**WHITE'S PATENT AIR-PURIFYING VENTILATORS.**—These ventilators are well spoken of by Dr. James Copeland, Professor Gardiner, of the Royal Naval College, and others. They are described as being "portable or fixed, and of various forms and capacities, for the purpose of supplying purified, medicated, perfumed, warmed, or cooled air, for sanitary and other uses, in public and private rooms, ships, mines, hospitals, sick-rooms, workshops, manufactories, sewers, chimney-shafts, &c.;" for preventing the injury of clothing, furniture, pictures, &c., in houses, and goods in shops, by cleaning the air of such places; and they are recommended for **COOLING THE AIR IN INDIA.** The air to be purified is brought into contact with water by the action of the fan of the ventilator, water being well known to be capable of purifying air brought in contact with it. A large amount of organic matter, of *miasma*, and of *malaria*, is soluble in pure water, but lime water may be used, and disinfectants such as the chloride of lime, Sir W. Burnett's, Condy's, or Macdonald's disinfecting fluids may also be mixed with the water when it is expedient to use only a small quantity of water. The air may also be impregnated with medicine, perfumes, or the components of sea water, by the addition of the substances respectively necessary to the water used; and the temperature of the air is regulated by that of the water. The ventilators assume various forms, such as the hand ventilator, which is a small fan ventilator moved by hand, and adapted for occasional use in a sick room, to supply pure air, and to prevent contagion; or the water-force ventilator, which is to be connected with a vessel of water at the distance of 4 feet at least above it, and means provided for carrying off the waste water from it: this fan is moved by the force of the water issuing from a Barker's mill, and the air is purified by the same; a modified form of this ventilator is recommended to arrest and carry down the solid particles of smoke in flues, and to ventilate sewers, and arrest the impurities which arise from them.

**GAS.**—At the annual meeting of the Stirling Gas Company, a dividend of 8 per cent. was declared.—Gas is being made in Copenhagen from a sort of peat, which is reported to produce a light whiter and stronger in flame than coal gas.

**DEODORIZING SEWAGE.**—We hear that a company is being formed in Manchester, with a capital of 20,000*l.*, to work a chemical and mechanical process, patented in England, France, and Belgium, by Mr. B. Standen, of Salford, for deodorizing and concentrating town sewage, with the view of enabling towns to sell their manure at a profit, instead of (including collection) at a loss. It is stated that the plan has been in operation for the last nine months in the manufacturing township of Hyde.

**THE INVENTOR OF VULCANIZED INDIARUBBER.** The *New York Tribune* records the death, in that city, on the 1st instant, of Mr. Charles Goodyear, the inventor of the art of vulcanising indiarubber. Mr. Goodyear was born in New Haven, December 29, 1800. The disease which terminated his life had its origin in the severe and long-continued privations and anxieties which he suffered, and struggles which he made, in order to perfect and introduce into public use the invention of vulcanisation, to which his whole life since 1839, the date of the discovery, has been devoted.

**ANTIQUITY OF STENCIL.**—In the "Philosophical Transactions" for 1738 we read that Procopius, in his "Historie Arcana," says, the Emperor Justinus, not being able to write his name, had a thin, smooth piece of board, through which were cut holes in the form of the four letters J V S T, which, laid on the paper, served to direct the point of his pen: his hand was guided by another. Possibly, this way likewise has given the hint to the first of our card-makers, who paint their cards in the same manner, by plates of pewter or copper, or only pasteboard, with slits in them in forms of the figures that are to be painted on the cards. Such is the art of stencil, which has been applied, in our time, to decorating the walls of rooms, as well as to the marking of linen.—*Timbs's Curiosities of Science.*

**STATUES.**—We mentioned that the Sturge Statue Committee had decided upon requesting three sculptors to send in designs or models for the statue and fountain to be erected as a memorial of the late Mr. Joseph Sturge. The three gentlemen selected are,—Mr. Peter Hollins, Mr. John Thomas, and Mr. E. B. Stephens.—The clay model of the proposed statue, at Glasgow, to the memory of the late Mr. James Lumsden, in the studio of Mr. Mossman, will probably be despatched to London during August, to be here executed in bronze. The figure appears with a loose overcoat. The statue is 8 feet in height, and is intended to be placed on a pedestal of 12 feet. It is to be erected on the esplanade in front of the infirmary, of which institution he was treasurer for many years.

