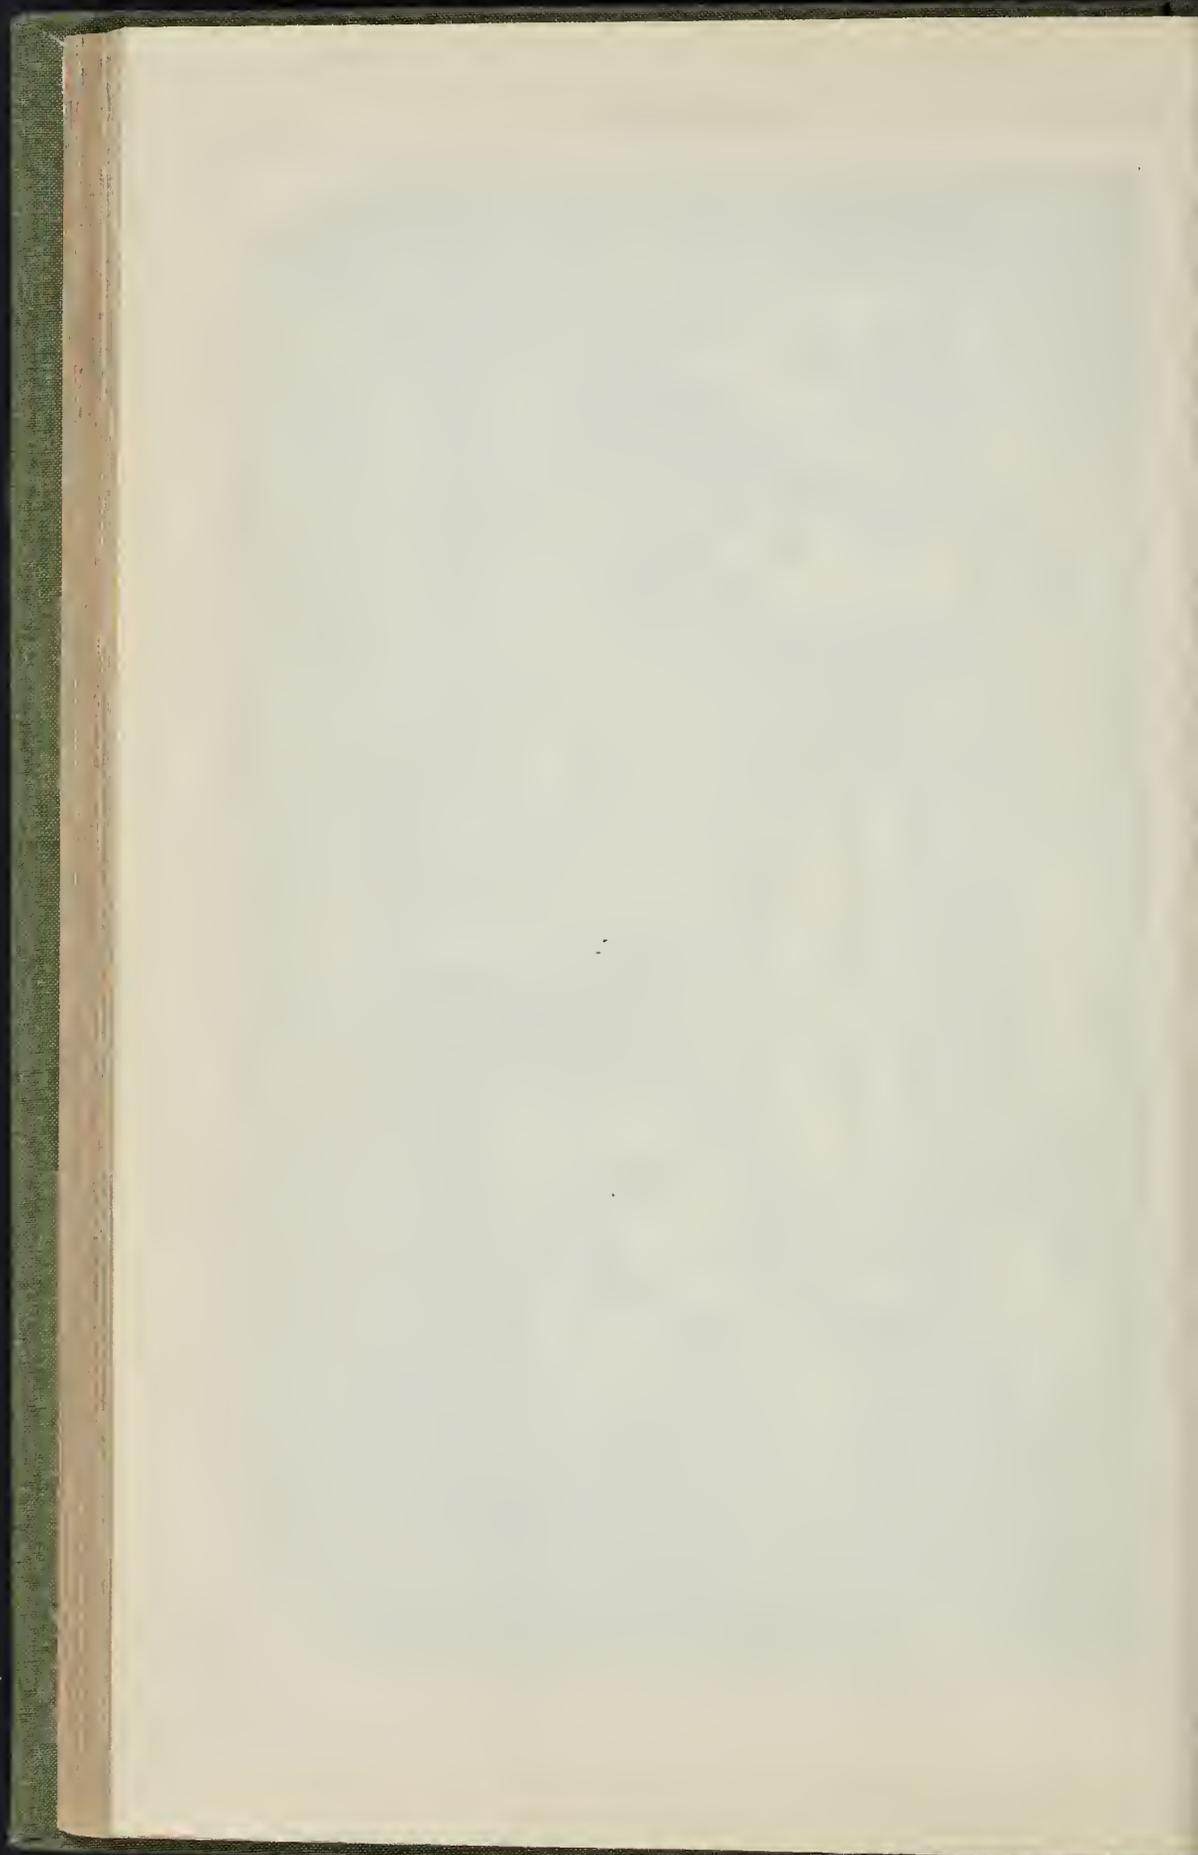

\* See vol. XIII. p. 349, and p. 367 (July and August, 1855).

to endeavour to ascertain how far improvement was to be attributed to each operation, and he therefore left some fields undrained which he manured in exactly the same way as those drained, and he also left drained and undrained land without manure. He found that, although the quality of the grass was improved by drainage, to obtain a fair return for his cost, it was necessary to apply manure at a liberal rate on the drained land, as the quantity and quality of the grass on the unmanured drained land was not in the same proportion to the outlay as on that which was drained and manured. On that which was manured but not drained, he found the quantity and quality of the grass improved; but the vegetation on the undrained was from ten days to a fortnight later in the spring, and gave out from ten days to a fortnight earlier in the autumn, thus giving nearly a month's longer growth in the season on the drained land, and that at two very important periods of the year.

Drainage in other respects is of the utmost importance. We may add, from Mr. Proctor, that his holdings and arrangements are open to any of his brother farmers who may desire to see them: they are at full liberty, he writes, to take measurements, and may have any information concerning them that they may desire. Mr. Proctor has strong notions on the value of interchange and experiences, and no faith in concealment. He wisely believes in the proverb,— "There is that scattereth, and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty."

STANLEY FARM, NEAR BRISTOL, THE PROPERTY OF MR. ALDERMAN PROCTOR.—MR. GODWIN, ARCHITECT.

## LONDON BORES.

NEVER, in the memory of that celebrated individual, "the oldest inhabitant," were the streets and thoroughfares of the metropolis so much disturbed as they have been recently. In all directions bands of workmen are busy as moles burrowing the earth, each in his way, advancing the great drainage works; and now operations have been commenced for making the underground of London available for railway purposes, and soon below the crowded streets the locomotive whistle will sound and trains roll rapidly along. The squares north of Hyde-park are blockaded, and poor ladies look out from their windows agast, and postpone intended "parties."

In the neighbourhood of King's-cross extensive works are in progress for the purpose of diverting the sewerage from the middle of the road to new sewers,—one under each of the foot-paths,—so that the centre may be left clear for the City railway tunnel. Deep diggings are also going forward in the York-road (Maiden-lane). We have watched with care the openings which have been made in this neighbourhood, in consequence of the tradition that Battle-bridge was the site of a great conflict between Alfred and the Danes. The soil has been turned up in all directions, and yet not a relic, so far as we can learn, has been discovered.

## PROFESSIONAL EXAMINATIONS.

SOME of our readers will be glad to hear that the council of the Royal Institute of British Architects have appointed a committee to consider as to the propriety of affording to members and intending members of the Institute facilities for passing a voluntary professional examination, of which certificates should be given. The Committee have already held one meeting, numerously attended, at which some important resolutions were passed, and are about to meet again.

## THE ARCHITECTURAL ASSOCIATION.

THE ordinary meeting of the Association was held on Friday, the 17th of February, at the house in Conduit-street.

The chair was taken by Mr. Penfold, the president.

Mr. T. Blasbill read an abstract, containing the principal views advanced by him in the paper read at the previous meeting, on the application of iron-work to architecture. In the course of his observations he exhibited specimens of iron in its various stages, and described the processes through which it passes from its native state, until manufactured into wrought iron and steel.

The Chairman said he was convinced of the importance of the subject in connection with their profession, though he differed from the writer in a few of his conclusions. According to Mr. Blasbill, if the Greeks had been initiated into the properties of iron, they would have thought the Parthenon a lamentable affair. The suggestion of introducing iron instead of brickwork into the facades of our street buildings was especially valuable. The writer considered it wrong to adopt curves in cast iron, or straight lines in wrought iron, and that there was abundant room in the same building for both materials. In connection with his observation on the introduction of iron into fireproof flooring, the chairman added that whoever could suggest a cheap system of such floors would benefit society.

Mr. Roger Smith considered the suggestion as to introducing iron into shop fronts peculiarly valuable. No doubt practical difficulties would present themselves to such application of the metal, but these were incident to every novelty, and by study and experience would be overcome. If we began with iron in the basement story, we should not turn therefrom to the heavier material as we went up. He (Mr. Smith) thought that the timber houses still to be seen in parts of Great Britain and France would be a good guide to us in the design of an iron front, as the material of which they were built was the same from bottom to top. In his opinion, Mr. Blasbill hardly spoke of ancient examples as they deserved. To have recourse to nature alone as our guide would lead us to absurdities. We could not now-a-days give up our hooks, and retire into the woods to study architecture. We must learn in bricks and mortar what had been done already; though we need not despise nature, and thus run into the other extreme. He wished to mention some remarkable instances of ironwork which the present day had produced. There was first the Crystal Palace, as it originally stood in Hyde-park. At the suggestion of Sir C. Fox, it was built on squares of a fixed

dimension—as few as possible. By this plan any column could be set up at once, and any girder upon it, without the trouble of scabring for the fitting-place of each. To bring about this certainty and facility in the erection, Sir C. Fox made all the drawings with his own hand, working sixteen hours a day for several weeks without intermission. Then there was the Great Western Railway Terminus, at Paddington; the dome of the British Museum Library; the roof of the new Covent-garden Theatre (a description of which had been given by its architect, Mr. Barry, to the members of the Institute of British Architects, and who had solved therein the problem of making fireproof roofs); and the roof over the courtyard of the new Museum at Oxford. He admired, especially, the imitations of foliage which had been inserted in the latter. He showed as specimens of this introduction of ironwork, drawings of fan-lights over the doors, ventilators in the ceiling, and spandrels in the roof which had been adopted in the design of a public hall at Maldon. These were cast at Messrs. Baker's Works, Falkirk, from the designs which he had furnished. These decorations corresponded to fretted work in wood; but had the advantage of finer lines, as cast patterns in iron were sharper than in any other material. Besides, a single design and repetition would afford the groundwork for any number of castings, and thereby the most skilful labour would be saved, namely, that of the designer and of the pattern-cutter.

Mr. Lewes observed that the principal objection in his opinion, to iron-work when partly covered, and partly exposed to the air, was liable to rust. This difficulty did not arise in the case of fire-proof floors, as no part of the iron was exposed, but would present itself in roofing. As was seen in the case of the Houses of Parliament, painting or galvanizing would not afford a sufficient protection, for the slightest defect in the coat, even a pin-hole, being uncovered, would admit the rust. The metal nickel, mixed with iron in certain proportions, would prevent rust, and prove superior to painting or galvanizing.

Mr. R. Smith exhibited some interesting photographic sketches, to show how ironwork could be adapted to architecture. Three of them represented views taken in Venice, one of them a building in Constantinople, and one a sketch from Florence. He might also refer to Mr. D. Wyatt's work for the same purpose.

The Chairman produced sketches, showing specimens of designs in iron of the seventeenth and eighteenth centuries, and observed that the gates to Queen Anne's Walk, in Hampton Palace, were very fine examples of the excellence to which wrought-iron could be brought. The apparent difficulty arising from the expansion and contraction of metals, under the influences of heat and cold, might, he thought, be got over in the same way as the same influences were counteracted in rails by fishing them.

Mr. Blasbill, in reply to the several observations, said neither nature nor any of the styles should be imitated; all styles copied their predecessors, but not entirely; they rather improved on them, as the Greeks did on the Egyptians. To show the folly of taking types, he begged to instance the drinking-fountains, which, as novelties in connection with their profession, might be expected to have elicited appropriated designs. And yet he would say that there was not a fountain of suitable design in London. The general design introduced was that of a shell looking out of a window, and no one seemed to rise further than the bivalve window. This afforded a proof that designers were trammelled by the study of the antique and the Medieval. As regarded the strength of cast-iron, there was greater danger of breaking it when made into patterns than when it was in the solid piece. The joints of the pattern would be the weakest part, as in the case of a beam let into a wall, which was less capable of resisting force at the part let in. In wrought-iron, on the contrary, the whole strength was brought into play in resisting the blow. He deprecated the folly of designing down to the ignorance of people who had no scientific knowledge.

Votes of thanks were passed to Mr. Blasbill and Mr. Smith, and the meeting separated.

ARTIFICIAL STONE.—Messrs. Pavin de Lafarge, Viviers, Ardèche, propose to employ a compound of quartz and clay as a substitute for sandstone. The dry portion of the compound is finely-powdered quartz, and the wet of aluminous earth. The mixture is cast in moulds, and then subjected to the necessary pressure.

## GLASGOW ARCHITECTURAL SOCIETY.

## THE WALLACE MONUMENT.

A PROTEST, it may be remembered, was made in our columns against the award of the committee in this competition, on account of a departure, in the successful design, from the conditions of the committee itself, as to colouring the drawings.

At a meeting of the Glasgow Architectural Society, on Monday evening, the 20th February, Mr. Thomas Gildard, architect, moved—"That the Glasgow Architectural Society views with, and hereby expresses its, extreme surprise, regret, and indignation at the recent adjudication on the competition designs for the Wallace monument, intended to be erected on the Abbey Craig, Stirling."

Mr. Gildard spoke at considerable length in support of his motion, chiefly dwelling on the fact that, while the advertisement mentioned that the plans and elevations must be tinted in Indian ink only, and no coloured drawing be received; notwithstanding this, seven coloured drawings were received, and to one of these seven the first premium was actually awarded by a large majority of the committee. "The competition system," said Mr. Gildard, at the close of his remarks, "has been long in corruption; but we, as a corporation, have surely something in our power to both stay the progress and restore it to its pristine health and influence; and towards this, I think it chiefly attaches to us to denounce every inance in which we find have been disregarded the common principles of moral rectitude. Let us, as an Architectural Society, show a bold and united front to all mal-practices in competitions, and very speedily committees wishing designs will be unable to afford to injure and insult us, and competitors will be found, as at least respects instructions, working more harmoniously."

Mr. Gildard's motion was seconded by Mr. Alexander Watt, architect, who also spoke at some length.

The motion was carried unanimously.

Mr. Gregory, Mr. Burnett, and others, remarked that they understood that the drawing of the successful competitor had been coloured by the artist in Edinburgh, without the competitor's knowledge or authority.

Mr. Baird moved, seconded by Mr. George Thomson—"That the remarks by Mr. Gildard, in introducing his motion, should be adopted as the expression of the mind of the society; and, to attain one of the objects for which such a society has been instituted, he hoped that the press of Glasgow and Edinburgh, and those publications throughout the kingdom more particularly devoted to the interests of architecture, would publish them *in extenso*, the subject being one of national importance." This also was agreed to.

## THE SHEFFIELD SCHOOL OF ART.

THE annual conversation of this school has just been held, Mr. Redgrave in the chair. The meeting was a good one. An extensive and varied collection of works of art on the walls formed the fourth annual exhibition of the School. Mr. Redgrave addressed the meeting at considerable length, and is fully reported in the *Sheffield Independent* of 25th ult. In allusion to British constructive skill and French taste in art, he said:—"Mr. Shepshanks, who has done so much for art, on the occasion of the Exhibition of 1855, gave an order for several pieces of furniture to be made for exhibition at Paris. I have seen the Frenchmen taking the drawers out of them, with perfect wonder at the ease with which they worked, holding up their hands in astonishment to think that such marvels of workmanship should be there from England. But they looked with equal astonishment at the absence of any display of taste in them. Whereas the French goods, though beautiful in ornamentation, are badly finished, and you might be pulling at a drawer for half an hour before you could get it out. The people, however, will take those works without utility, rather than those devoid of beauty. But as soon as the Frenchmen get the English tools, it will be found that they can make their articles beautiful, and at the same time as good as your mere fabrics, and they will be in London supplanting you."

After the prizes were distributed, Mr. Young Mitchell, the head master of the Sheffield School, remarked that, for each national medallion gained by the pupils, the school received from the Department the value of ten guineas in works of art. The School had already received these advantages to the extent of 150 guineas in the shape of rare electro-types and photographs of the cartoons of

Raffaello, &c. The present awards would entitle them to further contributions.

The School, upon this occasion, had twenty-nine out of the maximum number (thirty) of medals that could be awarded to any one school at one distribution.

#### FOREIGN RAILWAY WORKS.

THE important works for the enlarging of the Paris terminus of the Chemin de Fer du Nord are to be commenced at the end of February. The land has been valued, the plans completed and approved of, and all formalities gone through.

Many branches of the Pyrenean railway group are being already surveyed, especially between Bayonne and Pau, and from Pau to Bagueres de Bigorre. The inhabitants of the localities to be benefited by them are in anxious expectation of their being commenced.

The Minister of Public Works announces for 1860 and 1861 the opening of 450 kilometres of railways in France. These are Astricourt to Lillers; Aillevers to Favernay; Nonzon to Conlommiers, Bar-sur-Seine, Rennes to Redon and Montauban, Saint-Lô, Saint-Christophe to Rodez, Monet to Montargis, and Burgundy to Beaumont. In two years the Paris and Neviers line, a direct railway to Lyons, will be probably opened for traffic.

In a few years hence we shall have the two banks of the Rhine placed in direct communication on no less than six points between Waldshut and Cologne. Two permanent bridges, our readers are aware, have been already constructed and opened for thoroughfare; that of Waldshut, between Switzerland and the grand duchy of Baden, and that of Cologne. The Kehl bridge is in a fair way of construction, and will be open in a year. Two others are proposed between Mayence and Coblenz. The drawings have been got out and negotiations are on foot between the governments on each side the river and the different railway companies interested in their construction. As soon as some questions are settled, the works will be commenced. The sixth bridge is one that the Grand Duke of Baden has recently declared to be of paramount importance, viz, over the Rhine at Mannheim, and he has urged the necessity so forcibly that the project may be looked upon as decided.

In 1856 the concession of the Florence and Arezzo Railway was accorded to the Marquis de Flers, but the works were never terminated. The Tuscan Government has now issued a decree annulling the original concession, and ordering that the works be continued at the expense of the state.

#### GOthic ARCHITECTURE IN AUSTRIA.

THROUGH Herr Reichensperger's correspondence with the *Ecclesiologist*, we are from time to time informed of the architectural news from Cologne and the north of Germany. Being now in the south for the purpose of observing the advancement of the arts, perhaps a few lines may not be uninteresting to your readers. Having lately made the acquaintance of Herr Ferstel, I have had much opportunity of closely inspecting modern buildings. He has in hand, and nearly finished, the New Exchange and Bank Buildings, Vienna, a work of very high merit. In style it is difficult to describe, but by giving you some idea of this gentleman, you may conceive, perhaps, his last work. He is a great lover of Gothic, and gained the prize in the competition for the Votive Church, now being erected here outside the Schottenhof. Well, his design for this Exchange is, in motive, Gothic: the carving and general idea are Gothic; but the arches are round, and there are many Classic ideas in the building, particularly the pillars. The metal-work is very Gothic: the lamp-brackets, door-handles, &c., are cast in bronze, and very chaste in design: the gates are pressed and wrought. There is a great use of imitation stucco, marble, and Portland cement, designed in the style of the Italian very Early Gothic marble mosaic. In this manner many of the halls are decorated, and the effect is most charming. This seems to be a most legitimate ornamentation, as it is not a sham.

The Bank direction-room is very elegant, and the furniture admirable; patterns flat and inclined towards Gothic: the wood carving (only so far conventionalized as to be in good taste and according to decorative principles) is the finest and most life-like I have ever seen; and the polychromatic decoration is very elegant. Above the wainscot the wall is covered with pressed leather, diapers of which are very chaste, and much colour

and gold is used on this leather: the effect is excellent. The chairs are also of pressed leather, with gilded and coloured patterns.

Herr Ferstel's new church is a cathedral-like building, about 300 feet long, somewhat after Cologue in idea, and perhaps too German and liny for our taste, but still a noble work, and particularly as German Gothic architecture.

I think the future of Gothic domestic architecture is very hopeful and bright in Vienna; and in the next ten years I anticipate many fine buildings. Herr Ferstel has a thorough knowledge of what is required in modern domestic Gothic. Herr Schmidt, who gained the prize for the Berlin Town-hall (which of course was not executed), is a Goth, and is now professor in the Academy, and is a perfect master of his craft. Herr Ernst is now restoring St. Stephen's, but not at all according to our ideas: dreadful Vandalism, and no Conservatism, although the modern work is not bad at all. Of course Herr Ferstel has to feel his way here, and begins with round arches, &c. He is intent, however, on working in true architecture by degrees. As to Munich Gothic, it is ludicrous, Maximilian-street having become a proverb.

Vienna.

W. TAYLOR.

#### THE LATE W. H. PLAYFAIR, ARCHITECT.

ARCHITECTURAL INSTITUTE OF SCOTLAND.

AT a recent meeting of the Architectural Institute of Scotland, held in George-street-hall, Mr. J. Murray Graham, of Murray's Hall, read "A Notice of the Life and Works of the late William H. Playfair, Architect." The paper was illustrated by Mr. Playfair's own drawings of the most important works executed by him. The following abstract of the paper has reached us.—Mr. Playfair was born in 1789 in London, where his father, also an architect, carried on business. He came to Edinburgh at the age of fifteen, and for some time attended the classes of his uncle, Professor John Playfair. His architectural teacher was William Stark, of whom Sir Walter Scott had so favourable an opinion that he got from him the first design for his house at Abbotsford. When, in 1816, a Parliamentary commission was appointed to decide upon plans for the repair and removal of the Edinburgh University Buildings, Playfair's plans obtained the first prize, of 100 guineas, and with some slight modifications, his plans were carried into execution. The interior front of the buildings facing the quadrangle were universally admitted to furnish an excellent specimen of Italian architecture. In 1815 he supplied plans for the Astronomical Observatory on the Calton-hill, and for Dollar Academy, both in the Roman style of architecture. In 1810 he furnished an elaborate design for the Advocates' Library, with a colonnaded portico fronting George IV.'s bridge, on a much grander scale than was afterwards carried out. In the same year he designed the gateway and lodge for Heriot's Hospital, which is in admirable keeping with the main structure. In 1820 Mr. Playfair was employed by the magistrates and proprietors to plan various crescents and streets for the side of the Calton-hill and among other designs now filled up, were the Regent, Royal, and Carleton terraces, Brunswick-street, Hillside-crescent, Windsor-street, as well as the Royal Circus on the north side of the city. His reputation as an architect was now considerably raised, and in 1822 he was employed to furnish the designs for the Royal Institution buildings on the Mound. After describing the architectural features of this structure, Mr. Murray Graham said, as a whole, it was deficient in effect, and that chiefly on account of its position. The style of the Grecian temple required that the building should be placed upon a height, and in all the ancient specimens this condition was observed. In 1826 Playfair took part in furnishing the designs for the national monument, in the style of the Greek Parthenon, and also for St. Stephen's Church. Mr. Graham next remarked upon his domestic buildings in the Italian style, illustrated by Dumfries House, in Morayshire, the late Lord Mackenzie's house at Belmont (now the property of Mr. J. Hope, D.K.S.), and Drunbanagh House, Armagh; and those in the Scotch baronial style, which he had either wholly built, or materially added to—such as Baunore, Prestongrange, Craigcrook, Bonaly, and Islay House. One of his best strictly classical works was the College of Surgeons' Hall in Edinburgh, which, without being a mere copy of any ancient example, displayed in its front elevation the genuine air and spirit of Greek. His Calton-hill monuments to Professor Dugald Stewart and Professor Playfair deserved a word of commendation. The first,

effective and beautiful, and was finely placed on the edge of the rock; while the second was a good example of the severe classical style, and was monumental in its character. After a brief notice of Lurgan House, and the Mansion of the Duke of Roxburgh at Fleurs, designed by Playfair in the Tudor style, and the latter of which especially was very successful, Mr. Murray Graham referred to Donaldson's Hospital, which was his largest work in this style, and had gained for him a most extensive reputation. His only Gothic building were Minto Chapel, and the Free Church College in Edinburgh. The National Scottish Gallery, designed in 1850, was his last important work. Mr. Playfair's life, apart from his professional engagements, was not an eventful one, and he died in 1857 at the age of 68. He was an architect of consummate knowledge and taste, rather than of original genius. He kept within the rules of his art, and was most laborious and conscientious in his attention to correctness of detail.

#### A SUGGESTION AS TO THE WESTMINSTER BELL.

AT the meeting of the Institution of Civil Engineers, on January 17th, Mr. S. A. Varley exhibited a cracked bell, the metallic continuity of which had been restored, by simply soldering the crack with tin, so that the bell rang as perfectly as before it was injured. It was explained, that tin had the property, when heated above its melting point, to nearly a red-heat, of rapidly dissolving copper. If, therefore, the cracked bell, after being soldered, was kept at a dull red-heat, or nearly so, for a little time, the crack would become filled up with an alloy of tin and copper, of nearly the same kind of composition as the bell itself, and in absolute metallic union with it, and quite as brittle and as sonorous as the other portions of the bell.

#### DESIRED EMBANKMENT OF THE THAMES.

On Monday morning a deputation from the vestry of St. Luke's, Chelsea, waited by appointment upon the Right Hon. W. Cowper, at the Office of Works, Whitehall-place, to urge upon Government the equity of spending the money (£8,150*l.*) now in their hands, and voted by Parliament for that purpose, in continuing the embankment from Chelsea Hospital towards Battersea-bridge.

Mr. Fife, M.P., stated the case of the parish. He observed, that under an Act of Parliament, passed in 1816, the sum of 145,000*l.* had been voted for carrying out the embankment and road, the whole of which had been expended with the exception of the balance above stated. The powers of the Act, though renewed by a subsequent one, had ceased, and the object of the deputation was to induce the Government to recommend the revival of the parliamentary powers to acquire the necessary property to continue the embankment which now ended at Chelsea Hospital on to Cheyne-walk, and so to Battersea-bridge. The total expense was estimated at between 60,000*l.* and 70,000*l.*; but if the Government would authorise the appropriation at once of the 38,000*l.* balance from the former votes, the parish suggested that the remainder might be spread over series of years.

Mr. Byng, M.P., the Rev. Mr. Burgess, the rector of the parish, and several members of the vestry, represented the importance of the improvement in a public sense.

Mr. Cowper fully admitted the importance, both in a public and local sense, of the proposed embankment. The misfortune was that the 38,000*l.* referred to, not having been claimed within three years from the time specified, had gone back under a general rule into the Exchequer, and was treated as a saving, so that if anything was to be done again, in the present state of the public finances, he thought very strong and cogent grounds would be required to induce the House of Commons to pass such a vote. He assured the deputation of his entire sympathy with the object they had in view, and promised to represent their wishes to the Government, but he could hold out no hope of their accomplishment under present circumstances.

Members of the Chelsea vestry had another interview with the Chief Commissioner of her Majesty's Works on Thursday, March 1st, with reference to the bad condition of the new road leading from Lower Sloane-street to Chelsea Suspension-bridge.

## IRELAND.

ADDITIONS and alterations are to be made at Enniskillen court-house, according to plans by the County Surveyor; the expenditure not to exceed 2,500*l*.

A new minor model school is to be built at Monghan, by the Board of Public Works.

The Bagenalstown and Wexford Railway Company have received tenders for 20,000 sleepers of larch or foreign timber.

A trial will take place this term in the Dublin Law Courts, relative to the fall of house in Cranford-street (Kempston v. Butler, as already noted in the *Builder*); and some interest will be occasioned by the following cases, likewise announced to come off, viz.—Lord Gough v. Carmichael; breach of duty as an architect; Hugh Kelly v. Crampton; payment for ditto and labour as a builder; Bolton v. Tyrrell; ditto; Burke v. Carroll; damage to adjoining premises during building operations.

The county surveyors have had an interview with the lord lieutenant, relative to their memorial previously alluded to by us; and his Excellency, having acquainted himself with the detail of their alleged grievances, promised that the memorial should receive favourable consideration.

Numerous gentlemen of commercial status have requested the corporation to withdraw the proposed bill for the new water supply, until the citizens should have ample opportunity to study it, and form an opinion upon its features. It appears to be not unlikely that even at the eleventh hour an amicable and mutually satisfactory arrangement may be made with the Canal Companies, for the supply.

It is proposed to erect a new music-hall of spacious dimensions, at Derry. Subscriptions to the amount of several hundreds of pounds have already come in.

A new church, for Roman Catholic worship, has been erected at Gargary Dolly's Brae, after designs by Mr. W. J. Barre, of Belfast and Newry, architect. Another, for same purpose, is being built at Contraquaddy, and Lord Carew has subscribed 100*l*, and given a free site.

New convents are to be built at Mountlincrook (J. S. Dutler, architect), also at Upper Glanmirewood, Cork; and others are in progress at Roscommon and Sligo.

An asylum for twenty-six widows has been completed at New-street, Dublin, at the sole expense of Alderman and ex-Lord Mayor Atkinson, after plans by Mr. Joseph Maguire, architect. Mr. S. H. Bolton, the builder. Cost, about 1,000*l*.

The new station at Ballybay, on the Dundalk and Enniskillen railway, is a Gothic building, representing a frontage of 85 feet, and cost 1,700*l*. (Mr. W. J. Murray is the architect; Mr. John Nolan, the builder. The company are about constructing the line from Clones to Cavan. Mr. James Barton, C.E.)

## CHURCH-BUILDING NEWS.

*Castle Rising (Norfolk)*.—A commencement has been made to rebuild the south transept and aisle of the church of Castle Rising. Mr. G. E. Stretton, is the architect; and Mr. Wm. Brown, of Lynn, the builder.

*Saffron Walden (Essex)*.—The church here is to undergo an extensive reparation under Mr. Bussey, of London, by Mr. William Brown, of Lynn.

*Cambridge*.—For rebuilding All Saints' Church on a new site, about 3,000*l*. have been already promised towards the 5,000*l*. that are wanted. It is intended, says the *Chronicle*, to employ an architect of undoubted reputation, so as to have a church built in the true principles of Gothic art.

*Northampton*.—The committee for the restoration and enlargement of St. Sepulchre's Church, Northampton, have resolved to proceed in the carrying out of the plans prepared by Mr. Scott. There were seven tenders received, viz., from Messrs. Myers, Parker, Whitmy, Ireson, Jackson C. Co., and W. M. Cooper, of Derby, the last of which, being the lowest, was accepted. The work has been divided into three sections, the first one of which only it is intended to proceed with at present, the funds already promised and collected being only sufficient for that purpose. The committee have, however, reserved to themselves the option of accepting Mr. Cooper's tender for the remainder of the work, at any time during the progress of the first section. To carry out the complete design, an additional 3,000*l*. will be required.

*Islip (Oxford)*.—Of the Islip Church bells, the *Edinburgh Journal* says,—"Two of them were cracked and sent forth what might be called 'fractos

sonitos." The operation (performed on one of them) of cutting out the crack was by no means effective in restoring harmony of tone. In August, 1859, a generous offer was made by John Parsons, esq., of Oxford, to defray the expense of recasting the whole set. The offer was at once gratefully welcomed by the rector, churchwardens, and parish at large. The work was entrusted to Mr. Alfred White, of Besselsleigh. The five old bells were taken by rail to Mr. Menz's foundry, Whitechapel, and successfully re-cast into six, sent down to Mr. White, at Besselsleigh, for fitting and arrangement, previous to being re-erected, and brought back again to Islip on January 22nd, of this present year. The arrival being expected by the inhabitants, a large assembly spontaneously went to welcome the bells. They were played into the village by the Islip band, the rector, churchwardens, and others walking in a kind of extempore procession into the churchyard and up to the foot of the old church tower, where the rector read aloud the new inscription on the tenor bell, and delivered a short address, after which the work of raising the bells immediately commenced. Not the smallest accident occurred during the whole business.

*Brighton*.—It is in contemplation to erect a new church on a site in Victoria-road, in the west of Brighton. The architect is Mr. G. F. Bodley, of London. The style is to be Gothic.

*Cosham*.—A vestry meeting was recently held in the parish of Wymering, for the purpose of accepting the sum of 1,200*l*, left by the will of the late patron of the living, Mr. F. J. Nugee, towards restoring the parish church. The plans, executed by Mr. Street, were submitted to the meeting. The fund was thankfully accepted, and the plans adopted.

*Amsbury*.—The new burial-ground and mortuary chapel here, provided by Sir Edmund Antrobus, has been consecrated. The new ground is conveniently situated, and is enclosed by a wall. The chapel is constructed of red brick and mud (according to a *Wills* paper), and the entrance is surmounted by a bell-turret. The interior is paved with Minton's and Peak's tiles: the seats and roofs are of stained deal. Mr. Butterfield, of London, was the architect; and the works, which have cost about 1,000*l*, have been carried out by Mr. Edward Andrews, builder.

*Chetwode*.—The small church of Chetwode, according to the *Sherborne Journal*, having undergone, during the past nine months, a work of restoration and enlargement by the erection of a chancel, has been consecrated by the Bishop of Salisbury. The probable cost of the restoration and addition will be about 700*l*. or 800*l*. The new chancel was erected (under the superintendence of Mr. Slater, the architect of Sherborne Church restoration) by Mr. C. Down, of Sherborne, builder; the plumbing work being executed by Mr. Upsall, of the same place. The chancel is about 25 feet long, by 17 wide, is built of Ham-hill stone, and contains five windows, two in each side, and one at the eastern end, which was erected in memory of the late Major Chadwick, by his family. This window is of coloured glass, supplied by Messrs. Clayton & Bell, of London. It contains three lights. In the centre light is a representation of the crucifixion of our Saviour; and on either side are the "holy women" and Joseph of Arimathea. The tracery, which is in accordance with the style of architecture, is filled in with evangelistic symbols and the sacred monogram. On the north side of the chancel is a memorial window to the late ennobled, the Rev. John Sanctuary. This is also of coloured glass, and consists of two lights, representing the apostles St. Peter and St. John. It was placed there by public subscription. The floor is of black and red diamond-shaped tiles, laid diagonally. The roof of the nave (lath and plaster) was scraped, when the framework of an oak roof was discovered; this has been entirely restored, and is of a wagon-headed form. The old square oak pews in the nave have been removed, and open, stained-deal seats have been substituted. By the alteration, forty extra seats have been appropriated to the poor. The church will now accommodate about 250 persons. The cost of erecting the chancel (about 300*l*) has been chiefly borne by the Chadwick family, the restoration of the nave being defrayed by the parishioners.

*Yeovil*.—The restorations at the parish church have been completed. The works have been confined principally to the renovation of the interior. The whole of the internal space from west to east was crowded with heavy galleries, the beams and timbers being let into the stone piers, which were mutilated by their insertion, as were also the attached wall shafts and moulded window jambs. The ground-floor was filled over its entire area with

high pews, the principal framing, however, being of good wainscot oak. The timber roofs throughout were plastered and whitewashed internally. All these deformities the architect has had removed. The stonework throughout the church, as far as practicable, has been made good, the moulded bases and other piers restored, a single shaft in an obscure corner retaining its mouldings having been the authority for this part of the work. The mouldings and tracery of three side windows, in the south aisle, have been taken out and renewed, and the jamb mouldings made good; also the large window at the east end of the same aisle has been similarly treated. The three side windows just named have been filled with glazing by Messrs. Lavers & Barrand, of London, and in each are arranged various geometrical lines and figures, diapered with foliage and flowers, and enclosing coloured compartments, in which are presented the emblems of the Passion, the sacred monogram, and other devices of symbolical import. The whole of the lights of each window are surrounded with coloured borders and foliage, and surmounted either by a corona or mitre in the alternate compartments. The glass for one other window at the west end of this aisle is still in hand, and will be shortly completed. The eastern window has been executed by the same artists, at a cost of 150*l*. In the five principal lights are depicted five miracles of our Lord, viz., "The blind receive their sight," "The lame walk," "The lepers are cleansed," "The deaf hear," and "The dead are raised up." The tracery in the head of the window is filled with glass displaying foliage. The oak roofs and timbers of nave and aisles, and chancel, have been oiled, and the bosses and principal moulded ribs and plates have been decorated in gold and vermilion, and powdered with gold stars. The available area of the church, in nave, aisles, transepts, and choir, has been fitted up with open benches, framed with moulded and carved ends of wainscot oak, each exhibiting an appropriate device. Various other restorations have been effected. The north transept is enclosed; but much yet remains to be done to make a complete restoration inside and out. The oak fittings and carvings have been executed by Mr. Geake; the masonry and carpenter's work by Messrs. Harwood & Sons; and the ornamental painting by Mr. Foot, all of this town. The restoration of the Ham-stone work, and the execution of the new rosettes, &c., have been carried out by Mr. Joseph Staple, of Stoke-sub-Hamdon, and the entire work throughout, from the designs and under the superintendence of the architect, Mr. R. H. Shout.

## METROPOLITAN BOARD OF WORKS.

## TENDERS FOR DRAINAGE, &amp;c.

At a meeting of the Board held on the 24th February, the following tenders were received for sewerage works in the eastern division of the metropolis, viz.—

Munday, at 5 per cent. above prices in schedule.

Walker & Neave, ditto.

Messrs. Wood, ditto.

R. Robinson, 2½ above.

W. Lavers, at the schedule prices.

W. Hill, Whitechapel, 3½ per cent. under ditto.

E. Cole, 6 per cent. under ditto.

Dethick, 10 per cent. under.

Mr. Dethick's tender was accepted.

For Works in the several Parishes South of the Thames.

Dethick, 5 per cent. above schedule prices.

R. Robinson, 2½ per cent. above.

W. Lavers, 2 per cent. above.

Walker & Neave, 2 per cent. above.

W. Hill, at schedule prices.

E. Cole, 5 per cent. under ditto.

Mr. W. H. Rowe's tender for the Northern Middle Level Sewer (264,533*l*), submitted with others at the previous meeting, was accepted, his proposed securities being considered satisfactory.

It should be mentioned that at the previous meeting of the Board, a recommendation to increase the salary of the superintending architect from 800*l*. to 1,000*l*. was negatived. Further, a report was received from the Building Act and General Purposes Committee, on a letter from Mr. William Henry Smith, submitting, for certain reasons stated therein, that Mr. Reeves, Police Surveyor, does not fulfil the description of a "competent surveyor" as defined by the 33rd clause of the Metropolitan Building Act, and that the Board has done wrong in certifying that he is entitled to receive fees under the provisions of that Act for the supervision of dangerous structures.

The committee had replied to Mr. Smith that the Commissioners of Police and not the Board of Works, were responsible for the selection, and that they did not agree in his interpretation of the term "competent surveyor."

Mr. Smith had replied as follows:—

4, Devonshire-place, Brighton, December 6, 1859.  
Sir, Your letter, dated December 2d, has been forwarded to me here. Having neither the "Act" nor any advertisements aid, I answer it at a disadvantage.

Considering the great and irresponsible power with which the surveyor is invested by the Metropolitan Building Act, 1855, I regret to find the Metropolitan Board of Works willing to construe "competent" to mean only "reasonably skilful."

The competency of a surveyor is, ordinarily, matter of opinion, the opinion of one man not being binding upon another. Judging from his works at Westminster, I may entertain the erroneous opinion that Sir Charles Barry is not a "competent" surveyor. If he does his work to his satisfaction, a commissioner of police may consider 2 2/3 of the force a "reasonably skilful" surveyor.

The Metropolitan Buildings Act, 1855, has provided a standard by which the surveyors employed in carrying out its provisions may be measured. The survey (I quote from memory) is to be made by the district surveyor, or some competent surveyor.

The district surveyor must be a competent surveyor: the surveyor who may set in his stead must be a competent surveyor. We turn then to the Act, and that it considers those only competent who have received a certificate of competency from certain constituted authorities. I cannot conceive anything more clear.

I have addressed myself to this one point only, that I might not unnecessarily occupy the attention of the committee; but there are those who dispute the actual as well as the legal competency of Mr. Reeves, and the numerous names of staff who discharge his duties for him.

I decline to combat, but you must not therefore conclude that I concur in your definition or limitation of the duties of the Metropolitan Board of Works in this matter.

I presume I shall be informed of the decision of the Board, that I may, if I deem it expedient, bring the subject under the notice of other parties.

WILLIAM HENRY SAUNDERS.

The committee reported that this reply had in no way altered their opinion.

#### COTTAGE IMPROVEMENT.

You state Miss Martineau builds a cottage in Westminster for 60*l.*, the particulars of which I had already read of; but you will see that no details are given by that lady of any real weight to either landlord or builder.

I have not seen the Cottage Improvement Society's plans, alluded to in your last number; but what rent does a proprietor obtain for two cottages erected at the cost of 160*l.*? I erected two cottages (a pair) on my estate, with two living-rooms, three bedrooms, larder, and porch. The patent fire-range made by a firm in Newark. Fireplace in one bedroom upstairs (for woman in confinement or persons in illness); spouting carried to a soft-water tank under kitchen, with small pump. Built of my own stone, mabbled, slated, and white foreign wood; privy, ash-pit, and two pig-sties,—price 260*l.* Now the labourers about here (Yorkshire) obtain 15*s.* a week, and I only ask 4*s.* per annum for these cottages—5*l.* on 250*l.*—and yet they grumble at the rent, and think a hovel at 20*s.* for six months to be preferred.

My tenant-farmers came to me and complained of the want of labour, and proposed erecting cottages through the Lands Improvement Company. To this I acceded. Now the lowest-priced three-bedroomed cottage we can erect is 125*l.* (the tenant-farmer doing all the leading). The per centage of 6 2/3 per cent. charged by the Company for twenty-five years makes the rent of each cottage about 8*l.* 10*s.* per annum (independent of leading bricks and lime four miles). I, as landlord, do not obtain a sixpence, and my tenant pays between 8*l.* and 9*l.* for a cottage for his labourer. Too high a rent, in my opinion, remembering the wear and tear of twenty-five years. I consider the subject requires ventilation, which I trust it may have in your columns. Either cottages must be built cheaper or labourers at 15*s.* a week give higher rents than they feel inclined to do now.

A LANDLORD.

Sir,—In your last week's number you quote from *Once a Week* some particulars, by Miss Martineau, of a cottage building in Westminster; you give the sizes of the rooms, viz. "13 feet by 10 feet," and "12 feet by 10 feet 6 inches," and two bedrooms above; you then express a regret "that Miss Martineau should lead countenance to the construction of cottages with only two bedrooms," and recommend the plan issued by the Cottage Improvement Society, "the cottages with three bedrooms."

Every one will agree with you "that the male and female children should be separated," and that "cottages for families with only two bedrooms lead to an incredible amount of vice."

If you refer to the Cottage Improvement

Society's plan, you will see that the living room is 11 feet 4 inches by 9 feet 4 inches, and the kitchen 11 feet 4 inches by 9 feet 4 inches also; there is one bedroom over the living-room, and two made over the kitchen, one of which is 9 feet 4 inches by 5 feet 5 inches, and the other 6 feet 10 inches by 5 feet 9 inches, which must be admitted to be scarcely worthy of being called bedrooms, one having less than 300 cubic feet, and the other about 350 cubic feet.

Now, by dividing the smaller bedroom in Miss Martineau's plan, viz., the one 12 feet by 10 feet 6 inches, you can make two bedrooms larger than the Society's plan gives,—one would be 10 feet 6 inches by 6 feet, and the other 8 feet by 5 feet 10 inches,—each about one-third larger than the Society's plan.

My attention was called to this from having seen the Society's plan partially carried out about three miles from this place, by the Rev. Shelton Sackling, rector of Shippeadon, Suffolk, who purchased some wretched hovels in his parish for the purpose of pulling them down and erecting cottages fit for human beings. I happened to pass these a few weeks since, just before their completion, and saw the rev. gentleman. I asked him some questions respecting the Society's plan, as one of my employers (who has built several cottages with three bedrooms) proposes building from the Society's plan. I asked Mr. Sackling if he did not find the two bedrooms over the kitchen very small? He replied that he had not divided that part into two, as he found they would be small and useless if divided; he also said, that if he built any more, he thought of carrying the walls about 1 1/2 feet to 2 feet higher, and making rooms in the roof, which I suppose would add 20*l.* or 30*l.* to the Society's estimate of 168*l.* I thought this increased height of the walls would spoil the proportions of the Society's plan, and the rooms in the roof would be so hot in summer and cold in winter as to be of little service.

There is one other objection, I think, to the Society's plan; the pantry is only a very small closet under the stairs, with no chance of admitting external air,—not a very good arrangement for keeping the food, &c., of the family.

I think the Society scarcely give what their plan states: "A pair of inexpensive cottages, with three bedrooms each; cost, 168*l.*"

JOHN D. BOWWRIGHT, Builder.

#### HOLLOW WALLS.

Sir,—I take the liberty of forwarding to you my experience with regard to hollow walls. Several years since I introduced in the erection of a small detached house a 12-inch hollow wall, constructed with a 4 1/2-inch brick wall inside and outside, leaving a space of 3 inches between, and tied together with 12-inch headings at convenient distances, to make the work secure. Small air-bricks were inserted at the bottom and top of the wall, to give a current of air through the walls. I found it answer very well, and since then a number of houses have been built in the same manner: one especially I may name, that has been rebuilt by the side of a brook, in a very damp situation,—so damp that it was impossible to keep paper upon the walls of the house previously standing upon the same spot. I have taken the trouble to inquire at this and several houses if they find any damp at any time in any particular place, and the answer is in the negative. I therefore infer that the above experiment is successful, and that the damp does not find its way through the headers, neither does the admission of a current of air cause the inner portion of the wall to become damp; but, on the contrary, I think the admission of air would keep it dry; care, however, should be taken that a course of headers is not put under the windowsills, or the damp will find its way through them, especially if the sills are not properly throated. If I am in error I should be very glad to be set right.

WM. PEACHEY.

#### SOCIAL BRIDGES: THE SEWING-MACHINE.

EVERYONE remembers the immortal "Song of the Shirt" of poor Tom Hood, and the fearful revelations respecting the condition of the needlewomen in general. It seemed as if labour had been ground down to its lowest point, and that no prospect of relief were possible. The facility with which females could take to needlework always caused the labour-market to be overfull, and the rate of wages to be maintained at the very minimum, thus causing an occupation which might have afforded a chance of profitable employ-

ment to many to become one of the most precarious means of existence possible. This arose partly from a fact which is now ceasing one of the most remarkable controversies of the day, namely, as to the means of employment for females in general. How far the invention of the sewing-machine will affect the question it is impossible to tell at present, but its use has caused many of the former ill-paid needleworkers to receive good wages as machinists, while the greater number, if not all, of those who were temporarily deprived of work by its introduction have since found full occupation in the various finishing departments, because the increased facility of production has occasioned a large and steadily increasing demand. The strikes at Northampton, Stafford, and elsewhere, having ceased, and the above facts having become apparent, have occasioned the machines to come into general use, and led to many new and valuable improvements in their construction; so that, after being beaten for awhile, the English-made machines stand confessedly superior to all their foreign rivals.

House-decorators, upholsters, and others are availing themselves very largely of the sewing-machine in the getting up of tapestry fittings, curtains, hangings, &c.; and the value of the machine to them has been largely increased by the invention of a binding guide to fit on the machine for the purpose of binding the edges of the materials. The beautiful regularity of the machine-made stitches occasioned the less finished appearance of the hand-binding to spoil the harmony of the whole. Hence the value of the new invention. The best binding-guide seems to be that made by the Messrs. Bradbury & Co., of the Rhodes Bank Foundry, Oldham. It has come into extensive use, and is a beautifully simple contrivance, of a highly valuable nature to those who are in the habit of manufacturing textile decorations for mansions and large private or public buildings.

J. P.

#### WANTED, AN ASSISTANT!

Sir,—A relation of my experience in regard to answering advertisements may, perhaps, prove useful to others. A few weeks since I received an advertisement in your paper for an architectural assistant, with a salary of 70*l.* per annum, which, in the folly of my ambition, though young in the profession, I imagined myself to be fully worthy; especially when flattered by the firm that I should suit them. Judge, then, of my surprise, when admitted to an interview, at a country town not 100 miles from London, to find the firm are auctioneers, and therefore not requiring a junior assistant, as I admitted myself to be, but a gentleman competent to carry out all the various branches of a good professional practice, which they hoped to form out of his services; particularly mentioning designing, modelling and other drawings, preparing working and detail drawings and specifications, and superintending the works in progress; for which duties the magnificent salary of 70*l.* per annum is all the poor fellow might expect. AN ARCHITECTURAL ASSISTANT.

#### THE MAGNESIAN LIME-STONE FROM MANSFIELD WOODHOUSE.

Sir,—Observing a letter in your last number on this subject, I think it right, though that letter appears in the form of an advertisement, to send you a copy of the summary of the statements which it contains, so far at least, as my own observation extends. I have no opinion (though I am a matter of opinion only) that the Mansfield Woodhouse stone may be considered to be virtually though not nominally, that recommended by the Geological Commission. The parts of the Houses of Parliament in which it was made use of have been recently pointed out to me by a perfectly disinterested party, who was at the time engaged on that work, and these parts were certainly in a high state of preservation, so that one would suppose that, had the same stone been used throughout, the evils since complained of, would have been avoided. The structure of the stone, when examined with a magnifying glass, appears much more perfect and crystalline than some other stone, which seems to suggest a *prima facie* probability of its being more durable. As to colour and texture, it is about the most beautiful stone that I know of; indeed, I know no material preferable to it for work of a superior character, where beauty, compactness, and durability, are the chief desiderata.

GRD. GILBERT SCOTT.

#### WORKMEN'S INSITUATE AND BENEFIT CLUB, 34, YORK-ROAD, LAMBETH.

A LECTURE was delivered by Mr. J. Tild Pratt, registrar of Friendly Societies, to a large body of workmen and others, assembled in the reading-room of this insituate, on Friday evening, the 24th. The meeting was presided over by Jerome Smith, Esq., and the following gentlemen were also present, viz. Messrs. Charles Lucas, St. Leger Glynn, G. J. Bower, J. S. Gilhatt, A. West, F. D. Mucatti, C. W. Grenfell, W. B. Ranken, and W. A. Wilkinson.

In the course of the comprehensive lecture which Mr. Pratt gave "On the Constitution of Friendly Societies," he said there were six objects essential to their success to be provided for, viz.—relief in sickness, to the aged, sixty or sixty-five; a superannuation allowance after that age; medical attendance and medicine; endowments for children; a sum of money at death; and deferred annuities to members from the age of sixty-five. He said that sixty or sixty-five should be the limit of a sick-leave of absence, because after that age came infirmity and old age,

which should be met by insuring for superannuation; pointed out the advantage of members paying according to their age, and the importance of the rules and tables being duly certified; and added that, as the workmen's benefit club, the rules and tables of which he himself and an actuary had certified, included these several features, he considered it to be the best society in the kingdom. At the conclusion of his lecture Mr. Pratt was addressed by some of the workmen present, to whom he gave explanations; and a vote of thanks to him was passed.

STAINED GLASS.

Ardeur Church.—Lord Lorton is about to place in the church of Ardeur (now rehuilding) a memorial window, to the memory of the late Viscount and Viscountess Lorton, at a cost of about 300l.

Gloucester Cathedral.—Messrs. Clayton & Bell, of Wallis (of Newcastle), and Mr. Hardman (of Birmingham), have furnished the Dean and chapter with designs for the restoration of the east window of this cathedral. The window is 4 feet in height. Mr. Warrington has also sent a specimen of imitation ancient stained glass, with which he suggests the window should be filled.

St. Thomas's, Newport (Isle of Wight).—Two sections forming part of the great window proposed to be placed in St. Thomas's Church, says the Dorset Chronicle, have been forwarded to the churchwardens for inspection, and have been placed in one of the chambers of the Town-hall, they consist of two designs, completed in stained glass, from the original plans of the artist, Mr. Holland, of Warwick. The first one, having an arched top, represents the angel appearing to the Virgin Mary, with the Holy Ghost descending on her in the shape of a dove. The other section is a square one. The subject is "Christ's entry into Jerusalem on an ass."

Books Received.

Memorials of Workers: the Past to encourage the Present. A Lecture. By GEORGE GODWIN. Robert Hardwick, 192, Piccadilly; and at the Office of the Builder. 1860. Price 6d.

content ourselves, for obvious reasons, with announcing the publication of this lecture, and giving a few extracts from it. The writer says as follows:

"It happens that I am occasionally called on to correspond with men of the humbler classes who are reaching onward,—men who desire to cultivate the powers with which they are endowed, who have aspirations beyond their position, and, in many cases, courage and energy to carry them out if they could assure themselves that success was probable. The man, however, with which they are possessed that, work as they may, there is no chance of advancing, relaxes their endeavours and keeps them down. They are more ready to say with Emerson,

Rarely they rise by virtue's aid who lie Plunged in the depths of helpless poverty," than Milton, who teaches that,

"The mind in its own place and in itself Can make a heaven of hell, a hell of heaven."

But writes one, "I have neither money nor means. Strive as I may I shall never make myself felt." I may be wiser than he, but I will not listen. The obvious answer to this is,—recollect what others have done who were as ill-placed as yourself, and who laboured under similar difficulties,—that their number is not small; that they may be pointed to in every pursuit and every branch of human knowledge;—and it occurred to me some time ago, that it might not be useless on a fitting occasion, to describe some few careers which afford encouragement, and might induce to worthy efforts. When the heart of the striver sinks, when the world looks like a desert, and no pathway is visible; when energy has evaporated, and effort seems needless; then the recollection of what others have done, what difficulties they overcame, how bright a future they forged out of a dreary present,—how beautiful a tissue they wove out of tangled yarn,—has a value that can scarcely be estimated,—calls back the flitting powers, braces the mind, and encourages to fresh exertions."

Value of Perseverance.—"Is there a man reading these lines, who, recalling the cow-boy, the picker at the millinery, or the mender of clocks, uneducated and unprovided, will venture to say that his own opportunities and chances of progress are not as great as those of stout-hearted George Stephenson? "Do as I have done," he might say to those who complained to him of want of success,—persevere. Every step he made was conquered by patient labour and devotion to the work in hand, what is that might be? Take a lesson from him:—

Art thou poor? Does Fame pass by thee? Persevere: 'tis but to try thee."

Art and Manufacture.—"Flaxman was always proud of his early works in connection with Wedgwood. He is said to those who complained to him of want of success, his beautiful chessmen, or his exquisitely decorated cups, he was aiding in disseminating a taste and a love of the beautiful. It is to be hoped that the same will be the case with the article of domestic use which he obtained of tasteful designers: none the dearer because elegant, appropriate, and harmonious. To bring about, we wait, not merely educated art-workmen, but art-workmen, who will not act by vessels of beautiful form, or carpets of harmonious tints and possible truthful patterns, we may be sure that manufacturers will cease to produce such, and will content themselves with those works of questionable taste which command more favour."

Money Value of Art.—"The prices paid for specimens of pottery and porcelain afford striking instances of the power of art and opinion to confer value on mean materials. At Mr. Bernal's sale, one of Paisley's small dishes, 12 inches diameter, with a lizard in the centre, was sold for 162l. In the Ceramic Court of the Crystal Palace, a most interesting and important collection, there is a silver plate for which such a dish for which 1000l. have been offered. At one of the Government exhibitions at Gore House, two or three years ago, there were two small silver vases for which a dealer told me he would give 2,000l."

Soane and his Museum.—"Soane, the architect, born 1753, was the son of a bricklayer, at Reading. Poor and neglected, he came to London; and one of—

"The best spirits who go up to wood That terrible city whose neglect is death, Whose smile is fame."

He went into Dance's office as an errand-boy, but he worked his way—built the Bank of England—many structures for the government which Time's crasing fingers, helped by Sir John Soane, have spouted out,—became Sir John Soane; and, when he died in 1837, he left behind him, to say nothing of a fine fortune, a remarkable collection of books, prints, pictures, and antiquities for the benefit of the public. Whether this collection, boxed up in the house in Lincoln's-inn-fields, and approachable by tickets during a small part of the year, is made as available as it should be may be a question with some. It is certainly, however, no question with me, and I trust a long time will not elapse before a complete change in the management be made. It has, at present, all the silliness and repose of private property, and from year's end to year's end the books and folios remain closed."

The Scott Monument, Edinburgh.—"The ranks of the working masons would supply us with many examples of self-teaching and self-raising. George Mickle Kemp, who designed the Scott Monument in Edinburgh, was brought up an obscure carpenter, and impelled by his love for Gothic architecture became a working mason, getting employment, when he could, near an old building, so that he might measure and draw it. He worked his way all over Scotland and England, and in some foreign countries, and would walk a whole night to get a detail for his sketch-book, and this was not a chattering voice, for no one knew of his doings. When the Scott competition was advertised, he set himself to apply the knowledge he had acquired, and entered the lists without a friend. The design was submitted under the signature "John Murray," but, with a thoughtlessness that characterized him, he omitted to enclose his right name and address, so that for some time he remained ignorant of his selection, and the committee of him. Great was the surprise that followed when the author of the design was found to be a rough, self-taught man. Much controversy ensued; great anxiety for poor Kemp; then a triumph, and soon after an untimely death, which, but for a few common, but none the less fearful falling, had probably not occurred."

The lecture is published in a cheap form for distribution by such as may chance to think it likely to be useful.

Journal of the Bath and West of England Society for the Encouragement of Agriculture, Arts, Manufactures, and Commerce. Vol. viii. Part I. London: Ridgway, Piccadilly. 1860.

AMONGST the articles in this well get up Journal are reports on the exhibitions of arts, and of implements, live stock, &c., held at Barnstaple in June last. The Arts Exhibition appears to have been varied in detail, and attractive as a whole. In the fine arts department, which, together with a selection from the Brompton Museum, occupied the middle part of the building, were some drawings by Turner, "some of whose relations were living in Barnstaple as artisans, and came to look and wonder." The Arts Exhibition building was simply a wooden one, 100 feet long by 40 feet wide. The cost of the skeleton building, roof, and glass (the permanent property of the Society) was 250l.; and the hire of wooden flooring, sides, &c. cost 100l. There was also a canvas shed, 75 feet by 40 feet, hired for some 26l. to 30l., and other accommodations. The exhibition as a whole yielded a sum exceeding by more than 1,500l. any amount received at former meetings in the West of England.

The Journal under notice is in future to be issued in two semi-annual parts, instead of in one larger volume as heretofore.

Miscellanea.

A FREE LIBRARY FOR BIRMINGHAM.—It has been resolved by a large majority of a meeting of burghesses of the borough, called by the mayor, and held in the Townhall, to adopt the Free Libraries and Museums Act. There must have been about 1,500 persons present.

THE PROPOSED EXHIBITION OF 1862.—The council of the Society of Arts have begun to move in this matter. The guarantee deed for raising a sum of not less than 250,000l. on behalf of the Exhibition has been approved, and Earl Granville, the lord president of the council; the Marquis of Chandos; Mr. Thomas Baring, M.P.; Mr. C. Wentworth Dilke, and Mr. Thomas Fairbairn are made trustees of the fund. As far as the required amount is guaranteed, the intention and scope of the Exhibition must be made widely known, so that those who propose to take part in it may get to work. There is no time to lose.

BISHOP AUCKLAND TOWN-HALL COMPETITION.—We are informed that the first premium has been awarded to Mr. J. P. Jones. The design is Gothic in style.

THE IRONMONGERS' ASSOCIATION.—At a meeting, on the 24th February, a lecture was given by Mr. W. B. Tegetmeier, "On Lamps, their Chemistry and Construction," at 270, High Holborn.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—The first conversation of the season was held on Wednesday, February 29th, at the Gallery of the Architectural Photographic Association, Conduit-street, when Mr. G. Montague Davis, B.A., read a paper "On the Fine Arts, their Rise, Decline, and Present Aspect." And this was followed by a performance of vocal and instrumental music.

INSTITUTION OF NAVAL ARCHITECTS.—Meetings of this society are now being held in the Hall of the Society of Arts, Adelphi, Strand. On this Friday, March 2, there will be read at the evening meeting, papers "On an Improvement in the Form of Ships," by Mr. Joseph Maudslay; "On a Method of Constructing Diagonal-Built Ships," by Mr. J. White; and "On Certain Improvements in Marine Engines," by Mr. Robert Murray: and on Saturday morning, "On Mechanical Invention in Relation to Improvements in Naval Architecture," by Mr. N. Barnaby; and "On the Wave Line Theory, Part II.," by Mr. J. Scott Russell.

A WARNING.—A foreigner, who gives the name of John Bower, or Bauer, has for the last three years been living upon architects, by travelling from town to town and soliciting alms from them, upon the plea that he was formerly occupied in the drawing-office of the French sappers and miners, whence he deserted many years ago, and he has occasionally been employed in the offices of English architects; with the usual sequel that he has lately lost his wife, and been obliged to sell his instruments. On the 29th of February he was at Cambridge, on his way to London.—A. B.

THE SHEFFIELD TRADES UNION.—The "Association of Organized Trades of Sheffield and the Neighbourhood" have held their first public dinner at the Music-hall, Sheffield, under the presidency of the mayor; Mr. C. Beggshaw, the president of the association, occupying the vice-chair. Upwards of 400 persons partook of the repast. The after proceedings, which were protracted to a late hour, were enlivened by glee and songs. Much good sense (with an intermixture of less judicious material, however) was displayed in the speeches delivered in course of the evening. One speaker, the Rev. B. Herford, after referring to the vast power of the organization, and what it ought to do towards the promotion of education, the abolition of drunkenness, the payment of wages on Fridays, &c., went on to speak thus of the villainous doings which, as the mayor said, had made Sheffield an abhorrence and a disgrace to the nation. "As a friend and an outsider [we quote from the local Independent], he felt bound to tell them that the impression on numbers who would faint take their part—upon some who did take their part in spite of it,—was, that they did not always fight fair in Sheffield. There was sometimes kicking; and though they might each lay his hand upon his heart and say, 'I don't know who did it,' yet somebody did it; and it was done for the sake of the union. Those rattenings—that taking away—he would not call it stealing—of wheel-hands, was a silly trick. Then again, as they knew, there were worse things. He had been in Sheffield four years [the system was rampant at least fourteen years ago], and during that time those worse things had occurred, not only once, twice, thrice, nor simply half a dozen times. Those explosions, those assassinations—he did not speak of them as outrages; they were mean, dirty, un-English tricks, whoever they were done by. He did not say that unions, or union secretaries, could be held responsible for them, but he did say that unions could help them if they tried. If all the working men present at this meeting were to go away with the resolve to wipe this stain from their class; resolve that if they could catch a man who had done such a thing they would turn him out of their order altogether, would send him to Coventry, and have nothing to do with him; if they would look upon the thing in that way, these outrages would in a mysterious way cease. He wished to God it was so. Such proceedings cut away the ground from them (the middle-class men), who tried to defend unions; they made defence difficult because they were brought forward as the practices of unions. It was well enough known from what these arose, though it might not be known who did them."

**THE STATUE OF RICHARD CŒUR DE LION.**—Mr. Hankey asked the First Commissioner of Works in the House of Commons when the statue of Richard Cœur de Lion, by Baron Marochetti, for the erection of which a vote of 1,650, was granted last year, would be put up on the intended site. Mr. Cowper said that the delay had arisen in consequence of the difficulty of getting the granite pedestal out of the quarry. The statue was all ready except the pedestal, which would be ready within two months.

**MONUMENTAL.**—The committee of the Chester Memorial to Matthew Henry have completed arrangements for the erection of a polished granite obelisk. Mr. James Harrison, architect, has made the design, and will assist the committee in its erection. The obelisk will be 15 feet high, on a pedestal of the same, 2 feet 8 inches, and plinth 1 foot 6 inches, on a basement of steps 5 feet high, of Halkin limestone. The whole elevation will be 24 feet 2 inches; and, when completed, it will cost about 200l. The obelisk will be executed by Mr. A. McDonald, of Aberdeen.—The committee appointed, at Glasgow, for erecting a memorial window, to the late Professor Nichol, the astronomer, in the crypt of the cathedral, are sending proposals for estimates, it is said, to some of the most eminent designers in this country and abroad. The subscriptions have been limited to 1l. each. The treasurer to the fund is Mr. John Kerr, 14, Moore-place, Glasgow.

**BOROUGH SURVEYORSHIPS.**—The surveyor to the Worthing Local Board of Health (Mr. S. J. Smith), is said to have resigned his office.—We have received a suggestion, says the *Stockport Advertiser*, whether, on the appointment of a successor to the late Mr. Samuel Hunt, as borough surveyor, it would not be wise if the Town Council would select one for the whole borough, who could devote all his services to the office, and by which means a great deal of "petty jobbing" might be prevented, and money saved in the five townships, where there are as many district surveyors.

**GAS.**—The Liverpool Gas Company have just declared their usual maximum dividend of 10 per cent. per annum, for the half-year last past, free of income-tax. The continued increase of demand for gas has been met by an issue of 500 shares of 25l. for outlay.—The forty-sixth half-yearly meeting of the Cardiff Gas-Light and Coke Company has just been held, and a dividend at the rate of 10 per cent. on the old shares, and 8 per cent. on the new shares, declared.—From the "Report" of Dr. Lethely, the medical officer of health for the City of London, "On the Great Central Gas," it appears that this company's gas is 29 per cent. above the requirements of their Act of Parliament as respects average illuminating power; and that the chemical quality of the gas has been equally satisfactory as regards the absence of ammonia, sulphuretted hydrogen, and fetid raw water. During the last eight years, the report states, that illuminating power has been 25 per cent. above the standard, with an advantage of 11 per cent. in favour of the argand burner. The average chemical results are said to have been also favourable.

**SHORE TO SHORE TUNNEL, SCARBOROUGH.**—A scheme has been projected by Mr. Josiah Forster Fairbank, of Scarborough, civil engineer, for making a tunnel under the town, from the South Sands to the North Shore, and the scheme, with plans and sections, has been sanctioned by the local council. Mr. Fairbank stated to the council that he had entered into an arrangement with each of the owners of property under whose land the proposed tunnel is to be made. The engineering difficulties are not thought to be great, the nature of the strata being favourable for such an operation; and very little water is expected to be met with. The tunnel will be arched and lined with bricks from one end to the other. The length of the tunnel is 540 yards, while the distance over the hill to each end is 2,600 yards. It is not contemplated making a tunnel for horses and carriages, but only for foot passengers. The tunnel will be brilliantly lighted, and will be open all day, and about half-way there will be a daylight shaft, for ventilation, under which it is proposed to construct a stalactite cave, with rockery, and alpine plants. The probable cost of the undertaking will depend upon the size of the tunnel, but the engineer estimates it at from 6,000l. to 10,000l., according to size, which sum includes every expense. A company is to be formed under the Joint Stock Act, with limited liability, and it is thought probable that the work will be in progress during the coming summer season.

**THE SERPENTINE IN HYDE PARK.**—In the Commons Mr. Cowper has procured the appointment of a committee to consider the means of effectually cleansing the Serpentine.

**SCULPTURES OF ELEUSIS.**—The model of the newly-discovered sculptures of Eleusis, which have been placed in the Beaux Arts, is attracting crowds to view them. These sculptures were brought to light about a year ago, in digging the foundation of a school-house at Eleusis, and are thought to be the remains of the temple of Triptolemos, often mentioned by ancient writers as containing genuine specimens of classical sculpture.

**THE STRAND-BUILDINGS COMPANY.**—The committee of this company (for the erection of improved dwellings in Eagle-court, Strand) has just published their second report. The rents for the first half-year, ending at Christmas, 1858, amounted to 168l. 5s. 6d.; and they were during the past year, for the first half, 201l. 13s. 4d.; and for the last half, 225l. 18s. 9d. During last December all the sets of rooms were occupied, and the rental rose to 9l. 6s. a week. The efforts made to establish a laundry, washhouse, and baths had failed. The balance of income over the expenditure of the year, including arrears, amounted to 237l. 17s. 2d., of which 112l. 10s. had been distributed as dividend, at 4½ per cent. per annum to Midsummer, leaving 125l. 7s. 2d. for further dividend, at the same rate of interest.

**PURIFICATION OF THE THAMES AND THE SERPENTINE.**—Mr. C. M. Kottula, of Ely-place, Holborn, has patented (but offers without stipulation of fee or reward for purifying the Thames) the use of salt with which to increase the specific gravity of the fresh water in tidal rivers near towns in which the sewage is emptied into the river, the purpose being to cause the contaminated water to sink, and so pass off seaward, while it is replaced by clear sea-water. Whether Mr. Kottula has ever calculated how much salt it would require to salt the Thames we do not know, but we should fear it would be about as difficult to do so effectually to the end in view as to "set fire to the Thames." Still, even that is not an impossibility, if the old alchemist, Van Helmont, is to be believed; for he says that when Thames water is used on board of ships, it stinks in the tropics, and may then be set fire to, after which it becomes quite sweet and drinkable again! For the purification of the Serpentine Mr. Kottula proposes eighty tons of alum, which he says will sink a green matter to the bottom, and so freshen the water for many years.

**KETTERING CHURCH AGAIN STRUCK BY LIGHTNING: STILL NO LIGHTNING CONDUCTOR.**—On Sunday afternoon before last, as the congregation assembled at Kettering Church were engaged in Divine worship, the edifice was struck by lightning, and a scene ensued which will not be soon forgotten by those present. As they were on their knees repeating the General Thanksgiving, a mass of electric fire was seen to rush up the nave from below the western gallery, and a tremendous explosion was heard, resembling the report of artillery. Most of the people rushed simultaneously from their pews in frantic terror; some, who were too much excited to open the pew doors, climbing over the tops, and others, upsetting the forms with the school children, caused a general panic also among them. The confusion that ensued cannot be described. As the panic was at its height, a second flash, intensely vivid, followed instantly by loud and crackling thunder, added to the alarm. There was a great rush to the doors, and a frightful crush, and when egress was obtained, many fled through the storm, leaving their hats, cloaks, and other garments, behind. Most fortunately no one was seriously hurt. It was found that the spire had been struck near the second window on the west front, the mullion of which was driven in, and one of the pinnacles knocked off, as well as some other damage sustained. The chime wires were melted. Some of the stones forced from the spire fell into the bell chamber, and others outside the tower. It appears that the lightning ran down the stove piping near the western entrance into the church, the flue probably acting as a conductor, for want of a better one. Marks of its agency may be seen on the flue. This is the second time this spire has been struck by lightning within the past seven months. The *Northampton Herald* says it is now intended to provide an electric conductor; and full time too; had any lives been lost on this occasion, the churchwardens or other authorities of the church would have deserved trial and sentence for culpable homicide, in neglecting such a warning as the lightning stroke of last year: the want of a conductor still, betrays either gross carelessness or gross ignorance.

**NEW WESTMINSTER BRIDGE: HEINKE'S DIVING APPARATUS.**—Now that the new bridge is about to become partially available to the public, it is due to the ingenious apparatus of Mr. Heinke, of Portland-street, Portland-place, to state that all along it has been in successful use in doing the whole of the under water work. This same apparatus has been used in the demolition of Rochester-bridge, and Mr. Heinke was engaged by the Government to teach its use to the royal engineers for that and other purposes. One singular advantage of this apparatus appears to be that the life of the diver is not necessarily sacrificed by accidents to the apparatus, and the dress is used as an airholder, by means of which he can either ascend or descend at will, as, in fact, the fishes do by means of what is sometimes called "the swim."

**TENDERS**

For the erection of an additional wing and other works to the Tavistock Hotel, Covent-garden, for Messrs. Harrison & Co. Mr. Wm. Hunt, architect. Quantities supplied by Mr. R. L. Curtis:—

Nixon	£11,977	0	0
Brown & Robinson	11,924	0	0
Lawrence & Sons	11,891	0	0
Stoner	11,880	0	0
Hayward	11,492	0	0
Allen	10,960	0	0
Evans, Brothers	10,952	0	0

For new stables, &c., Over Lowey, near Bride-waters. Mr. H. Clutton, New Burlington-street, architect:—

Mansfield, London	£6,150	0	0
l'Anson, ditto	6,100	0	0
Myers, ditto	5,850	0	0
Polard, London	4,950	0	0
Pritchard, London	4,565	0	0

For Presbytery attached to St. Mary's Catholic Church, Leith, for the Rev. J. Noble. Mr. E. Welby Pugin, architect. Quantities supplied by Mr. Marples:—

Wells	£2,660	0	0
Kinghorn	2,437	0	0
Wilkie	2,370	0	0

For finishing three houses, Nos. 5, 6, and 7, Argyll-road, Kensington, for J. P. Shaw, esq. Mr. E. W. Crocker, architect:—

Macey	£1,129	0	0
Pritchard	1,065	0	0
Little	760	0	0

For the Abel Smith Memorial Schools, Hertford. Mr. John M. Hooker, architect:—

Coker, Ware	£1,665	0	0
Higgs & Barker, Dunstable	1,648	10	0
Rayment, Hertford	1,493	0	0
Collins, ditto	1,461	12	0
Ekins & Sons, ditto	1,447	0	0
Andrews, ditto	1,440	0	0
Kirkby, Henton	1,335	0	0
Brown, Ware, road	1,244	10	0
Pooley, Peterborough	1,240	0	0

**Morton Bagot Rectory.**

Hardwick & Son	£965	0	0
G. Street	965	0	0
Clark & Son	958	0	0
Wm. Grove	895	0	0
Thomas & Roberts	895	0	0
Wm. George	874	0	0
Messrs. Callaway	857	0	11
Hallan & Co.	850	0	0

**STR.**—We have received a letter from the architect explaining that our tender was not accepted because the rector was personally acquainted with Messrs. Callaway, builders, of his locality; but that otherwise our tender would readily have been accepted. Why did the rector advertise in a widely-circulated London paper for tenders? Why did he not limit his application to builders with whom he was personally acquainted, and so have saved the time and expenses of other competitors?  
HALLAN & CO.

For a dwelling-house at Newark for Mr. H. Hall. Mr. Alfred Allen, architect. Quantities supplied:—

Lane	£883	10	0
Mackenzie	834	10	0
Cooper	789	0	0
Henderson (accepted)	785	0	0

For building a storehouse and superintendent's rooms in Hyde-park for the Royal Humane Society:—

Lavers	£375	0	0
Nash	359	0	0
Tracey	330	0	0
Cassell	285	0	0

For re-erection of Star and Garter Tavern, Kensington-road, for Mr. John Compton. Mr. W. H. Heath, architect. Quantities supplied:—

	Each Stone.	Portland Stone, Extra for front.	Portland Stone, Extra for front.	Marble, Extra for front.		
	£ s. d.	£ s. d.	£ s. d.	£ s. d.		
Langridge	2,750	10	0	175	18	0
Lawrence	2,744	0	0	25	0	0

Smith (accepted)	2,250	0	0	20	0	0

# The Builder.

VOL. XVIII.—No. 892.

Art, not Style.

ALTHOUGH, according to Sir Charles Wood, it may be some time before the vexed subject of public for the new public offices is settled (the Indian department removing to the Victoria Hotel in June), it seems not improbable, that before many weeks have expired, the question will be again mooted in Parliament, what shall be the character of the building which must be erected for the Foreign Office. Regret how we may, that questions of art should find us continually unprepared for solution of them,—and, as in this case, in danger of a course that

ought, before the completion of the building, to be regretted,—there will be no means of longer giving off the decision in the case, unless the interests of at least one most important department of Government are to remain provided in a manner which, if the public have been fully informed, entails serious inconvenience and loss, national discredit, and expense which in many points of view needless, and is without justification as a constant recurrence. Wanting a building, therefore, the question is, whether the work is to be consigned to some speculative builder who, we will suppose, would house the department according to instructions from the Under-Secretary, but adding one of those so-called decorative features which, through similar agency, have formed the face of London and its suburbs with too much of ugliness; or whether the occasion is to be used, as every such occasion should, to substitute building also architecture, to thereby answer to what is an ever-felt and natural desire, to love of beauty and of art,—one which it approaches to criminality at any time to balk or to go unanswered,—and to perfect a work which, being that of the nation, shall be consistent with the national attainments in the present age, and up to the mark of those particular, existing somewhere, as proved in professional writing of the day, and by the executive skill of architects; by the knowledge that there is, at all events of certain examples; and which attainments were made manifest in the competition for the Government Offices,—as admitted; though it be understood generally, how much the management of that competition made it an adequate test. As straws that show which way the wind is blowing, we have before us a pamphlet and a book, that are as much coming from Anster and Boreas, whenever they meet. The blasts in this particular instance differ in quantity: by any test of mental effect, however, the impelling force, or logic, is not directly in proportion to the matter, or the volume.

Considering that the question of foundation

of style for the new building, is one on which much affecting a right decision may yet be said, it has been regretted that the question cannot be deferred for a year, or rather more, when there might be greater unanimity in the profession itself, if not amongst those who affect an interest in architectural art. We do not participate in the detraction of the merits of the Palace at Westminster; yet we think it possible that had the style or character for that building to be considered now, "instructions" very different would be issued to those of the competition in that case, which have brought into realization a work which is unsatisfactory to Gothicists, and which may not be equal to what its architect could have produced. As our readers are aware, however, we by no means hold, as to the Westminster Palace, that the building deserves the censure which it is just now the fashion to inflict upon it by a few amateurs of the Mediaeval way of thinking: its site may be had; its architect may have erred in the amount of ornament which he has given to the principal parts, or in the grouping of the building as a whole,—though here we should do right to take into account how far his judgment was subjected to distracting influences, as in the ventilation and other matters which have influenced the outline of the mass, including the towers; but the building, especially in its interior, has qualities of art that every considerable work of architecture should possess, and which seem by many of those who enter into the present discussion, to be held secondary in importance to the observance of a particular character of detail. Whatever it may be as Mediaeval or Gothic, the Palace at Westminster has features which are in every sense work of the art, and qualities which we should be glad to see recognized by some of those who are just now writing or talking about style. With such perception general, the selection for the Foreign Office of either groundwork, as compared with the other, would be of little moment; as, either way, the course taken by architects would soon merge into that best for future progress and future art. The question, however which, wanting the Office, we have to decide, is, how shall we, whilst the perception is lacking, best bridge over the interval between the present need, and the end, the higher character of all our future architecture? and, seeing there is no step, unless from the building of hints, to be taken without utilization of some previous gain or formation, shall we begin on this groundwork, or that other?

The advocates of a Mediaeval basis contend that "Italian" architecture is not English national, and that this is shown by the name, and that it was only a revival of what they call Pagan art; that it has never existed in this country but as an exotic, and is not suited to the climate; whilst Gothic architecture had its best development with us, and is associated with the recollection of Magna Charta, with some of the most interesting passages in our history, and with an age of faith and good deeds to which our money-getting propensities are in disadvantageous contrast; that if the Italian architecture be in possession of the field, it is worn out, and capable of no further expression, since it is bound by rules such as fetter the exercise of genius, whilst it is at variance with the complete attainment and expression of use in a building. Reject, therefore, they say, what is bad; go back and start again from the basis of a time when there existed what we regard as the best English architecture,—taking advantage of, however, and introducing all improvements that have been made since. The advocates of the existing basis which we call Classical would say, there is no style of architecture national by origin, more than there was, according to De Foe, the "true-born Englishman;" that styles of the principal countries of Europe started from Italy, and were then made by these countries their own,—somewhat as every style of architecture, unless the earliest, has had its precedent; that the question can only be between what is of the Teutonic family of nations, and what is European or universal;

that the "Revival" did not exist in fact, except in the general sense of revival of letters; as according to Michelet, it was more than the return to antique examples and to the forgotten forms of nature; and, whilst new liberty was given to the architect and painter, and a fresh development of art took place, it included the greatest of poets, jurists, and philosophers,—or if otherwise admitted of architecture at the commencement, that is to say, leaving out of consideration that the course in Italy, in some instances, had never been interrupted, the obloquy of such going back would be more fittingly applied to that reproduction of Mediaevalism which, if now repudiated by the more enlightened men of the present school, was the commencement of their career, and still characterizes their practice in church building,—that the term Christian art might better be confined to styles which are even of marked Roman origin, than to the Gothic styles which appear to have originated partly from, and in great part resemble, the Mahomedan; that the high-pitched roof is found in Italy in the Gothic, and in France and England in the Italian styles; that the pitch of roofs is governed as much by the material of the covering as anything else; and that there could have been no structural argument for a high pitch, involving great exposure to wind, where the covering was lead, and where there were parapets to retain the snow instead of preventing its lodgment; that the national greatness is rather to be dated from the time of Elizabeth, or the liberty from that of William III., than from the Middle Ages; and that in literature much is owing to Italy; that there is as much to recoil from as to admire in the annals of the Middle Ages, and more to be proud of than the reverse, in our present position; that the occupation of the field, by regular transmission, is a fact not to be altered or got over, since it is impossible to go back, unless by ignorance; that rules, "feters only to men of no genius," are needed to save us from that which is novel, but is nothing more; that symmetry is essential in a work of art, is accordant with the lesson of nature, and in plan of a building furthers even the use; and, in fine, that the low condition to which a style has been brought by ignorance or pedantry, is not a reason for saying it is worn out, but should be rather an inducement to turn to it and correct it through the study of other styles, and to add to it and invigorate it; thus bringing forth eventually new art by the line of action on which such art has been produced ever.

There is considerable difficulty, however, in setting forth the points of the controversy, because they are shifted from time to time, and we cannot exactly mark where issue is to be joined. Each army of disputants is divisible into two forces; and on the Mediaeval side it is hard to say whether most the Gothic revivalist embarrasses the progressionist, or whether the latter has convenient and imposing support from the appearance of the other at his heels. The author of the pamphlet asserts, with some reason, that this last is the case. He remarks that the Gothic style, properly so called, is already condemned even by its friends, as alike unsuited to the proposed building and the present age, being an idea associated only with the feudal system, with "the turbulence, ignorance, and cruelty" of the Middle Ages, the serfdom of the people, with faith which was but superstition, the dissoluteness of the clergy, and the reverse of all, of chivalry or religion, that is attributed to those times. The real question, therefore, he says, lies "not between Classic and true Gothic, but between Classic and a new imitation of Gothic," which, by confession of its advocates, is an infant groping its way,—

"... a state of the question which somewhat embarrasses the inquirer, and offers considerable advantages to the supporters of the new Gothic, by enlisting in its favour, under its name of Gothic, the admirers of that style, with a delusive promise of reviving it; eluding objections to Gothic by saying that the new style is not Gothic; and dexterously meeting criticisms on the violation of Gothic properties, by alleging that the nineteenth century Gothic is exempted

Remarks on a National Style in Reference to the proposed Foreign Office." 8vo., pp. 48; Bell & Daldy.  
Pagan or Christian? or, Notes for the General Public on our National Architecture," by W. J. Cockburn Muir, pp. xii., 289; Bentley.

from observing them, or that such and such details are not essential to the new style.

"Quo tenam vultus mutatem Protea nodo?"

It is Gothic for some purposes, and not Gothic for others, according as it suits the turn."

Though "the real Gothic" is thus, he says, not directly in question, the qualities and associations claimed for it afford the countenance to the infant Gothic which, deprived of that countenance, would be "a helpless bantling," and "would speedily perish by sheer neglect. It is, therefore, quite necessary and right to consider the claims of the real Gothic, for these are, in fact, the only claims of the mock Gothic," &c. The aim of the pamphlet, therefore, is to show that an assertion that Gothic architecture "is emphatically and pre-eminently the national architecture of England," is, in the ordinary sense of the words, "manifestly untrue," and that "any prejudice in favour of a style, arising from the fact of its being our national style, ought to be entirely on the side of the already domesticated Revived Italian, or some modification of it." He speaks of the change in sentiment, modes of thought, manners, tastes, and habits, wrought in the interval between this century and the thirteenth, and following the writer of a letter in the *Times* (November 1st, 1859), signed "A," says that the argument of nationality is worthless, through the fact that the style was the product also of other nations, and very different to our own; and therefore it had origin in circumstances common to all, namely, the feudal organization,—a position which Mr. Scott, in one of the lectures reported by us, adverted to, but did not answer. "A revived Gothic architecture, therefore, so far as the new style preserves the characteristics of the old, must be, in modern England, no longer the national, but both an exotic style and an anachronism," &c. "Nor is there," he says, "such a general feeling or taste for Gothic as to entitle it to be called National, even in a limited sense." The effort to revive it, great and earnest though it be, is made by a limited party, not agreeing as to nature and extent of the revival.

"It is popular with a portion of the more highly educated members of the Church, including the clergy, and that more numerous and enthusiastic class, the members of diocesan architectural societies, who, debarred of the opportunity of studying other than Medieval antiquities, have naturally been led to exaggerate the merits, and palliate the defects of the exclusive object of their attention; but it is discountenanced by the great body of our artists, architects, and men of taste, the influence of whose opinion is deservedly great, and is entirely disregarded by the mass of the people, if we are to judge by the aspect of our terraces and streets, of our manufactories, warehouses, docks, bridges—even ships; of those engineering works whose practical effectiveness, simplicity, and freedom from any littleness of aspect or purpose, recall to mind the monuments of Roman greatness, and even suggest a comparison between that people and the English nation."

To these instances of the exclusion of the Gothic should be added, also, fittings and furniture, porcelain and glass in common use, and jewellery and dress. Of the discordance noticeable even at the Houses of Parliament, where the greatest effort has been made to secure the reverse, we have spoken on previous occasions, and we should find the like in the houses and the studios of those who are our Gothic architects. How far are these circumstances to be taken as showing that Gothic and the national bent are opposed to one another? How far is that which is Gothic revived needlessly for the end of art, and operating to delay the general appreciation of the art, which are the chief aims, or should be so, of the practice of architecture?

Having shown how little claim there is to the title exclusively of Christian architecture, and remarking that the cell of the temple is reproduced in the chancel or sacrament of the church, the author adverts to that general progress which has been contemporary with the revived Classical style. He repudiates, however, any support from other sources than intrinsic merits, though he attributes the Gothic movement to an illusive view of the Middle

Ages. On the question of merits, he shows that the picturesque is not the exclusive property of the Gothic, since it may be doubted whether, in its highest degree, it is not rather to be found in the combinations of the severest Greek. The failure in the revival of the old Gothic, as confessed by the introduction of a different manner in the design for the Foreign Office, is attributable chiefly to the difference of feeling and circumstances between that time and this; and it is to be regretted that the attempt has been so extensively made in modern church buildings. The circumstances under which the revival commenced in church architecture, are to be explained; and the movement was greatly fostered by that in the church, towards what are sometimes called Anglo-Romanist doctrines. Significance was imparted to matters which had previously been left to the province of taste. Thus the depth of a chancel was regarded as affording a just estimate of its builder's piety.

But assuming the attempt at revival to be abandoned, and the necessity for new Gothic to be admitted, Mr. Scott, says the author, has not met the demand for a new style, his design having been condemned by persons who have intimate knowledge of old Gothic. Here we must interpose, and say the design has probably suffered through attempt to show the fertility and freedom of the style. But, qualities admirable in the old Gothic are unsuited to the present age, and no substitute for them is yet afforded in the new style. The "attempt to combine the sash with the tracery window, is sure to be unsatisfactory." Strip Gothic architecture of its mullions, and generally of its faults, excrescences, and elements of detail, to form the new style, and there will remain a mere carcass. Why not, therefore, he says, instead of this mutilated style, adopt and work upon the Classic, already perfectly adapted to modern civilization, whilst the Gothic is not in harmony. "It is a mistake," he continues, "to suppose that the Classic style prohibits any other than a flat roof." The roof was an architectural feature both in Greek and Roman temples. In many churches of the Renaissance, the pitch of the roof equals that in the Romanesque. The Mansard roof is well known, and Sir Christopher Wren's roofs were generally of high pitch. The omission in recent times to make the roof a feature, is not chargeable to the spirit or principle of Classic architecture. Regarding symmetry, this is essential in Classic and Gothic,—the author of the pamphlet says, in an equal degree. Readers of the *Builder* will discover much in these views that is identical with our own.

It is to be remarked that most of them coincide with those expressed by Mr. Scott himself in one of his lectures this year at the Royal Academy, already referred to. That lecture, in fact, expresses no more than would be said by those who believe that the nearest way to what can be the only object, namely, the general practice of art in architecture, is first through the prevailing or the classic medium. But it is time that we looked into the volume, before alluded to.