**LUDGATE HILL AND ITS ASSOCIATIONS.**—The Belle Sauvage, till very lately, afforded a curious specimen of the players' inn yard, where dramas were enacted previous to the building of theatres with roofs. Ludgate-street was famous for mercers' shops in Stow's day, and one of the old class, which has maintained its ground for upwards of a century (Hilditch's), still remains. At No. 65, the corner of St. Paul's-churchyard, lived John Newberry, for whom Goldsmith wrote "Goody Two Shoes" and a history of England. At "the Duncton," Ludgate-street, D. Griffith published the "Monthly Review," No. 1, 1749, perhaps the first of our critical journals. Fronting Old St. Paul's, Digby, Winter, Grant, and Bates were executed January 30, 1606, for their participation in the Gunpowder Plot. In 1792 was discovered a haribanc, or watch-tower, near Ludgate, forming part of London wall in 1276 (a fragment of it is preserved in St. Martin's-court, opposite the Old Bailey); and in the same locality, in 1800, a sepulchral monument was dug up. It is dedicated to Claudina Martina, by her husband, a Roman soldier. A fragment of a statue of Hercules and a female head were also found, and are preserved at the London Coffee House. At No. 32, for a long period, was the famous establishment of Rundell & Bridge, goldsmiths and diamond merchants. Flaxman's shield of Achilles, in silver gilt, was executed here, as was also the imperial crown for the coronation of George IV., 1821. At No. 45, William Hone published his "Everyday Book;" and it has still some splendid shops, especially that of the Everingtons, so remarkable for its display of rich silks and costly Oriental shawls.—*City Press.*

**BRASTED.**—The new national schools in this village were formally opened on the 23rd by the Archbishop of Canterbury. The building, which is situated in the village, was designed by Mr. Waterhouse, architect of the new assize courts at Manchester, and carried out by Mr. Singer, of Westerham, at a cost, inclusive of site and all extra charges, of 1,200*l.*

**HARROW-ON-THE-HILL.**—The foundation-stone of the new literary institution was laid on Wednesday last, by the Rev. M. Butler, head-master of the school. The style is Gothic, with red brick facings and Bath stone doorway, tracery, windows, and dressings. The building consists of library, reading-room (with open-timber roof), and apartments for keeper. The works are being carried out by Mr. R. Chapman, builder, at a cost of 800*l.*, from the designs and under the superintendence of Mr. Charles Laws, architect.

**CHURCH STRUCK BY LIGHTNING.**—During a recent thunder storm a flash of lightning struck the spire of Newark church, and the damage is estimated at 60*l.* It appears that the lightning entered at the north-east side of the steeple, injuring a portion of the stone-work, and thereby making an opening, which can be seen from the clock-chamber. This is the third time this edifice has been struck within the space of twenty-three years, and still there is no lightning conductor!

**HOPE FOR THE BALD.**—"Will Warners," of Stratford-on-Avon, whose casts of Shakspeare are known to some of our readers, writes as follows,— "Some six months ago I took a cast from the head of a bald-headed gentleman. My material was the pure Derbyshire plaster, mixed with a little clay from Broseley. Strange to say, a beautiful crop of down has sprung up on the gentleman's bald head. He attributes it to the cast being taken, the results of the material. If so, let all try it, and anyone can do it. I have devoted my time to casts many years, but never have had to record so strange an occurrence as the growth of hair after the cast was taken. I wish some of your correspondents would state the cause, and whether our bald-headed countrymen might with safety try the experiment."

**COMBINATIONS OF WORKMEN.**—The Middlesex magistrates sat on Monday in last week at the Guildhall, Westminster, specially to hear an appeal by John Goppin against a conviction by Mr. Corrie, the magistrate, for an offence against the Act relating to combinations of workmen. The appellant, John Goppin, was in the employment of Mr. Anley, builder and joiner, in Whitecross-street, and he with about thirty others, it may be recollected, struck against two men in the same employment who were working under the document. Being a member of the Association of Master Builders, Mr. Anley brought the case before the executive committee, and it was resolved to proceed against Goppin, and the result was that the magistrate before whom the case was heard, upon the evidence that was adduced before him, convicted and sentenced the appellant to a month's imprisonment, the Act not giving the option of a fine. The only question raised on this appeal was, not whether, in fact, but in the strict construction of the clause under which the conviction was made (George IV., c. 129, s. 3), the appellant had made "a threat." The Court held the conviction to be good, and confirmed it, with costs, against the appellant, who was then ordered to be sent to the House of Correction, in the terms of the conviction, for one month.

**PADDINGTON WORKING MEN'S READING-ROOMS.**—Sir,—In your impression of the 21st ult., an article appeared, headed, "The Wants of the Artisan in London," wherein you very justly alluded to the necessity of providing the industrious classes with the means of intellectual improvement. I beg to inclose you a copy of the last report of an institution established (now upwards of three and a half years) for the above purpose, by a few gentlemen in Paddington. Although not on a very extensive scale, still it has so far succeeded that our numbers last winter were about 300. To publish this would be more than I could expect; still I wish you to know that such an institution does exist; and when our report for the present year is printed, I will take the liberty of forwarding you a copy.—JAMES STUBBINGS, Librarian.

\* \* \* Various classes appear to have been established. The library is increasing; lectures are sometimes given, and the reading-rooms are open every evening but Sunday,—all for a subscription of 7*d.* per month of four weeks, or for 6*s.* 3*d.* a year.