We cannot but think there is reason for the regret of the author of "Pagan or Christian?" for the "little time" which he was able to devote to his "hurried pages," and which did not permit him to "bestow more thought on so essential a point" as the definition of Gothic architecture. Seeing that this is the only thing needed at the moment,—the definition of what is peculiar to, and characteristic of Gothic, and what is rather characteristic of all good architecture,—a book which, from the cause mentioned, puts forward apocryph in lieu of the definition satisfactory to the writer's mind, is not likely to be otherwise than injurious. There is much, it may be allowed, in the book, which, far from condemning, we recognize as in advance of popular views; the main argument, however, by which the author seeks to show that what he calls the national style and Christian architecture, is alone possessed of elements of further development, and that the Gothic (though the "English Gothic" rather than the manner of Mr. Scott's design) alone fitted to be used for the Government offices, is erroneous, and would lead to results which

the author is unable to foresee. The book not more appears to be "contradictory;" it is full of contradictions,—to the facts in history itself, and to statements and reasonings in the book itself, which would suffice to upset the last generalizations that are made. The imitation of Mr. Ruskin's manner is observable throughout, and with the ill effects which might be predicted,—although it is seven years since the author read any portion of "The Stones of Venice." Noting the contents of the book, we find they are divided under the heads,—"Introductory," "Faith," "Reminiscences," "Moorish Episode," "Pagan?" and "Christian?" Without pausing to expose half the mistakes that are made, we may say he states that the object of the "Notes" is "to evolve certain facts in the psychology of architecture, which may serve to conduct the mind of the untechnical public towards definite conclusions on the general controversy between the advocates of different architectural styles;" and in the course of the Introduction he does not escape the mistake of treating leniently the "reproductions" of Medievalism, whilst speaking of "flunkeylike conformity" to patterns of another character of style, or the fashion of calling the Houses of Parliament "that ornate blunder." The prejudice of the writer, also, is shown by his assertion of "the fact," that "we are so given up to the getting of gold, and the worship of it," that the cultivation of taste is not even thought of. He returns in the course of the last chapter to the inquiry, "How are we to conceive of this cotton-hestridden nation ever awakening to the amenities of art?" having just then forgotten how great is the diffusion of art, according to the painters and sculptors, which results from the money-getting; and his own reference to an example, though not the best he might have found, of the warehouse architecture of the north of England, which usually is in a style of modified Italian. Next, he endeavours to show that the artists of the Pagan time had only "the intellectual belief," and not the loving faith in art which animated "the artists of the Mid-Christian time;" and that the Italian artists relapsed into the scepticism of the Roman. In the "Reminiscences" and the following chapter, he reviews the characteristics, or as he states them, of the leading styles,—adverting to the pitch of the roof, and to the quantity of flat surface, which latter, he says, taking little notice of the pediments of the Parthenon, increases as we go southward. In the same chapter he speaks of the Conquest as the commencement of proper English history, saying there was no art prior to that time. He says the picture of vices in the Middle Ages is, as to the early period, "simply untrue," and judging from his words, the character of Front-de-Bœuf would be a very erroneous illustration. He "cannot think we outshine the old men in realness," and proceeds to show this by referring to the naturalistic ornament of their architecture. After endeavouring to prove that Gothic architecture had its earliest development in this country, and that English art kept constantly ahead of its cognate species in the rest of Europe, he finds that Englishmen of the early Medieval period had the three prominent attributes,—Religiosity; Realness arising out of that; and Love of Nature, akin to both." In proof of the first, he mentions the verticillity of architectural composition. He also adverts to reduction of the amount of flat surface. He mentions the number of years occupied in building cathedrals, as though this were a merit. Defining ornament as "structural" and "accessory," and saying that the claim to high art is in proportion to the prevalence of the former, he treats the columns of a Greek temple as accessory,—whilst they rather were "the virtual building." He also contrasts what he calls the Grecian Hecatombædonism, with the non-mechanical character of the Gothic,—a favourite line of argument with non-professional writers, and strangely at variance with what is recognized by those who seek to discover the system of proportion in the Medieval structures. To say that there was no idea of proportion at all, in the Gothic

architecture,—which alone can be the meaning of the contrast drawn,—would, indeed, be the condemnation of the style. Mr. Mit's grouping of Sculpture, Painting, and Poetry, as *Imitative*, or *Descriptive Arts*, and Music and Architecture as *Ideal Arts*, and his description of Architecture as the Idealization of External Nature, are correct, except that as to the first three, the common meaning of "Imitative" fails to convey that there is art; but his reference to the Gothic cathedral interior, as resembling the avenue of trees, whilst the Greek peripteral temple is like nothing in nature, displays as much misconception of the relation of art to nature, as does his reference to the non-uniformity of the landscape as in favour of inattention to balance of parts in a composition. Respecting the nationality, he endeavours to controvert the assertion of Lord Palmerston, that the Gothic was not an English style, but "was imported from abroad,"—not noticing such evidence as that of Gervase, of the employment of William of Sens at Canterbury Cathedral, and whilst speaking of the proneness of public men to hazard assertions without examining facts asavouring of "pervading untruthfulness," quoting passages from certain lectures and papers which prove nothing as to the point in question. From Mr. Scott, he would differ on matters of the greatest importance; but to these and other matters we must refer hereafter.

#### ON BUILDING-STONES—THE CAUSES OF THEIR DECAY, AND THE MEANS OF PREVENTING IT.\*

THE Portland oolite is the material which is most frequently used for the higher class of buildings in London, and which certainly has stood the action of time and atmospheric changes more satisfactorily than other stone introduced on a large scale. It is, as its name implies, obtained from the upper members of the oolitic series in the island of Portland, at least for the London market, but there are outlying patches of the same formation at Upway, near Weymouth, and near Fishery, in Wiltshire, which might be rendered serviceable, now that the railway communication with those parts of England has been so much improved. The colour of the Portland stone is at first of a rather cold chalky white, and indeed it is always rather objectionable, though the rapid accumulation of soot which takes place in London renders the consideration of colour one of very minor importance. Blocks of any required dimension can be obtained from the Portland quarries, and the stone is hard, dense, usually free from shakes or vents of a serious character, and yet it is easily worked either by the chisel or the plate-saw. The ordinary weight of a foot cube of this material is 147 lbs., and the load it would bear is stated to be about 3,297 lbs. per inch superficial. The upper beds of the quarries are used in some public works, under the name of "roach;" they are specifically lighter than the common beds, very full of fossil shells, and have a distinctly oolitic character, and from the more perfectly crystallized character of the carbonate of lime, which forms the cementing material of the mass, they are better fitted to resist deteriorations of dryness and moisture. It is for these reasons that the Portland roach is so extensively used in docks, piers, or other hydraulic works. The weight of the foot cube is about 127 lbs. The stone obtained from the eastern side of the island of Portland is very inferior in quality to that obtained from the western side, a fact of which the architects of the time of Sir C. Wren seem to have been aware, but which did not seem to have attracted the attention of their successors of some thirty years since; for the stone used in St. Paul's, the City churches, Somerset House, &c., was stated remarkably well; whilst that used in the gates and screen of Hyde and Green Parks is now decayed. The former was obtained from what is locally called the West Cliff quarries, the latter from the East Cliff, or near the extremity of the island.

The Bath stone is obtained, as its name implies, from one of the members of the great oolite in the neighbourhood of Bath. In colour this material is more agreeable than the Portland stone, and its texture is very similar, but it is softer (so much so, indeed, as to allow of its being worked with the tooth-saw), and more absorbent; and,

therefore, unless precautions are observed in the manner of using the Bath stone, it is exposed to rapid decay. Some very painful illustrations of this fact may be witnessed about London, and, amongst others, the restoration of Henry VII.'s chapel may especially be cited. The weight of the foot cube of Bath stone is about 123 lbs., and the load it will bear before crushing is estimated to be 1,800 to 2,000 lbs. per inch superficial.

The Caen stone is obtained from the great oolite of Normandy, near the town of that name, and is much used in building operations in London, on account of the beauty of its grain and colour, and of the ease with which it is capable of being worked; for when freshly quarried, the Caen stone can be cut with the toothed saw, and carved with ordinary carpenters' chisels, even more easily than the Bath stone itself. The upper beds of the quarries near Caen yields stone of small dimensions, but of a much more durable nature than those furnished by the lower beds. Unfortunately, however, the requirements of architects have induced the stone merchants to abandon of late years the material of superior quality, in order to secure the large blocks so universally called for; and thus the reputation of the Caen stone has rather unjustly suffered. But it is perhaps advisable here to remark, that in the public buildings of the town of Caen, the local material is not usually employed in positions where it would be exposed to the rainfall, or be able to absorb water by capillary attraction, and that the basements, or the exposed pinnacles, towers, or steeples, are built of other and more resisting stones. The weight of the Caen stone is about 120 lbs. per foot cube, and its crushing weight about 2,000 lbs. per inch superficial.

In addition to the Caen stone, the oolite of Normandy supplies the London market with a material of great beauty, known by the name of the Aubigny stone, which is harder, finer in its grain, more crystalline in its structure, and able to support a greater crushing weight than the Caen stone. From the fearful state of decay of the mediæval buildings of Falaise, the town in immediate proximity to the Aubigny quarries, it may, however, be suspected that this material would not be of a durable character, notwithstanding the fact that the supply is now obtained from different beds to those formerly worked. But there are other stones to be worked in Normandy, which might furnish our builders with extremely valuable resources, such as the Ranville, Fontaine Henri, Creully, Coursulles, and Quilly stones; but, unfortunately, they are little known amongst us, and the prejudice against the use of Caen stone (in consequence of its failure when injudiciously employed in such buildings as Buckingham Palace, Mr. Hope's mansion, &c.), has extended to the whole group of Norman stone.

All these varieties lately mentioned as coming from the oolitic series, are characterized by the remarkable purity of the carbonate of lime which constitutes the basis of the stones. The carbonate is often sub-crystalline, and generally speaking assembled in minute globules, similar to the roe of fishes, from whence the formation derives its name. Many shells, and vegetable and animal remains occur in some of the varieties, and they give rise to some peculiar and hitherto unexplained conditions of durability in the stones. Thus, when the test of the shells has been replaced by the decidedly crystalline carbonate of lime, they assume a remarkable degree of hardness, and if present in sufficient numbers they communicate great powers of resistance, as in the case of the Barnack, and the Roach Portland; but this influence of the shells may be imperceptible if the cementing material should happen to be of an earthy, or of a soluble character, and if much organic matter should be present, it would allow the formation of certain salts when the stone is exposed to air and moisture, which would seriously endanger its cohesion. The fossils also tend to define and separate their beds, and thus to render it more than usually necessary to pay attention to the practical law, that "stones should always be used bedwise;" and here it may be advisable to remark that whenever the materials of a stone have not been affected by their proximity to any source of igneous action, they will not admit of the stones being used in false bedding, although some varieties of the Jurassic limestone, or of the tertiary deposits of the Paris basin, are occasionally used in such positions without any immediate or apparent risk. Nearly all the oolites yield a pure rich lime, of great service in agriculture, but of little real value in building operations (on account of the solubility of the lime), unless mixed with some form of soluble silica. The blue lias lime, which contains a large proportion of the silicate of

alumina, is, however, much used for hydraulic works.

The Purbeck limestones were formerly much used in London for paving footpaths, and some varieties were worked for sinks, troughs, or cisterns, under the name of the Purbeck Portland, but the irregularity of hardness, and the small dimensions of the Purbeck flags have led to its almost universal abandonment in favour of the harder and more uniform Yorksire stones. The Purbeck and Petworth marbles (which are composed of an agglomeration of freshwater univalve and bivalve shells, united by a crystalline carbonate of lime, of a pleasant green colour, and some considerable beauty) were formerly much used in ecclesiastical decoration, and when placed bedwise they have resisted the action of time very satisfactorily, provided always that the earthy variety had not been used. Some of the shales of the Wealden series are occasionally used to cover the roofs of buildings in Sussex, but their weight, and their very irregular texture, oppose their general application at a distance from the quarries.

Now, the conditions under which the stones above described decay, when they are placed in a building, are partially mechanical and partially chemical. Of the former, the most important are, first, the dissolving properties of atmospheric moisture, in its various forms of rain or mist; secondly, the disintegrating action of changes in atmospheric temperature. Of the latter, the most important are, first, the chemical reactions which take place in the ingredients of the stones themselves; and, secondly, the new forms of matter which are superinduced from without, of a nature to affect the stability of the original combination.

The dissolving power of atmospheric moisture seems to depend greatly upon the quantity of free carbonic acid gas it holds in solution, and though this quantity in any given volume of water be extremely minute, in course of time every substance which has an affinity for it will yield more or less to its action. The silicates of potash and soda, for instance, which are present in the igneous rocks (or, to dwell especially on the class of materials under our notice, in the Devonshire granites), are easily decomposed when rain-water falls upon them; and, being removed mechanically by any of the countless actions of nature, they leave the other ingredients of the material exposed to the mechanical disintegration of changes of temperature. The simple carbonates of lime, again, sometimes absorb carbonic acid with much avidity, and pass into the state of the soluble bicarbonates, and, thus, in proportion as the original face of a stone is removed does the lower surface become exposed to the action of the rain. The rain-water of such a town as London not only does contain large quantities of free carbonic acid, but it also contains sulphuric acid and ammonia, which are capable of exercising a very deleterious influence upon the carbonates of lime. In discussing, however, the effect of these agents upon building stones, it is essential to bear in mind the fact that the mechanical state of the elements of those materials greatly modifies their resistance. Those which are of a crystalline character do not yield so readily as those which are amorphous, and the crystallisation produced by volcanic or plutonic influence appears to be even more permanent than that which takes place in the ordinary way.

It follows from these considerations that the stones of an irregular, confused, earthy texture (which are able to absorb considerable quantities of moisture, and which contain silica in a soluble form, or the carbonate of lime), should never be employed in positions where rain water could lodge upon, beat against, or be taken up from external sources by capillarity, or any other action. In positions exposed to any of the above dangers, none but non-absorbent and decidedly crystalline materials should be used, and as those qualities are almost exclusively possessed by dense stones, it may be considered that the mere specific gravity of a stone is a *prima facie* indication of its constructive value.

But atmospheric moisture, when absorbed into building stones, acts upon them quite as much through the changes in its own volume, in passing from the liquid to the solid state at the time of frost, as it does by the chemical dissolution it produces. If the stones should be placed in such a manner as that water should accumulate in any perceptible quantities between its various layers, and if the position of those layers be such that the expansion of the water in freezing cannot take place freely, the respective layers containing the water will be violently detached from one another. Now, all stones, even the crystalline limestones and slates, have certain planes, or directions of cleavage, or of stratification, along which water

\* See page 132, ante.

flows more readily than in any other course. If the stones be placed in a building with those planes in a direction likely to retain rain falling upon, or absorbed through, the surface (which is the case when stones are placed "bed to weather"), disintegration must ensue, unless the edges of the beds be left free; and even in that case there is danger of frost detaching one layer from another. It is indeed a primary law of construction that every stone should be laid "bedwise," and few modern theories have produced so much practical mischief as the one lately propounded, that "it was a matter of little importance in what direction of the bed a stone was laid." Fortunately, even unpractised eyes can detect the bedding of the majority of the London building stones, either from the position of the fossils, or the variety of texture, or of colour; in the less distinctly marked stones even, practised eyes can detect the planes of cleavage, and a good workman will hardly ever be mistaken in his judgment. It is unfortunate that the modern system of competition throws so great a temptation in the way of the practical builder, as to render it a mere matter of chance whether the constructive law, above mentioned, be observed or not, unless a costly system of supervision be organized, and thus the precautions often taken by the stone merchant, to indicate the upper bed of the material he delivers, are defeated.

In the stones which present distinct traces of bedding it often happens that a difference of the chemical, and even of the mechanical structure may be observed to exist in the respective layers about the lines of separation: under such circumstances, when the stones are laid bedwise, it is by no means rare to see the softer parts, near the lines of bedding, removed to a considerable depth from the surface. This action may be observed, amongst other instances, in the Purbeck marble of the pillars of Westminster Abbey, and quite in the protected parts of the building. It would seem that, in this particular case, the more earthy particles upon the planes of bedding are decomposed by the action of the moisture they absorb from the vapours suspended in the atmosphere, and that the cohesion of the various particles being thus destroyed, they gradually fall away. Westminster Abbey furnishes also numerous illustrations of the danger of placing stones, of whatsoever description they may be, in any other than the natural bed, for even a glance at the sheltered parts of the north transept, in the chancelyard, would enable anyone to detect, by their conditions of decay, the stones which have been laid well or ill.

The chemical reactions which take place in building stones, other than those resulting, in the interior of the country, from the agents directly presented by atmospheric moisture in the form of carbonic acid gas, sulphur, and ammonia, or upon the sea-shore, in the form of hydrochloric acid, or of common salt itself, in minute particles, are mainly those arising from the oxygenation, or the hydration of the various ingredients of which those stones are composed. Thus, if the oxide of iron be present in any notable proportions, it is likely to undergo changes of a nature to disturb the stability of the compound, and even the crystalline sulphates of lime are exposed to chemical decomposition, in consequence of the liberation of the sulphuric acid gas they contain. The other mineral salts, such as the silicates and the sulphates of iron, so often met with in building stones, are at times susceptible of very injurious decomposition, and the soda, potassa, or the organic matters the stones may contain, as frequently give rise to the formation of new salts; mainly under the action of the atmospheric moisture it is true, but also under the influence of the partial decompositions which take place around them. It is to be observed, however, that the danger to building stones from this peculiar class of actions, is very small and very slow in its action, compared with the dangers arising from the mechanical disintegration produced by atmospheric causes; and that, with the exceptions of the action of free carbonic acid upon the felspar of granites, of the changes of state produced in limestones by the same agent, and the modifications of the abundant salts of iron in some peculiar stones, there is little practical necessity for dwelling upon this interesting but obscure branch of applied chemistry.

The actions sufficient to affect the stability of the composition of ordinary building stones, by reason of the new forms of matter they superimpose, may principally be considered to be those resulting from the absorption of the gases of the atmosphere, and especially the extraordinary process known by the name of "saltpetering;" or, more correctly speaking, of nitrification. This

process displays itself in the formation of minute crystals, efflorescing from the interior to the exterior of the stone, and it leads to the destruction of the exposed surfaces of the latter, through the gradual removal of the minute particles, in consequence of the disintegration produced by the passive action of the crystals in process of formation. It is supposed that the organic matter diffused through nearly all stratified deposits gives rise to the formation of certain nitrates (such as the nitrate of lime, or the nitrate of soda), under the influence of damp, and of air, and of light of certain descriptions; for nitrification certainly takes place most abundantly near damp ground, rising in a wall *pari passu* with the range of the capillary attractions of its materials, and upon the northern or shaded faces of the said walls. Not only does this nitrification throw off the minutest and less adherent particles of the building materials themselves, whether they be stone or brick, but it is also able to detach any protecting coat which may be put upon them, if the adhesion of that coat to the adjacent material should not be of a very energetic nature. Let the adhesion, however, be ever so energetic, if once the action of nitrification should have been established, it must run its course, and the amount of evil it is capable of producing will simply depend upon the quantity of organic matter originally contained in the materials, or susceptible of being absorbed by them from the atmosphere. The secondary limestones which have not been affected by plutonic action,—the loamy clays, some kinds of pit sand, sea sand, and some descriptions of natural cements,—are particularly exposed to the danger of nitrification in damp positions; and, whenever it is once established, it is in vain to expect to be able to preserve any mural painting, or even a sculpture of a delicate character. Dumas and the French chemists appear to consider that the atmosphere itself would be capable of furnishing the nitrogen required for the production of the effect under consideration; but there is hardly any occasion to resort to so extreme a supposition, when we reflect upon the extraordinary diffusion of the remains of animal life in stratified deposits. It is also to be remarked that nitrification will frequently take place in the most dangerous manner precisely in those materials whose exposed surfaces are covered with coatings impervious to the air, and that in houses or buildings of that character it is most energetic on the interior faces of the walls, or precisely on those which are least exposed to the atmosphere. In fact, it is mainly in consequence of the absorption of moisture by the building materials, and of the chemical changes thus produced in the organic matter those materials may contain, that the peculiar form of decay which accompanies "saltpetering" arises.

Practically, then, the great agent of destruction of building stones, in any of its modes of exhibition, is the damp, or the water supplied by the atmosphere, either directly or indirectly, and the efforts of those parties who seek to prevent this destruction must be directed to combating this primary source of evil. Fortunately, the precautions to be observed for this purpose are very simple, and they only require a little common sense on the part of the builders charged with their application to the materials at least which have been long before the public.

The first and foremost rule is never to employ a porous absorbent stone in the ground, or in elevation, unless, in the former case, it be maintained constantly wet; or unless, in the second, the absorption of moisture from the ground be prevented by the interposition of some impermeable material. Stones of the description just mentioned should never be employed for the copings, parapets, window-cills, weather beds of the cornices, plinths, strings, or other parts of a building where water may lodge. Care must also be taken to bed such stones with mortars which are not exposed to develop in themselves, or likely to excite in the stones the efflorescence of any of the nitrates of soda, potassa, or of lime. If porous or absorbent building stones must, however, be used in exposed positions, and no efficient precautions be taken to prevent their decay, it will be found that the decay will commence, and be most apparent in the zone of alternate dryness and humidity, or, as the workmen say, "between wind and water." The stone work about that zone should, therefore, be executed in such a manner as to allow of its being easily replaced, if requisite, and in case the exhibition of the decay should take place inwardly, care must be taken to isolate the surfaces which are likely to be covered by efflorescence. These precautions are, after all, only very unsatisfactory palliations of an evil which

ought never to exist; and it is therefore, advisable to direct the attention of our English builders to the practice of their French neighbours, who use different stones according to their position in a building. In Caen itself, for instance, the plinths or basements of houses are executed in granite, or in the Ranville Chereux, or Creully stones, which are practically non-absorbent; and moreover, in the best buildings the Creully stone is used for the exposed parts of the elevation although the Caen stone is found at the very base of the town.

But even when every precaution has been taken to prevent the absorption of moisture from the ground, or the actual rainfall, it is necessary to protect the exposed surfaces of the soft and absorbent, or, to use a technical phrase, of the hygroscopic stones, by some coating which shall prevent their taking up the injurious moisture from the air. This is done in various ways. 1. By painting. 2. By impregnating the expressed surface with oleaginous or fatty matters. 3. By washing the face with some solution able to convert the material itself into an insoluble non-absorbent substance. 4. By filling in the pores of the stones with an insoluble material which should effectually exclude water.

1st. The objection to oil paints consists in the facts that in proportion as the oils which serve as their vehicles evaporate, the particles of the stone they originally protected become again exposed, and even the absorbent powers of the stone itself contribute to this action. It, therefore, becomes necessary to repeat the painting frequently, and thus, in the end, the delicacy of any mouldings or carving must be effaced. The unequal rates of expansion of the stone and of the oil paints in time of frost tend to increase the danger of irregular and unequal exposure above attributed to the evaporation of the oil.

2nd. As to the injection of oleaginous, fatty, or waxy matters, it must be evident that it likewise can only act mechanically by closing the pores of the stones; and, therefore, although instances may be cited in which when the surface so protected is maintained at a constant moderate temperature, the system of injecting those materials has succeeded; yet, if the protected surfaces be exposed to extremes of heat and cold, the heterogeneous materials thus affected must be acted upon in very different manners. Experience has confirmed this theoretical inference, and it has been found in practice that the protecting coats of any of the materials alluded to are gradually detached from the stone, and that they require to be renewed quite as frequently as oil painting itself does, when used on the exterior of buildings.

3rd. One of the most successful attempts yet made to prevent the decay of soft building-stones, by washing their exposed faces with a fluid able to affect their nature, is the process lately introduced by M. Kuhlmann, in which the carbonates of lime are washed with a solution of an alkaline silicate, with a view to converting them into silicates of lime, through the elective affinities of the lime and the silica. In some cases this ingenious and beautiful system has succeeded, and very great hardness, very resisting powers, have been communicated to the stones operated upon. But, unfortunately, the action of the silicic acid is a very slow one; and when the surfaces washed in the manner described are exposed to rain, it is by no means rare to find that the solution is carried away. There is another very serious objection to the use of the simple alkaline silicates, namely, that when they do act upon the subject stone, the soda and potassa (which are generally used) are left free, and in efflorescing, they are likely to moulding; at the same time, as they form, to some extent, deliquescent salts upon the face of the stone, they attract to it a dangerous amount of humidity.

4th. The problem of protecting the surface of a soft building stone, after every precaution had been taken, to be observed, to prevent the internal absorption of moisture, seems to me to have been the most successfully solved by Ransome's last patent process. In this process, a fine precipitate, clothing the whole of the pores of the surface of the stone, is produced by firstly cleaning the stone carefully from dust, or other extraneous matters; then the stone is made to absorb as large a quantity as possible of the silicate of soda or of potassa, and when this solution has dried into the stone, a second wash is applied, consisting of the chloride of calcium or of haryta. In practice, Mr. Ransome uses the most frequently the silicate of soda and the chloride of calcium; and the effect of the respective applications is, that a double decomposition takes place in the washes, giving

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

## BUILDING AND THE BIBLE.

rise to the precipitation of a finely crystallized silicate of lime or of baryta in the pores of the stone, and an efflorescence of extremely soluble salts of the chlorides of soda or of potassa. The former remain in the pores, the latter are speedily washed away by rain. As the rate of contraction and expansion of the silicate of lime is, as nearly as may be, the same as that of the stones it is intended to protect, there is no danger of the precipitate being detached by this cause. It may be added that Kuhlmann's process is only applicable to the preservation of the carbonates of lime, whilst Ransome's process is equally applicable to that class of materials, or to the sandstones, or even to bricks, or plaster, or cement. It was precisely to this process also that I referred when speaking of the use of chalk as a building material, and I am convinced that, by its application, that abundant and economical substance might be very advantageously applied to our daily wants.

Perhaps it is going a little beyond our immediate subject, but I cannot refrain from saying that the principle of the double decomposition, applied by Ransome to stones, might be applied to the precipitation of a soluble glass upon woods or textile substances, and even to the protection of timber from the attacks of the boring worms.

Finally, I repeat what I have said elsewhere, namely, that the common sense of the whole matter is to use only such stones as have been proved by secular experience in the locality of the building to be little exposed to decay. I use the term "secular experience," because the Commission appointed to select the building stone for the Houses of Parliament (which Commission cost the country 11,000*l.* for its report, and, perhaps, 60,000*l.* extra on the price of the labour of the building), recommended an untried stone, mainly upon faith in the indention of Brard's test, which had, even in those days, been seriously challenged. The consequences of this unfortunate error are now notorious, and it is worthy of remark, that the newest parts of the Houses of Parliament, viz., the west front, are precisely those which are most seriously affected.

There are, however, many economical and constructive reasons for resorting occasionally to the use of soft, easily worked, and, as such, almost always perishable stones. In such cases, those stones must be isolated from ground, or other camps, as effectually as possible, and their exposed surfaces covered at once with an efficient protecting coat, before the process of sulphureting can commence. I believe that Ransome's process is the best which has been yet presented to the public for this purpose; but, at the same time, I equally believe that if any internal decay, or any organic decomposition, so to speak, be once allowed to establish itself in a building stone, it will be impossible effectually to arrest its progress. The efflorescence produced by any serious tendency to nitrification will, in fact, continue, however effectually the exposed surface of the stone be closed by a mechanical or a chemical deposit, and it is precisely on this score that we may explain some of the equivocal results of even Ransome's process for preserving stones, which are said to have taken place. Whatever process may be adopted for protecting the surfaces of soft stones, it is, moreover, necessary to pay attention to the constructive law of laying them upon their true bed, and also to protect the more exposed portions of the work by covering them with harder, more resisting, and impermeable materials. Even the latter materials themselves are at times exposed to decay between wind and water, and therefore every possible precaution should be observed to limit the range of the absorptive powers of the stones; the first and foremost precaution for basement works being to establish an effective drainage all round the building, at such a distance from it as to prevent the capillary action of the stones themselves from obtaining any supply of moisture from the ground. In the upper parts of a building it is equally essential to prevent the rain from lodging upon any parts of the stone work, especially when absorptive stones are used above projections likely to arrest falling water.\*

The ordinary meeting of members was held on Monday last, at the house in Conduit-street. The chair was taken by the president, C. R. Cockerell, esq., R.A.

Mr. C. C. Nelson, hon. secretary, read the minutes of the last meeting, which were confirmed, and also a list of donations to the library. A vote of thanks having been passed to the donors.

Mr. Godwin, vice-president, observed that the committee appointed by the Society of Arts was again considering the question of copyright. He held in his hand a draft of the bill which it was proposed to introduce into Parliament on the subject, and his motive in mentioning the matter was, that architects, as a body, should aid in endeavouring to get protection for their copyrights. The bill went to this extent, that the author of any "architectural work," and his assigns, should have a copyright in the same for the term of his natural life, and for thirty years after his death. In looking to the interpretation clause, he found that the architectural work which it was proposed to bring within the provisions of the bill meant the representation of any design for any edifice or part thereof, by plan, section, or model; but it did not give any protection whatever to works executed. It, therefore, became a question of some importance to the profession, whether or not they thought themselves in a position to ask for some protection against the copying, and reproducing of works executed. He was induced to mention this subject in order that the Institute might, if so minded, offer suggestions to the Society of Arts, and which he felt persuaded would receive attention at their hands.

Professor Donaldson said he quite agreed with Mr. Godwin in the propriety of his suggestion. He hoped the subject would be taken up by the profession; and, if the draft of the bill were submitted to the committee of the Institute which had been appointed to consider the subject, they might be able to introduce words which would include the works of the architect, as it frequently happened that the works executed were of more value than the work drawn.

Mr. Papworth said he wished to draw attention to another subject of great importance to the architectural body. He found, on reference to a journal which he held in his hand, that the council of the Institute had appointed a committee to consider the expediency of instituting a voluntary examination of students, and the granting of certificates. If the paragraph to which he referred was correct, he must say that, as a member of the Institute, he was exceedingly glad to hear it, and was surprised that so important a subject had come first to his knowledge through the instrumentality of the press.

Mr. Nelson said it was certainly correct. A meeting of the committee had been held last Saturday week, and another meeting would be held next Saturday; and any conclusion to which it might arrive would be communicated to the Institute in due time.

Professor Donaldson observed that the question of Mr. Papworth was very *appropos*, and that as a committee was sitting on the subject, it was probable that many members of the profession might wish to submit their opinions to it.

Mr. Nelson said the council, having the power to appoint committees, had appointed a committee on this subject, and the scheme would be further considered, and, when ready, would be submitted to a general meeting of the members.

Mr. Robert Kerr then read a paper "On the historical References to Building and Art in the earlier Writings of the Old Testament," of which we give, for the present, the following abstract of conclusions:—

The only written record of the primitive ages ever likely to be at our command is that contained in the sacred writings of the Jews. To that the purely historical element of these, when separated from the purely theological, becomes of the utmost value in historical and chronological science, treating, as it indirectly does, of all that rises to the surface of society from the infancy of civilization to the very time of Herodotus.

The manner of free translation attributed to Ezra does not materially lessen the historical value.

Whether written by Moses himself or not, the account of the Exodus may be taken as belonging to the time of the events, and, therefore, directly historical.

The history of Genesis is of Chaldean type as opposed to Egyptian. Egypt is ignored.

It is, moreover, of pastoral type as opposed to the civil-agricultural of the time; the building of cities being always attributed to races accursed.

The ark of Noah, in description, is a timber house of the period, built free to float; not a vessel for sailing.

Nimrod was the founder of primitive empire, and, as such, execrated in tradition. From his Babylon sprang Nineveh, received chronology being here questionable.

The term *city* signifies an agricultural hamlet, large or small, generally fortified.

The principle of enclosures was described. The Babylon of Herodotus was alluded to, and proof offered in figures that his description might be reduced to credible form.

The Tower of Babel was probably the ruin of the first colossal effort in building, attributed in tradition to Nimrod.

The pastoral patriarchs built no cities; they introduced to us the altar, the monumental pillar, the grove, the sepulchre, the heap. The Pyramids of Egypt are of the class of the heap.

The manufacture of teraphim and amulets was the very first step in delineative art. The spiritual monotheism of the race of Abraham was specially directed against this, as the Protestantism of the age.

When we come to the time of Moses, we have to deal with direct history, capable of application to the theories of Egyptian and Assyrian chronology as connected with this by the date of the Exodus.

The period of the nineteenth dynasty of Manetho for the Exodus (it being generally supposed to correspond with this) can scarcely, without further inquiry, be accepted as regards Scriptural allusion, the state of Egyptian society described being not that of flourishing and powerful empire so much as that of a very primitive and simple form of government.

The usual proofs of synchronism being referred to, the question was, whether the Exodus could be thrown back in date to correspond with a period even before the Pyramid builders.

Future Jewish art was strangled by the prohibition of image-making. The works of Solomon were Tyrian. Their departure from the true principle of the Mosaic law occasioned the immediate downfall of the nation, as an evidence of the absolute necessity at that time of the Mosaic policy against art.

At the conclusion,

Mr. Lockyer said that no one could doubt the talent, industry, and great research, which Mr. Kerr had brought to bear in the preparation of his paper; but he (Mr. Lockyer) was of opinion that he was entirely wrong in the view which he had taken, from a misconception of the books which he had studied. The five Books of Moses had been written more as a body of law than for any other purpose, and as a short synopsis of the history of the Hebrews. Having referred to the various speculations on the subject of the precise period of the Exodus, upon which, he stated, the sacred records themselves were somewhat contradictory, Mr. Lockyer proceeded to state the reasons which induced him to believe that it must have occurred under Menepthah, a king of the nineteenth dynasty, for the following reasons. The Mosaic narration was corroborated in many particulars by the Egyptian tradition of the expulsion of the lepers, which occurred during the reign of that king. Moreover, the father and grandfather of Menepthah—Rameses, and Setbos—must have reigned previous to the Exodus, as they overran and conquered the whole of Western Asia, of which we find no record in Holy Writ. Their conquests are recorded at Karnak, and amongst the conquered tribes are found the Canaanites, Amorites, Hittites; Phœnicia also appears, Mesopotamia, Syria, and even Bactria. The land of Canaan was not, as was assumed, a hilly place, but Mesopotamia was. He also thought it hardly possible that the Egyptians would have called a city built by them Rameses, unless after the king who founded it, and there was no Rameses until the nineteenth dynasty. With regard to the manufacture of bricks, there was a view of a tomb at Thebes, engraved by Sir Gardner Wilkinson, in his work, showing the process by which they were made. Sir Gardner was of opinion that the manufacture of bricks was a monopoly of the Government, and that there was a tax upon them. There was no reason to suppose that Moses was ever at Thebes, for the Jews were in Lower and not in Upper Egypt. It was said that the shepherds were "an abomination to the Egyptians," and the only reason for supposing this to have been the case was, that the Hyksos invasion had oc-

\* THE ATLANTIC TELEGRAPH.—At a recent meeting of this company, a resolution was unanimously adopted, to the effect that an additional capital of 100,000*l.* be raised to attempt to bring the existing cable into working order, or, in the event of failure, to sell it.

\* Report of discussion which ensued we shall give in our next.

cluded previous to the events recorded in the Mosaic account. On the subject of Egyptian architects, it might be interesting to know that some of these individuals were better endowed with worldly possessions than their modern brethren, as one of their tombs at Thebes contained a record of the extent and nature of his possessions, which included 825 oxen, 760 goats, 970 rams, and so forth.

Mr. Fergusson said that there was comparatively so very little reference to architecture in the paper they had just heard, that he felt some difficulty in making any observations upon it. The Temple of the Sphæres, erroneously considered the ruins of the Tower of Babel, was undoubtedly built by Nchachaduezzar, for every brick of it was stamped with his name. Sir Henry Rawlinson had proved this to be the case, as he had dug up some of the bricks from the very centre of the pile, and the cylinders at the corners also showed that it had been constructed during his reign. There was not in his opinion any reason for supposing that the Temple of the Sphæres was the Tower of Babel. It had been built in stories of several colours to represent the planets; and, so far from being the tower mentioned in Scripture, there was conclusive evidence that it was not. The domical building in the diagram referred to by Mr. Kerr was a sepulchral monument,—a tumulus similar to the Assyrian tumuli,—but they subsequently became used in India as relic shrines, or as the sarcophagi of Catholic churches were subsequently converted into altars. With regard to the walls of Babylon, he thought the account, by Herodotus, of their extent, was extremely doubtful. There were no remains of them, and there was no proof that the city was so large as Herodotus represented it to be. The walls of Nineveh were not one-tenth of what Herodotus represented them to be; and therefore Herodotus could not be depended upon in his account of Babylon. Mr. Kerr stated that he had taken out the quantities of the walls of Babylon, but he (Mr. Fergusson) would like to ask an architect to build a perpendicular wall of mud 300 feet high, to stand near a tropical sun, and hear what he would say to such a proposition. Indeed, he considered the statement too absurd for a moment's consideration.

Mr. Ashpitel expressed his regret that not a single word had been mentioned in the paper about any building of which the record was preserved in the Old Testament. The first buildings we read of in ancient Scripture were the Temple of Jerusalem and the House of the Cedars of Lebanon, the dimensions of which were given, and which had attracted the attention of so many learned persons. He owned he was startled by many of the assertions made by Mr. Kerr, involving, as they did, vested matters of theology. As, however, they were not theologians, but architects, he would not attempt the discussion of them.

Mr. A. Beresford Hope wished Mr. Kerr had carried his investigation into the discovery not only of the houses and tents, but of the actual cities of the Moabites in the wild mountainous regions to the east of the Dead Sea, made by Mr. Graham, who, unfortunately, not being an architect, had merely played round the subject, and had not furnished any drawings from which a correct idea might be formed. There was a great field open in the treatment of early Christian architecture, and he would be a great benefactor to the science of ecclesiastical architecture who would undertake it. So little was known about the early history of the Cities of the Plains, that any researches on the subject could not fail to be deeply interesting.

A visitor said that it might, perhaps, be interesting to know that Mr. Graham's discoveries had been followed up by the Prussian consul at Damascus, and that some very interesting explorations had been made at the scene of his labours, of which accounts had been published in a German periodical.

Professor Donaldson expressed the hope that as Sir Gardner Wilkinson, whose name was celebrated in connection with Egyptian antiquities, was present, he would not allow the discussion to close without making some observations.

Sir Gardner Wilkinson said that he could not at so late an hour enter into details. The chronology of Egypt, to which Mr. Kerr had referred, was in a very uncertain state, and it was extremely difficult to say when the Pyramids and other monuments were built; but, in his opinion, there could be no doubt that they were built before the Exodus of the Israelites. The fact of the Pyramids not being mentioned in the Bible was no argument against their not being in existence, as it was not the object of the authors

of the sacred books to write the history of the Egyptians. He was not surprised, therefore, that no mention of the Pyramids was to be found in the sacred writings. It had been said that Homer had never mentioned them, and that consequently they did not exist in his time; but this was not a fair argument against their non-existence in Homer's time. Herodotus, who visited Egypt, scarcely speaks of Thebes at all; and did not mention the great temple of Caruæ. The question of chronology was, in fact, as yet in a very uncertain state; but something might possibly come to light one day to enable the curious to fix the date. It was remarkable that the horse was not represented on the tombs before the eighteenth dynasty, but as horses were mentioned in the Bible it was but reasonable to suppose that the tombs were anterior to the Exodus. With regard to the architects of the Israelites, all that was known was that they worked for the Egyptians; but with regard to their being prohibited from representing the human form, it should be remembered that the Arabs, who were similarly interdicted, had exhibited a good deal of taste in architecture.

Mr. Papworth said he found himself obliged to dissent from almost all the speakers who had preceded him. Sir Gardner Wilkinson said that the Arabs had a high style of architecture, but he (Mr. Papworth) challenged any one to point out a single Arab architect. The Byzantines furnished the first, and the Spaniards the second buildings, while the Armenian Greeks were in later times employed by the Arab Sultans. Mr. Papworth, in conclusion, proposed a vote of thanks to Mr. Kerr, whose lecture he concurred in thinking would form a novel introduction to the history of Early Eastern architecture.

The Chairman said, the lateness of the hour (ten o'clock) would prevent them from going into any further discussion, or, perhaps, he might say confusion. Mr. Kerr had favoured them with an eloquent and interesting paper, and it was to be regretted that more time was not left for its discussion.

The vote of thanks having been unanimously accorded,

Mr. Kerr, in acknowledging the compliment, said that the brief discussion which the paper had elicited showed that the subject was altogether uncertain. In treating the subject which he had selected for his paper, he had endeavoured to do the best he could; and, if he had shown that very little was known about it, he was quite satisfied.

The following gentlemen were on ballot elected Fellows of the Institute:—Raphael Brandon, of 17, Clement's-inn, Strand; John Loughborough Penson, of 22, Harley-street; John Pollard Seddon, Associate, of 6, Whitehall.

Mr. Norman Shaw, of 8, Albion-road, St. John's-wood, was elected an Associate.

#### PRIZES TO ART-WORKMEN.

##### THE ARCHITECTURAL MUSEUM.

On Wednesday evening last the prizes awarded to art-workmen for the most successful specimens of carving and coloration were presented in the theatre of the Brompton Museum.

Mr. A. Beresford Hope presided; and there was a numerous attendance of artisans and others interested in decorative art.

The Chairman observed that the present was, without exaggeration, one of the most gratifying, if not the most gratifying, of the many occasions which brought them together in that building. Many societies were formed for the purpose of social intercourse, to see and be seen, to be complimented and to compliment, to read instructive papers, and so forth. These were all worthy objects in their respective lines; but there was something in this world higher and greater than complimenting or being complimented, and that was work—the hard labour of the hand and mind; and this work was the object of the South Kensington Museum to promote. That institution was not only a museum and society, but it aimed at the realization of the old, emphatic word, a school—a place in which education went by precept and performance; and the sovereign way in which they taught by performance was to call upon their friends to come forward and produce the fruits of their instruction. They wished to show that, before schools of design came into vogue, there was a school of art-workmen. That school was established in no paltry or narrow spirit, for if Art was eternal and all-pervading, it must exist in the smallest as well as the largest affairs of life. The Venus, the Apollo, the Cathedral of Cologne, the Minster at Lincoln, were all grand illustra-

tions of art in its most elevated forms; but a turned candlestick or a piece of embroidery were also illustrative of the same feeling and taste for the beautiful. There was no reason why workmen should not be artists in their respective gradations. The master of a cotton-mill might, in his sphere, be an artist, and so might the smallest boy who gathered the floss from the machine. He did not wish to derogate in the least from the credit due to manufacturers; but as there were master manufacturers, so there were master joiners, mason artists, who might attain to a high position in the cultivation of the beautiful. The workman might be an artist quite as much, as his scope went, as the most accomplished sculptor or painter.

It was with the view of developing that art that the Institution in which they were then assembled offered prizes for wood-carving, for metal-work, for moulding, and for decoration or coloration. In fine, they proposed to give prizes for those particular branches of art for which Michael Angelo, Giotto, and Quentin Matsys had made their names famous in all ages. With regard to the prizes awarded in respect of the year 1859, he had to report that eleven specimens of wood-carving had been submitted, one of which, however, arrived after the 1st of December, and was, consequently, too late for the competition. It would be satisfactory, however, for him to state, that although the design in question exhibited much ability on the part of the author, the work was not one to which the judges could have awarded a prize. The first prize of five guineas for a specimen of Gothic wood-carving had been awarded to Mr. James Allen, in the employment of Mr. Phillip, and now engaged at Exeter College, Oxford. It was a most praiseworthy work, but he was sure the author would not be displeased if he (the chairman) were to criticize it a little, and to say that the only drawback which he observed in it was, that it was rather too solid and stone-like—too rigid to be formed of so plastic a substance as wood. In all other respects, it was admirable, and true to nature. The second prize was also in the Gothic style, and was the workmanship of Mr. Charles Allen. The production was a sort of foliage very common in the early Middle Pointed age. It was executed in soft wood (the first prize carving was in hard wood), and its great merit was, that while it represented a well-known type, Mr. Allen had exhibited originality of feeling, and a graceful combination of foliage which could not be too highly applauded. The third prize (which they were enabled to offer through the kind liberality of Mr. S. C. Hall), was a panel in the style of the sixteenth century, and was the work of Mr. William Bayliss. The artist had not strictly adhered to existing specimens, as he had introduced, among his flowers, the fuschia, which was not known in England two hundred years ago. He also had succeeded in producing a graceful and delicate combination of foliage, which attested not only skilful execution, but a conception of art in its most elevated phases.

The next prizes (given by the Ecclesiastical Society) were for coloured decorations, of which nine specimens had been submitted in 1859 against six in 1858. The plan adopted, with reference to these productions, was to select a well-known panel, and offer it for coloration. The two panels selected on the present occasion, although consisting of one figure only, were very different in the character of their decoration. In one, the colours were subdued, and in the other positive. In one, no gilding had been used, while in the other it had been applied with a judicious, but a glowing hand. The judges had awarded the first prize to that in which the colouring was subdued. They were of opinion that there was a higher tone of art in a coloration which consisted of nothing but dull yellow, lilac, and chocolate, than in the more attractive medium of diaper and gilding. The first prize, therefore, had been awarded to Mr. Simpkin, and the second to Mr. Harrison, a gentleman who had taken a first prize last year. The judges were extremely pleased with both works; but, after mature consideration, they resolved to award the highest prize to the design which, in their opinion, exhibited the greatest artistic feeling. Now, with regard to the campaign for next year, he was happy to say, that the prizes which it was intended to offer for works to be executed in 1860 would be more numerous than those which had been awarded in respect of those sent in in 1859, and he trusted that the larger opening to be made would create a more numerous band of competitors. In former years they had given prizes for stone carving. Now, as they all knew, stone was an ugly customer to deal with. The workman

was obliged to bring the block home to operate upon in his leisure hours, and he need scarcely say that small flakes chipped off flying into one's eyes, and the larger ones through the windows, were rather inconvenient, and perhaps not encouraging. In order to get rid of these physical difficulties, it was proposed to give prizes next year to the three competitors who should prove themselves to be the most successful in designing and executing a medallion in clay of the head of the Duke of Wellington, enclosed in a border of the Middle Pointed style. The prizes for these medallions would be five guineas, three guineas, and two guineas each. The next prizes would be for metal-work; two prizes of five guineas, and a prize of three guineas for the best specimen of a key in the Mediaeval or Renaissance style. Prizes would likewise be given for wood carving, and the work to be executed would be a carved oak panel, to be used as one side of a church Bible binding. The ornaments, figures, or inscriptions were to be in harmony with the sacred character of the volume which it was to enclose, but with this exception, the utmost scope would be given to the genius of the artist, who would not be bound to produce a strictly original design, as an old type remodelled would be considered a compliance with the conditions laid down. A new prize of three guineas would also be given for a cartoon drawing (not coloured) of a painted glass canopy head for a figure such as was frequently seen in cathedral windows. A figure itself would not be accepted, neither would the use of colours be admitted. A prize of five guineas would be given for a coloured decoration, and the Ecclesiastical Society would also give three guineas as a prize for the second best design. The specimen would be a group of two figures, and a cast of it would be supplied to competitors at a charge of five shillings each. Mr. Hope concluded by expressing his hope that these rewards would serve to stimulate art-workmen to aspire still higher, and to become more useful to themselves and to the age in which they lived.

The prizes having been awarded to the successful competitors, to whom the Chairman addressed a few words of congratulation and encouragement, The Rev. J. D. Maurice said, that many of the workmen belonging to the institution, at the north of London, with which he was connected, would have been present but for the distance, which would have trespassed too much on their brief period of leisure. They were, however, fully sensible of the value of the South Kensington Museum, and more especially of its architectural features, and they felt that it was not only a credit and a source of usefulness to the neighbourhood in which it was placed, but to the whole of England. He was much gratified to find working men speaking out as he had heard them that night through their art performances. It showed that they were gradually entering more and more into the institutions of the country, that they were identifying themselves with its progress in art and civilization, and that they were standing forward to take that place in society which their intelligence and good conduct entitled them to assume. The reverend gentleman also added that a good many of his friends at the north of London had joined the rifle movement, and that the circumstance of that being a drill night also accounted for the absence of many of them. The zeal with which the working classes had come forward to join in the national plan of defence, which Her Majesty had that day so signally recognized, proved that the artisans of England felt, in common with their countrymen in the upper circles, that they had an interest in asserting the honour and independence of their common country.

Mr. S. C. Hall expressed the gratification which it afforded him to meet so many of those art-workmen whose labour had so eminently contributed to improve not only the architecture of the age, but the public taste in reference to every-day objects. He showed that it had often occasioned him regret not to be able to ascertain the names of those whose hands and hands had produced so many graceful and artistic forms. When visiting that church at Doncaster built by Mr. Scott, which he had no hesitation in saying was, to his thinking, the finest specimen of ecclesiastical architecture which the last five centuries had produced, he had inquired in vain for the names of those who had executed the beautiful carving of the pillars. The name of the superintendent, it was true, had been mentioned, but he could not glean the names of those whose thoughtful heads and cunning hands had produced the works which elicited so much of his admiration. With regard to the growth of artistic knowledge among workmen, he was glad to say that an immense improvement had been effected in that respect within his own recollection.

He was old enough to remember forty years ago, and he could not but contrast the limited knowledge which then existed with the power and excellence which now prevailed in almost every branch of manufacture. There was no reason why the beautiful in art should not be carried into the production of domestic and familiar objects. In his opinion, the man who designed a tea-pot or a saucer of graceful and artistic form was a public benefactor; and, in the same sense, the man who produced the abominations which too often meet the eye was as much an offender against public morality as the delinquent at the bar of the Old Bailey.

Mr. George Gilbert Scott said he wished to add a few words, in order to guard successful competitors against exaggerating the results of their success, lest it might act as a stopping-place instead of an incentive to improvement. People who were fortunate enough to obtain prizes were, as a general rule, too apt to rest upon their triumphs as a proof of their skill. It was to be hoped that the entire world of art was advancing; and if those who got prizes did not go on improving, they would soon be left behind in the race. There were several objects which might serve as the inducement to art-workmen to compete.

In the first place they might wish to obtain more remunerative employment, which, however laudable in itself, was only a secondary and not a primary object. Neither was it by any means the object to single out individuals, and put them above their competitors. Emulation was no doubt an excellent incentive; but it was not desirable to put one workman in a marked degree above another. Neither should it be their object to give a positive stamp to their work as having attained to positive excellence, for in future years there might be absolute excellence. It must not, therefore, be considered that a prize was meant to be the stamp of positive merit. What those who gave the prizes wished was, to afford an incentive to future study and improvement. They did not wish that those who received prizes should say that they had attained to positive excellence, and that the fact of their having obtained a prize was a proof of it. The great and leading object of all competition was to encourage the student of art to renewed exertions in the path to excellence.

The Chairman then announced that the next lecture would be delivered on the 25th instant, by Mr. John Bell—the subject, "The Union of Sculpture with Architecture."

#### ARCHITECTURAL ASSOCIATION.

The ordinary meeting of this society was held on Friday last, at the house in Conduit-street, Mr. Penfold, president, in the chair.

Mr. Herring, honorary secretary, read the minutes of the proceedings of last meeting, which were then confirmed.

The president, in the absence of Mr. Thomas Purdie, read a paper written by him "On the Applicability of Fixed Mathematical Laws to the Production of Beauty in Architecture," to which we shall return.

Mr. T. Rickman said, as the present paper was an attack on one written by Mr. Hay, "On the Harmonic Law of Nature," and which this gentleman had entrusted to him to read before the society in April last, he would make a few observations upon it. To apply a fixed mathematical law to all buildings was now out of the question, but, as some system was wanted to which architectural designs would conform, he thought Mr. Hay's the simplest for that purpose. This system was founded on the harmony of music, and required to be examined with great caution, as a theory which professes to deduce an analogy between musical law and mathematical dimensions must require a vast amount of mathematical knowledge from any one who sought to establish or attack it. Mr. Purdie's objection to Mr. Hay's theory was, that there was nothing in the eye to enable it to measure angles and mathematical dimensions, as there was in the ear to judge of the vibrations of musical chords; but an examination of the mode in which the eye is hung, of the formation of its muscles, and of the fibres by which these muscles were connected with the brain, showed that the mind was made acquainted with the proportions of a figure by a muscular action returned through the eye to the brain; but, as Mr. Purdie thought these proportions were set aside in perspective, he (Mr. Rickman) would instance an equilateral triangle. It could not be said that the eye would measure the circle which the triangle will recall to the mind of some persons, nor the square in which it is inscribed, nor the arithmetical ratio between its height and

the width, nor the algebraical formula in which this ratio is stated. Undoubtedly, the mind seeking to store things for future use will resort to the algebraical as the simplest form to retain the impression of the triangle, but the difference between looking at it straight and in perspective is simply a difference of ratio in the width and height. If you look at the object straight, the rectile muscles of the eye are called into play; if in perspective, you must exercise the oblique muscles, and those which bring the eye to a focus at the nearer and more distant points; consequently, Mr. Purdie's theory, that there was nothing in the eye to appreciate these proportions, fell to the ground. He would observe, in conclusion, that these mathematical theories were worthy of attention, and were studied as classics, at the present time, in Modern Athens.

The Chairman observed that, in the case of the vibration of musical chords, the sound strikes the ear by a mechanical motion from the object, and the ear recognizes the motion in the drum; so that to hear requires the exercise of no faculty, whereas, in the case of seeing, the eye requires a faculty. Perspective was a stumbling-block, in his mind, to the reception of Mr. Hay's theory. Now observe a proportion; but, if you change your position in reference to the object, this proportion changes, and the eye seems to move in a different way, according as the object is ugly or handsome.

Mr. Hewitt, whilst agreeing with Mr. Rickman, thought that the question how or why impressions of beauty were conveyed to the brain from external objects was purely anatomical.

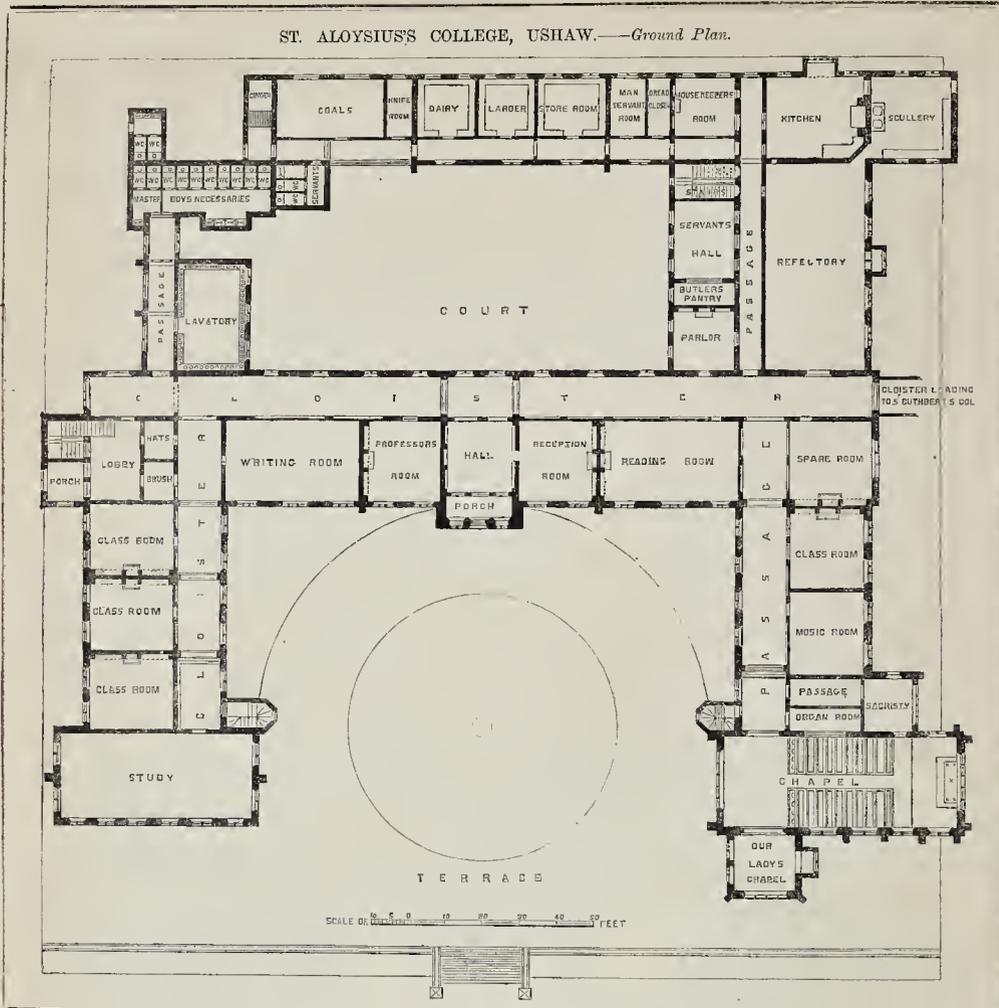

Mr. Brashill stated, that though an analogy existed to a certain extent between the organs of sight and hearing, yet that there was nothing in the vibration of musical chords correspondent to angles in buildings. The question how the impression of beauty arises is distinct from any anatomical one: we do not derive pleasure from sending our eye over a picture: we look at the picture as a whole: to do so the eye is adjusted as a telescope would be, and for the time being remains immovable.

The meeting then broke up.

Mr. Capes will read a paper, on the next night of meeting, on "Light; its Influence on the proper Arrangements in the Plans of Buildings."

#### LECTURES ON ARCHITECTURE. OXFORD ARCHITECTURAL SOCIETY.

At a meeting of the Society, on Tuesday, February 21, Mr. Parker read his third lecture on the History of Architecture in England, comprising the twelfth century, or rather the Norman style, beginning with the reign of William Rufus, and ending it with Henry II. He considered the last ten years of the eleventh century as belonging in architectural character to the twelfth; and he observed that the same rule applies in each of the following centuries. The change of style was not exactly coincident with the century, but the last quarter of each century was a period of change or transition in style. He then explained the gradual change of style during the Norman period itself—from the heavy massive plain work of about the year 1100, such as the White Tower and the transepts of Winchester, to the comparatively light and elegant work of the time of Henry II., or about 1150, such as the Hall at Oakham, and the Galilee at Durham; and exemplified this by examining all the different parts of a building, and showing the gradual change which took place in each, the letter workmanship, and the development of ornament; he included castles, houses, and churches, and showed the same progress in each. (1) Arches, showing by a model the mode of constructing a recessed arch, or an arch of two or more orders; at first square edged, then chamfered, then ornamented in various ways, and gradually developing into the succeeding style. (2) The pillars, at first of the same diameter as they are high, as at Westminster and in the crypt of Gloucester; these gradually increasing in lightness as much in crypts as in other parts, until in the latest Norman work they are six and even eight diameters in height, as in the crypt under Becket's crown at Canterbury, the Galilee at Durham, and the Hall at Oakham. The fashion of ornamenting the pillars and shafts was introduced in the time of Henry I., but became more usual in later work. (3) The capitals became gradually more enriched, and with deeper and better carving. Those of the early period are very plain and clumsy, and those of the eleventh century may generally be distinguished by a plain piece of stone projecting from the centre of each face, in the place of the anticelli of the classical capital, but never carved until the twelfth century. Late in the style, a close

imitation of the Corinthian capital is used, and then comes the change. (4) Doorways follow the same order; the deep, rich doorways are always late, very often inserted in earlier work. (5) Windows are very much the same as diminutive doors in the later period, in the early work they are small and plain. Round windows are not so common in England as on the Continent. Domestic windows are generally of two lights, while those of churches are of one light only, excepting in towers. (6) Early masonry is distinguished from late by the wide joints of mortar between the stones: in late work the joints are so fine as scarcely to be seen at all, as mentioned by William of Malmesbury, in describing the works of Bishop Roger, of Salisbury, about 1119. At Winchester, the work erected after the fall of the central tower in 1107, can be distinguished from the old work by the jointing of the masonry. (7) Surface ornament is used in the later Norman work, ornamental arcades included. (8) Sedilia are peculiar to England, and not found on the Continent; a few examples of this period were shown. (9) Mouldings and other details were taken in succession, and the gradual change illustrated by a great number of examples. (10) Norman keeps were the usual habitations of the nobility and gentry of the twelfth century in England, on account of their security, and houses were built in imitation of them in Scotland and in Ireland, and in many parts of the Continent, in disturbed districts, down to a very late period, sometimes as late as the seventeenth century. The Pell-towers of the border countries are diminutive Norman keeps. (11) Fireplaces and chimneys owe their origin

to the necessities of the Norman keeps of the twelfth century. (12) The practice of vaulting was also partly introduced in them, and the staircases and passages were made in the thickness of the walls, as security against fires, where there were no vaults. (13) In churches the aisles only were vaulted, until about the middle of the twelfth century. Barrel-shaped vaults and groined vaults were used simultaneously, and equally early. Ribs were a subsequent invention after 1100. (14) Houses of this period, as distinct from castles, are only found in fortified towns, and are rare; but the few examples we have are very interesting, and it is in these that the tall round chimney shafts were first developed. (15) The great number of buildings of this period still remaining, made it impossible to enumerate them. The number of monasteries of the Benedictine, Cluniac, and Cistercian orders, founded about this time, enables us to fix dates with accuracy, as there can be no buildings before the foundation, and these serve as a test to compare with other buildings of the older foundations, which have been rebuilt.

#### OPENING OF THE FLORAL HALL.

On Wednesday night, in the Floral Hall, the Volunteers mustered, both little and tall; in uniforms red (the "6 feet" were they), and uniforms green and uniforms grey: there patroness ladies, ranged all in a row, showed bravery, hearty, its prize as we know, and gaslights and wax stretched the roof-lines along, and Gye looked contentedly down on the throng; while Barry, designer, Lucas Brothers, contractors, on their

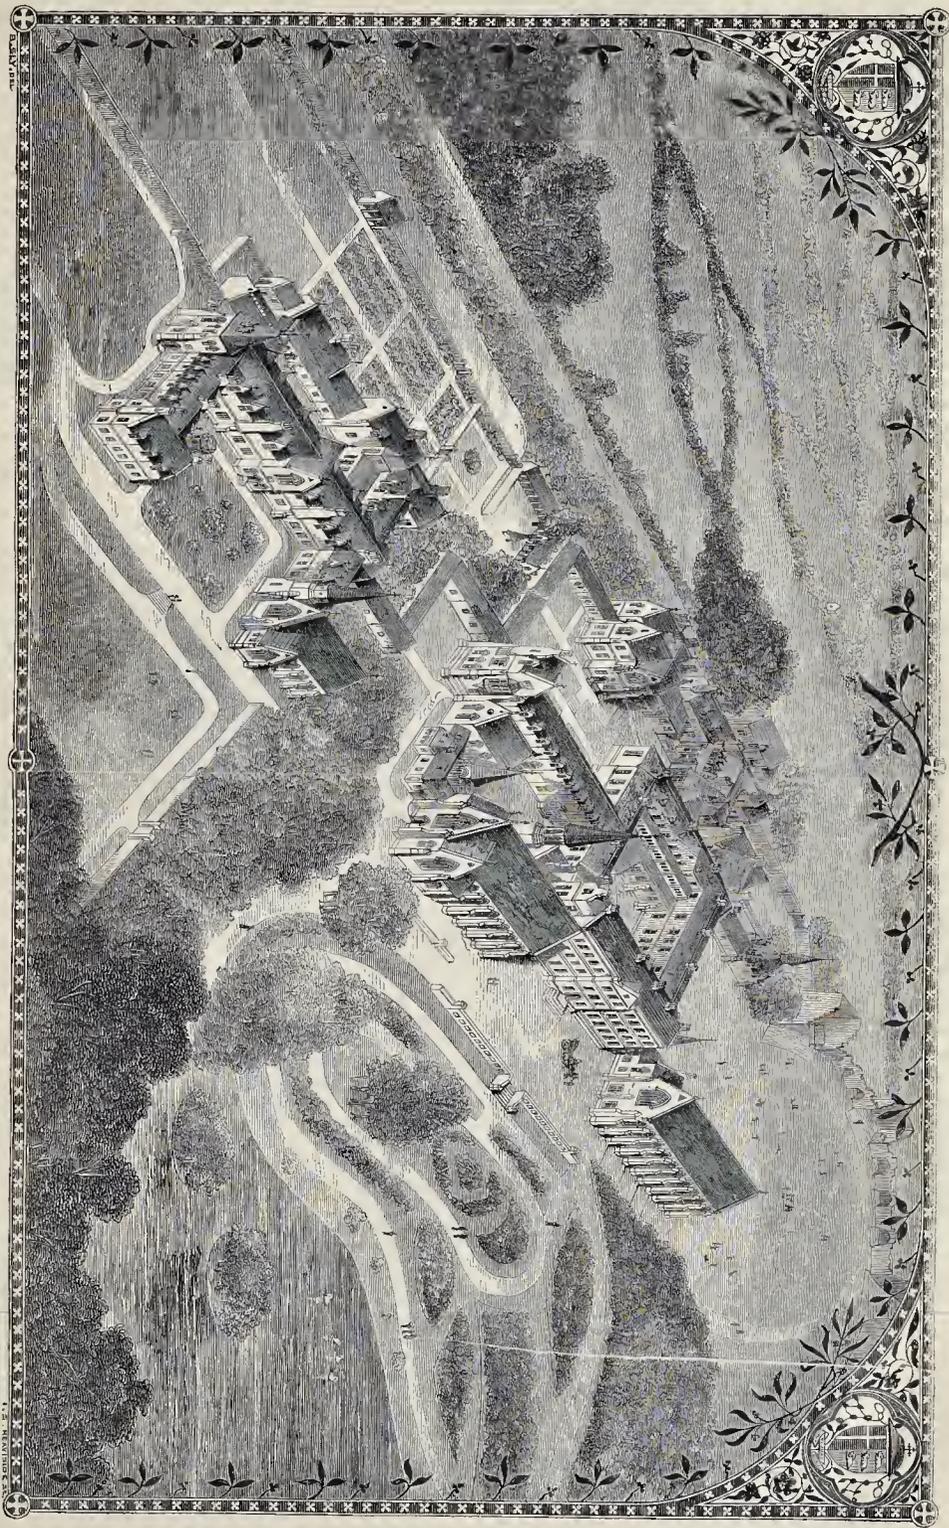

work gazed, complacent, and feared no detractors; though in truth we must say, and they'll not think us spiteful, if the doors had been larger, 't would have been more delightful; for brave volunteers, who are ever the best men, were forced against their will to be nothing but pressed men: still, sprinkled with roses and etched in with gold, no fault could be found with the glass vault so bold; and those who looked down on the floor of that hall, when the mass tried to move at music's sweet call (the moon shining glorious, above and through all), will not soon forget our brave Riflemen's Ball.

#### ST. ALOYSIUS'S COLLEGE.

The college just completed was commenced in 1856, from the designs of Mr. Welby Pugin, who obtained the commission in a select competition. It is erected with coursed stone, which is found in the neighbourhood; the dressings are in sandstone, which is brought from some distance south of Durham. The college is provided with accommodation for ninety students, with provision for a full staff of professors; and though attached by a cloister to the college of St. Cuthbert, it is arranged as a perfectly separate institution.

PROPOSED MACCLESFIELD INFIRMARY. — We believe the good people of Macclesfield have fixed on a site for their new infirmary. It is to be hoped they will make up their minds to have a building of the best kind,—one that will help to cure, not to kill.

ST. ALOYSIUS (R.C.) SCHOOLS, AND ST. CUTHBERT'S COLLEGE, USHAW, NEAR DUNHAM.—MR. E. WELBY PUGH, ARCHITECT.

E. WELBY PUGH

ON THE SUPERINTENDENTS OF ENGLISH BUILDINGS IN THE MIDDLE AGES; WITH AN ESPECIAL REFERENCE TO WILLIAM OF WYKHAM.\*

At Salisbury there appears to have been a "regular master of the works," although the nature of his duties does not seem to have been noticed by the historians of the reign of Henry I. In the agreement made with John the plumber, in 1307, it was arranged that he, the plumber, was to work with his own hand wherever he should be required by the master of the fabric or by another on his behalf; and if at any intermediate time of the year the fabric should not require his labour or repairs, having first asked and obtained leave of the chapter or of the master of the work, he might lawfully work elsewhere:—he was to return when required by the master of the work. At the same period there appears to have been a keeper of the fabric, who was to settle the amount of the day's work for the plumber and his servants, and who was to pay the salary at the stipulated periods. The master of the work, the keepers of the works, and the master mason are also all mentioned together in a document of the same period, so there is no chance of confusing them one with another. Henry VI., in his will, orders a payment of ten marks to be made to be paid to each of the masters of the works at his college of Eton, and of King's College at Cambridge, &c. &c. The appointment of the clerks at each building is given in the following manner:—Edward IV. erected Richard Beauchamp, bishop of Salisbury, to the office of master and supervisor of the works which I have mentioned. This was in 1471; and in the will of this monarch, dated in the following year, he says, "We wot that the church of the said college begunne by us of newe to be builded be thoroughly finished, and all things thereto appointed to be done by his sight and assent of the said Bishop of Sarum during his life, and after his decease by the oversight of the dean of the said college for the tyme being, so alway that he have a designer of architectural works than William of Wykham. He was the first Chancellor was, in the early part, the clerk of the works, but the name of his predecessor is lost. This Sir Reginald Bray has also mentioned, times out of mind, the credit of designing Henry VIII.'s Chapel at Westminster, but he died some few months after the first stone was laid 24th January, 1523; and the king refers in his will, dated 1509, to the prior of the works of the chapel, who had a picture, dedicated to him by the king, of the manner in which the chapel was to be desked. This prior was William Bolton, who was almost a great constructor of edifices.

I have no other noted officer for nearly 200 years, until so late as 1701, when Robert Strutter, painter, was master of the work to be done in the rebuilding of Windsor, with the privilege of doing and carrying out the works of the town, which was equal to that of the meaning of the term had been altered equally with that of supervisor. This officer would seem, if not almost the very similar position to that of the superintendent, at least to have been so well as himself as evidently was to keep the accounts as paymaster; occasionally giving directions as to carrying out the masonry. In the reign of Henry II., the name mentioned as "His Majesty's Surveyor" and also as "Master of the King's Works," being then engaged on the buildings at Holyrood House, near Edinburgh, executed 30l.

The keeper of the fabric, and the keeper of the works are two titles which have been already mentioned in conjunction with the master of the works. The earliest mention of these titles is appended to the names of Henry de Cerne, the treasurer, and of the case of Winchester, from 1222 to 1236, who are called Custodes Operamentum. About the same period, Odo, goldsmith, of Westminster, held the same position at the Palace of Westminster, and numerous others as well as himself as to his son and successor Edward, show that they bought things for the use of the king, and had works carried out "which we had enjoined him to have constructed." This Edward, more especially, was appointed one of the treasurers of the new exchequer constituted for carrying out the rebuilding of Westminster Abbey. The keeper of the fabric of the church at Westminster had upwards of 3,000 marks paid to him in 1257, the period of its rebuilding. The keeper of the works at the Tower had 30d. paid to him to provide necessaries for the works, Master Thomas of Saint Spulchre, being overseer of the works of the king, and also called engineer of the king's warships in the Tower. Our next keeper may not have been worthy of his office, if the following report of him be correct:—William de Wykeles, keeper of the old fabric erected of the cathedral church of St. Paul in London, received 40l. from the king for an iron tomb lately placed over the tomb of the Venerable Father Henry, late Bishop of London, purchased for the tomb of Philip, late King of France, the Queen of England, within the Abbey of Westminster, the custos at the Palace of Westminster in 1332 was required to report up some lead which he had in his care. In 1350, the roll of accounts kept in the wardrobe was that of the treasurer of Lincoln. But more especially from Browne's "History of York," published 1838-47, we obtain much interesting information. From the year 1311 until 1335—about the year of the death of the monarch's succession of the keeper of the fabric: they all were receivers of the contributions for the works, and paymasters of the expenses. The roll of accounts kept in their names: one is called the master of the fabric. But there is a curious incident connected with the three last persons who held the office of keeper, which most probably would not have attracted inquiry. These three are not pursuing this course of the roll of accounts kept in the wardrobe. See the successor of the Vicars Choral, and custos from 1315 to at least 1318, after which no fabric rolls are found until 1326, the Master Thomas Marsar was custos until 1355. In 1325, however, Master John Colman, treasurer of the church, was custos, as known from the

following circumstance:—that the adjoining church of St. Michael le Belfrey, belonging to the Dean and Chapter, was rebuilt in the time of Thomas Marsar, the second above mentioned, and there were, and there are perhaps still, existing in that church, three stained glass windows the memory of these three keepers, who, in the three inscriptions are recorded to have been called "the clerk of St. Peter's works" (not keepers of the fabric), and their inscriptions are in black letter English; therefore there can be no error except in the acceptance of the term in our modern usage of the word. Notice is also given of a person at present often in charge of carrying out work at our cathedrals still retains the title of the clerk of the works. From the quality of the persons above described, we might almost presume that the services rendered were somewhat akin to those of an accountant; the strange mixture of names and offices is most perplexing, and I fear I have much that requires further elucidation.

During the early years of the Medieval period, another title obtained, yet so rarely, that, but for the one name connected with it, I should scarcely have considered it of sufficient importance for introduction here. The name is that of *Revisor de Barchin*, or *Barchin*, and the office that of director or master. He is placed by English along with Wykeham and others in his list of the best of the English Medieval architects, on the ground, I presume, of the words by which he is distinguished, as the "rector" for twenty-five years of the new works of Salisbury Cathedral; at the same epoch, as we are told by some authors, *Leland*, "Robertus Cementarius rexit per viginti annos in officio rectoris, et in officio rectoris ad real meaning of these words applied to the two men:—one, who was rector the ruler; and another who rexit, was the ruler also."

About the same time we find that the works at Windsor Castle were placed under the direction of William de Burgh, who was succeeded by Walter de Burgh in 1210. This Walter was also keeper of the manor of Kenyngton (parish of Salisbury), and he issued many and numerous orders from the king for improvements and alterations; also for works at Brill, at Cliff, at Geddington; and he is likewise called "keeper of our demesnes." Under such a title, too, the monarchs were accustomed to appoint a person to each of the royal palaces for its care and preservation, often nominating some old servant to the office as a pensioner.

The last office which I noticed on the present occasion is one perhaps as important as any of those to which I have yet requested your attention. This is the clerk of the works. I have already mentioned how, in an ecclesiastical establishment, the clerk of the works is to be appointed, appropriated this title as well. We might almost conclude that the title was retained for use by royalty only, for it so happens that with two other exceptions this designation is not met in connection with any works other than those executed for the monarchs: one exception is on behalf of a member of the Royal family, and the other on behalf of the king's Warden. The three instances above mentioned appear to show that another name was adopted for this clerk when in other establishments. The household of the monarch comprised an office for carrying out the royal works. This fact would seem to have escaped the observation of all my predecessors commenting on the histories of the palaces inhabited by the sovereign, as well as by those who have investigated the history of this period. The earliest list of such an establishment which I have yet met with is that of Edward IV., whose reign comprised the years 1461 to 1483. The manuscript unfortunately is not dated. The clerk of the works therein has a fee of 2s. per day equal to 50l. 10s. per annum of the period; a clerk, for whose expense he is allowed an annuity of 20l. also, as per day for riding expenses, and 20d. for boat hire. The next officer in the list is the comptroller, then follow the clerk of the engrossment of the records, the purveyor, with an allowance for his horse; the keeper of the storeroom; the clerk of the check; the clerk of the comptrolment; the carpenter; the plumber (the mason in this list is omitted); the joiner; the glazier; the surveyor of the mines, who has also 30l. 10s. per annum; audially, to my great surprise, the devizer of building, who has the same amount. The Society of Antiquaries published so long ago the "Ordnance" of the King's Household, among which is one called the Liber Navi, from a manuscript of the period of Edward IV. Amongst these "Ordnances" is the following passage, commencing with the words, "Venerabilis:—Clerke of the works, called by the noble Edward, 'clerke des œuvres du Roy, praignant sa gages fees et autres choses appartenant a son office par l'assignement de Thomeas d'Angleterre de hors le charge de l'ostiel du Roy." This clerk hath no duetie looking to him in this household, by virtue of this office outward; but if he be appointed by the sovereignties of household to take wages and clothing with the household, it might cause him to be the more attendante for necessary byndynes in offices in this house; and so he may take livery as assuer of household." The next list is not earlier than the time of Elizabeth. In these the clerk of the works has become the surveyor and paymaster, and surveyor and clerk. In 1614 Mr. Basil is the surveyor; and for the year 1619 there is a list of the household of Prince Henry, in which is the very acceptable name of "Jaigo Jaunes, surveyor of the works," the paymaster and overseer is Mr. Smith; and the clerk of the works, Edward Carter. We here obtain the modern acceptations of the words of office, and the names of the persons who give the name of Jaigo Jaunes, surveyor: Denham, Peter still, was surveyor-general; and Wren, surveyor of the works, is also known as surveyor-general. I must not now attempt to cater upon any of the numerous observations arising out of these very important lists, in the history of our profession, which exhibit the precursor of our modern name of the clerk of the works. Many will remember the conjunction of this name with that of John of Padua, who is usually styled devizer of his majesty's buildings, on the faith of certain patents dated 1544 and 1549, respectively, Henry VIII. and Edward VI.; but, on referring to the documents as printed, I cannot find the slightest mention of the word devizer; nor have I been able to discover the name of any person appointed to that office. Various writers, Walpole says, John of Padua's office seems to intimate something novel in his practice. He was termed devizer of his majesty's buildings. In one of the office books which I have quoted before is paid to him of 30l. 10s." To this office book, however, he does not afford any clue; and were it not for the lists I have already

quoted, I should have felt inclined to consider the whole as one of his mistakes. Dallaway, in the notes to Walpole in 1820, observes, that John of Padua "acquired a title not before this patent given to any architect," so that he evidently was not aware of the lists to which I have referred.

I will now refer to the list which I have compiled of those who have held the appointment of clerk of the works. The earliest is in 1241, 25th Henry III., when directions were given for certain works at Windsor Castle begun by these officers: similar orders were issued in 1242 and 1244. During the reign of Gaerwarren a Castle, begun 1284, the clerk of the works was paid 2s. a day, and the master of the works 13s. a week, or 2s. 2d. a day, the Sunday not included. The Sunday, it appears, was paid for to such officers who had a yearly salary, as the accounts often mention the 365 days at the 6d. or 1s. per day. A lapse brings us down to 1316, when Nicholas de Wykeham, late clerk of the works at the king's palace at Westminster, was paid 14l. and upwards, for certain timber and planks used against the coronation of Edward II. In 1320, John de Ditton was appointed clerk and keeper of the king's works (this recalls the nomenclature of the officer at York) at the palace of Westminster and the Tower of London. In 1326, William de Chailion, who was acting as surveyor or supervisor, was appointed clerk of the works at both places, which also entailed the honour of looking after St. Stephen's Chapel at Westminster. About three years afterwards William de Kellesey succeeded him. Both these clerks kept the accounts of receipts and expenditure. Peter de Bruges, in 1347, was clerk of the works at Westminster, whilst Westmister was keeping the accounts at the Tower until 1351, when Robert de Campsalle succeeded him at both places; and he was succeeded by Thomas de Stunford, who appears to have been acting previously as controller. William de Lambeth was appointed surveyor, and two years afterwards clerk of the works. In 1361 William de Stunford was also appointed surveyor, and in the same year he was clerk of the works, whilst in 1365-6 he is termed clerk and supervisor, and was paid 15s. per day.

Returning to the year 1327, I find the constable of Windsor Castle directed to pay Ralph de la More, clerk of the works, an amount for wages at 2d. per day (as before stated, I consider this a mistake for 2s.). No other mention has been found of such an officer at Windsor, until 1380, when William de Mulsho was appointed clerk of the works at Windsor and elsewhere. After him came Adam de Hertyngham in 1366. In 1370 Robert de Sybthorpe was clerk of the works at Sheen, Eltham, and Rutenburgh; Henry de Mannesfeld, at Chiddingfold; John Edward, at the castle of Lodes; Richard Berens, at the castle of Odylian; and Richard de Blore, at Queensburgh Castle,—all royal property. I must not forget to mention here William de Wykeham's appointment, for five months only, at the manors of Heule and Yeshampton. In 1382 Arnald Brocas was clerk of the works at Westminster, the Tower, Windsor Castle, and divers others of the king's castles and manors. In 1395 John Godmanston was clerk of the works of the king's Great Hall at Westminster, although Strype and Stow state that John Boterill was the clerk; but as there appears to be a slight error in the date of 1395 for 1397, he may perhaps have succeeded Godmanston. On the 12th July, 1397, Geoffrey Chaucer was appointed a clerk of the works, his patent mentioning not only Westminster and the Tower, but also Beckenham, Kennington, Eltham, Chiddingfold, Sheen, Byflete, Chiddingfold, and Fekelsham, a careful consideration of the life of Chaucer, by Godwin, I cannot find any circumstance to warrant a supposition that he was so minutely occupied with building operations as to be qualified for the practical duties of the office: the short time he held it affords some grounds for the supposition that he had not the requisite knowledge; and the permission to appoint a deputy would also lead one to the same inference. The next, too, at which the office was given to him, strongly marks the favour of the king, bestowing on a favourite a gift for good services rendered: John Gadney, his successor, 27th June, 1391, also appears to have been allowed a deputy; and he is the first clerk of the works I have found recorded as having had a certain quantity of cloth given to him for a livery. In 1407 this office was given to Henry Nerston, who also had a livery. From 1411 to 1413 Robert Rolleston's name is met with as acting as deputy-master and the Tower. He was succeeded by John Strange in 1413, who recorded having received the office of livery in 1416, and as being engaged at Sheen Palace in 1413 and 1418. In 1422 John Ardenhe held the office. In 1440 William Lynde, as early mentioned herein, was clerk of the works at the College of Eton. In 1415 William Cleve, "the king's poure chapelyn," petitioned for the payment of 1,000l. for works done at Eltham, Sheen, Westminster, and the Tower. John Canterbury was clerk of the works at the commencement of the erection of the King's College chapel, Cambridge, in 1451, having previously been engaged at Eton as Lynde's successor. In 1474 Thomas Gauceler held that situation at Windsor, where he had 10l. per annum and a livery; in 1483 his accounts were ordered to be determined. In the early part of the reign of King Richard II., Thomas Hunt was appointed clerk of the works for life; and in 1481 Thomas Danyell is named. A lapse of some sixty years brings the date down to about 1559, when Eustace Mascall was clerk of the works to Cardinal Wolsey at the building of St. Dunstons, in Oxford; this is one of the exceptions in the office of the title, and who was for seventeen years chief clerk of accounts for all the buildings of King Henry VIII. within twenty miles of London. From 1553 to 1559 Michael Woodward is named as the "clerke of the works and castle of Windsor." And lastly, in 1575, Humphrey Michell, the clerk of the works at the castle, asks leave to resign his office on account of the difficulties and opposition met with in discharging his duties, and the delays in procuring money and passing his accounts. Most probably he was acting as the clerk of the works as now understood. The effects of this remonstrance appear to have been his appointment as superintendent of all payments for repairs done to the castle, under a warrant from the constable, the Earl of Leicester, who at the same time nominated Henry Hawthorne to be surveyor of the works. The salary of each of these officers was 2s. per day. There is much similarity in the office held by Wykeham to this appointment of Michell, as superintendent of all payments for repairs done. In this case, however, Michell is under the constable, in Wykeham's case, by his second appointment, Wykeham was also the constable, "capitalem custodem et supervisorem."

The second exception, which I mentioned at the beginning of this division, comes under the date of 1435. The name of our Supervisor?

\* Some other references to him as a director will be seen in the Winchester volume, to which allusion has already been made.

clerk of the works is once named in the contract for the erection of Fotheringhay church, for the Duke of York, in the paragraph—"And if so be that the said Will. Horwode (the freemason or builder employed), may not have full payment of all or any of his workmen, then the clerk of the works shall pay him in his presence, and stoppe as may be in the said Will. Horwode hand, as the payment that shall be due unto the workmen comply to," clearly showing what was at least one part of his duty.

Among the foregoing observations will be found, I think, an elucidation of some points hitherto generally considered obscure. The salary of the clerk of the works has been considered exceptional, whereas I have shown that it existed for many years, and at nearly the same amount. Sir Christopher Wren received 45*l.* 2*s.* 6*d.* the usual fee for the office of surveyor-general being, for himself, at 2*s.* a day, and a clerk at sixpence a day—a sum now equivalent to about 15*l.* If I mistake not, it has always been considered that the livery of this royal officer (withdrawn temp. Charles I.) was first given to Luigo Jones, whereas it was a customary present some 150 years previously; and at the burial of King Edward VI., the surveyor of the king's works had seven yards of cloth, and each of his three servants three yards.

There is one circumstance respecting nearly all these officers which, perhaps, needs a passing comment. It will have been remarked how very many of them were either ecclesiastics or were rewarded with ecclesiastical preferment. But it must be remembered that, during the period to which our attention has been directed, the church was the only field for exertion open to those of the nobility and gentry who were not inclined to embrace the profession of arms, and also a means by which to obtain remuneration for a livelihood; therefore the clergy, so called, would thus secure the offices at the disposal of the monarch and of the nobility. Some few, however, of those thus employed appear to have been unconnected with the church.

It is very difficult to understand clearly the duty of these officers. The overseer would be, perhaps, the most easily explained; but his Latin designation, as in the Records, is unknown to me, unless the Latin word "supervisor" has been the one our translators have found. The English word "supervisor," if that of steward be questionable, is, I think, best kept for those who, acting on behalf of others, as Wykeham for the monarch, have yet no grounds to be considered the designers of the building. The master of the works, a designation scarce in the monastic establishments, whilst in Scotland it took the place of the English king's chief professional man, was, I feel certain, one of the talented advisers of the day. The English king's clerk of the works is clearly stated in the obituary of the architect. The master or keeper of the fabric was, probably, the keeper of the whole structure; and the keeper of the works was, perhaps, only the custodian of the particular works then in progress; the duties, under these circumstances, being developed by the master of the works, or by the master mason, to the latter of whom I may, perhaps, be permitted to return on a future occasion. But there is one title in the list of the royal establishments of whom we should desire to know much, but of whom, at present, nothing whatever is known; I mean the divisor of buildings.

*Postscript.*—Whilst this paper has been in course of printing, my attention has been directed to a passage in Hunt's "Tudor Architecture," 1856, p. 24, who states that "it appears indeed, that in these times, the duties of the works" acted invariably under a supervising officer, who, leaving the artist's fancy and genius unshackled, controlled and restrained the expenditure of money." This latter is exactly the position held, I consider, by Wykeham at Windsor. Also, that "it was common to depute the superintendance of buildings to churchmen, from an idea of their superior prudence and ability," quoting Warton ("History of English Poetry," 1774-81), who also states that Wykeham "is supposed to have recommended himself to Edward III. by rebuilding the Castle of Windsor. This was a recent and notorious instance" (alluding to Wicliffe's Sermon, and see previous note). "But in this appointment," he continues, "the King probably paid a compliment to that prelate's singular talents for business, his activity, circumspection, and management, rather than to any scientific and professed skill in architecture which he might have possessed. It seems to me that he was only supervisor or controller on this occasion." "Mr. Dallaway," adds Hunt, "without mentioning his authority, says the name of Wykeham's superintending architect was William Wynford. Assuming this to be correct, Warton's is a fair inference. So that I have not the merit of originating the suggestion, 'Was Wykeham an architect?' Whereas, 'it is to be lamented,' writes Gwyn, in 1766, 'that Wykeham did not pay more regard to the science to which he owed the greatness of his fortune, by establishing a foundation for the study of his own art, and others that depend upon it. Had he fortunately done this, there is no saying what the consequences might have been: possibly by this it would have been the fashion for ingenious men to come from Rome hither to perfect themselves in the arts, and have bartered Italian for English performances.'

#### DRINKING-FOUNTAIN MOVEMENT.

At Shrewsbury, the Fountain Committee report two models of drinking-fountains, prepared by Mr. Hollins, of Birmingham, at the request of Viscount Newport, M.P., and either of which his lordship has offered to have executed at his cost, and erected in the town;—the one, a stone structure, of a Classic design, containing a centre fountain, and also four drinking-fountains; the other, a mural fountain. The committee unanimously preferred the former one, recommending that it should be erected by the corporation in the Market-square.—At Falmouth, Mr. David Barclay, of Grove-hill, has made arrangements for the erection of a fountain near the Custom House. The fountain is now in course of preparation at Messrs. Freeman's granite works, Penryn.—At the Bradford Council Board recently, it was stated that there had been four or five applications from various gentlemen to erect drinking-fountains, but the Street and Drainage Committee had considered that they could not determine the

sites until they had all the designs before them. It was also stated that two designs—one from the Beaumont Testimonial Committee, and another from the Band of Hope—would be presented to the Street and Drainage Committee. The Beaumont Testimonial Committee have not yet selected a design for the fountain to be erected to commemorate the services rendered to the borough by the late Mr. Alderman Beaumont. Several designs were sent for inspection. A design was forwarded by Mr. E. Milnes. The height of the whole, from the pavement to the extremity of the lamp, is about 26 feet. The style of architecture is Italian Renaissance. Two designs were also sent by Mr. T. C. Hope, one of Gothic architecture, about 27 feet in height. The second is of Italian architecture, height 25 feet. Each of these designs will cost more money than the committee has been able to raise up to this time.

#### THE HULL SURVEYORS.

ACCORDING to the statements made at the meetings of the local Board of Health, the differences between Mr. Marillier, the surveyor, and Mr. Butler, the assistant surveyor, have reached such a pitch that they correspond in writing as strangers, and the business of the town suffers. Some of our correspondents ascribe it to the fact that the assistant surveyor's plan of drainage was accepted in preference to that of the surveyor. A committee has been empowered to inquire into the differences; but the right constitution of the committee is questioned.

#### BASINGSTOKE BUILDING COMPANY. COMPETITION.

DESIGNS having been sent in, in compliance with particulars advertised in the *Builder* by the directors, the premium has been awarded to Mr. G. B. Mussellwhite, of Basingstoke.

The designs submitted by the successful competitor comprehend perspective views of two villas in the so-called Italian style, and one in the Elizabethan style of architecture, together with a "bird's eye" view and block plan giving the houses a south aspect with the frontage to the town; also a block plan giving the houses an east aspect, with the frontage to Reading road. The preference has been given to the latter arrangement.

One of the Italian villas has been selected for erection at a cost not exceeding 1,200*l.*

#### IMPROVED GAS CHANDELLER.

MR. HUGHES, of the Atlas Works, Hatfield-garden, has recently patented improvements in sliding chandeliers for gas, to remedy the defects that exist in chandeliers constructed upon the old principle.

The ordinary mechanical arrangement, by which the body of all sliding chandeliers of the old principle is sustained, and made to slide upon the upper or supply-pipe, is by means of small brass chains, to the end of which are attached the counterpoise or balance weights; these chains, from repeated exposure to a heated atmosphere, containing a portion of carburated hydrogen, become rotten, consequently break, and allow the weight to fall.

The improved counter-balance is in one circular piece (as a coronal); and if one or two chains break, it still remains suspended; and should all the chains break simultaneously (a very unlikely occurrence), it then falls upon the body of the chandelier, and brings into action a valve and stop, which immediately shuts off all escape of gas. Another advantage is also obtained, namely a longer slide, so that the light can be lowered to the table with in the height of any ordinary lamp.

#### MACHINE-MADE NAILS.

THE manufacture of wrought-iron nails by machinery, instead of by hand, was, as has often been the case, stimulated by the continued strikes of the nailmakers. The problem of furnishing the market with machine-made nails, capable of competing with those forged by hand, was first solved by Messrs. Ewbank; and these nails have now become a regular staple of English commerce, and are as punctually quoted in the colonial price-lists as any other article of British export. This success has recently led to the production of another patent process for the accomplishment of the same object, which is now in the hands of Messrs. Halkett & Bates, of Manchester, who are at present supplying the London market, through

their agents, Messrs. Richards & Co, with machine-made nails.

The patent wrought nails claim to be superior to those made by hand in this respect, that the head, being made at the same stroke with the remainder of the nail, is not liable to break off when hammered even into the hardest wood. Another advantage is, that the full count is always found to go to the same weight of nails, they being more regularly and accurately made by machinery than by hand. Not having had large experience of these nails, we simply bring the fact of their manufacture before our readers.