**HALIFAX.**—The corner stone of a new chapel has been laid at Ambley Thron for the New Connection Methodists, cost, about 1,100*l.* Mr. John Davidson, of Halifax, is the architect.

**THE SHOP SUN-BLIND NEIGHBOUR.**—At Ipswich this dangerous nuisance seems to exist as in London and elsewhere; but as a local commissioner of the pavements has just received a serious blow from one, the evil will likely be remedied. The particular blind with which he had come in contact was not 6 feet high. At a recent meeting of the local commissioner the surveyor brought the subject under consideration. The town clerk said the height was laid down by Act of Parliament at 8 feet. After some conversation the committee resolved that the surveyor immediately take steps in the matter: 7 feet appeared to be considered enough, but to this we demur, as a very ordinary sized person walking along the pavement with an umbrella on a rainy day would still be annoyed by these abominable nuisances, which ought to be clear of the heads, hats, and umbrellas of all and sundry the leges. We only wish some London commissioner of pavements had this necessity of ridding us of these detestable projections *knocked* into his own skull for once and away: we should then have some hope of the many offenders against the law being brought to book about them.

**A NEW PATENT FIRE-ESCAPE.**—Dr. R. Gardiner Hill, of Inverness Lodge, Brentford, has recently introduced a fire-escape which consists of a rectangular framing of wood, bound together by means of the rods. The bottom part of this frame is formed of a lattice-work of thin iron. One side of the frame is made with a half door, to afford facility for getting out of the escape. The frame is covered at the bottom and round the sides with non-inflammable canvas. A ring is securely fastened to the floor or window-sill of the house, and to this ring is simply hooked the end of a chain carrying a block through which the tackle of the escape is rove. The whole of the tackle and block are kept inside the frame when the escape is not in use, the hooking of the block chain to the ring being the only thing to be done when the escape is required to be brought into use. The lowering rope is thrown to the persons below, or the occupant of the escape may lower himself by its means. The escape is then hauled up to bring down other persons, or for removing property from the upper part of a dwelling. The frame of the escape is fitted with castors on the inner side, and when not in use it stands upon them, and is covered with an ornamental cover, which converts the escape into a convenient ottoman. It can be used also as a dressing table; for which purpose it is placed on its side, and fitted with a loose deal top and muslin hangings in place of the cushion. In this way the fire-escape may at all times be kept near the window from whence it would be used if required.

**GAS IN THE UNITED STATES.**—Our Transatlantic cousin are still, in respect to the price and consumption of gas, much in the same position in which this country was when we first originated the gas movement, some twelve or fourteen years since, in the *Builder*. Prices are absurdly high, and the natural consequences are that dividends are low, and gas scarce. As the American *Gas-light Journal* of 16th ult. states, there are in England no less than fifteen gasworks to one even in the metropolitan state of New York. But no wonder when the high prices and the low dividends are considered. Prices in the States generally seem to range from two and three dollars up to seven, eight, and even ten (!) per 1,000 cubic feet, and dividends from 3 to 5 per cent. on the former, to none at all on the latter. The American *Gas-light Journal*, however, being convinced that "there are not less than 20,000 gasworks yet to be built" in North America, has the enlightened policy to urge on, their chief constituents, the companies, our own now fully confirmed and established principle of lowering the price that the dividends may be raised. "There is no question," remarks the editor, "that the lower the cost at which good gas is furnished, the greater will be the consumption, and necessarily the greater the profits to the manufacturers." And he is of opinion that "this is beginning to be understood by the companies," and "the sooner it is acted on," he adds, "the better we are sure it will be for themselves." Meantime, a vast field lies fallow in the States. Pennsylvania itself, which owns more capital in gas than any other state in the Union, has only 48 gasworks in its 63 counties, for a population of 4,000,000. And so of other states which are still worse off for the best light in general use, either with us or with themselves. The number of gasworks in 36 states at present is only 381.

REAPING MACHINES.—It is worthy of remark that at the competition of reaping-machines at the imperial farm, near St. Cloud, the three foreign prizes were carried off by British manufacturers. The prizes were 1,000 francs and a gold medal for the first; 500 francs and a silver medal for the second; and 300 francs and a bronze medal for the third. The competition took place in the presence of the Emperor, who, notwithstanding the unfavourable nature of the weather, closely watched the operations. The jury awarded the prizes,—foreign machines, first prize, to Messrs. Burgess & Key, of London; second, to Mr. Cuthbert, of Bedale; and third, to Messrs. Cromston, of London. The large gold medal of Honour was awarded to Messrs. Burgess & Key.