#### THE BRADFORD WATERWORKS.

THE corporation of Bradford (Yorkshire) some time ago purchased the works of the company by which water had been supplied to the town therefore, as well as the privilege of carrying out a scheme for a very large extension of the works, for which the old company had obtained the sanction of Parliament. The scheme was designed by Mr. J. W. Leather, for the water company, and the corporation have retained his services for carrying it out. The corporation have taken power to borrow in the whole a sum of 650,000*l.* They paid 40*l.* for every 20*l.* share of the stock of the original company, and took also the whole of the company's liabilities. The new scheme, with the mains and distributing apparatus, was estimated to cost up to 300,000*l.* The larger reservoirs, tunnels, and other works, were let at the end of 1856, and are now approaching completion, when Bradford will have 10,000,000 gallons of excellent water daily. The engineer's estimate for contract M, recently let, was 13,800*l.* The work was let to Mr. John Metcalf, of Bradford (whose tender was the lowest), for somewhat less than 13,000*l.* There were also tenders from Messrs. Barton & Son, Shipley; Mr. T. Gowing, Ripon; Mr. S. S. Buxton, Hunslet, near Leeds; Messrs. Moulson, Bradford; Mr. Ingram, Laphis, Shipley; and Mr. J. Taylor, Clitheroe. The highest tender was 16,200*l.*; there were, besides the highest and the lowest, one for 13,200*l.*; another, 13,500*l.*; another, 13,586*l.*; another, 14,100*l.*; and another, 14,131*l.*; the average of the whole seven being about 1 per cent. over the engineer's estimate.

#### BISHOP AUCKLAND TOWN-HALL AND MARKET COMPETITION.

We mentioned last week the award of the first premium in this competition. We may add that twenty-three architects competed. The design by Mr. Hill, of Leeds, was second in favour. The secretary states that the Northern Architectural Association (which lately protested against the terms of the competition), "was represented by four or five of the members, among whom was one of the highest officers of the Association. The successful design will not be adopted in its entirety, but will undergo some modifications."

#### CHURCH-BUILDING NEWS.

*St. Ives.*—The following tenders for the erection of new entrance-lobbies to and re-seating the Wesleyan chapel were received:—

	Sents in Deal.	Seats in Oak.
Mr. Skeels, St. Ives	£296 0	.. £41 0
Messrs. Abbott & King, Somersham	322 10	.. 357 10
Messrs. Thackeray & Son, Godmanchester	297 10	.. 336 0
Mr. Sault, St. Ives	269 0	.. 260 0
Mr. Alpress, Broughton	255 0	.. 378 0
Mr. Wheatley, Bluntham	215 0	.. 293 0
Messrs. Smith & Salt, Hemmelford	229 0	.. 259 0
Messrs. Allen & Smith, ditto	196 0	.. 226 0

The lowest tender was accepted, and the contract signed. The work is to be commenced immediately. Mr. Robert Hutchinson, of Huntingdon, is the architect.

*Basford, near Nottingham.*—Last week the church of St. Leodegarius, Old Basford, near Nottingham, was reopened after its restoration. The ground-plan of the church is the same as before, with the addition of a vestry at the east end of the north aisle. The tower, clerestory, north aisle and porch, with the roofs throughout, are new, and built in the Early English style, to correspond with the nave arcades and chancel, the oldest parts of the building remaining. There are low open benches inside, and elbow-stalls in the chancel; and the pulpit is of Caen stone, carved. Mr. Arthur Wilson, of Nottingham, is the architect; Mr. Garland, of Nottingham, the contractor, and the works have been carried out at a total cost of 3,000*l.*

*Kinstone (Staffordshire).*—In consequence of the dilapidated and insecure condition of the parish

church at Kinstone, in the county of Stafford, and of the inadequate accommodation it affords for the wants of the neighbourhood, it is to be taken down and a new church will be erected upon a larger scale. The present building consists of a nave and chancel, probably built in the thirteenth century, to which were added a modern transept and tower about fifty years back. The windows of the chancel on the north and south sides are the only ones in which the original stonework appears, and they will be re-used in the new chancel. The proposed church is to be built in the Early decorated style of Gothic architecture, and is to consist of a nave, north aisle, and chancel, with a tower and spire at the north-east angle of the nave. It is intended to accommodate 300 persons. The Earl of Shrewsbury and Talbot, being the principal proprietor in the parish, is the largest contributor to the funds, and also gives land adjoining the present churchyard for a new site. Mr. D. Brandon is, we believe, the architect. It is also in contemplation to build schools for 250 children, with an attached residence for a school-mistress.

**Gloucester.**—Mr. H. Evans, of Highgrove, is about to place a window in the nave of Gloucester Cathedral, according to the *Chronicle*, in memory of deceased members of his family, making the fourth within a year; and it is anticipated that a fifth will be commenced before the two already decided upon have been completed. It is proposed that the designs of these windows shall represent events which have occurred in the building, and thus illustrate its history; and the new windows will aid this design. The paper named suggests that the two western windows should be converted into memorials of two of the worthies of the diocese—Bishop Warburton, the scholar, and Bishop Hooper, the martyr. Messrs. Bell and Clayton have been selected as the artists of the Evans window.

**Rumney.**—A correspondent of the *Cardiff and Merthyr Guardian* (Mr. E. A. Freeman) says:—"I expressed to you my fear that the repairs of the roof of Rumney Church would lead to the loss of one of the architectural antiquities of the neighborhood. The old roof has now been wholly destroyed. No architect, as far as I know, was called in to examine. An entirely new roof, of the very poorest kind, has been put up: even the old pitch has not been followed; the new one is much lower, and the eastern gable of the nave has been lowered in proportion. Within, the roof is a mere ugly piece of carpenter's work, with two beams, gable-posts, and very thin rafters: without, it is covered with blue slabs. The pews, some of the worst anywhere, and wretched tumble-down things to boot, are now all moved out of the church. If they are put back again, Rumney will become even more a by-word than it is already likely to become on account of the roof."

**Holmer (Hereford).**—The parish church of Holmer, near the city of Hereford, is about to be repaired and freed from the disfigurements which at present mar the general effect and diminish the amount of accommodation within its walls. The tower has been repaired, and a vestry erected at the west end, which has been restored. Mr. J. H. Ewins is the architect, and Messrs. Morgan and Price are the contractors. Tenders will shortly be received for the work of restoration and re-peaving of the whole of the church under the same architect.

#### BLACKBURN UNION WORKHOUSE COMPETITION.

It will be remembered that we reviewed the designs sent in competition for the Blackburn Workhouse. Three architects were selected to compete a second time, and one of the conditions sent to them was that the successful competitor should be appointed to carry out his design; but, it went on to say, at 4l. per cent. commission. Some, if not all the competitors, replied, acknowledging the receipt of letters, conditions, &c.; pointing out the clause as to commission, and expressing conviction that on objection the Guardians would consider the successful competitor, whoever he might be, would, after such a severe competition, be fully entitled to at least the usual commission of 5l. per cent.

Designs were afterwards sent in, and one by Messrs. J. E. and J. D. Oates, of York, architects, was accepted. They have since been called upon to agree to accept 4l. per cent. commission, and that the Guardians shall appoint a clerk of works. They naturally object, and ask 5l. per cent. commission, and that they may nominate a clerk of works for the approval of the Guardians; his salary to be paid by the Guardians over and above the 5l. per cent. The decision is adjourned until

this Saturday. One of the Guardians, it appears, insists that the usual practice amongst architects is, that if 5l. per cent. he paid, the architect out of it pays the clerk of works!

We hope he will believe us when we say he is in error; and that, in conjunction with his brother Guardians, he will agree to pay their architects the fair and customary charge of 5l. per cent. As to the appointment of clerk of the works, Guardians who are wise will leave the responsibility in the hands of their architect.

#### FALL OF RAMSAY TERRACE, EDINBURGH.

ON the 1st inst. the terrace erected by the late Lord Murray, on the slope of the Castle-hill at Ramsay-gardens, and which has been gradually yielding, gave way altogether. It is about three years since the erection of this terrace was commenced. At the east end was erected a lodge, and at the west end the terrace curved outwards; and in the centre of the circle had been placed a pedestal, which was to receive, as soon as ready, a statue, by Mr. Steel, of the poet Allan Ramsay, from whose patronymic the locality derives its name. The terrace was supported by a massive buttressed wall, 30 to 40 feet in height, built on a slight inward angle, while the space between the original slope of the hill and this wall was filled in with an embankment of earth. The foundation of this artificial mound and wall would now appear to have been insufficient. The superstructure is, we are informed, set upon a stratum of clay, which ought to have been built into and not upon. From the opposite point of view, we see the terrace as if it had fallen askew to the westward, the lines of the masonry, which are to a great extent traceable, being broken and twisted, and set on angles that make the vision giddy. Masses of stone have been confusedly hurled into the garden below, while the sloping ground is gaping with chasms, and seems as if upheaved by some volcanic agency. From the top of the fallen mass the scene of ruin is still more disastrous to behold. It must be matter of great regret to the public to witness the destruction of this terrace, which cost the late Lord Murray, we believe, six or seven thousand pounds.

#### REMARKABLE BUILDERS TRIAL IN DUBLIN.

THE action touching the fall of a house in Grafton-street, Dublin, viz., Kempston v. Butler, a builder (alluded to on page 111), after being five days at hearing in the Court of Common Pleas, and before a special jury, resulted in a disagreement,—*six* being for a verdict and *six* against. The main points of consideration were, did the house fall owing to the negligence or incompetency of the contractor? Did he take precautions for necessary shoring, bracing, and strutting—during the progress of the re-building—of adjoining premises? Was he, by the custom of the trade—and without a special contract to that effect—bound to prop up adjoining houses? and, by same alleged custom, did he incur responsibility in falling so to do? Numerous witnesses were examined on both sides. The professional men for the plaintiff were Messrs. Louch, J. S. Butler, J. J. Lyons, and Courtenay, architects; Donnelly, Murphy, and Nolan, builders; and for the defendant, Sir F. Deane, Jacob Owen, Wilkinson, and Carson, architects; Norwood and Leech, builders, besides plaintiff and defendant personally, and various other parties. Plaintiff's witnesses chiefly deposed to the right and responsibility of a contractor undertaking to rebuild a house to shore up effectually adjoining premises, also to the "custom" in the absence of special contract; that the measures adopted by the defendant were insufficient, and that owing to his fault the house fell; that the divisional wall was a party-wall. The witnesses for defendant maintained that there was no custom,—which, however, on cross-examination Mr. Wilkinson admitted,—that the fallen house had been in a dilapidated and insecure state, beyond the power of propping up with any amount of ordinary caution after the lateral support was withdrawn, that it had been tampered with by injudicious alterations; that bad weather was the immediate cause of its fall; that the wall was not a party-wall, and that all that could be done was done by the defendant. The Chief Justice (Molnahan) in summing up remarked, that the evidence was most conflicting; that the jury should consider if the custom had been fully proved; and, if so, had the defendant done all in his power to prevent injury to adjoining houses? and were the precautions such as he should have taken? Was the house

in that state of insecurity as to render *effectual* propping impracticable? After the utter impossibility of the jury agreeing to a verdict had been announced, one of their number (Mr. Alex. Parker) suggested, that as the case involved such serious considerations to both parties, the jury would, by permission of the court, constitute themselves into a committee of arbitration, with a view of effecting some amicable arrangement and prevent further litigation; to which his lordship readily assented, and complimented the juror upon the good taste and judgment displayed by his suggestion. The plaintiff's counsel also assented, but the defendant's dissented, observing that he would stand on his right on the law of the case. Sergeant O'Hagan (now Solicitor General) and Mr. Armstrong, Q.C.s, with Dr. D. C. Haron, were counsel for the plaintiff; and Sergeant Fitzgibbon, Messrs. McDonagh and Breton, Q.C.s, with Messrs. Eham and Osborne, were counsel for defendant.

#### FALL OF A SCHOOL BUILDING IN STOCKPORT.

DURING the prevalence of the high wind on Tuesday last week, a day-school, in connection with the Wesleyans, 84 feet long by 30 feet, was destroyed, killing one child and wounding seven others: 420 children were in the school, and miraculously escaped. At the inquest which was held, on the 1st inst.,—

Mr. James Wilson, of Bath, architect, gave evidence, to the effect that he prepared the plans for the schools, and forwarded them to Government. He estimated the cost to be about 4,000l.; and for that amount, the plans for this building could be well and judiciously carried out. The contract for the school alone was let to Mr. Warburton, of Manchester, for 1,917l. 10s. 8d.: that for the whole work was 2,600l. Saw the building occasionally while it was being erected,—last saw it when it was completed,—before that saw it when the roof was covered in. The committee appointed Mr. Hunt to see the building practically carried out, according to the plan; witness was only applied to for his certificate, for money to be advanced upon the work as it proceeded. Was expected to see that the plans were carried out in an architectural point of view. According to the specification, the walls were to be 18 inches thick, without the buttresses, from the plinth course to the roof. The width of the buttresses, including the wall, was 3 feet at the bottom, and at the top 3 feet 6 inches thick. The walls were to be built of brick, faced with Yorkshire stone. The breadth of stone on the bed of the boundary walls was not stated in the specification. Would think 4 to 6 inches, with binders; would be a fair breadth for a building of that description. The contract stated that the walls were to be properly bonded together, without defining the exact walls, leaving it open to the clerk of the works: the reference is to the inside walls. Those walls, to be properly bonded, were to be so every 10 feet, each course, the wall length. The inner walls to be of brick, filled up with rubble stone. That was the original specification, but by agreement it was to be backed up with brick. There is nothing in the contract to show that the lining should be bonded to the outer wall. The wall was to be 18 inches wide, properly bonded. Have examined the building this morning. The height of the roof, from the eaves to the ridgeing, was to be 26 feet, and the width of the span is 29 feet, by 30 feet long. The length 84 feet, from gable to gable, by 28 feet. There were eleven principals and two binders. The strength of the timber is specified. The collar pieces were to be 9 inches by 5 inches; king post, 9 inches by 3 inches; pullies, 7 inches by 4 inches; common rafters, 4 inches by 2 inches; wall plates, 2 inches by 4 inches; intermediate principals, 9 inches by 3 inches,—to be covered with blue Carnarvon slate. If the walls had been properly bonded together, the timber was sufficiently strong to support a roof covered with 40 tons of slate. Saw the roof when it was put on, and approved of it, after a few suggestions to Warburton, the contractor, had been done. His clerk came over two or three times, and measured the work. Had not heard, until this morning, that the roofing had been nearly blown away on a previous occasion. Made an examination of the building this morning, and am enabled to say that the fall of the chimney, having made an opening in the roof, allowed the gale to be introduced, and acted on the opposite or east side of the roof and wall. Should think the upper part of the easterly wall had swagged a little, causing the roof to be dislodged from the corbels, and thus let it down. The walls, as far as he could say, judging from what was remaining, are substantially built, but not sufficiently bonded. The outside casing has left the inner wall entirely. The separation would be caused by the want of bonding or defective mortar, though the upper portion of the back wall appeared as if they had been carried off separately. The better, as a matter of science, even if they had been properly mortared, or were of strength, could not have resisted the wind after it got in; outside, no gale could have touched it. If it had not been for the opening at the base of the chimney, the building would have resisted the gale.

By the Coroner: The great benefit to the workmen would be to leave out the "ties," because they could get better on with their work, and regularly if one party carried on without the other. There appeared to be want of adhesion in the mortar.

Mr. Marshall said, Mr. Hunt offered his services to superintend; he attended at the commencement of the works, but latterly he, as one of the trustees, appointed Mr. Beeston at 1l. per week for his services, which were returned to Mr. Hunt. But Mr. Hunt was not officially appointed, nor was he considered responsible.

Mr. John Whitaker, builder, said he had examined this building, and found that the walls had not been sufficiently bonded. This wall, as left by the contractor, was not sufficient to resist the fall of the roof, notwithstanding the fall of the chimney. The roof and gale would have thrown a stronger wall over. The weak points in this wall were where the glazed bricks terminated and the others began, which would be from five to six feet from the upper floor.

The mortar has not a sufficient quantity of lime in it, neither is the sand of the specified quality, being loamy. The timbers at the foot of the arches of the roof were not of sufficient strength—that was its weak place.

Examined by Mr. Cobbett.—Am a builder, and practice in Stockport; have done so for five and twenty years,—including my apprenticeship. Do not believe with Mr. Wilson, that the wall would have resisted the wind, if the roof had not pushed it down. The wall was 29 inches thick, and was without buttresses, of any kind.

Other evidence having been heard, the jury retired; and, after an absence of three-quarters of an hour, returned the following verdict:—"Accidental death. The jury cannot separate without expressing, in the strongest terms, their entire disapprobation of the loose manner in which the specifications had been drawn up, and the building details carried out by the contractor."

#### WHY NOT ENGLISH?

AMONGST the extraordinary changes which have taken place during the last half-century, it will be noted that education has been advanced amongst the masses more than formerly; and the practice of reading amongst the industrious and working classes has increased greatly. While this improvement has been going forward, it is observable that amongst the same classes the taste for the cultivation of the dead languages is but little encouraged, and thus many, who read the newspapers and other popular sources of information, where professional Latin and other terms are extensively used, are puzzled.

For instance, the useful reports of the medical officer of health are quite unintelligible to thousands who understand diseases by their English names, who know what consumption is, but not phthisis. A surgery or apothecary's shop presents mysteries which not ten persons in a hundred can fathom. In botany, chemistry, and some sciences, several of those who would study them for the purpose of adding to their general stock of useful information, are beset with the learned terms which might be simplified with advantage to the present generation. On the tombs even of popular personages, it has been the custom to place Latin inscriptions.

The use of the English language is spreading in all directions: might it not be worth while to endeavour to simplify and render more suitable to the living and succeeding generations the learned terms of science?

INQUIRER.

#### BUILDING STONE.

SIR.—The paper of Mr. Burnell, in your last number, on the varieties of stone used in architecture, especially in this metropolis, treats of a matter the importance of which can scarcely be exaggerated, but which requires to be elucidated in a still more searching manner than it would seem, from the portion of Mr. Burnell's paper already printed by you, that gentleman is inclined to employ. The fact of course is, that ornamental architecture is utterly thrown away, with all its cost, when employed upon a material which crumbles away, or peels off, after a few years' exposure to the atmosphere. The superficial durability of the stone employed in any building, but, above all, in one which is designed to be admired, is, or ought to be, the very first consideration with all the parties concerned in the erection of a stone building, whether those who pay or those who are paid for the work. Far better were it to condemn the use of stone altogether, and employ brick coated with plaster or cement, to receive a coat of paint every five or six years, than (as happened to Buckingham Palace, for example) employ stone of so untrustworthy a character as to make it necessary within a few years to resort to plaster and paint to heal its sores and hide its superficial decay.

Should you, as you propose, introduce some comments upon Mr. Burnell's lecture, after completely putting it before your readers, they would, I feel sure, be obliged by your affording some information as to who is responsible for the selection of the stone that has so egregiously failed in the new front of Buckingham Palace and the Houses of Parliament. Why was it supposed necessary to resort to the experimental use, in these important and costly buildings, of a kind of stone which had never been tried in the atmosphere of London before? and that when so many examples are to be met with of the almost perfect resistance to the influence of that atmosphere of the varieties of stone which our forefathers successfully (and as the event has shown) wisely employed, I mean the Portland and Bath stones. How admirably preserved is the Portland stone of St. Paul's, and of Greenwich Hospital! We have indeed "gone farther to fare worse," in going to Yorkshire for a novelty in London building materials. As for the Bath oolite, let any one examine either the highly-chiselled decorations, or

the plain superficies of the numerous beautiful Medieval churches and towers of Somersetshire or Wiltshire, and he will find that from three to six centuries have had scarcely any perceptible effect upon their surfaces. I believe the mistake has arisen from consulting chemists and geologists instead of experience. We cannot remedy the errors already committed; and yet we shall do wisely not to repeat them in our future metropolitan buildings of any pretension to architectural character, but to employ those qualities of stone only which have stood the test of ages, instead of listening to the opinions of closet experimentalists, however scientific. RESTRICTS.

#### RIFLE BUTT.

I BEG to send a suggestion for what I consider a good, cheap, and lasting rifle butt, easily made, and, when damaged, easily repaired.

The framing is made by fixing into the ground unpeeled larch poles, 30 feet high and 5 feet apart: to them fix ties and braces. The face of the butt is made by driving stakes, 8 feet long, 6 inches diameter, into the ground, to form a base, facing and hiding them well together with hazel limbs (not less than 3 inches diameter), similar to wadding; then fill and pun with clay and dry rubbish up to the top of the stakes. Proceed with the second tier in a similar manner, taking care that the lower ends of the second tier of stakes are well bound to the first tier.

In a country where rough timber is cheap, the cost of this butt, 50 feet long, 30 feet high, would be 160*l.*; but, if the volunteers themselves formed working parties some few evenings during the summer, and worked at the punning and filling, &c., only employing a good hedge carpenter to fix the frame and wadding, the cost would be but trifling.

RIFLEMAN.

#### THE "BUILDER'S" LAW NOTES.

**Statute of Limitations.**—Two persons, partners, became jointly indebted, in 1850, to a third person. The partnership was dissolved in 1853. An action was brought in 1859 for the debt, and it was proved that an acknowledgment in writing took place in 1856, before the Statute of Limitations operated. It was held, however, that, as this acknowledgment was only made by one of the two debtors whose partnership had ceased, it was not such an acknowledgment as kept the debt alive, which was accordingly declared, by Vice-Chancellor Kindersley, to be barred by the Statute of Limitations.—*Re Hindmarsh.*

**Lands Clauses Consolidation Act.**—Certain lands in Berkshire were purchased by the Great Western Railway Company; and, at the time of the purchase-money being paid into court, the "uses" of (or legal rights connected with) the land were not the same as they subsequently became. The tenant for life petitioned that the money in court should be invested by the company in accordance with such new rights, and that the company should pay the expense of such investment. Vice-Chancellor Kindersley made an order that the money should be paid out of court for the purpose of being invested, and that the company should pay the costs of the application; but he refused to compel the company to pay the expenses of investment.—*Re De Beauvoir's Trusts.*

**The Winding-up Acts.**—A person held a debenture-note of the Royal Bank of Australia, payable in February, 1850. A winding-up order against that bank was made in the July of that year. The debts were all paid before 1857, and a dividend was made amongst the contributors. The present claimant only came forward with his claim in 1859. It was held by Vice-Chancellor Stuart that he was barred by the Statute of Limitations, as well as by other causes. The manager to be precisely in the same position as an official assignee in bankruptcy. The latter is a trustee in the complete sense of the word; and, notwithstanding lapse of time, he must pay as long as there are assets.—*Re Forrest.*

**Partnership-Debt.**—Two persons carried on business in partnership. One drew out of the partnership cash 2,000*l.* more than the other partner. It was held by Vice-Chancellor Wood that, though this became a debt, yet, in the absence of any agreement, it did not bear interest.—*Rhodes v. Rhodes.*

**Seizure of Goods.**—It has been held by the Court of Exchequer that the County Court Act does not authorize a bailiff under a County Court warrant to distrain and sell the goods of a stranger which are on the premises of defendant.—*Foulget v. Taylor.*

#### Books Received.

*Some Account of the Condition of the Fabric of Llandaff Cathedral, chiefly from 1575 to the present time.* By the Bishop of LLANDAFF. London: Rivingtons. 1860.

It is this, which is a second edition of an account of the cathedral previously published, will be found twelve illustrative plates, showing as well the design of the old parts as the absurdity of the beauty for restoring it in 1736. In earlier volumes of the *Builder*, at the time when an architect was connected with the restorations at Llandaff, whose name, oddly enough, is not once mentioned in the book before us, full particulars of the history and condition of the fabric will be found,\* so that we need not now go into it.

The great object the bishop has in view in the publication of this book is to invite the assistance of the friends of the church in providing an organ, which Llandaff Cathedral has not had for the last 170 years, and which the members of the chapter, it appears, have no means of purchasing for themselves.

It is certainly a reproach that any cathedral should be in such a condition; and, as the bishop and chapter have been doing their best, almost, it may confidently be hoped that when their case is known an organ of proper character will be provided.

One thousand pounds would do what is requisite, and this might easily be raised if a few friends would take the matter up.

#### Miscellanea.

##### ENGLISH ENGINEERS AT CONSTANTINOPLE.

A general strike has taken place amongst the English engineers employed at the Arsenal, and those recently arrived for the service of the new steam corvettes and gunboats. The former, it is said, have consented temporarily to resume work on the understanding that the grievances they complain of—irregularity and delay in payment of their wages—shall receive the immediate attention of the authorities.

##### BATHS AND LAUNDRIES IN MANCHESTER AND SALFORD.

The annual meeting of the Manchester and Salford Baths and Laundries Company was held at the Town-hall, on Wednesday morning, Alderman Neild presided. There are two establishments in connection with the company, one at Greengate and one at Mayfield. On comparison with 1858, the past year showed an increase of 36,432 bathers, and 547 washers. There was an increase in the expenditure, which was partly owing to the repairs necessary in the swimming-bath, and partly to the increase of business. The net profit for the year had been—at Greengate, 233*l.* 9*s.* 9*d.*; at Mayfield, 432*l.* 19*s.* 11*d.*; making a total of 666*l.* 9*s.* 8*d.*, being an increase over the previous year of 250*l.* 9*s.* 6*d.* To this was added a small amount carried over from last year, which left a disposable balance of 702*l.* 12*s.* 3*d.*, from which the directors recommended that a dividend of 3 per cent. on the year be declared to the original shareholders.

##### A NEW CLASS OF OLD IRISH MONUMENTS.

At a recent meeting of the Royal Irish Academy, the Rev. Charles Greaves, D.D., made a statement "of a hitherto undescribed class of ancient Irish monuments," some of which had first attracted his attention while on a tour in Kerry, examining oghams. The first he saw consisted of a portion of rock, denuded from a bog. It was found to be covered with circles and dots. He afterwards saw others in various places. Describing them generally, he says,—"I thought that possibly they might have something to do with what is called the spectacle ornaments found upon Pictish stones, but here there were but two of these circles. Those I have been speaking of were arranged systematically, so as to form a symmetrical ornament. I at last saw the figures had certain geometrical relations; that is to say, that the circles or dots upon them tended to arrange themselves into groups of three in a straight line. At once the perception of this led me to the conclusion that these figures must represent some circular objects geometrically related to one another in their positions; and I could not forget that in Pettie's Essay on Tara, there is a map of the monuments at Tara, similar to these figures. Thus I came to the conclusion that these inscriptions must have been intended to represent groups of what we call forts; that is, the circular earthen structures of our ancestors in this country."

\* See vol. vi. pp. 182 and 211, and afterwards.

**FREE LIBRARY AT BALMORAL.**—A library of 400 volumes, the gift of her Majesty and the Prince Consort, for the benefit of the tenants on the estates of Balmoral, Abergeldie, and Birkhall, has just been opened.

**CAMBRIDGE ARCHITECTURAL SOCIETY.**—The second meeting in the Lent term of this society, was held in the Philosophical Society's Rooms, on the 23rd ult., the Rev. H. R. Luard, in the chair, when the Rev. G. Williams, of King's College, read a paper on "Roman Basilicas." Mr. Williams traced back the history of the Basilica to the original Stoa Basilieos at Athens, which derived its name from the Archon Basilieus, as being the court where he administered justice. The first he remarked was introduced to Rome by the celebrated Marcus Porcius Cato (B.C. 210), from whom the Basilica then erected was named Porcia.

**BRAY'S TRACTION ENGINE.**—The company who purchased Mr. Bray's invention, have forwarded to us a printed report of their first general meeting, with a request that we will aid in correcting an *ex parte* law statement to the prejudice of their engine, which has been largely quoted by our contemporaries. As we refrained from even alluding to the obviously fancy sketch of the special pleader referred to, we have the less occasion to enlarge on this subject; but we may state that the chairman explained at the meeting that "three hundred gallons of water were requisite to work the engine and tender; but Mr. Myers made no provision for keeping up the supply, depending mainly upon the water he found in the ditches and ponds on the road-side. That source, as might have been expected, failed, the summer being unusually dry, and the water, when obtained, was frequently dirty and unfit for use, so that both boiler and cylinders were much damaged, the tubes burnt, and the safety-plug, which was filled in with lead to prevent explosion, was burnt away no less than five times during the journey. But the object of the plaintiff was to evade the claim of the company against him for thus damaging the engine, by setting up a counter claim, as was obvious from a letter on the subject, in which he said he was afraid he should have to "advertise" the engine as a perfect failure." The principle of the wheel of Bray's engine, we may here note, is to put forth the claw, to gain the traction; and that being done, the claw is withdrawn by the eccentric, and a flat surface presented, which acts upon the road like a heavy roller. The printed report contains documents, from which it appears that Bray's engine has given satisfaction to the Woolwich dockyard authorities, and to Messrs. Maudslay, Penn, and others.

**THE NEWSPAPER STAMP.**—Mr. John Gray, a proprietor of the *North British Advertiser*, makes the following practical and excellent suggestions. "Firstly, to accept the Chancellor's proposal, that all newspapers not exceeding four ounces in weight go by post if hearing the common penny stamp; and that all newspapers above four and not exceeding six ounces in weight may be conveyed by post if hearing a three-halfpenny stamp. But, secondly, that it shall be optional for every newspaper proprietor to be furnished with either one-half penny and three-halfpenny adhesive stamps, bearing the name of his own paper, and to be sold to him only; said stamps to convey the paper only, the name of which it bears; it being at the same time rendered illegal, and punishable with fine or imprisonment, for any person whatsoever, except himself and his own servants, to use, or to be found in possession of, one or more of these distinctive stamps in an unholiered state. The general use of these stamps by any newspaper proprietor should not, however, preclude him from using the common penny and three-halfpenny stamp whenever chance or convenience might require him to do so. Under this law every newspaper proprietor would be enabled to protect himself against any loss of stamps by peculation. His stamps would be of value to himself only, precisely as is the distinctive stamp impressed upon his paper now. Temptation would not be presented to office boys or others to steal these stamps; and as they would be required in very large numbers at a time, the printing thereof would create no extra trouble or expense whatever, original type or engraving only excepted." A correspondent of Mr. Gray's paper also suggests what Mr. Gray regards as a good idea, in addition to his own, namely, that "should Government be unwilling to print the name of each newspaper on the stamps, a special newspaper stamp might be issued with a blank in the design, and this could be filled up by the proprietor of the paper printing its title at his own expense;" and that the same stamps might be sold conditionally to the public.

**OUR FORTIFICATIONS.**—The Fortification Commission have finished their labours, and sent in their report. The minister is sitting upon it, and what he will hatch we do not know.

**WANTED, AN ASSISTANT!**—With reference to the notice in our last, of the experience of an assistant under the above heading, we have received several letters complaining of ill treatment under similar circumstances.

**NEW WESTMINSTER BRIDGE OPENED.**—On Thursday, the 1st, the completed half of the proposed new bridge, already fully described in these pages, was quietly opened to the public by the Chief Commissioner of Her Majesty's Works, Mr. Cowper, and the engineer walking over it, and then admitting the crowd who had gathered to look at them.

**SALE OF THE MILTON CLUB HOUSE.**—Messrs. Norton, Hoggart, & Trist, have sold by public auction, at the Mart, the freehold property known as the Milton Club-house, No. 14, Ludgate-hill, with a public-house and two dwelling-houses and shops, in St. Martin's-court, having a frontage of 30 feet to Ludgate-hill, a depth of 108 feet to Little Bridge-street, and occupying an area of about 7,500 square yards. The houses in the rear let at rents amounting to 175*l.* per annum. The property sold, subject to yearly rent charges amounting to 700*l.*, for 8,900*l.*

**BERKELEY HOUSE FOR THE BOARD OF WORKS.**—In reply to Mr. E. James, in the House of Commons, as to the sum paid by the Metropolitan Board of Works for the site of Berkeley House, upon which the board is erecting a building for their own use, and what sum was to be expended by the said board in the construction of such building, Mr. Cowper said that the Metropolitan Board of Works had given 500*l.* for the site, and 799*l.* for the old materials. They had a lease of the ground for ninety-nine years, at 5,000*l.* a year for the first ten years, and 350*l.* for the remainder of the term; and the amount to be spent in the whole on the construction of the building, including all extras, would be 16,000*l.*

**STRIKE AMONGST THE MASONS FOR NINE HOURS.**—Just when the neighbourhood of Huddersfield promises most work a difficulty has arisen between the masters and men. The operatives gave notice six months ago. The notice expired on the 1st of March, and they, sending a second notice to their employers to say they adhered to their purpose, all struck work on that day. The masters met the men by declaring their determination to resist the movement. Yesterday, however, the masters (eighteen in number) issued an announcement that they would give 4*s.* 6*d.* a day instead of 4*s.* The men have not, however, as yet accepted the offer, and thus we are threatened in Huddersfield with a repetition of the disaster which has so injured the metropolis, harming all concerned, paralysing labour, and crippling capital.—*Leeds Mercury.*

**THE PRINCE CONSORT AT THE ROYAL EXCHANGE.**—On January the 3rd, the Prince Consort inspected the fresco decorations in the Royal Exchange, and was met at the entrance to the building by the Lord Mayor and others, members of the committee. Mr. Tite, M.P., the architect of the building, and Mr. Sang, who has executed the late decorations, were also in attendance. His Royal Highness spent about half an hour in examining the various designs. While his Royal Highness and suite were in the quadrangle of the Exchange, Mr. W. G. Rogers, the carver, invited the Prince, in the name of the churchwardens, to inspect the redecorations of St. Michael's Church, Cornhill, which have been lately carried on by Messrs. G. G. Scott and H. Williams. The invitation was accepted, and the Prince went over St. Michael's, and duly examined the carvings there, of which we have already given a description.

**THE LONDON DISTRICT TELEGRAPH.**—The half-yearly meeting of the London District Telegraph Company has just been held. The report stated that of the first call of 1*l.* per share, 10,740*l.* had been paid, leaving only 160*l.* unpaid. The capital paid up amounted to 21,320*l.* The new lines completed during the past half-year comprise extensions to Kingsland, Mile-end, London Docks, Greenwich, Clapham, Camden Town, and Highbury. The length of the line completed consists of two miles under ground, and 10½ miles over house; lines contracted for in progress, but not completed, under ground, ½ mile; over house, 20 miles. In progress by the engineer, 11½ miles over house, making, with 22½ miles previously completed, 67½ miles. The report was adopted, and the directors were authorized to extend the wires of the company beyond the radius of four miles from Charing Cross, and within a radius of 12 miles, for fire and police purposes only.

**ENGLISH PAPER-HANGINGS.**—A deputation of paper-hanging manufacturers, consisting of Messrs. Heywood, Thos. Cooper, H. G. Ashton, R. Watson, Ridley, Whitley, D. Graham, W. Haselden, W. Woollams, W. Cooper, Joseph Albright, Wm. Snape, James Solomans, Henry Lighthour, John Lindsay, and S. M. Hubert, accompanied by Sir J. Duke, had an interview with the Chancellor of the Exchequer last week.

**THE BRITISH MUSEUM.**—In reply to a question by Mr. Joseph Locke in the Commons, as to whether the Natural History Collection is to be removed from the British Museum, and if so to what place, Lord Palmerston replied that although the trustees had decided to remove the Natural History Collection, and retain the library and other departments, no decision had been come to as to the particular place to which the removal should be made; but that Government would consider the matter a little farther before anything was done.

**CLEANSING THE SERPENTINE.**—The contract for engine-house and other buildings, groundwork, and sculpture, required to carry out Mr. Hawkesley's plan for cleansing the Serpentine, has been entrusted, according to a return just published, to Messrs. J. & E. Bird, of Hammersmith. The tenders were called for on 9th November, and five were sent in. Messrs. Bird's was the lowest, the amount being 13,023*l.* The works were commenced on the 28th December last, and are to be completed on 1st May, 1860. Messrs. James Watt & Co. have the contract for the engine and machinery. Meantime, Mr. Cowper, the Chief Commissioner of Works, has proceeded, in the Commons, the nomination of the following select committee on the Serpentine:—Mr. Cowper, Lord J. Manners, Sir J. Shelley, Mr. Blackburn, Sir M. Peto, Mr. Joseph Locke, Mr. Walter, Sir J. Paxton, Lord Fermoy, Mr. Byng, Mr. A. Egerton, Capt. Archdall, Sir F. Smith, Mr. Beach, and Sir M. W. Ridley. Power to send for persons, papers, and records; five to be the quorum. The decision will, we hope, be revoked.

**A STREET GRIEVANCE: DONKEY TRAPS!**—I venture to ask the influence of your journal in behalf of the poor hardworked costermongers' donkeys, whose feet so frequently get caught in the iron traps of the water-mains. Why should the water companies have iron-fanged holes in the pavement of the streets, dangerously placed at almost every corner of the chief thoroughfares, whereby the most excruciating suffering is inflicted on poor animals whose burthen needs no addition? The holes, too, seem made expressly to catch a donkey's hoof without admitting its withdrawal, and the check thus given to the progress of the poor victim is sufficient to cause, if not a broken leg, a sprain that will take some time to cure. There are covers for cellars, and for every other thing which interferes with the traffic: why not, then, covers for the street water-cocks? The expense, surely, can have nothing to do with it. I saw a safe to-day, where, in addition to the strain already endured, the farrier was wrenching off the shoe from a poor donkey whose struggles were most piteous. I trust such cruelty will no longer be permitted, and that the *Builder* will urge the necessity of an immediate remedy. It is time a little science, or common sense, was brought to bear on the ironwork of our street water-cocks, if only for the prevention of cruelty.—J. B.

**COMPENSATION IN PARIS.**—Juries are constantly engaged just now in settling the amount of compensation to be paid to owners and tenants of houses required for the improvement of the streets of Paris. The late proprietor of the Café de Foy, in the Palais Royal, when driven thence, had taken refuge in the Rue Batte. According to the *Morning Star*, M. Foy (as he is called) had amongst his customers many of the leading artists of the day, to whom he had been useful, and they set about rendering his new abode attractive, and installed him in a magnificent Louis Quinze salon—a Swiss chalet smoking-room, and a Chinese summer-house, all beautifully executed by Horace Vernet, Paul Delarocche, and others. When the city of Paris, therefore, came to bid M. Foy and his attractive museum adieu,—a sort of rival Luxembourg, in which he had been distributing his coffee and gloria,—M. Foy refused, naturally, to do so, without a most powerful consideration. The case was referred to the tribunals. The city of Paris offered M. Foy an indemnity of 300,000*fr.* Maitre Freslon, the advocate employed by M. Foy, insisted upon no less than 700,000*fr.*, not, as he observed, for the physical importance of the place, but for the moral and intellectual value of the thing. With such an argument as this what course could possibly be pursued? The 700,000*fr.* were accorded.

ARTISTIC COPYRIGHT.—The Council of the Society of Arts propose to bring the Amendment of the Law of Artistic Copyright before the Legislature, at the earliest possible moment.

A UNION FOR PURCHASE OF BOOKS.—A correspondent, "C. E." referring to the fact, that in consequence of the cost of architectural and engineering works, many of the junior members of the profession are debarred from obtaining a suitable library, suggests that an association be formed on the principal of "Art Unions," for the purchase of architectural and engineering publications, each subscriber of 10s. to have one chance of a prize. The holders of prize tickets to select the works, subject to the approval of the committee.

SAND IN LIEU OF STRAW FOR HORSES' BEDS.—Mr. Small, a veterinary surgeon of considerable experience and successful practice in Ulster, states that in the present scarcity of straw he uses sand for horses' beds in his repository, and further observes that sand is superior to straw, inasmuch as the former article does not retain heat, and also serves horses' hoofs. Mr. Small's alleged successful experiment deserves extended circulation, now that the market price of straw is so high. We should be glad to know the opinion of our local veterinary surgeons on this discovery.—Kilkenny Moderator.

MEMORIAL OF MRS. HEMANS.—It is proposed to erect a stained-glass window in the chancel of the parish church of St. Anne, Dublin, to the memory of the celebrated poetess, Felicia Hemans, whose remains were there buried. The window will represent the leading female characters of the Old and New Testament History, selected with regard to Mrs. Hemans's series of admirable sonnets on that subject, and with the view of illustrating her own writings and character. The execution of the window will be intrusted to first-rate artists. The probable cost will be 250l., and of this sum 40l. have been already promised by a few friends. Subscriptions will be received (among others) by Mrs. S. C. Hall, 27, Ashley-place, Victoria-street, Belgravia. There is also a Dublin committee; and at Edinburgh Messrs. Blackwood & Son, the publishers, will receive subscriptions.

THE ROYAL SOCIETY.—The President of the Royal Society gave his first *soirée* for the season on Saturday last, at Burlington House. All the rooms were thrown open, and an unusually large collection of interesting objects in science and art was exhibited. Among these were the extremely beautiful machine for weaving by electricity, invented by Mr. Bonelli; Mr. H. Bradbury's engraving machines, which were exhibited in action; specimens of the newly-invented process of photo-zincography, by Colonel James, director of the Ordnance survey; models of Mr. Whitworth's guns, and specimens of the actual shot used, explained by Mr. Whitworth; a very interesting series of portraits and relics of Dr. Priestley, including two of his electrical machines; Trevithick's original locomotive engine, exhibited by Mr. Woodcroft; curiosities from Japan, exhibited by Captain Osborn and Dr. McGowan; model of an iron fortress, exhibited by Mr. Hall; and a series of experiments, showing electric discharges *in vacuo* by the voltaic battery, by Mr. Gassiot. The Prince Consort was present.

ACCIDENTS.—A scaffolding has fallen at Oxford-street, Ecclehall-road, Sheffield, at some houses which are being built by Mr. George Seville. The walls were raised to the height of about 24 feet, and the men were going on with their work as usual, when the fastening, connecting two lengths of planks to one of the poles, gave way, precipitating five men, who were standing on them, to the ground. Two of the men, Mr. Seville and a labourer, received no injury beyond a mere shaking.

During the late tremendous storm of wind much damage has been done in various parts of the country, as well as in the metropolis. At Derby, when the storm seemed at its height, the spire of St. Alkmund's church, including the vane and many feet of solid masonry, was blown down, and, crashing through the church below, caused great injury, which will take a considerable sum of money to repair. One of the pinnacles of the Roman Catholic church tower was also injured in a similar manner.—At Nottingham considerable damage was done to the church of the Holy Trinity, portions of which were torn away, and for some time fears were entertained that the spire would be blown down. A pinnacle of St. Stephen's church, Sneiton, near Nottingham, was blown on to the roof, damaging the latter. The roof was torn from St. Anne's chapel-of-ease, Nottingham.

DISCOVERIES IN EGYPT.—Lord Dufferin has been excavating on the banks of the Nile, and we understand that a small temple, with the columns *in situ*, and a considerable number of inscriptions, have rewarded the search.

A MEETING FOR EAST LONDON.—A deputation attended the Chief Commissioner of her Majesty's Works, the Right Hon. W. Cowper, last week, to present a memorial, setting forth the necessity for a public museum and library which should be accessible to the inhabitants of the eastern and south-eastern districts of the metropolis, and soliciting the aid of Government to facilitate the attainment of the objects desired.

FOUNDATIONS OF BUILDINGS ON FIRE.—For several days the singular circumstance was presented of the foundations of a packing-house, &c., at the manufactory of Messrs. Boote, in Waterloo-road, Burslem, being on fire. It seems, says the *Staffordshire Advertiser*, that the building rests on a foundation of rubbish, in which there is an admixture of a kind of cannel coal, and this, there is reason to believe, had taken fire from a flue in the saggar house, which is on a very low level. By means of the fire-plug hose a large quantity of water was turned into the foundations, and the fire appears to be now subdued; but it seems to have extended to the foundations of the adjoining residence, and so injured a pile of building at the rear that it has been deemed requisite to support it with planks. The walls of the packing-house, &c., are also cracked.

TENDERS

For the erection and completion of three mortuary chapels, with lodges, entrance gates, iron railing, boundary fences, &c., at Over Darwen, near Blackburn. Mr. J. Stevens, architect, Manchester. Quantities supplied by the architect:—

Table with 2 columns: Name and Amount. Includes Kay, Darwen (£3,310 0 0), Brown, Stockport (£300 0 0), Howarth & Son, Blackburn (£3,270 0 0), Knowles, Darwen (accepted) (£3,220 0 0).

For building ten houses, for the London and Suburban Mutual Benefit Building Society. Messrs. Hammaek & Lambert, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Jones (£3,614 14 2), Furnival (£3,200 0 0), Heath (£2,925 0 0), Perry (£2,870 0 0), Ennor (£2,867 0 0), Helges (£2,865 0 0), Tolley (£2,857 0 0), Derby (£2,170 0 0), Scott, Bow (£2,170 0 1).

For alterations and additions to the Manor-house, Caterham, Surrey, for Mr. Parbury. Mr. Hahn, architect. Quantities supplied by Mr. B. Roberts:—

Table with 2 columns: Name and Amount. Includes Browne & Robinson (£3,217 0 0), Piper & Sons (£3,190 0 0), King & Burton (£3,155 0 0), Perry (£2,746 0 0), Rider (£2,350 0 0).

For new Catholic church, Brentwood, Essex. Mr. G. R. Blount, architect. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes White, Romford (£2,941 7 8), Roper, Chelmsford (£2,750 11 4), Wood, London (£2,745 0 0), Bird, London (£2,694 0 0), Patman & Fotheringham (£2,659 0 0).

For new chapel and vestries, Ledborough road, Brixton, for the Rev. D. A. Herschel. Mr. W. G. Habersham, architect. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Green (£2,990 0 0), Conder (£2,909 0 0), Patman & Fotheringham (£2,895 0 0), McLennan (£2,835 0 0), Simpson (£2,255 0 0), Evans (£2,250 0 0), Tarrant (£2,100 0 0), Seagrave & Bloomfield (£1,990 0 0).

For new printing-office, Fountain-court, Shoe-lane, for Mr. Thomas Harlid. Messrs. Arding and Bond, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Patman & Fotheringham (£9,440 0 0), Brown & Robinson (£2,419 0 0), Brava (£2,351 0 0), Axford & Co. (£2,223 0 0).

For house at Windsor, for Rev. Mr. Hawrcry. Mr. Street, architect:—

Table with 2 columns: Name and Amount. Includes Lawrence (£2,641 10 0), Holden (£2,384 0 0), Hardy & Soa (£2,360 0 0), Silver (£2,361 0 0), Snowball (£2,360 0 0), Hoils (£2,160 0 0).

For rebuilding No. 14, Minorities. Messrs. Smith & Williams, architects:—

Table with 2 columns: Name and Amount. Includes Patman & Fotheringham (£1,470 0 0), Little (£1,414 0 0), Wilson (£1,434 0 0).

For new rectory-house and offices, North Searle, Notts. Mr. Goddard, architect:—

Table with 2 columns: Name and Amount. Includes Semper, Searle (£1,100 0 0), Walls & Son, Ruseson (£1,007 0 0), Crosby, Coleby (£900 0 0), Reed & Macdonald (£98 0 0), Clapham, Norwell (£84 0 0).

For the erection of house, No. 27, Aldgate, for Mr. James Brown:—

Table with 2 columns: Name and Amount. Includes Ashby & Horner (£1,238 0 0), Ashby & Sons (£1,150 0 0), Broadbent (£848 0 0), Thompson (£1,135 0 0).

For parsonage-house, Sutton Cheney, Leicestershire. Mr. Edward Browning, architect, Stamford:—

Table with 2 columns: Name and Amount. Includes Lawson & Joy (£1,449 10 0), Neal & Hextall (£1,298 0 0), Skelchley & Co. (£1,150 0 0), Broadbent (£1,135 0 0), Harrod (£1,096 6 0), Gutteridge (£1,064 10 0), Cogswell & Day (£1,055 0 0), Harrod (£1,048 0 0), Osborne (£1,028 0 0), Spencer (£991 0 0).

For alterations to No. 59, Crown-street, Finsbury. Mr. Charles Lewis, architect:—

Table with 2 columns: Name and Amount. Includes Brown & Robinson (£298 0 0), Ripper (£299 0 0), Patman & Fotheringham (accd.) (£75 0 0), Faxley (£64 0 0).

For alterations to a shop-front, for Mr. Jesse Jones, No. 273, Pentonville-road. Mr. R. J. Breda, architect:—

Table with 2 columns: Name and Amount. Includes Williams (£160 0 0), Batechelor (£135 0 0), Barnes (£121 6 0), Webber (£118 0 0).

For alterations to the Phoenix Tavern, Smith-street, King's-road, Chelsea. Messrs. Finch Hill & Paraire, architects:—

Table with 2 columns: Name and Amount. Includes Mills (£520 0 0), Purkis (£485 0 0), Turner & Sons (£411 0 0), Jells, Brothers (£402 0 0), Hodges (£377 0 0).

TO CORRESPONDENTS.

P. B.—G. M.—F. R. W.—E. B.—A. Kiffeman (if danger can be proved, the practice can be stopped).—H. B. (Will you send us a plan of cottages built for the sum named?).—H. C.—G. B. M.—W. H. W.—J. M. (we are unable to comply).—A. Clerk.—J. N. P.—W. and R.—J. P. (P.—W.—H. B.—J. W.—J. N. P.—W. C.—J. G. A.—H. M.—G. P.—A Workman.—Ema.—A. J. H. (next week).

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and not to the "Publisher."

Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

ADVERTISEMENTS.

MR. WILLIAM ELLISON, CONSULTING SURVEYOR, RATE OF STAINSBY ROAD, THE LARK OFFICE, 13, FENCHURCH-BUILDINGS, FENCHURCH STREET, E.C. AND IN BREACHES OF CONTRACT, DISPUTED ACCOUNTS, &c.

SWANSEA UNION.—CLERK OF THE WORKS WANTED.—The Guardians of the above Union hereby give Notice that they will, at the Weekly Meeting of their Board on THURSDAY, the 2nd MARCH Instant, at ELEVEN O'CLOCK in the forenoon, proceed to the APPOINTMENT of a CLERK of the WORKS, to superintend the Building of a New Union Workhouse at Swansea. Salary two guineas per week. Duties to commence immediately. Applications and testimonials to be sent to the Clerk to the Guardians, on or before WEDNESDAY, the 21st Instant.—By order, CHARLES COLLINS, Clerk to the Guardians, 6, Fisher street, Swansea, 1st March, 1860.

THE TOWN OF BURTON-UPON-TRENT

ACT, 1833.—TOWN SURVEYOR WANTED.—The Commissioners under the above Act will, at their monthly meeting, to be held at their Offices, No. 33, High-street, Burton-upon-Trent, on WEDNESDAY, the 4th day of APRIL, 1860, at HALF-PAST-TEN in the forenoon, proceed to the appointment of a TOWN SURVEYOR, who will also be required to undertake the Office of Inspector of Nuisances, Lodging-houses, and Slaughter-houses, and Superintendence of the Fire Brigade and Sewerage Department. Salary, 150l. per annum. The person elected to devote the whole of his time to the service of the Corporation, and to be bound to consent to prepare plans of new works, and additions to, or alterations of, existing works, for the effectual drainage of all houses, buildings, and other premises within the district, and to perform all the duties required by the Town Improvement Clauses Act, 1857, and to take charge of the streets, and of the cleaning, watering, lighting, cleansing, and watering, all the streets, roads, and highways, and of cleansing and repairing all sewers and drains within the said district. Also of carrying out, as far as law requires, the Inspection of Nuisances, Lodging-houses, and Slaughter-houses, Superintendence of the Fire Brigade, and all such orders and regulations as shall from time to time, by the said Commissioners or their successors in office, be found necessary to be made for carrying out the provisions of the said Act, and of the several Acts incorporated therein.—Applications in writing, accompanied by recent testimonials of character and competency, to be delivered to the undersigned, or to the Office of Town Surveyor, on or before THURSDAY, the 29th day of MARCH Instant. Candidates whose Communications will be deemed a disqualification.—By order of the Commissioners, W. M. COXON, Clerk to the Commissioners, Commissioners' Office, St. Hill-street, Burton-on-Trent, March 3, 1860.

A GENTLEMAN, residing within ten miles of London, Land Agent to a nobleman having considerable property in two of the southern counties, has a VACANCY for a FIFELDER.—Address, R. care of Messrs. Warr, 65, High Holborn, W.C.

# The Builder.

VOL. XVIII.—No. 893.

Domestic Architecture.—An Experiment in Scotland.

NOT long ago mention was made in these pages of a house erected in Merchiston-park, near Edinburgh, by Mr. Gowan, and of a paper descriptive and illustrative of the structure, read by that gentleman before the Scottish Architectural Institute. Experiments, founded in reason and intelligently carried out, can scarcely fail to be valuable to the community, whatever the result may be to the individual; and our readers will thank us for placing before them the result of that made by Mr. Gowan. We have engraved a view of the house from a photograph,\* and avail ourselves of the owner's paper to show the ideas that influenced him. Two very valuable, though of course not new, principles are urged,—that the interior should be so arranged as best to meet the requirements of those who are to occupy it; and that the exterior should be designed with a view to the proper application of the materials at hand. He dwells upon the value of designing upon geometrical lines, not only with reference to the production of order and regularity, but as bringing out all the doors, windows, and finishings of one uniform size, and so admitting of their execution by machinery, at a considerable reduction of cost. The stone obtainable in his neighbourhood required the adoption of random masonry, thus using up the waste stone from quarried masses, and then to bind this together light material was used, hewn without much accuracy, to please the eye.

"In the country," says Mr. Gowan, "where small houses suitable for agricultural labourers and others have to be provided, and where economy in the use of material is a chief requisite, it is of the first consequence that the truthful application of the material in the district should be scrupulously attended to; and there is no part of the country where proprietors or others have to go far to find material fit for building purposes."

It is no uncommon thing for an architect or builder to carry stone from a distance, while material equally fitted for the purpose is lying at hand, or, if not seen above ground, should be brought to light by studying the run and lay of the strata in the vicinity.

"I have given my attention for some time to the proper and economical use of materials for building purposes, and I have come to the conclusion that architects and builders have much to learn in the way of using truthfully and economically the material which in almost all places is to be found. When an architect is employed to design a building and furnish specifications, he too often adopts some favourite style of building, and a stereotyped specification, which, not being applicable to the district from which he has to get his material, involves a great and unnecessary expense; and in consequence the building comes to too much money, and, to get it to go on, the accommodation must be curtailed; if cottages be the case, and one or two are built at the increased expense, it has the effect of deterring others from anything of a similar kind. In fact, I have known a proprietor who came from a sale quarry at a distance when stone was good a quality was to be found almost under the site of the building he was erecting."

The writer says he had no desire in design-

ing his house to create a novelty; all he wished to do was to erect a building which, without borrowing from any example, would test, in a practical way, what he could attain by a truthful use of materials worked out on certain geometrical lines. He also wished so to dispose the colour of the materials as best to show the details of the structure. The several objects he endeavoured to secure shall be set forth in his own words:—

1. That the principal rooms of the day portion of the house should be so situated in respect of aspect as to command the best views of the locality and the greatest share of sun-light, and, at the same time, be so placed that they shall all have ready access from a corridor or saloon, which would have the same importance in style as the rooms to which it forms the entrance; and these rooms should have, also, a ready access to and from each other. In the case of the dining-room, the servants' access should be distinct from that of the public.
2. That the kitchen and servants' working apartments have a distinct and separate portion of the building allotted to them, so placed as to give the servants private and ready access to the day and night portions of the house, and also ready access to the principal entrance-door, without having to pass through the corridor or saloon.
3. That the principal sleeping-rooms be of a large size and high in the ceiling, and have easy access from the stair-landing or lobby. I have secured what is desirable in this respect by making the principal bed-rooms enter from a spacious lobby, which is lighted and ventilated by a well-hole up to the roof, which also supplies light and ventilation to the attic rooms.
4. To have the children's sleeping and day rooms placed on one side of the building, and, at the same time, convenient to and distinct from, the chief bed-rooms.
5. To place the closets belonging to each department of the house in such situations as, while admitting plenty of light and thorough ventilation, will secure convenience and privacy."

As the subsoil on which this house is erected was of a very damp and retentive nature, the whole area of the building was drained to a depth of 4 or 5 feet. This was done to prevent, as far as possible, the effect which freestone has, by capillary attraction, of sucking up the moisture from the soil on which the foundation of the building rests; and further, as there was a vacant space of 4 or 5 feet from the surface of the ground to the first-floor level, this space was ventilated by admitting fresh air from the exterior at one point of the building, which found an outlet into a receiving chamber connected with the kitchen flue, which is made of cast iron. To prevent this cold air from finding its way into the rooms, the whole of the deal-floored apartments on the ground-floor were pugged.

He proceeds to show how the external features and outlines of the building are brought out by the semicircle and the angles of 22½ degrees, 45 degrees, and 67½ degrees:—

"The geometrical lines I adopted were 2 feet squares, the building on the whole being multiples of that scale, or aliquot parts of it. The same lines which fix the internal arrangement of the plan were carried up on the face of the building, so that, working on these lines, and admitting only of the necessities of the building for the production of the architectural features, I have succeeded in realizing to some extent the idea I had in my mind's eye before I commenced the erection.

This idea of designing upon squares and fixed angles, although new to me, must have been, I am convinced, known to the master masons who produced the best examples of those styles of architecture which we so much admire. These lines are more observable in the Gothic than in other styles: the more rich and elaborate the design, the easier it is to trace the leading lines of the structure.

From the experience I have had in drawing out the details of this building, I can understand how our old master masons were able to revel in endless design and combination of figures.

Apart altogether from the facility this system gives to the architect in combining the different parts of his design, it leads more effectually than any rule of thumb principle can, into that variety of form and device, so apparent in some of the

more elaborate specimens of the decorative Gothic, and which are so richly delicate, and yet so constructively correct.

As architectural efforts in the shape of design are produced at the present time, it is an easy matter to dispense with such a principle; but we must recollect that the men from whom we borrow had in the beginning to adopt some such fixed rules, and by the aid of modelling or other practical methods to work out what was to them an original design. It may be said that an architect who has a true genius for his profession requires no such aid to guide him in the development of his ideas, and would feel himself trammelled by any such restrictions. But this I deny, because I hold that no science can be perfected unless it rests upon certain fixed principles."

The writer urges that an architect who has this higher genius for his profession should look into the leading principles of his art, and, by the truthful application of material, seek to create a design which would bear undoubted marks of originality on the face of it.

We shall not annoy Mr. Gowan if we do not offer any great admiration of the external appearance of the house he has raised, because he himself does not point to it as anything more than the result of a first experiment:—

"In dressing the stones thus roughly, and by the use of one simple geometrical form of moulding, and without anything in the shape of carving, I have endeavoured to produce a rich effect by the frequent repetition of this moulding wherever such was necessary, and causing it to take new conformations as the respective necessities of the positions required.

Clothing over in this way the framework of the building, and where it would enhance the constructive effect, I have given prominence to certain leading or radical lines of the skeleton. The windows stand out as separate designs, springing from the lower base of the building, and extending to the apex of the tympanum; and while they form integral parts of the skeleton of the building, they contribute to the general effect."

We give the ground-plan of the house: the dining-room is 24 feet by 16 feet; the drawing-room the same size; the business-room 20 feet by 14 feet; the hall 18 feet by 14 feet; and the staircase 12 feet square. Hot water and gas are laid on to the various parts of the house. The water from the roof appears to be brought down by pipes inside the walls; while, impressed with the importance of ventilating the drains,—of preventing what at times necessarily occurs under the ordinary arrangement of drains, the escape of deleterious gases into the house, to the injury of its inhabitants,—a flue is provided, which is carried up as high as the top of the chimney-shaft.

ART, NOT STYLE.\*

Under the heading "Pagan?" the author of the volume that we were noticing last week, first observes that the medley of existing architecture is an expression of our social condition, in which he finds much to admire; and, for example, the pretence, as he regards it, that our system of law is founded in Christianity, though we have admitted "the professed unbeliever to share in the enactment of law," &c. The question is, he says, whether the characteristics of the Italian style are such as render it a true expression of our national life in the future. He calls the Italian nothing more nor less than an extended application of the late Roman,—all the characteristics of it being in the Pantheon,—assertions which only prove his entire ignorance of the styles. Perhaps he will be able to show, should his work come to a second edition, the likeness between the Pantheon and the Farnese Palace, or the Library of St. Mark, or the Strozzi. The statement that the Italian is incapable of verticalism would be more deserving of examination: it may be that the old style does not attain that characteristic, though some have expressed a different opinion; what has been done, however, is not the question, but what may be; and it might be more accurate to say that for the future, any style started from is capable of becoming anything. We showed in a recent article, how serious is the mistake made by writers who, having only knowledge of a limited field of the past, regard this chiefly in an antiquarian point of view, and do not quite reach to the conviction that new art,

\* See p. 169.

\* See page 145, ante.

and not old style, is what is needed for the architecture of the future. But there is a question as to verticality, distinct from that of style,—namely, is the verticality the most appropriate for buildings which are divided into several floors? If not, the argument made to serve for Gothic secular edifices had better not have been used; though it would have been fairly applicable to churches. It has been said by some writers, however, that the Italian domical vaulting system is not less expressive of that which distinguishes the art of a building devoted to religious uses, than is the aspiring character of the Gothic. The gable, therefore, would alone remain to be contributed to the secular building by the Gothic,—assuming advantage in the high-pitched roof to be admitted. The fact of the Elizabethan style shows that some combination of this with features of the Italian style, even with the orders, could be made; and we doubt not, in many cases, a combination will yet be made, and in a manner that will be highly effective. It follows, therefore, that without going back, and without taking either of the courses, the revival of the old Gothic, or creation of the new Gothic, an architect may be perfected that will not violate associations, and will have been corrected and invigorated by the use of what is valuable in the Gothic. All that is stated as to the misuse of three-quarter columns and pilasters deserves consideration: but it can serve no purpose of art to interdict such features in certain cases; or the parallel should be kept up, and the responds carrying arches, and the engaged shafts of the Gothic should be similarly treated. The objection to three-quarter columns, where there are no other columns, is a fair one; where their office is merely subordinate to that of isolated columns, they or pilasters may be consistent with preservation of a general harmony. We perfectly agree that great has been the misuse of the portico, and of columns generally; but not so that the force of the classical architecture, whether columnar or fenestral, has been worked to the extent of being productive of nothing further. The Classic architect is not bound to the “everlasting acanthus-leaf” nor in friezes to festoons, even adopting the antique and Italian models; but the “luxuriant sculpture” which is beginning to be carved in capitals (where a flower or a branch is pitched on, rather than architecturally designed), fills us with apprehension for the success of the effort to educate a class of carvers, and shows that the taste for mere novelty and for copyism of natural forms, has been introduced without the art-study wherein the teaching of Nature, and the practice in the Classic and the best Gothic, are one and alike. Our author not only does not see the superiority of the square abacus in Gothic capitals, but tries to argue against conventional treatment of the foliage. The grotesque sculpture, he remarks, was only used externally until the fifteenth century. In this later time, he says,—“the spire disappears altogether,—forgetting Louth.

In the course of the “Moorish Episode,” when reverting to the subject of naturalistic ornament, in Gothic as contrasted with the conventional of early and late periods, he must be understood as defending what is erroneous in principle. When treating the question of realness, and contrasting the “stalactite” arches and domes of the Moorish with the Gothic vaulted ceiling, he keeps out of sight the fact that the latter was not the actual roof, and that the justification for the one, namely effect, affords the excuse for the other. In all architecture there are features, like the Gothic spire, which are designed for the effect. As regards details, the mind is satisfied if these are only quasi-structural, or if these decorative features and the structure are visibly tied together. Only injury is done to the progress of art, and the growth of public perception of it by the prevalent abuse by modern Gothic architects, of the classic manner of detail. How can we even believe the true perception of art to be existing with those who adopt a course which would be equally applicable to the shafts, arcades, mouldings, and other most cherished features of the Medieval architecture? Truly the dispute that is rife amongst us is the enemy of art,—art which which properly exists irrespective of style. Mr. Scott, see again his lectures, is far in advance of his fellows.

It is curious that after saying, we may see that imitation is implied in the very nature of Italian and other “Pagan” architecture, and without ceasing to be Italian, the author comes afterwards to the discovery that the Italian has had new energy breathed into it. He attributes indeed the improvement to the

Gothic; and no real artist-architect, though calling himself Classic, will dispute the fact. But he thinks that the horizontality, Italian roof-pitch, non-constructural ornamentation, rectangularity and regularity, and so forth, weigh upon the style to prevent further progress. Why, it is the very point of our argument against the revivalists, that our architecture should be neither Medieval nor Italian, unless in name for want of better,—that we should be English, and cannot revert either architecture or associations, but must advance. Every source is open to each architect, and every form that is consistent with use and is harmonious with the lines of other forms. On which groundwork to begin, were there no associations of the present time, honourable and glorious, it would matter little, since each style has value, and what one might lack would become infused into the other; but it matters much when it is considered that there is an existing style in our towns and the majority of our public buildings, and that furniture, costume, and mode of speech prevalent, would be anachronistic and inharmonious with any sort of Medieval.

The question for decision is not, it must be recollected, that which presents itself to either the antiquary or the Anglo-Romanist clergyman, but relates solely to the art. This art in architecture is, we fear, not the better perceived for any exclusive attention that is given to Gothic architecture. It is certainly not so perceived by the laical and clerical amateurs who write on the subject. Witness what is said by Mr. Denison in his lectures on “Church-building:”—“It must be admitted,” he says, “that there has not been a single modern church yet erected, much less any other kind of building calling itself Gothic, which any person of experience could for a moment suppose to have been built in Medieval times.” . . . “It will be time enough for us to begin inventing new styles, or even modifying old ones, when we have learned to design and execute the old ones decently.” We will not affront our readers by supposing they would couple together, as interchangeable ideas, the matter of design and that of mere reproduction. They will observe that the lecturer regarded it as the object in modern church-building and modern Gothic, to produce that which would be mistaken only for the work of Medieval times. We had thought that the church-building had too nearly succeeded in this reproduction, and that the error was one which all the recent efforts of the new school of Gothicists were aimed at overcoming. But, even by the architects, the necessity for art,—for something more than is to be given by authority of examples, or study restricted to those of one school,—has been but recently, if indeed, it is quite yet, admitted. It is perfectly true that the extended and intelligent study of examples which we desiderate, not bounded by England, or merely inclusive of the English provinces of France, Alps, or both sides, and the better knowledge of architectural history, are wanting in more than one class of the profession. We have heard somewhat too much in the course of discussion on the Government offices, of the Banqueting-house, as a standard and a model: we scarcely think that many of those who refer to it, have the perception of the merit which indeed it has as work of art, and the interest which belongs to it in the history of architecture. Had they this perception, they would not quote one building without reference to other examples of the revived Italian, which there are in England as well as on the Continent, equally, and probably in a greater degree, characterized by the element of art. Many such examples, however, are rising about us both in London and the country; and the competition for the Government Offices itself gave the opportunity of seeing that true art, on the classical foundation, was a breathing thing in a school of architecture which was not Gothic. Again, it is perfectly true that there should be but one style for churches and for that one style was to be tolerated for one class of structures and not admitted for the other, betrayed operation of architectural art in their hands. We do not hesitate to say, as we said long before these secular buildings, that the application of Gothic to secular buildings, that there should be but one prevailing style, susceptible of a name; though there should be an infinite number of secondary formations; and that real progress and popular perception and appreciation of art, would be served by such a condition of things.

We do not believe that, given a clean sheet of paper, and denuding the architect of all prejudice, there would be more difficulty in evolving art on either one basis of observation or example,

than on either other. Of the material contributed in the art-work of time, the features were the invention of different periods. The Egyptian massiveness, perspective, and depth of shade, and treatment of lotus-adorned capitals; the Grecian picturesqueness of combination with scenery, exquisite proportion, portico and pediment, horizontalism, and sculpture; the Roman, Romanesque, and Byzantine arcuation and ornament; the Saracenic domes, and surface-work beautiful and varied, and using nature on nature's principle,—art-work, and not the attempt to imitate; the Gothic verticality, “long-drawn aisle and fretted vault,” pinnacle and buttress, enrichment of window-opening, gable, chimney-shafts, spire and tower; the different versions of the Renaissance, of which so much is said on the score of their “impurity,” or transitional character, but in forgetfulness that on the same grounds every work might be called impure, and every style transitional, and that these “transitions” are abounding in materials, and may offer the very lesson which is needed at this juncture; our own Elizabethan and Jacobean versions, uncouth perhaps in details, but suggesting other combinations, which we should be able to make, of the decorative gable, as other forms of Medieval origin, with features Italian and columnar; the Italian of the sixteenth century, different in every city of Italy and every country on this side the Alps, and with fresh forms and features infused into it by each architect who took it in hand,—from every one of these something should be contributed to what may become the architecture of the future. Call the architecture Gothic, may we not have not only the dome, but conventionalized ornament; proportion, which it is futile to contend is a thing not to be attended to; sculpture of the highest class, and whatever there is in architectural art, of feature or quality that can be made harmonious each with each other? Call the architecture Classic, may we not have the lotus-capital; something else than an obelisk or a sham vase on the pedestal of a balustraded parapet as substitute for a statue, the enrichment of the opening, the gable, the chimneys,—Vanbrugh made one application of them; the spire,—Wren showed that something might be done; and the tower,—though so far, this last, if only by the Victoria Tower at Westminster, stands as Gothic, unequalled and alone? The idea, however, of invigorating to this extent one style by another, though without producing discord in lines and forms, seemed scarcely to have occurred to either of the now disputing forces in the professional world, till the question of a Gothic dome was mooted in our pages, and we ourselves suggested that there had yet to be produced for a building of Classical architecture, the spire; that is to say, one not injured like that of St. Bride's, by the recurrence of prominent horizontal lines.

Whether the modified Italian already spoken of is capable of further development, the writer whose book has led to these remarks, seems to decide in the negative, though the question is qualified by the words “without essentially changing its nature,”—a change over which those who both admire the Italian and are artists would not grieve. The tendency now, he says, is towards freedom; and this he will not allow can consist with horizontalism and rectangularity. He concludes that “the Italian has no vitality of progressive growth; that it becomes extinct in the endeavour to give birth to a higher existence.” Surely the writer misunderstands the law of progress;—extinction is an inevitable truth; the giving birth at same time to a higher existence, is the end and highest possible manifestation of vitality. Take the Italian architecture at the author's own estimate, we cannot be brought “back again to the Gothic,” and he artists.

In the last division of the book, which he entitles “Christian?” he comes again to abuse of the Houses of Parliament, which he says “are not a reproduction of English art at all” (the very thing, the reader will observe, which they should not be), saying that “the genius of an original and faithful artist has nowhere breathed upon them,” that they exhibit “the bathos of art,” that the clock tower is the only good feature, and that they are only an instance of the ignorant application of Gothic to civil edifices. His statement of a second source of prejudice, that inconvenience of plan is part of the Gothic, is more to the purpose; and at length he comes to find that the character of reproduction in ecclesiastical edifices is not that which art demands, and to contradict in much besides that he had previously argued. As instance of the pedantry which re-acts on art, he quotes the church of All Saints, Margaret-street. In discussing whether we are to have two distinct

styles, one for churches and the other for a different class of edifices, whilst stating erroneously that we have had no native domestic style except the Gothic, he quite forgets points which excuse the existing difference between church architecture and domestic architecture. He also does not inquire whether the Gothic design for the Canadian Parliament House, which he names, is not due to mere imitation, rather than to the discovery of beauty in the Gothic style.

There is matter to be considered in these questions, as also in the author's condemnation of "the odious unrelieved square top to windows and doors," on which much might be said that is particularly important to right judgment in the general question. But the points that we should desire to treat, for the removal of prejudice and error existing amongst the public, and largely infecting our own profession, are far too numerous for our present space.

**SYMBOLISM AS A SCIENCE.**

In the remarks which I hope to have the honour of reading on Monday evening, before the Institute of British Architects, I have endeavoured to give a scientific character to symbolism in art by tracing it up to its first principles in the theologies of ancient nations, the Chinese, the Indians, the Egyptians, and others.

In this way I have arrived at two principles, or agents in nature, which do not admit of further analysis, LIFE and LIGHT: these I find will furnish, or rather explain, the most recondite symbolism with which we are acquainted.

Of these, LIFE is the most important, and would seem to be the most ancient source of symbolism; first, as *universal life*; and secondly, as *specific or special life*, the life of animals and plants. The first of these, considered in reference to the *sexual system* of nature, will supply the otherwise mysterious symbols of the *equilateral triangle*, the *lingam-yoni*, and the *cruz-anata*; whence we come to the *tau* and the *cross*, the present received symbol of eternal life, and one of the most ancient also. The equilateral triangle is the symbol of all trinities in unity, for the ancients thought much of this arrangement, and had their triads, excepting, it would seem, the Hebrews, though in some places in their Scripture, where it was no longer permitted to put the tetragrammaton, or the most sacred name of four letters, three *jods* disposed in the form of an equilateral triangle take their place, thus combining all that the equilateral triangle in the universally applied sexual system was intended to express, the union of the male unit with the female dual. To us moderns this may seem the merest trifling; it did not so seem to the wise Chinese, to Con-fu-tzee, to Pythagoras, to Dante, and others; but foolish as it may appear, by looking at the early symbolism of the ancients from this bi-sexual point of view, we are enabled to understand the meaning of some things not otherwise easily explained.

That *three* should be the symbolical basis, or source, so to speak, of nature and art, may be only perhaps a corollary from Mr. Hay's "Harmonic Law of Nature," whence, in his theory, "Triangulation," or the triple ratio as applied to buildings, follows as a matter of course.

In the pictorial art three objects are required to produce a picture: one is nothing, two will not suffice, but with three, he it only three dots, or three *jods*, we get a form: there is something for our eye to figure, there is a triangle. In building, three is the prolific element of all construction; it would seem to be the primary element, two uprights, and a cross piece over, the *tri-lithic* system of Stonehenge; two piers, and an architrave above, were what a very great many buildings may be resolved into; by the multiplication of this arrangement we might erect a second Thebes.

The *lingam-yoni*, however varied in its forms, is, in fact, nothing more than a symbolical union of the two sexes, the unit, the male, and the dual or female. The *cruz-anata* is a form of this *lingam-yoni*, with a handle to it. I think it may be shown, also, that the Pyramids of Egypt, which consist of four equilateral triangles, inclined to each other, and meeting at the apex, are symbolical. It is well known that the equilateral triangle, among its other functions, was a symbol of Osiris, and also of Siva; and from what we can gather from the Indian and Egyptian theologies, it would appear that, in some important respects, these personified beings or operations agreed; and I think I shall be able to show that the Pyramids are Osiridian monuments, as well as tombs, and intended to symbolize the resurrection of the dead, and to transmit the memory of that most import-

ant credence among the ancient Egyptians to the latest posterity.

Special life, as in animals and plants, will furnish all the specific symbolism in use among the Egyptians, Persians, Greeks, and others, down to the modern days of Christianity. The lion, the eagle, the ox, the peacock, the dove, &c., will be found to act pretty much the same parts now, under different theories, as they did formerly.

The palm tree, the holm, the lotus, or water-lily, the ivy, &c., still figure in Christian architecture and sculpture. And these animals and plants, which stand for certain things, do so in virtue of their characters, habits, properties, and qualities, which have never changed any more than our human notions of them have altered.

From LIGHT is derived the symbolism furnished by the sun, the titles and glories of celestial personages, divine beings, and temporal rulers, more recently of saints and holy persons. While LIGHT, combined with LIFE, leads us, in an ascending scale, from earth to Heaven, embraces Christian martyrs, and would carry us to the consummation of Dante's beatific vision, amid cherubim and seraphim, and all the shining host, according to the most orthodox dicta of Dionysius, and the modern gloss of Mrs. Jameson.

In our Christian church architecture, by which I mean the architecture of the palmy Middle Ages, when faith and hope were overflowing with zeal in raising up structures symbolical of the spirituality which mounted on high, with spires and pinnacles, and winged buttresses, only still too heavy to rise, and arches pointing upwards, and trifolts, and triangles, and the triple ratio peeping out everywhere,—with a cross for the plan, and the most ancient symbol of nature, now of the blessed Trinity, ruling, governing, and controlling all the members, and most of their details, in these marvellous monuments of Medieval science, and patterns of structural invention,—we have, as in the church on earth, the type and prefigure of the church in Heaven, life and light symbolically and truly combined; and these records in stone of the piety of our forefathers appeal to us, as did the Pyramids to the ancient Egyptians; and we, like them, would seek our final resting-place, where faith has raised its most durable monuments.

H. C. BARLOW, M.D.

**ON BUILDING-STONES—THE CAUSES OF THEIR DECAY, AND THE MEANS OF PREVENTING IT.**

At the close of the paper on Building Stones and the Causes of their Decay, read lately at the Society of Arts, and printed in full in previous numbers of our Journal, —

The Chairman (Mr. Godwin) said the subject introduced by Mr. Barlow's paper was so very important, that he collected so large an amount of information bearing upon it. No one could walk through the thoroughfares of the metropolis, or any other large city, without observing the remarkable effect which the touch of even a very young Time had had upon nearly all our modern buildings. He had no doubt, most persons present could recall to their minds some building or tower which had been refaced, even by the same parties who had originally erected it. It was of the utmost consequence, not only that the public should fully feel the necessity of selecting a good stone in the first instance, but that, if possible, some means of indurating the softer stones, which were driven by economy to use, should, if possible, be discovered. There were a number of points offering themselves in this paper on which he had no doubt they would hear comments. There were texts for many essays, and perhaps there were some opinions to which gentlemen present would take exception. He was not quite certain whether the expression which Mr. Barlow made use of, that the decay of the stone in the Houses of Parliament was very painful, not to say "shameful," was justly justified, because he rather thought Mr. Barlow considered it more easy to distinguish between a good stone and a bad stone than most persons found it in practice to be. In fact his impression was—and it was borne out by the opinions of many practical men—that when a stone was once out of the quarry, it was almost impossible to say whether it was a good stone or a bad one. It would perhaps have been well if Mr. Barlow had referred to the numerous varieties of Bath stone, because that stone, when taken from the softest quarries, stood very well, whilst that from other quarries, not far distant, would not answer for external work in England—certainly not in large towns. Touching Can stone, it was clear that much of it was really good, but the conduct of the stone quarry owners seemed to him to be of a suicidal character. Not many years ago, having occasion to use Can stone in large quantities (although he had not himself recommended it), he visited the quarries in company with Mr. C. H. Smith, and they then made an examination into the condition of the quarries. As many of them knew now, although it was not so well known then, more than one of the beds of that stone were notoriously bad. Stone from these would not stand when exposed externally. Those beds yielded much larger blocks; they were easily worked, and they offered great temptations to builders, and, consequently, this inferior quality was sent to London and other places indiscriminately with good stone. Mr. Smith and himself called together some of the quarry owners, and suggested to them that they should mark all the stone

from the soft beds, so that it might only be employed internally; and, if it was used externally, the fault would be the builders'. Only one firm would promise to do that. The other quarry owners said, "What are we to do about the soft? Some persons think it is the best stone. We must send it wherever they will have it." The announcement that that one firm had made the promise had the effect of increasing their business, but whether they had ceased to carry out that suggestion, or whether the amount of bad stone sent was so much larger than the better qualities, certainly the Can stone which was sent to this country could not be depended upon for external work. He had himself been grievously disappointed with it, and should fear to use it. With regard to Buckingham Palace, where Can stone was used, that was perhaps the most remarkable failure that ever was witnessed. He recollected seeing the new front of the palace about a year or a year and a half after it was finished, and he found many parts in a state of ruin. Large masses of stone were in the habit of falling from the cornices, to the great danger of the sentries below, and the result was the necessity of knocking off vast portions of the decorations, and making them good with cement, painting them several times, with a frequent necessity for repeating that costly process. The late Mr. Thomas Cubitt felt this most acutely; and he (the chairman) alluded to it rather in justice to the memory of that gentleman, who always asserted that he was not to blame in the matter. The circumstance affected him deeply, although he had not proposed the use of the Can stone, and had employed every means to obtain it of good quality; watching processes which had been brought before the public from time to time to harden this and other descriptions of stone, only one or two were now at all spoken of. He had watched with considerable interest the proceedings in Rausome's process, especially in the case of the chapel in Bloomsbury; and he should be delighted to find, when sufficient time had elapsed to enable them to judge properly, that it had the effect which theoretically they so justly look for. He thought he should now best discharge his duty by abstaining from further remarks, and by inviting gentlemen to favour them with their experience upon the subject treated of in the paper.

Professor Ansted, F.R.S., said, as he had taken considerable interest in the subject of building materials, and the decay and preservation of them, he would offer a few remarks. The variations in the Bath stone were, as the chairman had said, very remarkable. He had seen many cases in which that stone was used with success, whilst stone from the same quarry had decayed in other situations almost immediately. Mr. Burnell had remarked that the decay of granite arose from the decomposition of the felspar which it contained. There could be no doubt that those felspars which contained soda generally decomposed, whereas those which contained potash did not. There were, however, exceptional cases, arising from peculiar conditions of hardness. With regard to the causes of decay of limestones, they were, to a great extent, mechanical. Limestones must absorb more or less of water. The water must absorb more or less of water. They were, however, exceptional cases, arising from peculiar conditions of hardness. With regard to the causes of decay of limestones, they were, to a great extent, mechanical. Limestones must absorb more or less

when the materials of the stone or the particles with which the grains of the stone were cemented together, were exposed to the action of the atmosphere. The deleterious atmospheric influences consisted partly of carbonic acid gas and partly of sulphurous acid—ultimately sulphuric acid in a diluted form; and if there were any other substances present in the air which had not yet been sufficiently examined. Those were enough to injure by dissolving the material of which the stone was composed. Then came the question—How was this to be prevented? Kuhlmann's process, although very ingenious, was not a modern one. Kuhlmann believed that, by washing the surface of the stone, or soaking into the substance of the stone a solution of silicate of potash or soda, or of water-glass, as he termed it, a permanent surface could be produced without much difficulty. Robinson believed that by putting in that solution of silicate of potash, he should produce a chemical change in the limestone, and form a silicious carbonate, or perhaps a silicate of lime. As far as the silicate was concerned, it would only be in a granular form. When silicate in this form was produced, it was deposited in detached grains, therefore he feared that little good would result from this process. It was true that it succeeded, by a slow process of change in a dry atmosphere, in obtaining a hard and durable surface; and he thought that perhaps when this process was very carefully adopted—when the material from which the soluble silicate was made was pure, and the operation was carried out in a dry atmosphere, it might be once or twice repeated, so that that method could not be adopted in any building in our own climate. It had been tried in the less humid atmosphere of France and Ireland, and if there were any other world so more rapidly in England, because the climate of the former country was better adapted to help forward the process. Mr. Ransome had reinvented Kuhlmann's manufacture of water-glass. Mr. Ransome had made the same experiments and found them fail, and then it suggested itself to him whether, after all, he could not produce an effectual process, which should be independent of the dryness of the atmosphere, and, by combining the first wash of the soluble glass with a subsequent wash of chloride of calcium, he seemed to have succeeded—theoretically it had been, no doubt, successful. The double decomposition took place in the mortar, and the silicate of lime, the formation of a chloride of sodium and silicate of lime. What was the silicate of lime? They had only to look at the specimens of mortar which they found in the old buildings to see the effect of this silicate of lime deposit. The cause of that peculiar power of the mortar to attach different pieces of stone together, was that the grains of sand and lime in the mortar became coated with a silicate of lime, and the surface to which the mortar was applied was coated in the same way; and this silicate of lime adhered so strongly to substances foreign to it, which it attached to each other, that practically the most perfect junction was effected; and when the mortar was very old the substance of the stones would separate more easily than the mortar. If they could deposit this thin film of silicate of lime, which would do that which was required. In large quantities silicate of lime was not so available as in smaller quantities. There was something in this thin film attaching itself to a foreign body, and it was this silicate of lime which was found which produced the remarkable effect which was found in old mortar. But still to doubt time had something to do with it. The deposit of the thin film of silicate of lime, he imagined, was hardly in the first place, but no doubt this deposit was the whole secret of the success. There could be no doubt but that the silicate of lime was deposited, for all who looked at the specimens of Houses of Parliament which had been washed by Ransome's process, after having been exposed for four winters, would see how the case stood.

Mr. G. H. Smith wished in the first place to correct the statement made in the paper with regard to the expense of the commission which was appointed to report on the best description of stone to be used in the construction of the Houses of Parliament. He was one of the four commissioners appointed, and he was able to state that, instead of the cost being 11,000*l.*, it was under 1,400*l.*, and the commissioners were travelling exactly fifty days whilst occupied in their investigations, and in the specimens of all the descriptions of stones brought under the notice of that commission had been deposited in the geological museums of England, Ireland, and the continent, and the Institute of Architects, he thought the most, and had not been entirely thrown away. With regard to the selection of magnesian limestone for the Houses of Parliament, he believed that if other parties had to consider the same investigation over again, they would come to the same decision; but in this case no person was appointed to exercise a supervision or inspection of the stone as it was delivered from the quarry. They need not, therefore, be surprised that the quarriesmen pushed in all the stone they got; and there was a great temptation to use had stone which they thought would be best to use. The commission to which allusion had been made consisted of Sir Henry De la Beche, Dr. William Smith, Sir Charles Barry, and himself, and they were occasionally assisted in their investigations by Dr. Buckland and Professor Phillips, and Wheatstone. Seeing there was no supervision of the stone as it was delivered for use, his only surprise was that things were not worse than they were. As examples of the same description of stone, he might mention the Museum of Practical Geology, in Jernyn-street, in which there was scarcely a bad stone; also the offices of the Amicable Life Assurance Company, in Fleet-street. The latter building was finished within about seven months after the return of the travelling commission, and in the stone of that structure there was scarcely a trace of decay, indeed, it was sent from the quarry as a specimen of the best to be found there. When the defective state of the stone used in the new buildings in Lincoln's-inn was discovered, he (Mr. Smith), having been at that time sent by the Government to see whether the quarries were being worked well, took the opportunity of inquiring of one of the foremen where the stone used in Lincoln's-inn came from, and he was taken to the quarry. Upon putting his finger upon the stone that was then being quarried, it left an impression, which showed the stone to be in a state of decay, even while in the quarry; and he replied to his inquiry, how that stone came to be in that state, that the builder would not have any other, because it yielded him the best profit. He might mention the case of another building in London, of magnesian limestone, erected by Messrs. Day & Martin, in the Strand, in 1810. It appeared that one of the partners, having an interest in some particular quarry, insisted upon that description of stone being used for the building. It decayed so rapidly that it had to be plastered up in many places, and had been often painted since. Mention had been

made of the decay of granite. He believed that was occasioned by the decomposition of the felspar, and this was done by the action of the atmosphere, and it was which there were the grains of sand, the plates of mica, and the clay which, he thought, indicated the decomposition of the felspar in granite. He considered that the best land stone, he considered as one of the finest in the world, and, owing to the facilities for water carriage, was well situated for the London market and England generally. Previously to the decision being given as to the description of stone for the Houses of Parliament, there was some doubt expressed whether the merchants would be able to supply a sufficient quantity of Portland stone for these buildings, and it happened that, at the same time, Sir Charles Barry was about to build the Reform Club-house in Pall Mall. For this building Portland stone was selected, and as the decision with regard to the Houses of Parliament was then doubtful, the quarry proprietors naturally supplied the best stone for this club, wishing to gain for it a favourable reputation. He did not think there was a bad stone in the whole structure, and though exposed to three different aspects for upwards of twenty years, it had stood perfectly. It seemed to have been a mania, of late years, for architects to use soft stone, and spend large sums of money to preserve soft stone decay, which in the end cost as much as if the best stone was used. With reference to the bedding of stones, allusion had been made to a remark which had fallen from him some years ago, that it did not matter which way the stone was put upon its bed. What he stated was, that sandstones would be sure to decay if they were placed (as he had seen Craigleith stones) edgewise, because that stone would decay away more rapidly, but with regard to oolitic stones, he thought the most experienced in such matters could not say which way the bed was. With reference to the class of sea air, and salts, and alkalis, upon stone, he would not say that it was not injurious to good stone, and bad stone would decay, but it were they were the sea air, and yet that structure existing was as good as new. He thought that the "sapping" of stone, he thought this must come from the brickwork behind, and it was not confined to any one description of stone. In the analysis of the stones examined by the commission before alluded to, as shown by the report of the commissioners, they did not find a trace of any salts in the stones which could produce this action, but efflorescence would come through a stone, however thick it might be, in contact with the sea air, and he was named for preserving it, the great difficulty was to get the preservative material deep enough into the stone to be of use; it was not merely upon the surface, he considered it would require to be carried down, and he considered it did not penetrate deep enough into the stone to be beyond the influence of wet, the stone would come off in sheets. In the commission before alluded to, he had taken care for the preservation of stone from decay, which was accompanied by hosts of certificates of a commendatory character. Trials almost without end had been made upon the stone, and he was satisfied that it was not possible, indeed, until time and weather had operated upon them, it was impossible to say how they would answer. Nature found out means of decay which the most scientific chemist never thought of. He had misgivings that, in the past, in association with eminent chemists, to trace those causes, but, even when they had found out the causes, it was doubtful whether they could find a remedy. As far as his own knowledge and experience went, he preferred to Mr. Ransome appeared to possess an advantage over others.

Mr. Robert Hunt, F.R.S., was desirous of correcting what he considered an error, into which the author of the paper, his friend Professor Ansted, and the last speaker had fallen with respect to the decay of granite. It had been stated, as the opinion of the gentlemen, that the disintegration of the granite was due to the decomposition of felspar. He was prepared to maintain that it was not due to that cause. Passing from that subject, they had entered upon the consideration of the decay of the decomposition of the ordinary sandstone was effected. Let them see what were the conditions. If they went to the old abbey and churches, they found stones which were taken from quarries, and they found the same marks of the tools of the workmen made 800 years ago were still perfect; and yet they found stone from the same quarries, when taken in London, Liverpool, Manchester, and elsewhere, in most cases showing lamentable decay. Let them ask themselves how that arose? There appeared to be one set of circumstances which had been overlooked by those who had been called upon practically to attend to the matter. They must remember that in large towns an atmosphere was produced which was more or less impregnated with gaseous exhalations, and they found the water—the dew and the rain—impregnated with sulphate of ammonia and carbonic acid. Discussion was comparatively of little value; there must be extensive experiments made before they could arrive at the truth. But, seeing that it was the porous condition of the stone which they had to deal with, the great question to be decided was, how they were to prevent that extraordinary porosity? It was true that, theoretically, Kuhlmann's process about ammonia solution, when they placed a stone in a solution of silica, there was a process of substitution by which they got it thoroughly saturated with silica. But this took time, and during that time the silicious solution was frequently washed off. His attention had been called, during the last two or three years, to Ransome's process. It appeared to him more satisfactory than any other, and met with success. There they had a silicate of potash applied to the surface of which had been rendered as clean as possible. The result was absorption. They then applied to the surface of the material, which was to be treated within the stone by two different means, one being the force of capillary attraction, the other of chemical affinity. Chloride of potassium and silicate of lime were the one being soluble in water, and the other remained to fill the pores. The great success of this operation, which, after all, could only be decided after a lapse of years, depended upon the fact that, by filling up the pores with the silicious solution, there was a silicious action going on within the pores of the stone. He was satisfied that they could only come to a correct conclusion upon this question by experiments, which the Institute of Architects would be wise to undertake.

Professor Tennant and Mr. Warrington having spoken, on the motion of the chairman, were voted to Mr. Barry for the paper he had read.

ON THE APPLICATION OF FIXED MATHEMATICAL LAWS FOR THE PRODUCTION OF BEAUTY IN ARCHITECTURE.\*

OF the 15th of April last a paper was read before this Association, entitled "The Harmonic Law of Nature with reference to Architectural Beauty." It was intended to illustrate a theory which professes, by the application of certain so-called geometric laws, to guide invariably architectural beauty, or, at all events, to guard against deformity.

I have much pleasure in complying with some remarks towards the discussion of the subject, which was then left over for a future occasion. Any one professing to guide us to an end so devoutly to be wished as the unflinching production of the beautiful, merits our best thanks, and I purpose now, with all respect, to discuss this theory, although I am free to confess that a careful consideration has brought me to a very decided opinion that it has no foundation in truth.

I shall, for the sake of clearness, first state in order my objections to the theory, and then I shall enlarge a little on each objection.

First, then, I propose to consider what proof is offered of the assumed existence in the human mind of a mathematical faculty or principle of harmony, as it is called, which would be the foundation of every scientific and external nature of the ratios which govern musical harmony.