THE STATUES AND FRESCOS AT WESTMINSTER PALACE.—In course of a discussion in the Commons on the supply question as to 39,597l. for works connected with the Palace, Mr. Cowper, the Chief Commissioner of Works, stated that the question as to a statue of Cromwell did not press for a decision, because the proposition of the Fine Arts Commission was that the artists should begin with the later sovereigns, William IV. and George IV., and go backwards. Proceeding in that manner, at the rate of two sovereigns a year, there would be work to occupy them for a considerable time. The artists who were to execute these statues (for which 800l. each are to be given) were Mr. Thornycroft and Mr. Theod. As to the frescoes, Mr. Herbert was to receive 6,000l. for four pictures which he had in hand. He had already received 3,500l.; and, although he had executed very little on the wall, he had given three or four years of intense labour to the composition of these works, and had produced very noble cartoons, which were of themselves worth all the money. So again with Mr. Maclise who, though perhaps he had not advanced quite so rapidly in his work as might have been anticipated, had yet bestowed immense labour upon it, and was executing paintings that would uphold his reputation. Mr. Dyce might not have devoted himself to his work so exclusively as Mr. Herbert and Mr. Maclise, but he also had finished his cartoon, which was the result of great labour and skill. With regard to the Tudor portraits, they might be obnoxious to those who disliked everything belonging to the Tudor period, but they had been copied very carefully from what were called Holbein's originals, and their production had been very useful in forming a school of young artists, whom it was desirable to accustom to minute and faithful drawing.

TENDERS

For a pair of villas at Isleworth, for Mr. Geo. Imrie, jun.; Mr. Charles G. Searle, architect:—
Turner & Sons £1,350 0 0
Burchett „ 1,250 0 0
Ennor „ 1,175 0 0
Patman & Potheringham „ 1,098 0 0
Howell & Brown „ 1,055 0 0
Nias „ 1,002 10 0

For alterations at 33, Haymarket; Mr. C. W. Crocker, architect:—
Watson „ £333 0 0
Jackson & Sbau „ 290 0 0
Macey „ 264 0 0
Turner & Sons „ 214 0 0

For second portion of proposed restoration and re-seating of Kington Church, Herts; Mr. J. Clarke, F.S.A., diocesan architect:—
Kingham „ £797 13 0
Jeetes „ 745 0 0
Kibby „ 726 0 0
Warren & Allen „ 577 18 8

For third portion of proposed restoration of Middlewich Church, Cheshire; Mr. J. Clarke, F.S.A., architect:—
Farman „ £2,835 0 0
Wilson & Jones „ 2,450 0 0

For shops, stores, &c. at Kildgrove, Stoke-upon-Trent, for the Kildgrove Industrial Co-operative Society; Mr. Robert Chapman, architect, Newcastle. Quantities supplied:—
Cotton & Wood „ £1,850 0 0
Baylor „ 1,744 10 0
Harley & Denn „ 1,550 0 0
Fryer (accepted) „ 1,565 0 0
Pallin „ 1,500 0 0

For the Hartley Institution, Southampton; Messrs. Green & De Villis, architects. Quantities taken up by Messrs. Strudwick & Co., and Mr. Gritten, of West-minster:—
Mears „ £9,900 0 0
Watts „ 9,400 0 0
Marriott „ 8,950 0 0
Stevens „ 8,577 0 0
Eull „ 8,537 0 0
Gambling (accepted) „ 8,430 0 0

For alterations and additions, Lower Thames-street, for Messrs. Symonds, Sharpen, & Co.; Mr. H. H. Collins, architect:—
Picard & Co. „ £3,311 0 0
Macey „ 318 0 0
Ashby & Horner „ 275 0 0

For building a new chapel in Pemberton-street, Sunderland; Mr. John Tillman, jun., architect. Quantities supplied:—

For the whole Work.
Young „ £935 5 2
Hopper „ 913 9 6
Snelclaire, Thompson, & Young „ 838 0 0
Thompson & Terry „ 814 0 0
Pear & Humble „ 802 0 0
D. & J. Ranken „ 725 15 0

Executives, Mason, and Bricklayer.
Younger, jun. „ £320 13 3
Wardropper „ 312 15 9
Stonley „ 487 15 4
Hopper „ 433 10 0
Snelclaire, Thompson, & Young „ 415 10 0
T. & A. Cooke (accepted) „ 379 0 0
Thompson & Terry „ 311 0 0

Plastering.
Wardropper „ £291 4 7
Atkinson „ 58 8 8
Stonley „ 58 8 8
Hopper „ 58 8 8
Snelclaire, Thompson, & Young „ 58 8 8
Thompson & Terry „ 54 3 7
T. & A. Cooke (accepted) „ 47 0 0

Slating.
Preston „ £44 0 0
Dawber & Son (accepted) „ 40 0 0
Joiner and Carpenter.
Bates „ £330 9 6
Conyers „ 296 0 0
Snelclaire, Thompson, & Young „ 290 0 0
Pear & Humble „ 285 0 0
D. & J. Ranken (accepted) „ 258 12 9

Painting.
Bamlett „ £14 10 0
Gowdy „ 11 10 0
Kirkup (accepted) „ 8 2 4

For additions and alterations to Jews' Burial Ground Forest-gate, Essex; Mr. H. H. Collins, architect:—
Rivett „ £492 0 0
Mortler „ 383 0 0