Secondly, I will show that the musical ratios are inapplicable to form for the production of the beautiful, from a consideration of the physical properties of the objects of sight and hearing.

Thirdly, I will show, in a third place, that the musical ratios are inapplicable to form, for the purpose of producing the beautiful, from the fact that if they could be so applied, beauty would be found only at certain points or coincidences of instances. Such an objection implies that the external nature of the ratios which govern musical harmony.

In the fourth place, I will ask you to consider whether—granting, for the sake of argument, that proportions can affect the eye mechanically, as musical sounds do the ear—there is any reason to suppose that the proportions of the figures as the basis of the harmony, than the angles of imaginary diagonal lines.

In the fifth place, I will show that the proportions of the Parts of Beauty do not furnish any satisfactory evidence in support of this theory, give the most direct and conclusive evidence against it.

It is to be learned, through the eye, to judge of distance and magnitude, and to be sensible of the laws of perspective, and through the musical ear to appreciate the beauty of sweet sounds, in total ignorance of the theory of vibrations, and of the laws of musical harmony. A mathematician, a mathematician, a mathematician, and the author of this theory choose to call it by such a name, though with other men it passes under the familiar name of instinct. Such an objection implies that man and other animals have been furnished with original capacities wisely and beneficently adapted to the world in which they have been placed, and that these become perverted, and do not march along on an ascending evidence in support of this theory, give the most direct and conclusive evidence against it.

It is to be learned, through the eye, to judge of distance and magnitude, and to be sensible of the laws of perspective, and through the musical ear to appreciate the beauty of sweet sounds, in total ignorance of the theory of vibrations, and of the laws of musical harmony. A mathematician, a mathematician, a mathematician, and the author of this theory choose to call it by such a name, though with other men it passes under the familiar name of instinct. Such an objection implies that man and other animals have been furnished with original capacities wisely and beneficently adapted to the world in which they have been placed, and that these become perverted, and do not march along on an ascending evidence in support of this theory, give the most direct and conclusive evidence against it.

But these geometrical laws which regulate the machinery of nature, which are the basis of the beauty that is perceived by the eye; in fact, the whole theory is founded on a total misapprehension of the nature of beauty, and of the faculties to which it addresses itself. In the intelligent or intellectual perception of the operation of the laws of nature there is a beauty of the very highest order, as revealing to us the physical means by which God has created the world, and the laws of the material, and does not concern itself with the form or proportions of visible objects, except in so far as they may be types which the mind can decipher. I use the word "types" to denote those forms which are the basis of the beauty that is perceived by the eye; in fact, the whole theory is founded on a total misapprehension of the nature of beauty, and of the faculties to which it addresses itself.

During the Middle Ages speculations such as those on which I have been commenting were not only in vogue, but in great favour. Did your time permit, many amusing examples might be given: they seem to have attracted the attention, and drawn down the condemnation, of Galileo, in a passage of admirable power. It seems so much to the point, in considering a theory founded entirely on these exploded notions, the beauty of the harmonic ratios, they understand not, or rather do not care, to quote it. The fallacious nature of these speculations, in numbers and proportions, and has expressed his sentiments concerning them very unequivocally—

"He that views the common appearance to be the mistake of those who persevere in making their knowledge and apprehension the measure of an apprehension and knowledge of God, as if that alone were perfect which they understand to be so. But on the contrary, we serve that nature has other sides of perfection which we cannot comprehend, and rather seem disposed to class among imperfections. For instance, among the relations of three numbers, there appear to us most perfect, which exist between numbers nearly related to each other, as the double, the triple, the proportion of three to two, &c.; those appear less perfect which exist between numbers remote from each other, as 7 to 11, 13 to 17, 17 to 19, &c.; and most imperfect of all do those

\* From a paper read by Mr. Thomas Purdie at the Architectural Association, mentioned in our last number.

appear which exist between incommensurable quantities which by us are nameless and inexplicable. Consequently, if the task had been given to a man of establishing and ordering the rapid motions of the heavenly bodies according to the laws of perfect proportions, I doubt not that he would have arranged them according to the former rational proportions; but, on the contrary, God, with no regard to our imaginary symmetries, has ordered them in proportions which are irrefragable and irrational, and altogether inappreciable by our intellect. A man ignorant of geometry may, perhaps, lament that the circumference of a circle does not happen to be exactly three times the diameter, or some other assignable proportion to it; rather than such that we have not yet been able to explain what the ratio between them is, but one who has more understanding will know that if they were other than they are, thousands of admirable conclusions would have been lost, and that none of the other properties of the circle would have been true; the surface of the sphere would not be quadruple of a great circle, nor the cylinder be to the sphere as three to two; in short, no part of geometry would be true, and as it now is. If one of our most celebrated architects had had to distribute this vast temple of fixed stars through the great vault of heaven, I believe he would have disposed them with beautiful arrangements of squares, hexagons, and octagons; he would have dispersed the larger ones among the smaller, and the less, so as to correspond exactly with each other, and then he would have had continued admirable proportions. God, on the contrary, has shaken them out from his hand as if by chance, and we are, therefore, not to think he has scattered them upon earth, without any regularity, symmetry, or elegance.

I propose now to show, in the third place, that the musical ratios are inapplicable to form, for the purpose of proportion. It is evident from the fact that if they could be so applied, beauties would be found only at certain points of coincidence, and deformity at all the intermediate stages.

In the 1<sup>st</sup> paper read to the Association in illustration of this, I find the following passage:—"That the eye is capable of appreciating the exact subdivision of spaces, just as the ear is capable of appreciating the exact subdivision of sounds, and that it seems to be the precise meaning of the phrase, it contains an obvious fallacy. Adopting the words of the passage itself, and employing them in the sense which, I presume, they are intended to express, I find that the eye is capable of appreciating the exact subdivision of spaces," in the same sense, or in the same degree, as "the ear is capable of appreciating the exact division of intervals of time."

Every one knows that in music the ear receives pleasure only from one class of sounds, and feels every departure from these, however slight, to be a positive pain. On the other hand, our taste for visual beauty is so varied and capricious, as to include objects the most opposite qualities. Not only so, but that which seemed beautiful a few years or months ago, seems now devoid of every quality which could render it pleasing. At all times the eye may recognize the objects as exceedingly beautiful, without feeling any slight departure from its proportions to have a jarring effect—the proportions may be considered as being destroyed—the beauty being destroyed—there may be great beauties, and the greatest beauty and positive ugliness, but the musical ear admits of no modification in the pitch of the notes: the instant a musical chord ceases to be a chord, it becomes a discord.

I propose to show, in the fifth place, that the proportions of the Parthenon, which are much relied on as conclusive evidence in support of this theory, give the most conclusive evidence against it.

I do not intend under this head to enter on the general question, as to what was the law, if any, by which the Greeks adorned themselves in arranging the proportions of their temples. That is a question which I have already treated by the measurement of such examples of Grecian architecture as have descended to our times, and by the light which they afford on the subject.

I may, however, remark in passing, that the notion of the Greeks having acted on any such general law, seems at least highly improbable for three reasons.

First, the dimensions of ancient Grecian architecture still in existence differ very much from each other in their general proportions as well as in their details. The Doric column varies from 4 diameters to the length—the proportion found in the temple at Corinth—to 6½; its upper diameter from 7 to 8 1/2ths of its under diameter; the height of the capital, in terms of the lower diameter, from 37 to 56-10ths. In Athens, the height of the columns is generally 5 diameters; in Selinus, from 5 to 5 3/4; at Egina and Agrigentin, 4. The anulets differ in different examples. The entablature ranges from 1½ to more than 2 diameters, and the angle of the pediment varies from 12° to 14°. These variations occur in the Doric alone, which is known to vary less than any of the other orders. If we fail, therefore, in discovering the operation of a fixed law from the proportions of this order, we are not likely to find it from those of the Corinthian or Ionic.

Second, that the Greeks, in common with the Gothic architects (and, I believe, modern architects follow the same rule) modified the details according to the height or width of the building. A striking example of this principle appears in the details of the Parthenon and of the Temple of Theseus. The first was situated on a height, and, as generally seen by a spectator, the vertical lines were to be much more elevated than in the other, which was situated on a plain. Accordingly, we find, in the Parthenon, the cornices, moldings, and general details, have less projection and greater thickness than those of the temple of Theseus; and, I believe, the same principle will be found universally applied, not merely in Grecian, but in all good architecture.

Third, the notion against the notion of the ancient Greeks having acted on any such principle is the silence of all contemporary authors on the subject. Neither the works of Plato, when treating on the subject of beauty, nor of Aristotle, who was himself a sculptor, contains one word to countenance such an idea. On the contrary, the doctrines they teach as to the nature of beauty seem to differ but little from those which are taught by the best writers and thinkers of the present day. It seems, therefore, to be pretty well proved, from negative evidence alone, that the Greeks had no other aids in the erection of their temples than those which are available to the modern architect. But at this point, I must to those whose inclinations lead them to its investigation, and return to the question before us.

It is scarcely necessary to say that, although the proportions of the Parthenon had coincided exactly with those which this theory would establish, they would have afforded a very insufficient basis for such a superstructure. The fact is notorious that proportions must vary indefinitely, according to the purpose of the erection, the position of the building, and the material employed. If iron had been the material which had come most readily to the hand of man for the construction of his edifices, Greek architecture would have been impossible. If for four thousand years mankind had used iron alone for architectural purposes, or even as the skeleton of edifices, our ideas of beauty would have been associated with such forms of construction as must have led us to consider a Parthenon, erected for the first time in our days, as altogether monstrous.

Besides, there is no unanimity among men of taste in allotting to the Parthenon among works of art the high position which this theory assigns it. One great authority could be named who condemns Grecian art as altogether base and depraved. Very many prefer Gothic to all other styles of architecture. I myself cannot see why the comparatively heavy Doric should be preferred to the more light and graceful Ionic, or to the Corinthian of the Chæric monument. But this theory has not even the slight support which the proportions of the Parthenon might have afforded. On the contrary, such evidence as they give is conclusive against its truth.

Substantially the same results are obtained by the angles which the theory prescribes, and compare them with the actual proportions of the building itself.

1st. To obtain the height of the colonnade to the top of the abacus, we are instructed, on a base supplied by the length of the uppermost step, to employ a diagonal line forming an angle of one-fifth, as it is styled, or in other words 38°. But this angle so employed gives a height of 22.92 feet only, the actual measured height being 34.25 feet, leaving a difference of nearly 1 foot 4 inches between the two.

2nd. The angle columns have a diameter, from file to file, of 6.82. To find the proportions of these we are directed to use a line forming with the perpendicular an angle of one-ninth, in other words of 10°, which gives a height of 6.94, being 1.94, or nearly 2 feet more than the measured height. It will thus be observed that the different heights are obtained for the colonnade, the one actually 3 feet 3 inches more than the other.

3rd. The average diameter of the six centre columns, from file to file, is 6.97, and a diagonal line forming an angle of 9° with the vertical line, is given to find its proportions. But this angle gives a height of 39.42, being 6.45 feet more than the measured height, or 61 feet more than the height measured by the angle given for the colonnade itself. A Doric portico of any one of the three heights here given would present a sufficiently strange appearance. I fear it must be left to the author of this theory to explain how the three are to be combined in one, or how any one of them is to represent the portico of the Parthenon.

4th. The angle given for the intercolumniation is one of 15° with the vertical line, which gives a width of 9.77—being 1 foot 4 inches more than the measured width, which is 7.84.

The author of the theory does not give us an angle by which to find the proportions of the ground-plan. Taking the length of the building, as measured by Mr. Penrose, at 288.14—the breadth at 101.34, its diagonal forms angles of 19° 23' 33", and of 70° 36' 27" with its sides. These angles do not bear a simple ratio to an angle of 90°, and are therefore not recognized by this theory.

Now, it would not have been surprising if, in applying a theory of this kind to a building, some coincidences should have been discovered. As I have already shown, the system gives certain points where its supposed harmonies are found. These points occur at minute intervals, and every part of a building must have one point, or another near it. By adopting, therefore, the nearest, either above or below, an apparent coincidence might be made out. Nothing less than absolute exactness could meet the requirements of such a case. But the coincidences here are so glaring as to admit of no explanation or apology.

It will be observed that, by a very slight change in the angle given for finding the form of such details as the columns, they may acquire absurd proportions. The slightest alteration in the angle makes a very great difference in the height of a narrow object—a fact which of itself shows in a strong light the great improbability of the Greeks having worked by any such system, in finding the proportions of their edifices.

I have applied this theory precisely in the mode prescribed by its author, and have founded an objection on the method, notwithstanding that it is arbitrary and inconsistent in the extreme. In fact, before drawing the diagonal lines in the elevation of the Parthenon, rectangles are assumed to exist, which have no existence at all, and the whole form of the building is changed. Under the treatment to which it is subjected, the entasis of the column entirely disappears, and imaginary diagonal lines are drawn to imaginary vertical ones, and among these imaginary proportions the supposed harmony is to be found.

In conclusion,—The theory we have been considering has been brought before the public in a great variety of ways. It has been discussed in papers read to many of the literary and scientific societies of Great Britain. In these papers the method of teaching in our drawing-academies has been condemned, the copying of the ancient models has been denounced as ruinous to art, and the adoption of the principles of this theory has been recommended as the fitting substitute. It seemed to me, therefore, that a service would be rendered to the cause of art and of truth if we could ascertain whether these "first principles, or teachable laws of beauty," as they are called, were built on a solid foundation.

After a full and I trust a candid examination, I have come to the conclusion that, instead of a well-founded theory, we have a fanciful and untenable hypothesis, without the slightest basis either of facts or philosophy.

CAMP HOSPITALS A HUNDRED YEARS AGO.

WE are going to gossip to the length of a column or two about a famous physician of the eighteenth century,—rather, to tell the exact truth, we are going to use that hundred-year-old worthy as a peg on which to hang some desultory chat,—and we cannot better introduce a notice of him and his work than by a quotation from a still more famous physician of the seventeenth century. "Non occides," says Sir Thomas Browne, "is the commandment of God, yet scarce observed by any man; for I perceive every man is his own atropos, and lends a hand to cut the thread of his own days. Cain was not therefore the first murderer, but Adam, who brought in death." There are irreligious people who may say that it is irrelevant to suggest such solemn, and, indeed, awful thoughts, when one is only going to talk about ventilation, ague, and fever, and such common things; but, indeed, if the thought has been suggested to us that we deal too lightly with the sixth commandment, when, through neglect or indifference, sickness is not warded off, and death is not prevented, we owe the suggestion, just at present, to the good and eloquent Parson Lot, than whom no one does more, in these days, to teach a true, because an informed and enlightened reverence, and whose sanitary lectures and addresses, now first presented to us, in a collected form, by Mr. Parker, we counsel all readers to study. It is a passage in the address delivered at Bristol, that has sent us back to the *Religio Medici* to seek for a sentence which Mr. Kingsley himself would not scorn to put in the place of honour at the head of one of his sanitary discourses; and if such solemn words can ever be fitly used on this subject, it is surely most fitting that they should be used to introduce the first and the greatest British sanitarian, Sydenham, the father of English medicine, had done something for the sanitation of certain special diseases; but it was reserved for Sir John Pringle to be the first to lay down general principles, and to go back, in the spirit of the philosophy of observation, from the discourses to their particular causes. In many respects he was a remarkable man. A hundred years ago, sanitarians were not ashamed of being physicians. There was then no arbitrary and pernicious division between the art of preventing and the art of treating. They made a campaign in the Low Countries, or they accompanied the fleet to the West Indies and the Spanish Main, and then they came back, enriched by a novel experience, to practise in Jermy-street or Pall-mall. Now-a-days, they are called commissioners, and write blue-books. Then, they believed in logic and inductive philosophy. Now, they believe in statistics. When Pringle accompanied Lord Stair to the Low Countries and Germany, and was present with George II. at the victory of Dettingen, he was, at the same time, professor of moral philosophy at Edinburgh. After his return to London, he became president of the Royal Society. And, what is still more honourable to his memory, considering the way in which it came about, he, not long afterwards, vacated that chair. Some discussions about the then infant science of electricity had arisen in which the king had adopted the side of error. Pringle was obliged to bint that the laws of nature would not bend even to the command of a king, and it was intimated to him that no one who cultivated science in so democratic a fashion, could be permitted to occupy the chair of Newton, whereupon he resigned. Another great medical philosopher now gracefully fills that chair. How strange it would seem if, in our happier days, Sir Benjamin Brodie were to become the victim of such another instance of royal folly!

When recalling attention, the other day, to Dr. Brocklesby's little work, and glancing some extracts from it, we pointed out that he offered us the record of three distinct, successive experiences. Pringle's Notes of the Campaigns of 1742-3-4, and of that of 1745 in Scotland, do not admit of such a precise division. They are very pleasant reading, and present some amusing and interesting pieces of information. It is amusing to read of the gift of flannel underwaistcoats, presented by the good Quakers of Lichfield to the Duke of Cumberland's army; and it is interesting to read of the many broadsword wounds of the head, which were treated after the battle of Culloden. Interesting, too, is it to see how he scouted the idea of injury from the ripe fruits of the country; and that he was careful to remark, that the autumnal diseases arose from quite other

\* See "Science of Beauty."  
\* The Builder, February 4, 1860.

causes than the free use of these. Reading what he says, one's mind is carried back to the camps around Varna, when death was popularly supposed to lurk in magnificent melons and figs; whereas, in fact, it was blown about with every breath of wind from a pestilential marshy lake, or from the decay of milk, pulsed vegetation. And again, one thinks of the march across the valley of the Beibce, of an exhausted and plague-stricken army, a march which more resembled a procession of Bacchus and Silenus than that of a reduced army in the close neighbourhood of an enemy; with mules decked with vine-leaves, shakos and gun-buckets filled with grapes, and every havresack gaping with rich fruit. One remembers how loudly and terribly foolish generals shouted to see men, already marked with scurvy, obeying a true instinct in gorging themselves with fruit; and one cannot help thinking it a pity that a little of Pringle's old-fashioned sense is not more generally diffused now.

The main practical interest of the book centres on two prominent points; the sanitary condition of the hospitals, and the sanitary condition of the countries in which the campaigns were made. That is to say, we are invited to consider the condition which nature presented, and the condition established by art; a condition preventable, and a condition non-preventable. Both were exceedingly bad. To specify the results, we must attempt to generalize. It is a very broad generalization, but one sufficiently accurate for present purposes to say that the products of vegetable decay cause diseases of a periodic or intermittent character; and that the products of animal decay, in which must be included those caused by overcrowding, induce diseases of a continued or non-intermittent character.

Thus, when the troops were influenced only by the flat, humid, marshy, raw country which was the scene of their tedious activity, they suffered from ague and remittent fevers. When they were pent up in the close-packed garrison towns of the "cockpit of Europe," or huddled together in villages on their line of march, or, still worse, when they were crowded into transports, then there appeared the devastating jail fever, or typhus, which Pringle, from the experience here and at the Savoy prison, and other places, was the first to distinguish and describe with sufficient accuracy. The course of disease seems to have been, every year, uniformly the same. In the summer and autumn the troops were marched and counter-marched in a country such as that watered by the "lazy Scheldt," which was flat, intersected by canals and ditches, without hills to direct the wind in streams on the lower grounds, with occasional forests which arrested it and made it stagnant; or they were in a country which was all sand, with much water immediately below it. Add to this that the well water became speedily putrid, so as to be scarcely potable; then appeared the intermittents and remittents. This was most noticeable, as has frequently been observed, under similar circumstances since, where there was an estuary near, in which fresh and salt water intermingled. In winter, the troops were huddled into cantonments, inactive, and with their systems impregnated with miasmata. Then there came the fevers of continued type, and the intensity and urgency of the disease were in exact proportion to the degree of overcrowding. How truly here does a saying of the late M. Baudens apply, which he used when speaking of his experience of typhus in the Crimea:—"On pourrait le faire naître et mourir à volonté." There is another observation which has been frequently confirmed by Indian experience, which we must give in Pringle's own words:—"In marshy grounds, intense and continued heats, even without rain, occasion the greatest moisture by the exhalation which they raise and support in the atmosphere; whereas frequent showers during the hot season cool the air, check the rise of the vapours, dilute and refresh the corrupted water, and precipitate the putrid and noxious effluvia. But if heavy rains fall in the beginning of summer, and are followed by great and uninterrupted heats, the water stagnating in the lower grounds, and corrupting there, furnishes matter for more exhalation, and thereby makes the season more sickly and the diseases more fatal."

Take up any sanitary book you please; read, for instance, what may be called the first and the last sanitary books that have been published, this book of Pringle's, and Mr. Kingsley's recently collected addresses, and you will find, in a very different dress, according to the period, in Pringle's rotund, Johnsonian periods, in the sharp, incisive sentences with which Mr. Kingsley lays precept upon precept,—in all you will find but one text

preached from, which, indeed, contains the sum and the substance, the beginning and the end of all sanitary teaching.—*That which is dead, and that which has been thrown off as effete or dead by the living organism must be removed from the neighbourhood of the living.* Much has yet to be done in the way of proving the application of this proposition to particular circumstances and conditions of disease. The method of connection between the cause and the result has yet, in many cases, to be ascertained. An immense deal remains to be done in the way of applying the principle. But we know enough to be able to say that the proposition is true and irrefragable, and that, looked at with the eye of understanding, it will be found to comprehend all. Pringle and his contemporaries saw it as through a glass darkly, and made much effort in groping their way to a clearer light. Much has been done since that time; much is doing now. It would seem as if the work of the future were for the chemist, the engineer, and the architect, rather than for the medical theorist.

It would be unpardonable in a notice of Sir John Pringle, to omit mention of the question of ventilation,—the subject of all others about which people seem most apt to grow dogmatical,—the subject of all others about which it is most unsafe to dogmatize. Here is a passage which will show how much he was in advance of some even in the present day,—of some who seem placed in positions of obstruction, solely to clog the wheels of improvement, and to be on the watch for the purpose of repelling and hindering the slightest advance. "With regard to preserving the purity of the air, the best rule is to admit so few patients into each ward, that to those unacquainted with the danger of bad air, there may appear room to take double or triple the number. It will also be found a good expedient, when the ceilings are low, to remove some part of them, and to open the garret-story to the tiles. Constant experience evinces that in a few days the air will be corrupted in close and crowded wards; and what makes it hard to remedy the evil, is the difficulty of convincing either the nurses or the sick themselves of the necessity of opening the doors or windows at any time for air. I have generally found those rooms the most healthful when by broken windows and other defects, the air could not be excluded." Let us say a word or two, while space lasts, on this question,—not on the grounds of exceptional difficulty. If you want a "frightful example," you cannot do better than take the case of the military hospitals, built on the unfortunate corridor principle, which are so universally to be met with. The construction is deplorably bad. What requires to be done is to make the best of them. You will generally find, in them, oblong wards, much over-crowded, with a window over the door, a fireplace, and one window. In most you will also find ventilators, erected by a recent royal commission, which consist of gratings intended for entrance of air, and a box shaft for exit, both, of course, communicating with the external atmosphere. These are supposed to be beyond the control of the patients by means of locks and keys; but soldiers, like love, laugh at locksmiths, and, in fact, do obtain complete control of the ventilators. Further, it is easy to discover that the gratings admit but a very slight current. As to the aperture of exit, strange as it may seem, nature is stronger than a royal commission! Nature has decreed that cold air shall descend; and, in point of fact, these shafts do pour down a cataract of cold air on the head of the luckless tenant of the nearest bed. Under these unhappy circumstances, one will probably, first of all, remove the door-window, leaving a simple *fenestra*. But, unfortunately, in the corridor there are water-closets, and these have no exterior ventilation, and the consequence is, that your *fenestra* causes an interchange, not of pure air with foul air, but of foul air with foul air, of sewer air with air poisoned with the exhalations from skin and lungs. There is but one thing to be done,—to open the window; that is the only channel through which pure air can be procured. All that seems necessary to improve the atmosphere very materially, at least, is to fix the window so that it shall be open from the top to the extent of two or three inches, or, what would be better, but more expensive, to have louvred or perforated panes. Even with the windows thus open, and with the ventilators open, there is not a perceptible current in the ward. But a proposal to open a window would be a terribly bold one, and it evokes many old-fashioned prejudices. What one has to accomplish is to overcome these prejudices, and to demonstrate that the right way of ventilating and

warming a ward is to have a good fire, plenty of blankets, and—an open window.

We have been speaking of the rebellion of "Forty-five," and we have been speaking of ill-ventilated hospitals. It is a very natural transition to speak of a particular, well-known hospital which, in a striking way, illustrates both the systems on which a hospital may be constructed. When the men of Sir John Cope's division were wounded at Prestonpans were sent to Edinburgh, they were admitted into the spacious, lofty wards, with cross windows and thorough ventilation of the infirmary just then erected, by Lord Provost Drummond, on what is essentially the pavilion principle. It is melancholy to reflect that should such an occasion ever again require such an admission in that neighbourhood, the wounded would be placed in a building erected within the last few years on the corridor principle, and with that principle applied in an elaborately bad way. Low-lying, in the midst of a filthy and populous neighbourhood, with every sin of omission and commission in its plan, the new Edinburgh hospital seems to have been contrived for the production of hospital diseases, and it fulfils that object.

This paper was commenced with an apt quotation from Sir Thomas Browne: we cannot do better than conclude it with another from the same well-stocked armory. "There are two books from whence I collect my divinity; besides that written one of God, another of his servant Nature, that universal and public manuscript that lies expanded into the eyes of all." C.W.M.

#### THE ARCHITECTS' BENEVOLENT SOCIETY.

The annual general meeting of the members of this society was held on Wednesday last, in the Rooms of the Royal Institute of British Architects, 9, Conduit-street. The chair was taken by the President, Mr. Sydney Smirke, R.A.

Mr. John Turner, honorary secretary, read the minutes of the last meeting, which were confirmed.

Mr. Maïr (referring to a paragraph in the report in relation to the limited measure of support awarded to the society from members in the provinces), expressed his regret that such was the case, and inquired what means had been taken to bring the claims of the society under the notice of the profession, residing out of the metropolis.

Mr. Turner said that every member of the society was furnished with a copy of the report, and that a number of copies were forwarded to all the corresponding members.

Mr. Turner then read the report of the council, detailing the operations of the society during the year 1859. It congratulated the society upon having arrived at the tenth year of its existence, and observed that the course of sound practical benevolence rarely, if ever, failed in this country, but from the incompetence of its promoters. The council expressed the deep regret they entertained at the loss they had sustained by the decease of the society's late noble patron (Earl de Grey), as well as of several warm friends, subscribers, and donors to its funds. It was, however, with great satisfaction that they announced the addition of many new annual subscribers, besides several kind donors. On the other hand, it was necessary to state that the applications for relief advanced at an accelerated rate. Ten of these cases, all undoubtedly deserving cases, had been relieved during the past year, and it was painful to observe among the recipients those hearing the names of men who had already attained honourable distinction in the profession, but who had stopped in their career by sickness or death, before they had had time to reap the fruits of their talent and labour. These were the cases, which it was the peculiar province of the society to relieve. The mere uneducated pretender and the dishonest practitioner were alike held to be unworthy of their sympathy. There was no doubt that the members of the profession were annually increasing largely in number, and the claims on the funds would as certainly increase. The members were therefore urgently entreated to use their best endeavours to promote the extension of the society, by obtaining new members, and by making its objects more extensively known among their professional friends in the provinces. The council also took the liberty of suggesting for the consideration of those of their brethren who were blest with prosperity, that, according to the rules of the society, they were bound to invest all donations in the public funds; therefore, every donor would, according to the amount of his gift, be, *pro tanto*, adding to the permanent yearly income of this truly useful

society. It was the pleasant duty of the council to report that the Royal Institute of British Architects had again testified its approval of any sympathy for the society, by granting the use of its new and commodious apartments as its place of meeting.

The Chairman in moving the adoption of the report, said that in doing so he could not claim attention on the score that it contained any large amount of statistical information. It was a difficult and delicate matter in the administration of funds of this kind, to give details without giving publicity to that which might occasion pain to individuals; but the financial statement would throw some light upon the subject. In the past year they had added the new subscribers to their list of subscribers, but still their income was far below what they might reasonably expect, regard being had to the work they had to do, the status of the profession, and the great number of practitioners. The list contained nearly 230 members, and yet it was a subject for regret that the number should be so limited, when it was borne in mind that there were in London alone, 500 gentlemen practising as architects or surveyors. He suggested that they might make a great and important move, if each individual member would evince his anxiety for the welfare of the society by making a compact with himself to obtain the accession of at least one new member. He found on looking at the balance-sheet of the Artists' General Benevolent Institution, that it had received seventy cases in one year. It was true that the society included all members of the fine arts, indiscriminately, and that it was forty or fifty years old, while the Architects' Benevolent Society had been but ten years in existence; still it was impossible not to admit that the latter society might effect a much larger measure of good if it was better supported by the profession. He begged to move, in conclusion, that the report be received and adopted.

Mr. Mocatta seconded the motion, and observed that, regard being had to the fact that the society had been in existence ten years, there was certainly a want of *esprit de corps* among the members of the profession. He regretted that the architects in the provinces had not come forward with greater alacrity and in greater numbers to support the society.

Mr. Mair said he could not understand upon what principle the society was not better supported in the provinces, but he had no doubt that, if gentlemen would exert themselves among their friends and connections, many new subscribers might be obtained. He had himself written to eight gentlemen, and inclosed them copies of the rules, &c. To seven of these letters he had received answers. One gentleman said he would subscribe next year; six had sent their names and small donations to the fund, and one had taken no notice of the application. Now if each gentleman who felt an interest in the society would ask a friend to join it, the society would soon be placed in a position to increase its usefulness and to carry out still further the benevolent designs of the founders. He assured the meeting that many of the cases which came before the board were of an extremely painful character, and that the council would often be glad to give an extra 5*l.* note if their funds would admit of it.

The Chairman said he had himself endeavoured to excite the benevolence of his professional friends. He had addressed about forty letters to gentlemen whom he had reason to believe would be willing to assist the society, and the applications had produced ten additional subscribers. Thirty, however, were silent; but he hoped, upon reflection, they would come forward and aid in a work which had so many claims upon the consideration of the profession.

The motion for the adoption of the report was then put and agreed to.

Mr. Turner read the balance-sheet, which showed that the receipts of the society, including a balance carried forward from the previous year of 18*l.* 13*s.* 8*d.*, amounted to 417*l.* 13*s.* 9*d.* Of this sum 24*l.* 3*s.*, had been received for subscriptions in arrear, 140*l.* 13*s.* for subscriptions due and paid in 1859, 43*l.* 11*s.* 6*d.* in donations, and 26*l.* 10*s.* 7*d.* from dividends. The principal items of expenditure during the year were advertisements 9*l.* 12*s.* 8*d.*, stationary and printing 10*l.* 4*s.* 3*d.*, collector's commission 9*l.* 14*s.* 9*d.*, gifts to applicants 185*l.*, cash invested in the funds 37*l.* 16*s.*, leaving a balance of 147*l.* 8*s.* 11*d.* The amount of stock belonging to the society on the 31st. of December last, was 904*l.* 9*s.* 6*d.*, and the arrears of subscriptions, in respect of the years 1857, 1858, and 1859, were 51*l.* 9*s.*

On the motion of Mr. Mayhew, seconded by Mr. Mair, the statement of accounts was received and adopted.

The following gentlemen were, on the motion of Mr. C. C. Nelson, appointed the council for the ensuing year.—Mr. W. A. Boulnois, Mr. R. C. Hussey, Mr. William Moseley, Mr. R. L. Roumieu, and Mr. George Wiles.

The various other officers of the society were also elected, and, on the motion of Mr. Mocatta, seconded by Mr. Moseley, the best thanks of the meeting were given to the president and the council for their continued exertions on behalf of the society.

Thanks were also passed to Mr. Tite, M.P., the treasurer, who was prevented by business from taking part in the proceedings.

A vote of thanks to Mr. Smirke for presiding terminated the proceedings.

PROGRESS OF RAILWAYS IN SPAIN.

SOME weeks ago the opening for public traffic of the Seville and Jerez railway was announced to take place shortly; but, though numerous trains have transported war appliances, wounded soldiers, and railway materials, the day was not fixed for the opening when our correspondent wrote. This is owing to the very bad state of the weather for the last two months. Throughout Andalusia, circulation has been so impeded, that the principal towns are completely cut off from all communication with each other, and the Seville and Cordova line resembles an island surrounded by a sea of mud. So the *Madrid Railway Gazette* reports.

Most active steps are being taken for the speedy construction of the line from the sea coast to Tetuan, in Morocco, lately taken by the Spanish troops. Don Mariano Elna, government officer of the province of Seville, has already arrived at the camp in the Tetuan valley, in charge of railway materials, &c. The line is to be nine kilometres in length.

At the close of the year 1859, the following was the state of railways in Spain, with their annual receipts:—

	Kilometres in length.	Receipts 1859. Reals vellon.
Madrid to Alicante .....	482	44,228,893
Madrid to Saragossa .....	87	2,129,729
Cordova and Seville ....	131	4,259,146
Valencia and Almansa ...	138	6,439,425
Alar and Santander, ....	91	9,540,572
Barcelona to Saragossa ..	37	2,905,860
Barcelona to Martorell ...	27	2,083,765
Barcelona to Arenys ....	36	4,185,787
Barcelona to Gironelles ..	294	2,742,056
Jerez to Trocadero .....	273	3,717,408
Langres and Gijon .....	39	—
Tarragona .....	14	761,198
Totals .....	1,169	81,991,444

The Langres and Gijon line, in 1858, received 1,832,071 reals vellon (*l.* = 96 reals vellon).

Five locomotives, of the most improved workmanship and solidity, have arrived at Santander from Havre, on board the French vessel *Salamandre*, for the Northern Spanish railway.

On the 2nd February, the first gas lighting was inaugurated in the flourishing city of Jerez. Much praise is given to the Spanish "*Compañia de Credito*" for this enterprising work.

The works of the fourth, fifth, and sixth sections of the Alcazar de San Juan and Ciudad-Real portion of the Madrid and Saragossa railway have been advertised for contract, tenders being received up to the 15th February. The total estimate for the three sections is 5,850,000 reals vellon, or about 58,500*l.*

In 1860, according to the laws of the different concessions, the following railways are to be opened for public service:—Granollers to Santa Coloma; Valladolid to Burgos; Duenna to Alar; Arenys de Mar to Santa Coloma; Avila to Valladolid; and Burgos to Vittoria. In 1861 are to be completed the sections, Madrid to Saragossa; Saragossa to Barcelona; Madrid to Avila; and Mouthlauch to Reus. In 1863 are to be finished the Tudela and Bilbao; Saragossa and Alasasia; and Vittoria to Iruan, at the French frontier.

Taking as a standard of comparison the velocities of the trains on the Valencia and Alicante railways, and their fares, we have the following results for calculating a voyage from Madrid to the French Frontier.

Madrid to Valladolid in 6 hours, at a cost of 98 reals first class, and 44 third class; Madrid to Burgos in 11 hours, for 145 reals first class, and 66 third; from Madrid to Iruu, in 10 hours, at a cost of 253 reals first class, and 114 third class. The distances are as follows.—Madrid to Valladolid, 215 kilometres; Valladolid to Burgos, 150

kilometres; Burgos to Iruu, 269. Total, Madrid to Iruu, 534 kilometres.

When we consider that the distance from Bayonne to Paris (776 kilometres) is accomplished in 17½ hours, deducting the long stoppage at Bordeaux, and the Paris and Calais train runs over 354 kilometres in 7 hours, we must conclude that the distance between Madrid and Iruu can be performed in 12 hours. In the above calculations, 96 reals may be taken as *l.*

The following authorizations have been granted by the Spanish Government for various works, &c. To D. José Blazquez, a term of eight months to make necessary surveys for a line of railway, from La Roda to another point on the Madrid and Almansa Railway, terminating in the Hinajeros coal-fields. To D. Sebastian Gonzalez y de la Fuente, for surveys to be made for the following lines. A line starting from a point in Madrid called Red de San Luis, by the Calle de Puencarral, and La Fuente Castellana, passing through the promenade of Recoletos, the Salon del Prado, Puerta de Atocha, Portillo de Embayadores, the road which leads from the Puente de Toledo to the Puerta de San Vicente, and terminating in the Puerta de Hierro. Another railway is to start from a convenient point in the interior of the city, and terminate at the Puente de Toledo. A third line is to start from the Plaza de Santo Domingo, passing by the Calle Ancha de San Bernardo, and ending at the above-mentioned Puente Castellana. A fourth railway is to join the Puerta del Sol with the Venta del Espiritu Santo. Lastly, another line from the Puerta de San Vicente to the Ermita de San Isidro del Campo.

To D. Juan Llanos and D. Juan Manuel Fernandez Vitorcs, authority has been given to complete plans for the water supply of Valladolid, from the rivers Duero and Pisuerga.

To D. Miguel Montalvo y Collantes, to make surveys for a railway from the town of Logroson to Villanueva, or some other town on the Ciudad-Real and Badajoz Railway. Time allowed, a year.

To Don Vicente Sanchez Garcia, for surveys, to be completed in a year, also, for a line from near Granollers to the coal basins of Sarroca and Ogasa, at San Juan de las Abadesas.

MONUMENT TO THE LATE SIR JAMES M'GRIGOR, BART.

AN obelisk to the memory of the late Sir James M'Grigor has just been erected in Aberdeen. It stands in the centre of the Quadrangle of Marischal College, within the venerable walls of which building the deceased baronet was educated. The height of it is 72 feet, and the material of which it is composed is polished granite. The latter was brought chiefly from quarries near Peterhead. The shaft of the obelisk is 48 feet in length, and the plinth from which the shaft rises consists of two stones, weighing each five tons. The stones of the base vary from two to four tons, while those of the pedestal are rather larger. In the pedestal, which, like the remainder of the structure, is composed of red granite, a slab of grey granite, from the Cairnrigg quarry, near Peterhead, has been introduced, for the purpose of containing the following inscription:—

"This obelisk is erected to the memory of Sir James M'Grigor, bart, M.D., K.C.B., F.R.S., &c., for thirty-six years Director-General of the Army Medical Department, and several times Lord Rector of Marischal College, Aberdeen.

He was born in Strathspey, North Britain, on the 9th of April, A.D. 1771.

He entered the army as surgeon of the Connaught Rangers in 1793, and served the two following years in the campaign of Holland.

He was afterwards medical chief in the expedition against the island of Grenada; in the expedition under Sir David Baird, from Bombay through the deserts of Thebes and Suez to Alexandria; and also in the Walcheren expedition.

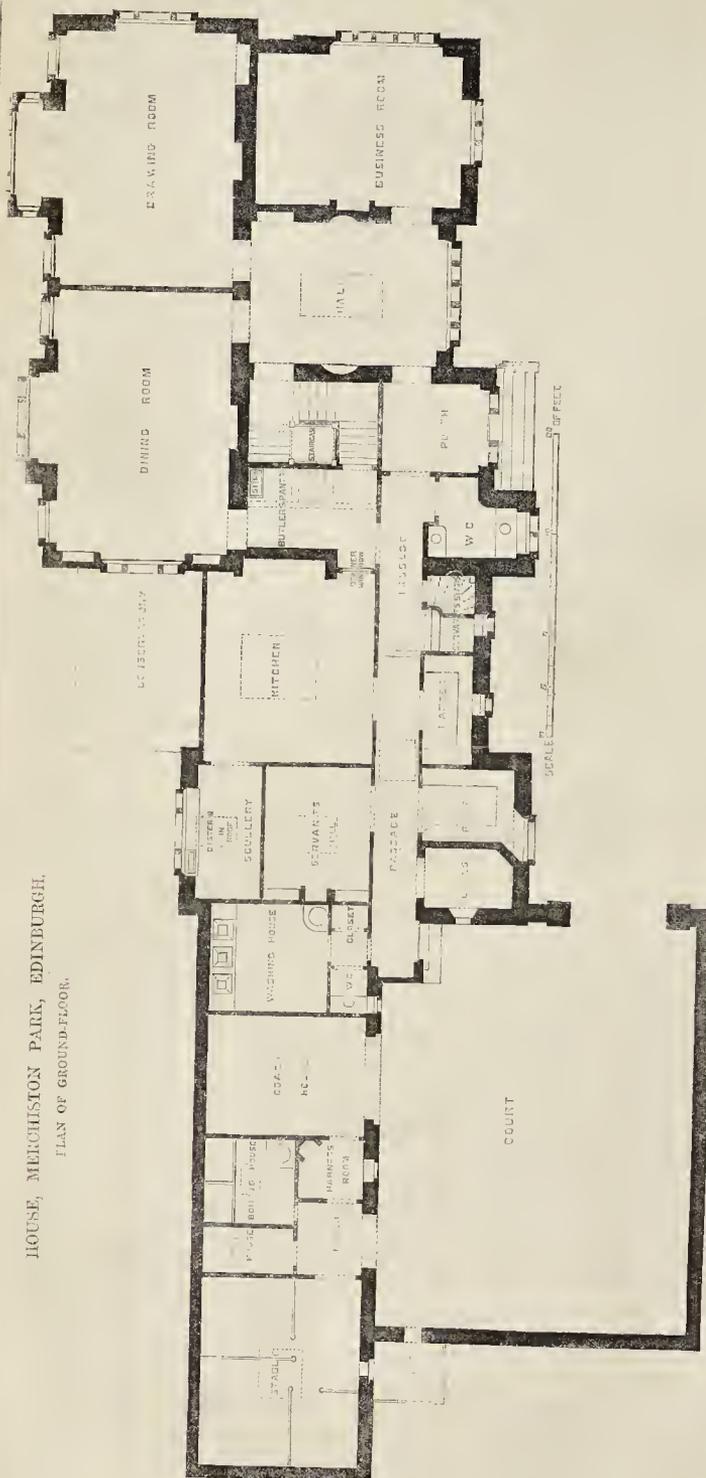

He was chief of the medical department of the army under the Duke of Wellington in the Peninsula War, from the siege of Ciudad Rodrigo, in the year 1811, to the final battle of Toulouse, in 1814.

He was favourably mentioned in the despatches of all the generals under whom he held these responsible posts, and was repeatedly noticed in those of the Duke of Wellington, who, on the 26th of July, 1814, referring to the manner in which Mr. M'Grigor had conducted the department under his direction, wrote thus:—"I consider him one of the most industrious, able, and successful public servants I have ever met with."

In the course of fifty-seven years of active service, he was exposed to the vicissitudes of war and climate, besides encountering shipwreck and other dangers at sea, yet he lived to attain a tranquil and happy old age.

He died in London, on the 2nd of April, A.D. 1858. This memorial is erected near the place of his education and the scenes of his youth.

The base of the obelisk is surrounded by a platform of grey-coloured granite, from the neighbourhood of Aberdeen.

HOUSE, MERCHISTON PARK, EDINBURGH.  
PLAN OF GROUND-FLOOR.

THE WESTMINSTER BELL.

Dr. PERCY, of the Government School of Mines, has made his report to the Board of Works, dated March 7, the day before Mr. Cowper told the House of Commons "that he could not state the precise cause of the cracking of the Great Bell, but that either the hammer must have been too heavy for the tenacity of the bell, or the bell too little for the hammer (laughter)," which was the effect of the previous report on the bell, by Professor Tyndall. Dr. Percy confines himself to the question of the composition, and gives the following analyses, which we designate thus for distinctness:—

*Tm* is a piece cut from one of the upper "wires" or rings on Mr. Mears's bell. *Bm*, from one of the lower wires, just above the sound-how, up to which the largest crack extends. *Tw* is from the top of Messrs. Warner's former bell. *Bw*, from the bottom of it; and *D* is the composition prescribed by the contract.

	Copper.	Tin.	Specific Gravity.
<i>Tm</i>	76.01	23.89	8.32
<i>Bm</i>	74	25.98	8.8
<i>D</i>	75.86	24.13	8.8
<i>Tw</i>	75.31	24.37	8.847
<i>Bw</i>	75.07	24.7	8.869

In other words, the metal on the outside of Mr. Mears's bell has nearly 2 per cent. more tin, and 2 per cent. less copper than the prescribed composition; and there is a difference of composition between the top and the bottom equal to 37 lbs. of copper to every 1 cwt. of tin.

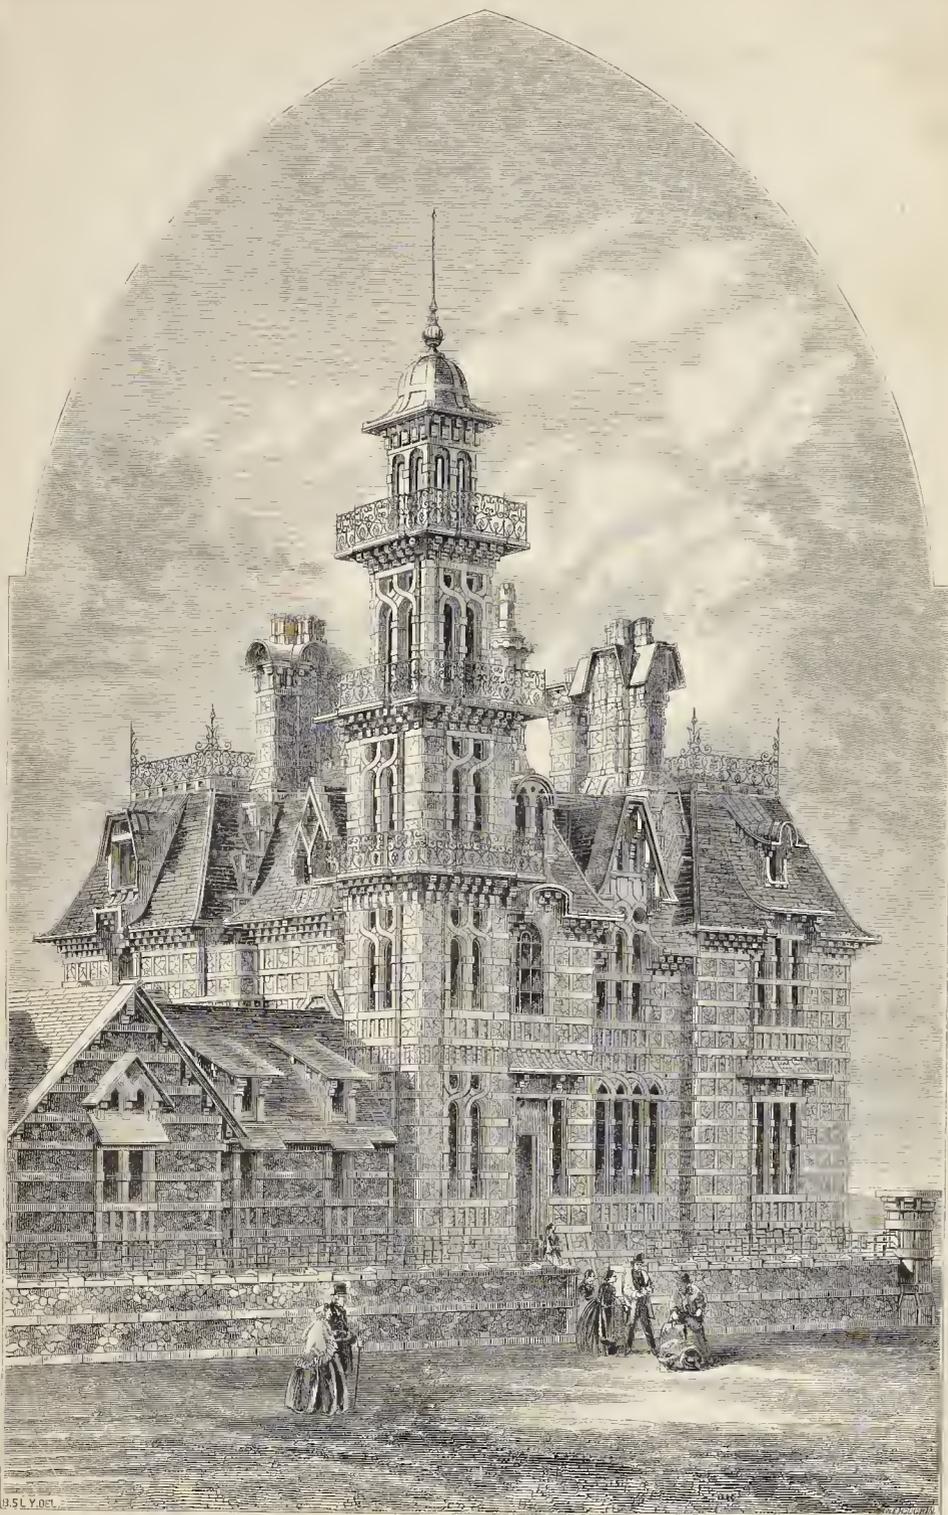

In Messrs. Warner's bell there was no material deviation from the prescribed composition, and the bell was homogeneous; although it appears to have had an internal defect of a different kind, a sort of natural crack or non-junction of the metal, which was found when it was broken up, and a piece of it was lately exhibited at the Institution of Civil Engineers. The difference of specific gravity is also to be noticed.

MANCHESTER SCHOOL OF ART.

At the annual meeting held on the 1st instant, Mr. R. N. Philips in the chair, the secretary stated that the subscriptions had gradually fallen off from 357*l.*, in 1852, to 240*l.*, in 1859. No effort had been made to replace them when they had fallen off from the death or removal of subscribers, but it was now essential that this should be done.

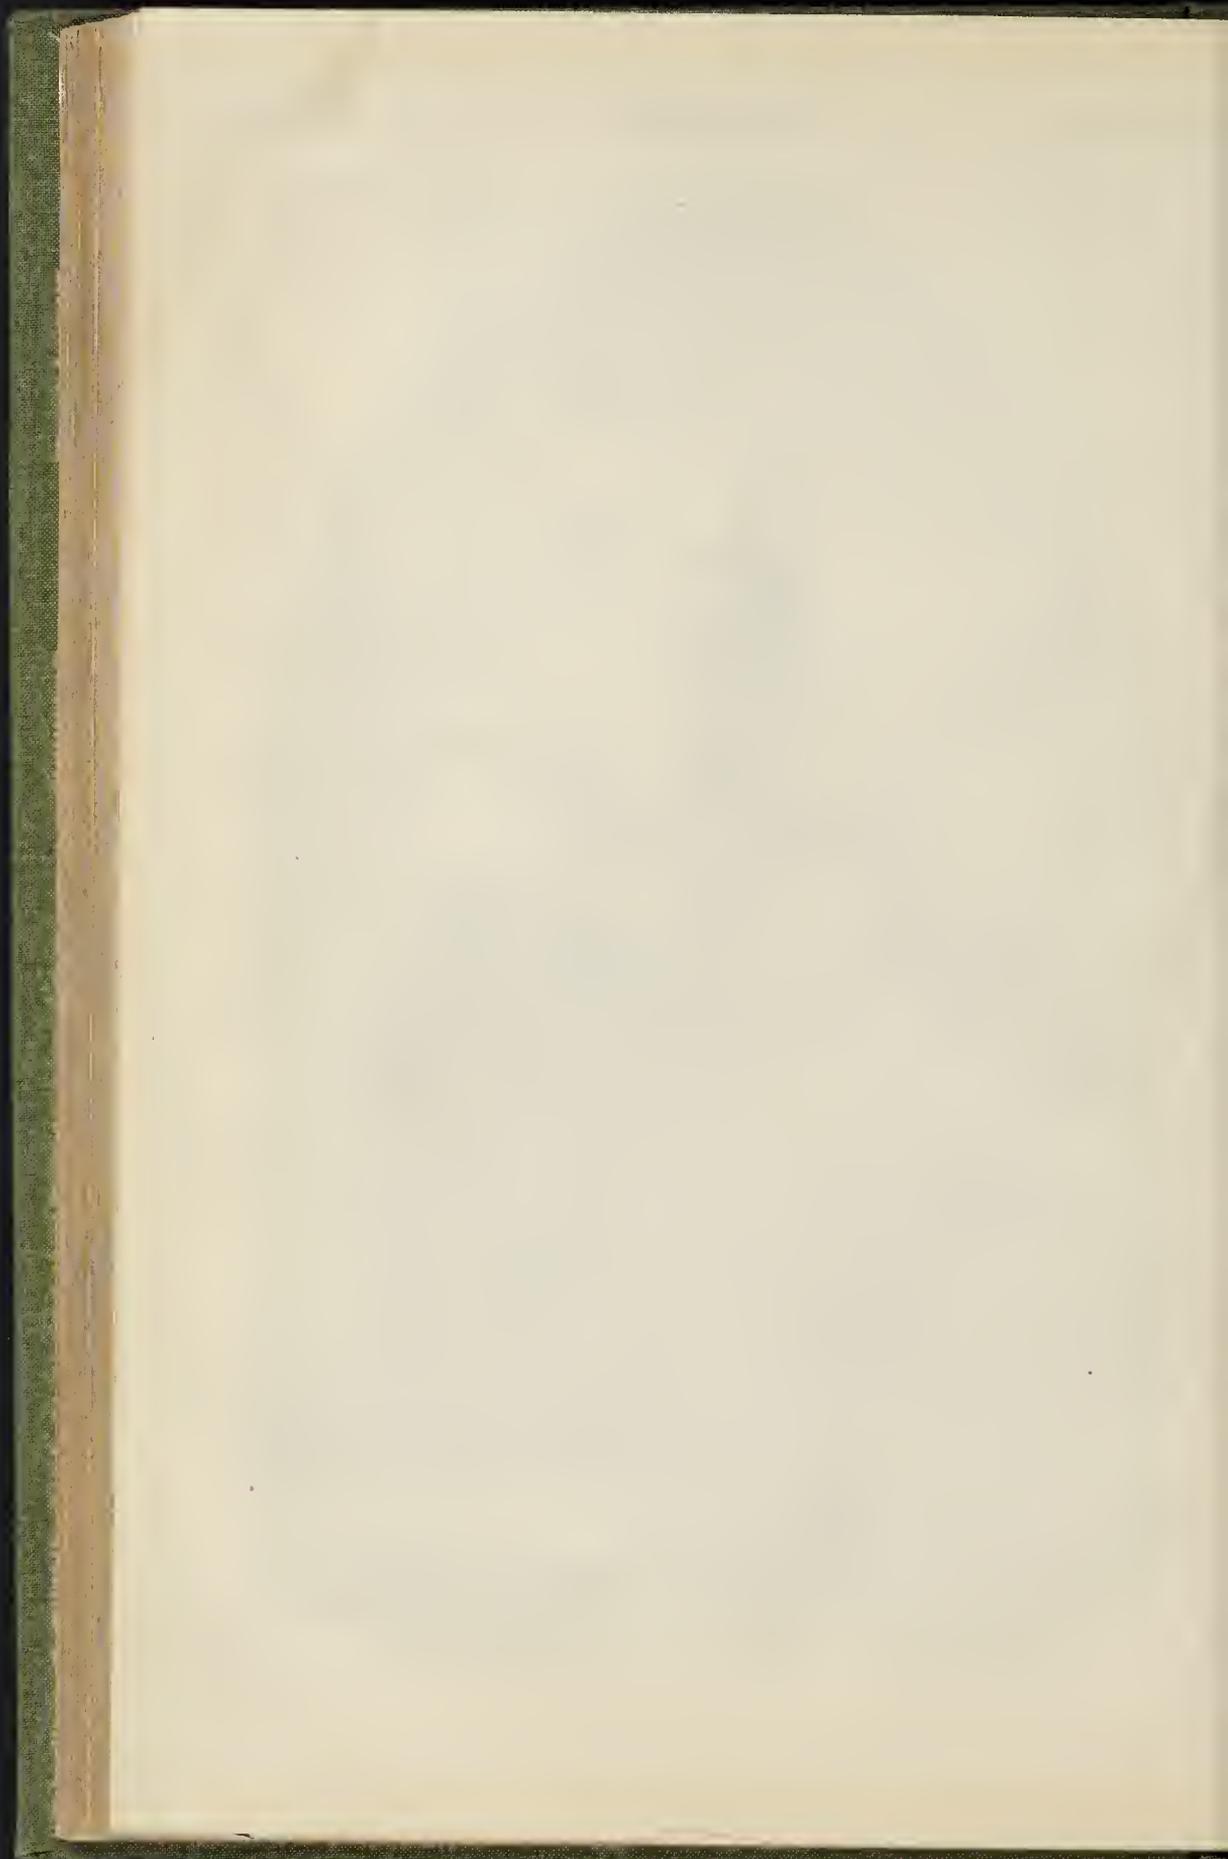

The report of the head master showed that the total number of prizes awarded in 1859 was 483. In 1859, the total was 476—a diminution of seven, which was only explainable upon the supposition that, as these examinations became more familiar to the schools, a much higher test was applied to the efforts of the pupils, as the work in 1859 was greatly in advance of the previous year. What were called slate examinations had been instituted. The parochial schools, receiving instructions in drawing, were visited once a year by the head master, and tested by drawings on a slate. A prize was awarded to one in every twenty of those who executed the best work: 416 prizes had been awarded in this way; and, adding this number to the total of the School of Art examinations, the grand total of prizes, awarded to the Manchester School of Art, for 1859, was 922. It was worthy of notice that the number competing at these slate examinations amounted to the large aggregate of 9,037 children in public schools.

SOCIETY OF ARTS. — Wednesday, March 14th, Sir Thomas Phillips, F.G.S., chairman of the Council, in the chair, the paper read was "On the Art-Treatment of Granitic Surfaces," by Mr. John Bell, sculptor.

DOMESTIC ARCHITECTURE. HOUSE, MERCHISTON PARK, NEAR EDINBURGH.\*

[\* See p. 161.

## FRENCH PORTALS.\*

EVERYBODY knows how odious it is to make comparisons, more especially when the said comparison is not to the advantage of the individual whom you may happen to be addressing. Now, if we compare the ancient and modern state of the arts, in no one respect do we make a worse show than in our sculpture and in our coining. It is not so much in the mechanical and technical processes that we fail, for the muscles and bones are generally in their right places, and the drapery, such as it is, is for the most part studied from nature; but it is in the total want of interest in the subject. We see that the artist has taken a model and copied some hap-hazard attitude, and, when the work was finished, has been obliged to cudgel his brains for a title. If it is a female figure, he adds a bird, and calls it "Innocence;" or else he provides chains, and the composition forthwith becomes a slave; while a male figure is turned out as "Ajax defying the Lightning," by the addition of a helmet and spear. But, by whatever name the work is called, very few care about it, for it tells no story, and comes home to no hearts. Why is this? Simply because the sculptor is obliged by circumstances to work for individuals instead of for the public, and where by any chance he has a public work to do, it is for the most part totally unconnected with architecture; for the employment both of painting and sculpture, but especially the latter, without architecture is very like wearing jewels without their setting; and we shall, moreover, find in all the best periods of sculpture, that the art was intimately connected with architecture, and, in fact, was part of the architect's design. Indeed, I am afraid that until this order of things is re-established, we can never hope to see a revival of the art in question.

In the meanwhile the sculptors will probably still go on studying from the objectionable Venus de Medicis, and the still more objectionable Apollo Belvidere, and will still produce such things as we see congregated at the Brompton Museum, and in our public squares, all the while lamenting that they have no opportunity of showing what they can do, and forgetting that their real mission is to make looks of stone to instruct their fellow-citizens, and not to fill the so-called sculpture gallery of rich manufacturers, or the stair-cases of large houses, or to make ridiculous busts of respectable nineteenth-century people, with nothing round their necks, and a toga on their shoulders. Were our buildings properly decorated, there would be employment, doubtless, for twice or three times the actual number of painters and sculptors; and these latter gentlemen would experience the pleasure of hearing their public works praised, instead of seeing every person with any taste turn his head away whenever he passes a new statue. All know how much sculpture was employed in their buildings by the Greeks,—those thirteenth-century artists of antiquity,—and how their architecture is, in fact, but little more than the bones which were afterwards clothed with sculpture. The buildings of the thirteenth century were far too vast for this to be the case with them; but there were almost always parts in every edifice where sculpture was employed with so lavish a hand, that the architecture becomes almost an accessory. One of these parts was the altar and its dossal; others were the portals, those great hooks of living stone where the whole history of man and his redemption, and his future state, were written, in such characters that the most ignorant could read and the most learned be instructed. To such an extent was this instruction carried, that many portals, such as that erected at Notre Dame, by Guillaume de Paris, that of the Ste. Chapelle, and those built by Nicholas Flamme, were supposed to have a hidden reference to the preparation of the great talisman of the Middle Ages, viz., the philosopher's stone; and thus a science forbidden by the ordinances of the Church was taught to those who could read the characters on the very threshold of the Church itself. So much was this the case, that in the sixteenth century, and probably long before, the portals of sundry churches had become the common evening rendezvous of the numerous adepts engaged in the great work.

In the present day the very name of the philosopher's stone is sufficient to call up a smile, but perhaps it might be as well to recollect that our modern chemists, like learned and modest men as they are for the most part, have pronounced the transmutation of one metal to another not to be

an impossibility; they only deny that it has ever been done. On the other hand, viewing the numerous accounts we have of metallic transmutations, and making a very liberal allowance for both self and willful deceptions, there would remain as much evidence in their favour as there is regarding any ordinary historical event.

But to return to our portals. We had better first see how the architect prepared the skeleton, and then how the sculptor clothed it with flesh. Probably, one of the most curious portals we have existing, is that of St. Trophimus, at Arles; it is exactly the thing an ancient Roman sculptor would have drawn had he been asked to design a portal in his own style, after having once had (if such a thing were possible) a sight of a thirteenth-century one. It is, in fact, the converse of the classic sketches of Wilars de Houcouc. At the same time must be confessed that the *ensemble* far surpasses anything the Romans ever did in architecture, for their works were works of engineers and not of architects. Nearly all the parts of the Pagan orders can be found in the portal at Arles, but all transmuted into other forms. Thus the pedestals of the columns are changed into lions, while the caps are historiated with figures. The mouldings of the entablature disappear, and its surface is occupied by a continuous procession of figures, while the recesses between the columns become shallow panels of ornament, and act as a diaper to throw up the statues. Altogether it is a most charming composition, and appears to me a far preferable development of the Roman style than that popular commercial style called the modern Italian.

There were four systems adopted in the arrangement of the jambs of the great doorways of the Middle Ages, all of which are good, and all of which succeeded each other. 1. The columns are placed in nooks formed in the jamb. 2. The jamb is formed by one large splay, and the columns placed in front of it. Sometimes the wall of the splay is likewise cut away, and another row of columns and small arches are seen behind. Of course, the tops of these smaller arches do not reach above the necking of the great columns. Great variety was got in both these arrangements by alternating the sizes of the columns, as at Amiens, or working the angles of the nooks into smaller columns and carving them as in the west doorway of Chartres, or putting foliage in the chamfered angles, as at Rouen.

The third plan was to leave the splayed jambs without any columns at all, simply putting a row of figures, standing on a continuous pedestal, and surmounted by a series of canopies. This occurs at Noyen; and the only objection to it, is that the arch moulds must spring from a continuous frieze instead of columns.

A fourth variety occurred when art began to wane in the fourteenth century; then the great columns disappear altogether, and the jamb becomes a series of hollow nooks, into each of which is placed a pedestal figure and canopy. See the *portal de la calande*, Rouen, and those at Cologne.

But in almost all the earlier works one great point was well attended to, viz., obtaining a good reveal before beginning the splay of the jamb. There was indeed often space enough for two or more figures in this reveal. The artist, having chosen which system to go upon, arranged the other parts thus: first of all there was a plinth or dado. The dado is variously decorated. Sometimes it has an arcade, as at Bourges. At Paris this arcade is hollowed out so as to form a sort of niche for any one resting on the seat, which almost invariably occurred in every portal. At the side-door at Troyes there is a double arcade, i.e., one beyond the other. The dado was often divided into two or more parts; thus, at Rheims, the upper part is filled with a representation of drapery, doubtless suggested by some one of the numerous Roman works remaining in that city. At Amiens the upper part is occupied by small subjects in compound quatrefoils, and the lower is diapered. The order was of course this: the highest part was assigned to figures, if there were any, or else to diaper if there were none; and if there was no diaper, mouldings would be above and splays below.

We now come to the column and figure. The column had often the usual base and cap, but the shaft contained, in addition, a pedestal, a figure, and a canopy. Underneath the pedestal was often a little group, illustrative of the personage above. Sometimes the canopy on the shaft is omitted, and the capital of the column has its apex developed into a canopy, as at Rheims, and at the west door at Chartres. At Chartres we see the beginning of the fashion, as the tabernacle work is very small, and springs from under-side of abacus.

At Rheims, on the contrary, it hangs down a great deal.

The mouldings of the arches are generally exceedingly simple, and may be described as a series of large hollows occurring over each column. Now, if these hollows were vacant, the pillar would appear to support nothing; but they are filled with figures and tabernacles, the tabernacle of the figure below serving as the pedestal to the figure above. In good work these tabernacles are exceedingly simple.

But the great object of the sculptor's care was the tympanum, which occupied all the space confined by the arch moulds, and euded at different levels in different buildings; it was supported in the middle by the centre shaft of the doorway, which generally contained the image of the divinity or saint to whom the portal was dedicated.

The composition of the tympanum of course differed in almost every work; but the general practice was to divide it into two or more horizontal compartments by means of foliated strings, or by narrow tabernacle work, or by a series of angles issuing from clouds. The top compartment was almost always left very much larger than the others, as in it was represented the principal event of the story; and if it was a question of the Last Judgment, the figure of Our Lord was also enlarged.

As to the gable over the arches, it is sometimes occupied with a plain three-foil, as at Amiens; or by a small niche, as at Chartres; or occasionally by a most elaborate composition, as at Rheims. This latter is, however, rather an exceptional case inasmuch as the tympana are occupied by glazed tracery, and I suspect the architect found that, if he put sculpture in them, the work would look overcrowded. He therefore put the subjects up in the gables of the portals, supporting the figures by a series of projecting stones, which are carved to represent earth or clouds, and covering them by means of a series of tabernacles attached to the outer mould of the pediment. Even as it is, the work looks slightly overdone.

However, there is no doubt that both the pediment and tympanum occasionally received figures at Chalons-sur-Marne, and at Strashourg.

Such is the general arrangement of the French portals; but of course every portal had something in it different from the others: thus the figures front of them, or there was a distinct series of tabernacles above the caps of the pillars, as at Paris, or the figures were confined to the tympanum.

In England we appear to have followed the steps of the French at some distance. Our west doorways were always very small compared with the size of the building, the English architects preferring to make niches all over the front of the building, and to put their figures in them; in fact, it is nothing more than the genus of the Perpendicular style, which afterwards took so fatal a root, and spoilt all our buildings of the fifteenth century. The most considerable approach to a foreign portal is, or rather was, to be found at Westminster, where we find so many French features; but even there the figures must have been very small, and the tympana of the side doors simply consisted of a diaper. What was exactly in that of the great doorway is rather doubtful, inasmuch as it has been restored by Sir Christopher Wren, with a series of circles containing quatrefoils, the one in the centre having the arms of Westminster playfully inserted.

It is sincerely to be hoped that the dean and chapter may hand over this doorway to the care of my friend Mr. Scott, and let him do as he likes with it. There is no old work to be destroyed, and should the work be delayed a few years longer, a restoration will not take place at all, for by that time we shall probably be so far advanced that we shall put in our own notions and our own work in every instance where we now restore, thereby imitating the good artists of every age.

One other celebrated door is that on the south side of Lincoln Cathedral; but there the columns are very small and thin, while the French idea of one arcade behind another is rendered by a rather meaningless row of arches and pediments, running in front of the columns, and having no connection with the general composition, and supporting nothing whatever.

Exeter has a series of arches placed in front of the doors, and Peterborough must be considered as a compound of the portal and narthex, carried up to an extravagant height.

The sculpture of the French portals was as different in the arrangement of its subjects as can possibly be imagined. It is true that the same subjects were common to nearly every cathedral, but they were arranged in the most different

\* Read by Mr. William Burges at the Architectural Photographic Association.

manner. Thus, a very common subject for the principal west door was our Lord in Glory, or the Last Judgment, which, by the way, is only the former subject extended. Now this at Rheims gives way to the Coronation of the Virgin, because the cathedral is dedicated to her; but probably the best way will be to point out the various classes of subjects and their usual places. The tympana generally had scenes from the Last Judgment, or the life of our Lord, or the Blessed Virgin, or the life of the saint to whom the portal was dedicated, the northern portal of a west front being generally assigned to the local saints. The pediments contain a single subject. At Rheims they are respectively the coronation of the Blessed Virgin, the Crucifixion, and the Last Judgment. At Strasbourg we find Solomon's throne supported by the lions mentioned in Scripture.

If the portal was divided in two by a centre shaft, that shaft contained a great statue of the personage to whom the portal was dedicated. At Rheims, it is the Blessed Virgin; at Amiens, our Lord. Over the head of the Virgin, at Paris, and in the Portal St. Honoré, at Amiens, the tabernacle assumes the form of a little edifice containing a box. This is the symbolical fœderis arca, or ark of the covenant, a type of the adler and bslitsk beneath his feet. The statue on the central shaft does not stand on a bracket, like the other statues at the side, but rests upon a pedestal going right down to the ground, and although agreeing in its general divisions with those of the base, is so arranged as to contain certain subjects on its sides; these of course refer to the statue above, either in a direct or indirect manner.

The side statues have generally some relation with the principal statue: thus, at Rheims they represent the various events in the life of the Virgin, such as the Presentation in the Temple, the Salutation, the Annunciation, &c.; the statue of our Lady being repeated several times.

Often they are the ancestors of our Lord, such as David, Solomon, Bathsheba, &c., or types of some such as Melchisedec or Jonah, or the prophets who have prophesied respecting the great scheme of human redemption; or, if it were the northwest doorway, the local saints.

At Strasbourg, we find the wise and foolish virgins, and in the now destroyed church of the Cemetery of the Innocents, the three *vifs* and three *morts*.

Nothing can be more various than the subjects of the voussours; sometimes we find the whole of the heavenly hierarchy in the concentric rings, the nine orders of angels being the nearest to the tympanum, and then going on through apostles, confessors, martyrs, &c.; sometimes the days of creation; sometimes histories of the types of our Lord, or the Blessed Virgin; sometimes the virtues and their corresponding vices; or the Tree of Jesse, &c. The smaller and flatter surfaces, such as the jambs of the doorways, or soffits of arches, or quatrefoils in plinths, received such subjects as the virtues and vices, the signs of the zodiac, the labours of the year, the good and bad tree, besides other subjects.

One or two things are specially to be remembered. 1st. That all the sculptures are in very high relief, and, indeed, for the most part very nearly detached from the ground. 2nd. That they are cut square, like Greek work, and have not got the edges rounded off; and, thirdly, that they are placed together, so that the whole effect is that of forms drawn by shadow upon a light ground. This last has not been attended to in the new tympanum of the south portal of Cologne. The consequence is, that although the individual figures are most exquisitely designed, the whole affair looks poor and meagre in the extreme.

The variations in drapery of the Medieval figures, and, indeed, the general change of style, offers a very curious parallel with the same things in Greek art.

Thus, first of all the figures are straight, and have very little action, and the drapery is represented by an infinite number of small folds. This we see equally in the western doorway of Chartres and the preëphidian Venus or Minerva, still preserved in the Acropolis.

Afterwards the figures get more action, and the folds become less confused, but still evidently formed of a light material. See the Early thirteenth century sculptures at Chartres and Amiens. Afterwards the folds become much larger, the dress is evidently of a different material, and the figures have a very considerable action, as at Rheims and Strasbourg; both these later stages are, I believe, to be found in the Athenian marbles.

It is very much to be wished that the nineteenth century would take the same views, with regard to painting and sculpture, which the Classic and Middle Ages took of them; there would then be work for twice the number of artists, and more work would be done both better and more expeditiously. At present our efforts would appear to be confined to decorating pediments of buildings utterly unsuitable to our minds; it is of no use to say that we care as little for the portico as for the Britannia, Commerce, Neptune, Amphitrite, and other monstrousities which are placed above it; all the new and rising school ask for its permission to the same thing for our national religion and history that the competent persons and people of taste insist upon doing for a foreign and effete mythology. Let us, at all events, be allowed to put the great truths of our religion, and the parables of our Lord into living stone; and when we have once begun to do so, there will be very little complaint, either concerning the work or the talents of our sculptors; for depend upon it that there is plenty of the latter to be found, if it is only called for in the right direction.

#### EDINBURGH SOCIETY OF ENGINEERS.

This society met at 57, North-bridge, on the 5th of March, Mr. A. Wilson, president, in the chair. Mr. F. J. Thomson read a paper on "Waterworks," or the supply of pure water to towns. The principal points treated of in the paper were, the different systems of supply by wells, gravitation, and pumping; the rainfall of districts; descriptions of the various wells and aqueducts of the ancients down to the modern works of the Croton river at New York, and the Loch Katrine works at Glasgow, as specimens of the combination of aqueducts of stone and iron, tunnels and siphons. The water-supply of Edinburgh was also referred to as an example of the exclusive use of iron piping, the supply being brought from the collecting reservoir in the Pentlands, a distance of 8½ miles, by means of iron pipes, varying from 24 to 36 inches in diameter, laid underground, and rising up to the reservoir on the Castle rock, a height of more than 200 feet above the surrounding valley.

In the discussion which followed, the chief points taken up were, our inferiority to the Romans in the supply of pure water to towns; artesian wells; oxidation of iron pipes; pumping-engines, &c. The paper to be read on 19th of March is on "Boilers and Boiler Explosions," by Mr. R. Davis.

#### THE STONE OF THE HOUSES OF PARLIAMENT.

In the House on Friday Mr. Wise asked the First Commissioner of Works whether any report had recently been made on the condition of the stone-work of the Houses of Parliament, and what had been done with the 7,292 voted last session for the purpose of indurating the external stonework. Mr. Wise said the commission reported that the Bolsover stone combined the requisites of durability, economy of conversion, beauty of colour, and other qualities; but the contract entered into for the supply of the material was cancelled, and a new quarry opened belonging to the late Duke of Leeds, the stone obtained from which, was in the estimation of experienced builders, of an inferior description. He referred to Mr. C. H. Smith's charge, that proper supervision had not been exercised over the delivery of the stone, and the question was, who was responsible for so serious a neglect? The consequence of this was, that they now found inferior material had been used, and large sums, in addition to the enormous outlay already incurred, would be required to preserve these buildings from a decay which ought to have been foreseen and guarded against. At the bottom of that state of affairs, he believed, the modern system of contracts, which gave great profit to the few and inflicted great injury on the many, and increasing disruption of the surface of the stone, especially on the terrace front. The decomposition was not confined to the plain face of the stone, but extended to the sills, bases, capitals, plinths, and the stonework above and below all these. He should be glad to know from the Chief Commissioner of Works what remedy he proposed to adopt for this state of things. We had not yet done with building; we were to have a new Foreign-office and other public buildings, and he hoped that Her Majesty's Government would consider this great stone question, and would not leave a stone unturned until they had arrived at a satisfactory conclusion in regard to it.

Mr. W. Cowper, in course of reply, said that what was supposed to be the best stone that England could produce had been found not to combine those exact proportions of carbonate of lime and carbonate of magnesia which were expected to make it indurately. On the contrary, the action of the weather upon it had been such, that on the river front, not merely on the carved portions, but on many of the plain surfaces where the water did not impinge, the decay was advancing most rapidly. The only thing which could now be done was to find some composition which would render the stone impervious to moisture, and would, in fact, have the same effect upon it as paint had upon wood and iron. There were several patented compositions which professed to attain that object, and two of them,—one patented by Mr. Rausome, and the other by Mr. Sordelmy,—were now being tried upon the river front. As far as ordinary investigation could form a guide, they seemed to promise very fairly; but he had thought it desirable to ask Mr. Faraday and Sir R. Murchison to examine and report upon these experiments, and he trusted that their labours would be more successful than were those of the commission which sat sixteen years ago, to which the hon. gentleman referred. He did not think it right to expend any of the money which had last year been voted by Parliament, until it had been shown that this operation was successful in excluding moisture and preventing decay of the stone.

#### THE HARTLEY INSTITUTE COMPETITION, SOUTHAMPTON.

At the last meeting of the Town Council, it was moved and seconded:—

"That advertisements be inserted in the same papers in which the Corporation advertised for the plans for the Hartley Institution, requesting the architects to withdraw their plans, and to return them, accompanied by estimates and contractor's name, with the names of two sureties for the due completion of the contracts for the specified sum; and that should the Council deem it advisable to submit any or all the plans to the same or another London architect, they reserve to themselves the right of final selection."

After long discussion, the following amendment was carried, by twenty to seven:—

"That the matter be referred back to the Council of the Hartley Institution, with instructions to select, after further consultation with Professor Donaldson, not less than six designs for ultimate selection by the Council, regard being especially had, among other things, to the modification and alteration of such plans which may be necessary, in order to bring their cost within the sum limited by the scheme; and that they also prepare a tabular statement of the various arrangements, and report on the responsibility of merit in such designs, and also any defect or omission in the same, and suggest any improvement which in their judgment may be judiciously made."

#### LECTURES ON ARCHITECTURE.

##### OXFORD ARCHITECTURAL SOCIETY.

On Tuesday, February 28, Mr. Parker read his fourth lecture on "The History of Architecture in England," relating to the period of transition from the Norman to the Gothic style. He began by recapitulating the chief points in the history of the twelfth century, and showing the progress which prepared the way for the greater change of style which was a natural development from what had gone before. It was not the invention of any one mind, nor an importation from any foreign country, but the gradual work of many minds, and of more than one generation, assisted by hints and ideas, taken from many different sources and different countries, with which the people had the opportunity of friendly intercourse. The history of the change is more clearly traced at Canterbury than in any other building, with the help of the contemporary records of Edmer and Gervase, translated and applied by Professor Willis. The coronation chair of Canterbury, but not the coronation, is so much in advance of the work of William of Sens, that the chief merit belongs to the pupil, who had greatly improved upon his master. The cathedral of Sens closely resembles the choir of Canterbury, but the latter is more than a century before they had these in the same. He showed by drawings of the two (kindly lent by Mr. Scott for the occasion) that Sens is later than Canterbury, and believed that the choir of Canterbury was finished after the fire in 1184, the year that Canterbury was finished. Other buildings in France were in advance of Sens, such as the south transept of Soissons, probably building at the same time, and respecting the hall and chapel of Angers, built by Henry II., who frequently held his court there while this work was going on; and to these meetings the leading men of the north and south in friendly intercourse. The history of the change is more clearly traced at Canterbury than in any other building, with the help of the contemporary records of Edmer and Gervase, translated and applied by Professor Willis. The coronation chair of Canterbury, but not the coronation, is so much in advance of the work of William of Sens, that the chief merit belongs to the pupil, who had greatly improved upon his master. The cathedral of Sens closely resembles the choir of Canterbury, but the latter is more than a century before they had these in the same. He showed by drawings of the two (kindly lent by Mr. Scott for the occasion) that Sens is later than Canterbury, and believed that the choir of Canterbury was finished after the fire in 1184, the year that Canterbury was finished. Other buildings in France were in advance of Sens, such as the south transept of Soissons, probably building at the same time, and respecting the hall and chapel of Angers, built by Henry II., who frequently held his court there while this work was going on; and to these meetings the leading men of the north and south in friendly intercourse. The history of the change is more clearly traced at Canterbury than in any other building, with the help of the contemporary records of Edmer and Gervase, translated and applied by Professor Willis. The coronation chair of Canterbury, but not the coronation, is so much in advance of the work of William of Sens, that the chief merit belongs to the pupil, who had greatly improved upon his master. The cathedral of Sens closely resembles the choir of Canterbury, but the latter is more than a century before they had these in the same. The change of style had begun at an earlier period, and although the general use of the pointed arch was a matter of fashion, its introduction was primarily owing to the necessities of vaulting. It is recorded that three Greek models from Byzantium were present at the foundation of St. Bartholomew's, Smithfield, and they were probably consulted by the founder as to the plan of the church. The vaulting of the aisles is peculiar, and the vaulting of the central space seems to have been part of the original design, though not carried out by the founder: if so, it is the earliest instance in England of this idea being formed. The round churches of the Templars had probably some influence in giving new ideas. Balthams and St. Cross have pointed arches before 1150. Considerable stress was laid on the use of the chisel not being applied to stone carving before 1120, according to Gervase, verified by an examination of the work at Canterbury, and in all the early Norman churches in England, compared with those of later date. After the completion of Canterbury, in 1184, the progress of the new style was very rapid. The Hall at Oakham and the Galilee at Durham are good examples of late transition about the same date. Before 1200 the Early English Gothic was fully established. In most parts of the continent it was later, but the stamp of each century, and especially of the thirteenth, is distinctly visible everywhere, even where the round arch was continued. A number of drawings and engravings, photographs, casts, and models were employed to illustrate the subject.

#### CHURCH-BUILDING NEWS.

**Hatfield (Stiffell).**—The new stone reredos which has been erected in this church has lately received the addition of "The Lord's Prayer," "Decelegue," and "The Apostles' Creed," in polychrome, by Mr. A. Sprague, of London. The work is wrought on five tablets, the centre panel, containing a quatrefoil design, being the monogram of the Saviour.

**Goodrich (Herefordshire).**—Colonel Myrick and other gentlemen offered to undertake the complete restoration of Goodrich Church, provided the parish would raise by loan and place at the disposal of the promoters and churchwardens the sum of 500*l.* towards the expenses, and would also consent to the execution of all works in accordance with its architectural design and with ecclesiastical usage, and more particularly to the following works: 1. The pulling down of the gallery and pews, and the substitution of appropriate seats in lieu thereof. 2. The taking up and re-laying of the floor. 3. The restoration of the chancel. 4. The erection of a comely and decent pulpit and reading-desk near the line of separation between the nave and the chancel. 5. The restoration of the windows. 6. The removal of the ceilings and plaster. 7. The elevation and removal of the nave to its original pitch. 8. The thorough reparation of the wall and roofs. 9. The building of a vestry-room. 10. Efficient means of warmth, ventilation, and drainage. A vestry meeting, however, according to the *Hereford Times*, rejected this offer, which would have cost the gentlemen making it 1,000*l.* and consequently it has been withdrawn.

**Liverpool.**—St. Aidin's Church, Victoria-road, Liverpool, has been consecrated. The church is built of red sandstone, the style being old English, and cost 3,500*l.*, exclusive of endowment. The length is about 100 feet, breadth, 51. The chancel is laid with ornamental tiles. At the west end there is a gallery calculated to hold about 100 persons. The church contains 900 sittings, one-half free. Mr. A. H. Holme was the architect, and Messrs. Holme & Nichol the builders.—A general vestry meeting of the parishioners of Liverpool has sanctioned the borrowing of 75,000*l.* at 4 per cent. interest, from the Economic Insurance Company, for the purchasing and laying out of a new local cemetery. The principle of redemption over a period of forty years was such that the rate of interest was virtually during the whole period, a little over 5 per cent. per annum. The Burial Board have agreed as to a circular for the guidance of parties sending in plans and specifications for the laying out of the new cemetery. The circular directed that thirty acres of ground should be appropriated to members of the Church of England, fifteen acres to Roman Catholics, and fifteen acres to Protestant Dissenters; the reserve of twenty-eight acres to be so situated in relation to these three divisions that any one or all of them may be enlarged therefrom. The sites of designs for the chapels are to be shown on the plans, the designs for the chapels and lodges to be the subject of future competition. It was resolved that the name of the cemetery be "The Liverpool Cemetery, Anfield-park, Walton."

**Sale, near Manchester.**—The chief stone of a new Wesleyan Chapel has been laid here. The new edifice is being built from a design by Messrs. Pennington & Bridgen, of Manchester; and the contractor is Mr. Robert Neill, also of this city. The building is Italian in style, and will be of brick and stone. There will be an attached lionie portico and open vestibule. The entrance to the galleries will be by staircases at each side. At the

pulpit end of the chapel there will be a deep recess, with Ionic order and pilasters, with a large semicircular window over, which it is intended ultimately to fill with stained glass. At the rear of the chapel schools will be erected. The cost of the erection is estimated at 2,196*l.*

**York.**—Towards the cost of widening Little Blake-street, and thus throwing open the west front of York Cathedral, the Dean has subscribed the sum of 1,000*l.*

**Wakefield.**—A contract has been entered into for the taking down of the old spire of the parish church, and the erection of a new spire.

**Bradford.**—The first of the ten new churches which it is proposed to build at Bradford has been consecrated by the Bishop of Ripon. The church is situated at Girlington, a new and rather populous suburb of Bradford, overlooking the Thornton valley. The church, dedicated to St. Philip, is built from the designs of Messrs. Mallinson & Henley, of Bradford, and has cost about 1,400*l.* The style of architecture is the Decorated, which prevailed about the time of Edward III. The church will accommodate about 600 worshippers. The pews and roof are open.—The church of St. John the Evangelist, Tong-street, has been consecrated. The edifice, which is of a simple character, is of the Geometric Decorated style of architecture, about A.D. 1270. It is of transeptal form, having its western gable surmounted with a bell-turret. The windows at the east and west ends of the church are similar, of three lights, carrying three three-foiled circles. The centre lower light is five-foiled, the side ones three-foiled. The windows in the transepts consist of three lights each, carrying a five-foiled circle in the head. The roof forms one continuous unbroken line, and is of blue slate. The porch is built to carry a tower. The nave is lighted north and south with two windows of two lights, three-foiled. The woodwork of the roof is open, and of deal, stained. The pewing, pulpit, and reading-desk are also of stained deal. The accommodation is for 500 persons, and the cost of erection has been about 1,100*l.* Two hundred and fifty of the sittings are free. The architects were Messrs. Mallinson & Healey. There have also been built here within the last two or three years a parsonage and school, and schoolmaster's house.

**Whitwell.**—The new church, which is being built here (from the designs of Mr. G. E. Street, London, and superintended by Mr. John Chick) at the expense of Sir Edmund and Lady Lechmere, is so far advanced as to admit of a peal of six bells in the tower, the opening of which took place on the 31st of January. The York ringers were engaged for the occasion. The bells were cast by Messrs. Warner, of Loudon, and hung under the superintendence of Mr. Boswell, bellhanger to the firm. The bells are said to be sweet and musical, and have been heard at a distance of five miles. The weight of the tenor is about 13 cwt., note G. Four bells are also being cast by the same firm for the new church in course of erection at Howsham, at the expense of Mrs. Chohnley, from the same architect's designs, also superintended by Mr. Chick. Mr. John Shaftoe was the contractor for both.

**Middleton.**—The foundation-stone of a building at Middleton, near Leeds, intended for a Wesleyan chapel and schools, has just been laid. The building will be 45 feet long by 30 feet wide. The centre will be used as a Sunday school, and will accommodate upwards of 100 scholars. With pews placed down each side it will altogether hold 250 persons. The architect is Mr. George Smith, of Leeds, and the cost of the building and land is estimated at about 400*l.*

#### PROVINCIAL NEWS.

**Lowestoft.**—The new townhall at Lowestoft has been formally opened. The style of architecture adopted is the Italian. The facade towards the High-street consists of a rusticated basement,—a first-floor, containing two semicircular windows, with caps and bases and entablature,—and an attic above with two circular windows, giving light and ventilation to the gallery in the hall. The whole is terminated by a projecting cornice formed of moulded brick modillions, and having in its frieze a design composed of Maw's encaustic tiles. At the angle of the building, towards the south, is a campanile, containing in its lower story the entrance to the hall and various parts of the edifice; on the first-floor, a staircase to the gallery of the ball, and above that the clock and bell chambers. The great hall is 68 feet long, 26 feet wide, and 26 feet high. The sides are panelled out by means of pilasters, and have windows with semicircular heads. The west end contains a large window,

above a platform, filled in with painted glass. At the east end is a gallery, carried on iron columns and girders. The ceiling is segmented, and the room is surmounted with a cornice. The rooms on the ground-floor are appropriated respectively as a waiting-room, town surveyor's office, lower hall (25 feet square), mechanics' library, retiring-room, and store-room. The whole of the works have been carried out from the designs and under the superintendence of Mr. J. L. Clemence, architect, by the following tradesmen:—Bricklayers' work, Mr. John Newson; carpenters' and joiners' work, Mr. Swatman; smiths' work, Mr. Skyles; plumber, Mr. Turner; gas-fittings, Mr. Park; and the carving of the town arms, by Mr. Toulie, of London. The hall was recast by Messrs. Warner, of London. The three painted-glass windows in the room have been presented by Sir S. Morton Peto, bart., M.P. The large window, which cost Sir Morton 700 guineas, is intended to commemorate the union of France and England during the Crimean war,—as Sir Morton Peto owes his baronetcy to the circumstance of having rendered great services in the Crimea, in the formation of a railway from Balaklava to Sebastopol. In the centre compartment is a representation of the tournament of the Field of the Cloth of Gold, being the celebrated interview between Francis I. of France and Henry VIII. of England (a parallel alliance to that of the Crimea). Sir Richard Jernegan, one of the lords of the manor of Somerleyton and Lowestoft, greatly distinguished himself both at tilt tournament and barrier on the occasion, as we are told by Hall, the historian. Dexter and sinister to this incident are the effigies of St. Denis of France and St. George of England: in base are the respective shields of both nations and the national flags intertwined; and the compartment, which is of an architectural character, is surmounted by the medallions of "Victoria and Albert," and "Napoleon and Eugenie," supported by angels, and surmounted by laurel and other emblems of peace and plenty; and crowning the whole composition is the figure of Peace holding a crown over the heads of the allied sovereigns. The whole is surrounded by a bordering of the rose and fleur-de-lis alternated. The designs and cartoons for the windows were made by Mr. John Thomas, and the window was executed by Mr. James Ballantine, of Edinburgh. This window was at the Paris Exhibition of 1855. The two smaller windows contain, respectively, the arms of Sir Morton Peto, bart., as lord of the manor, and the arms of the town of Lowestoft. The windows were illuminated at the inauguration of the hall.

**Spalding (Lincolnshire).**—At a recent meeting of the local Improvement Commissioners, the chairman, in allusion to the Corn Exchange building, said, that since their last meeting a fire had occurred upon the premises, happily to no great extent, but it had disclosed a state of things reflecting great discredit either upon their architect or their builder. The fire occurred in what was called the news-room, and originated under the hearthstone, boards having been placed under the stone, which was cracked, and they had become charred and ignited. After that warning, he suggested that the other hearthstones should be taken up, to see whether they were in the same state. It was remarked that all the other hearthstones were cracked.

**Southampton.**—The interior of the building in Carlton-place, heretofore known as the Riding School, has undergone a transformation, according to the *Hampshire Independent*, the owner having determined on converting it into an assembly-room or music-hall, for literary, musical, and other entertainments. The decorations of the hall were entrusted to Mr. C. Vaughan. The ceiling has been drawn out in panels of colours, to harmonize with those of the carved beams and the projecting columns between the windows. Cartoons are to be placed beneath the windows: these consist of views of the town and neighbourhood, and other sketches.

**Wolverhampton.**—The borough surveyor, at the request of the local Sewerage Committee, is about to prepare plans for severing the borough, by which the existing drains are, as far as possible, to be rendered available, the object being to make the sewers low enough to drain cellars, without making provision for discharging the contents of waterclosets. This proposition is understood to obtain the support of those who opposed former plans.

**Bridgwater.**—The chimney over Messrs. Heal & Cook's brewery, High-street, was blown down during a late gale, the masonry falling upon the roof of the malthouse and shed, and doing considerable damage. A workman who was standing near at the time received a severe blow on the

head from a brick. The chimney was about 20 feet high.

**Halifax.**—Mr. William Atkinson, a superintendent of works under Messrs. Lockwood & Mawson, architects, has been appointed inspector of works, under the Halifax corporation, of the new storage and service reservoir, at Pellon.

#### THE "BUILDER'S" FIRE, AND MODE OF HEATING HOUSES.

OBSERVING a letter in your paper respecting the *Builder's* fire, arranged by placing sheet-iron above the bottom bars, and lighting the fire at the top, I am induced to point out another mode of economizing coals.