For the erection of a primary, alterations to adjoining buildings and counting-houses, at Rotherhithe, for Messrs. Groves & Sons; Messrs. Snooke & Stock, architects:—
Cubitt & Co. „ £9,609 0 0
Hill „ 7,483 0 0
Ashby & Sons „ 7,182 0 0
Munlay „ 7,170 0 0
Ashby & Horner „ 7,090 0 0
Rider „ 7,065 0 0
Maecrs „ 6,973 0 0

For house, Maze Hill, St. Leonard's-on-Sea; Mr. F. H. Fowler, architect. Quantities by Mr. Smith:—
Stap „ £2,750 0 0
Ayers & Co. „ 2,642 0 0
Fish „ 2,430 0 0
McLennan & Bird „ 2,293 0 0
Howell „ 2,238 0 0
Hughes & Hunter „ 2,223 0 0
Kenwood „ 2,193 0 0
Donnelly „ 1,683 0 0

For the reseating and restoration of St. Luke and All Saints' Church, Wellingborough, Northamptonshire; Mr. E. F. Law, Northampton, architect:—
Cox & Son „ £2,748 0 0
Coxswell & Day „ 1,612 3 6
Watkin „ 1,225 3 0
Bradshaw „ 1,199 0 0
Burkitt & Cheater (accepted) „ 1,140 5 0
Reed „ 871 2 0

For additions to Newington-green Chapel; Mr. T. H. Hovenden, architect:—
Harvey „ £974 0 0
Dave, Brothers „ 930 0 0
Thompson „ 868 0 0
Axford & Co. „ 772 0 0
Brewster „ 757 0 0
Corder „ 752 0 0

For villa at Sharnbrook; Mr. Noble, architect:—
Reid „ £1,458 0 0
Perry „ 1,430 0 0
Conder „ 1,414 0 0
Saville „ 1,409 0 0
Pritchard „ 1,400 0 0
Dave, Brothers „ 1,375 0 0
Hill & Son „ 1,367 0 0
Rivett „ 1,347 0 0
Arber „ 1,335 0 0
Heiges „ 1,286 0 0

For schools at West Ham, Essex; Mr. J. Johnson, architect:—
Wright „ £3,499 0 0
Myers „ 3,369 0 0
Nixon „ 3,209 0 0
Hill „ 3,143 0 0
Dave, Brothers „ 3,075 0 0
Todd „ 3,059 0 0
Hedges „ 3,036 0 0
Rivett „ 3,033 0 0
Saunders, Brothers (accepted) „ 3,009 0 0
Stevenson „ 2,974 0 0
Wood „ 2,973 0 0
Fillington „ 2,953 0 0
McLennan & Bird „ 2,777 0 0

For stables, lodge, &c., at Newlands, Berks (near the house now in course of erection), for Mr. John Simmonds; Mr. Charles Smith, architect, Reading:—

Table with 4 columns: For Stables, Pulling down the old Newlands House, £ s. d.

For pulling down and re-erecting premises in High-street, Camden town; Mr. M. P. Manning, architect:—
Seagrave & Blodfield „ £999 0 0
Stevenson „ 995 0 0
Batterbury „ 988 0 0
Matthews (accepted) „ 942 0 0

For altering and restoring Heathfield Church, Sussex; Mr. J. Billing, architect:—
Tyler „ £979 0 0
Dove, Brothers „ 900 0 0
Adamson & Son „ 933 0 0

Bishopsgate Infant School, Alderman-walk; Mr. J. S. Scott, architect:—
Lawrence & Sons „ £1,050 0 0
Axford „ 935 0 0
Cannon „ 929 0 0
Heath „ 900 0 0
Asby & Sons „ 897 0 0

For repairs, alterations, and additions to the "Cower Testimonial" National School, Hertford; Mr. W. Willis, architect:—
Ravment „ £249 5 6
Norris (accepted) „ 248 11 9

For repairs, &c., to four houses, in Arnwell-street, Clerkenwell, for Mr. Simons; Mr. W. P. Griffith, architect:—
Brice „ £298 0 0
Brake „ 195 0 0
Baldwin „ 138 0 0
Powler „ 127 0 0

For building a public house and a dwelling-house adjoining same, on the Cotton Estate, Limehouse, for Messrs. Tuman, Hanbury, Buxton, & Co.; Mr. W. E. Williams, architect. Quantities supplied:—

Table with 3 columns: Public-house, Dwelling-house, Total.

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher." Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

ADVERTISEMENTS.

DIED, on the 4th instant, at his Residence, Priory Cottage, Dawlish, Devon, ROBERT EBBELS, Esq., Architect, formerly of Exeter and late of Wolverhampton, in his 70th Year.

MR. WILLIAM ELLISON, CONSULTING SURVEYOR, late of STAINSBY ROAD, Has taken Offices at 13, FENCHURCH-BUILDINGS, FENCHURCH-STREET, E.C. Where he continues to receive BUILDERS ON BEHALF OF CONTRACT, DEBITED ACCOUNTS, &c.

A JUNIOR ASSISTANT WANTED, in an ARCHITECT'S OFFICE.—Address, stating terms, to W. C. R. M., Station's Office, 64, Old Broad-street, E.C.

NAVIES WANTED.—Good Men or getting 3s. 6d. per day at LUMP'S POINT, Southsea, Portsmouth.

TWO GRAINERS.—WANTED, TWO good HANDS. Constant employment if skilful, steady, and industrious.—Address, J. C. Rastall's Library, Euston-street, St. Pancras, S.W.

WANTED, TWO MEN who have been accustomed to WORK a CIRCULAR SAW-BENCH.—Apply, by letter, to WILLIAM RAY & SON, Portsmouth.

WANTED, in a Builder's Office, a JUNIOR CLERK.—Address, stating where last employed and salary required, to M. N., Office of "The Builder."

WANTED, a General Builder's FOREMAN, thoroughly efficient in setting out and measuring up large works, and managing workmen. State salary, age, and last employer.—Address, J. W. Post-office, Newcastle-upon-Tyne.

TO GLAZIERS. WANTED immediately, some good practical HANDS to Glaze Stained Glass.—Apply to FREDERICK FREEDY, No. 13, York-place, Baker-street, London. Satisfaction references to former employers required.

WANTED, TWO GOOD MAP DRAUGHTSMEN, to go on the Continent for three months.—Address, with terms, T. Z. Office of "The Builder."

TO MASONS AND CARPENTERS. WANTED, to proceed to one of the Colonies, a MASON and a CARPENTER, of good character and steady habits. It is required that both should be capable of planning and setting out ordinary works in their respective trades. The climate is very healthy, and constant employment will be given.—Address, with references as to character and ability, A. Z. Office of "The Builder."

TO ARCHITECTS' ASSISTANTS. WANTED, a thoroughly qualified ASSISTANT in an Architect's Office. One accustomed to assist in taking out quantities preferred.—Address, with full particulars, to G. Post-office, Birmingham.

WANTED, a good JOINER, and if married, his Wife to take charge of a LAUNDRY.—Address, A. R. Post-office, Apsleigh Hill, Herts.

WANTED, eight miles from London, CARPENTERS—two good bench hands—some hands accustomed to taking down old joiners' work and refitting, and to assist with carpenters' work. The jobs are in addition for a reading-house, Millidge.

TO BUILDERS AND PLUMBERS. WANTED, by a Young Man, a SITUATION as IMPROVER.—Address, S. W. G. Office of "The Builder."

WANTED, by a Carpenter, aged 37, a RE-ENGAGEMENT as SUB-FOREMAN, or otherwise, his present job being near completion. Has a knowledge of the building trade in general. No objection to free-work. Good references.—Address, M. N. 19, Wellington-street, Pall-mall.

TO ARCHITECTS. WANTED, an ENGAGEMENT, as CLERK OF WORKS. Terms, Three Guineas per week.—Address, X. Y. Z. Office of "The Builder."

TO BUILDERS AND CONTRACTORS. WANTED, a PRINCIPAL FOREMAN.—Address, Y. Z. Office of "The Builder."

TO BUILDERS, ARCHITECTS, &c. WANTED, by a Young Man, aged 20, a RE-ENGAGEMENT in either of the above offices. Understands book-keeping, and has a good knowledge of drawing. Salary references as to character and capabilities from his employers, with whom he has been engaged for the last five years.—Address, W. S. Mr. Eubery's, 39, Leaden-street, W.

TO BUILDERS, &c. WANTED, by a competent Person, a SITUATION as GENERAL or OUT-DOOR FOREMAN. Has a thorough knowledge of the whole of the building trade, in and out of shop, and can take charge of work in town or country. Most respectable references.—Address, E. M. K. No. 15, Mexican-terrace, Cheltenham-road.

TO ARCHITECTS AND SURVEYORS. WANTED, by the Advertiser, an ENGAGEMENT in London. Has a knowledge of the business, estimates, drawing, perspective, and the usual routine of an Architect's and Surveyor's office. Age 27. Addressed at 13, Redcross-street, London, N.

TO MASTER PAINTERS AND BUILDERS. WANTED, by the Advertiser, aged 35, a SITUATION as WORKING FOREMAN OF PAINTERS. A ten years' experience in the above capacity can be given. No objection to the country.—Address, W. G. 16, Leard-street, Cheltenham-road, Ilington.

TO SURVEYORS AND LAND AGENTS. WANTED, by the Advertiser, a SITUATION as UNDER AGENT, or ASSISTANT SURVEYOR. Has a good knowledge of surveying and managing estates. Age 23. Address, J. B. Post-office, Shively, Barrow, Merth.

WANTED, by a Joiner, a permanent SITUATION. No objection to town or country.—Address, G. T. Post-office, Buxbury.

TO BUILDERS, HOUSE AGENTS, &c. WANTED, by a Young Man, aged 21, a RE-ENGAGEMENT in a Builder's or other office. Is an excellent book-keeper, accountant, &c. and can be well recommended by his late employers.—Address, J. M. L. No. 18, Cloudesty-terrace, Kingston, N.

TO SAW-MILL PROPRIETORS, BUILDERS, AND OTHERS. WANTED, by a respectable Man, aged 30, a SITUATION as SAW SHARPENER, or to sharp for or work a frame, or to take the management of the cutting department. Has a thorough knowledge of saw-mill machinery. Three years' character.—Address, Y. Z. at Mrs. Billington's, 5, Belvidere-road, Lambeth.

WANTED, a RE-ENGAGEMENT, in a Builder's Office, by a respectable Young Man, aged 24. Has a practical knowledge of the business, and is thoroughly acquainted with the routine of the office. Reference from a London or country builder.—Address, M. N. 47, Crown-street, Upper Holloway, N.

WANTED, by a Young Man (married), aged 25, a SITUATION as CLERK and ASSISTANT. He is the son of a builder, has a practical knowledge of the business, and understands estimating, measuring, drawing, &c.—Address, A. B. C. Post-office, Woodford, Essex.

WANTED, by a thoroughly practical Man, a RE-ENGAGEMENT as CLERK OF WORKS or GENERAL FOREMAN.—Address, H. T. Office of "The Builder."

TO GLASS CUTTERS, BUILDERS, AND OTHERS. WANTED, by a respectable Young Man, aged 35, now leaving a city firm, where he has been for the last two years, an ENGAGEMENT, as cutter of the best, glass, &c. Has a knowledge of shade, and is willing to make himself generally useful in a warehouse, or any other capacity.—Address, P. R. 11, Wilson-street, Gray's Inn-road, W.C.

WANTED, a SITUATION, as MANAGING or GENERAL REPAIRING ENGINEER, or to TAKE CHARGE of an ENGINE. Has been for the last nine years in the heavy engineering machinery, and throws out of employment by the late fire.—Direct, R. M. No. 63, Cowley-street, Back-road, St. George's East.

WANTED, by a steady Young Man, a permanent SITUATION as BRASS FINISHER and GRINDER. Can make himself useful in the steam and hot-water work. Thoroughly understands the general work. Town or country; town preferable. Can get a reference from a late employer.—Address, R. Z. 91, Drury-lane, Strand.

TO PAINTERS, DECORATORS, AND OTHERS. WANTED, a SITUATION as GRAINER, WRITER, and SIGN-PAINTER, having a general knowledge of the trade. Town or country.—Address, H. J. 25, Huntly-street, Tottenham-court-road.

WANTED, SIX MONTHS' IMPROVEMENT as CARPENTER and JOINER.—Address, S. J. 15, Hawley-crescent, Camden-town.

TO SAW-MILL PROPRIETORS, BUILDERS, &c. WANTED, a SITUATION, to work Sawing, Planing, or Moulding Machine, and Sharpening or Joining work by Machinery. Capable of managing or directing the working of a mill, or any part, having fitted the same before. Excellent references to be had.—Address, H. J. W. 24, Thayer-street, Manchester-square.

WANTED, a RE-ENGAGEMENT, in England or abroad, by a Young Man who has served his time to a Civil Engineer, and since which he has been engaged in Town Surveyors. He has had experience in making, sewerage, water works, and town improvements. Can give good testimonials.—Address, P. S. Office of "The Builder."

WANTED, a SITUATION, by a Young Man, as PLUMBER. No objection to the country.—Address, A. R. Z. 25, Vine-terrace, Lambeth.

TO BUILDERS' CLERKS. WANTED, a Young Man, thoroughly conversant with OFFICE BUSINESS.—Apply, by letter only, stating salary required, references, &c. to A. B. 13, Blackman-street, Borough, S.E.

WANTED, by a respectable Young Man, a SITUATION, as JUNIOR CLERK, or TIME KEEPER. Salary not so much an object as a comfortable situation. Good testimonials and references.—Address, B. S. 3, Maberly-place, Bell's-road, King'sland, N.

TO BUILDERS AND OTHERS. WANTED, by a Practical Joiner, a RE-ENGAGEMENT as SHOP FOREMAN or otherwise. Is well acquainted with the duties of the same, and capable of carrying out work of first-class description. References good.—Address, P. B. Tolson's Library, Hampstead-road, W.

TO SAW-MILL PROPRIETORS, BUILDERS, AND OTHERS. WANTED, by a steady middle-aged Man, a SITUATION to TAKE CHARGE of a small SAW-MILL. He is practically experienced in engine work, saw sharpening, and all kinds of saw-mill machinery. The best references given in town or country.—Address, M. M. BROWN, No. 2, Dorset-place, Dorset-street, Commercial-road, London, E.

WANTED, by a Practical JOINER, a SITUATION as FOREMAN. No objection to a Jobbing Shop. Good reference.—Address, J. A. P. 27, Whitkin-street, Clerkenwell, Broadway, Westminster.

TO BUILDERS AND CONTRACTORS. WANTED, by the Advertiser, a SITUATION as FOREMAN OF MASONRY, or would take any amount of masonry by sub-contract.—Address, R. A. Post-office, Broadway, Westminster.

TO MERCHANTS, BUILDERS, AND CONTRACTORS. WANTED, by a Gentleman of thoroughly business habits, with twenty years' experience, and good references, an ENGAGEMENT as CLERK and BOOK-KEEPER in a London office. He is well acquainted with the duties of the office, and conversant with accounts.—Address, R. B. Office of "The Builder."

TO BUILDERS, &c. WANTED, by the Advertiser, a SITUATION as MANAGER or otherwise. Is proficient in measuring and estimating, and conducting building works generally. Salary moderate. Good references.—Address, A. B. Post-office, Brompton-road.

TO BUILDERS. WANTED, by a Young Married Man, who has been nine years in the trade, a SITUATION as MANAGER of a BUSINESS, or as CLERK. First-class references as to character and ability. Terms, two and a half guineas per week.—Address, E. W. K. Post-office, Melbourn, near Royston.

TO ARCHITECTS, &c. WANTED, a SITUATION, either in the OFFICE, or as CLERK OF WORKS, by the advertiser, who can prepare finished work and drawings, write specifications, take out quantities, &c. Salary, 35s. per week. First-class references.—Address, Z. B. G. Mr. Duffie, 18, 17, Fore-street, S.E.

TO ARCHITECTS AND SURVEYORS. THE Advertiser requires EMPLOYMENT as an Architect and Surveyor's Office. Is qualified to design and prepare perspective, finished, working, and detail drawings of buildings, in both styles, and has also a good knowledge of taking out quantities and measuring work.—For further particulars, address, R. H. P. Office of "The Builder."

THE Advertiser wishes for EVENING EMPLOYMENT in COPYING, TRACING, ENLARGING, or REDUCING Mechanical and Architectural DRAWINGS.—Address, R. M. care of J. Hickson, 45, 14, Mincing-lane, E.C.

TO BUILDERS AND CONTRACTORS. THE Advertiser desires a RE-ENGAGEMENT as CLERK OF WORKS or JOINTER, in London, to be in charge of a fortnight, and is highly recommended.—Address, W. M. 11, Crown-tow, Walworth, S.

TO ARCHITECTS, ENGINEERS, AND BUILDERS.—A GENTLEMAN, of great architectural experience, and a good knowledge of the business, is desirous of entering into partnership in good practice, with a view to future PARTNERSHIP.—Address, stating terms, to H. R. 34, Sutherland-place, Baywater.

TO ARCHITECTS, &c. EVENING EMPLOYMENT WANTED, by a good Draughtsman, who has had five years' experience in his profession. Terms moderate.—Address, E. P. No. 3, Warrington-street, Oakley-square, N.W.

TO BUILDERS, &c. ASSISTANCE.—PLANS, SPECIFICATIONS, &c. prepared or copied, quantities taken out, and estimates made on reasonable terms.—Address, Mr. STIRLINGFELLOW, 2, Adelaide-place, London-bridge.

TO MERCHANTS SUPPLYING BUILDERS, &c. A GENTLEMAN, thoroughly conversant with the building trade, and occupying a position of trust, desires to meet with a SITUATION as COLLECTOR, TRAVELLER, or otherwise, in connection with the above business. Highest references from present employer, and security, if required, can be given.—Office of "The Builder."

A DRAUGHTSMAN, aged 26, having finished an ENGAGEMENT, desires another in an Architect's or Builder's Office. No objection to the country. Terms, for a permanent situation, £25 per week.—Address, A. B. care of Messrs. Gowers, 5, Upper-terrace, Upper-st.-ct. Ilington.

TO PAINTERS AND GRAINERS. A FIRST-CLASS OAK GRAINER is open to an ENGAGEMENT.—Address, W. 4, Wellington-place, East-street, Walworth.

TO HOUSE DECORATORS, PAINTERS, &c. A RESPECTABLE YOUTH, aged 16, would make himself useful to an employer in a way of a lad. Respectable reference.—Address, A. B. 17, Morton-street, Belgrove-road, Kilnic.

TO ARCHITECTS, &c. A NEAT and ACCURATE DRAUGHTSMAN wishes for EVENING EMPLOYMENT at his own residence. Terms moderate.—Address, K. M. 204, Clarendon-road, Kentish-town, N.W.

TO ARCHITECTS. A YOUNG MAN whose articles with an Architect have expired about two years, and who has since been employed in the office of a London architect, is desirous of meeting with an ENGAGEMENT in an ARCHITECT'S OFFICE.—Address, and references, to apply, K. M. care of Messrs. Carter & Son, 3, Newgate-street.

AN ACCOUNTANT, possessing a knowledge of the building trade, would be glad to devote a few evenings a week to KEEP THE BOOKS of a BUILDERS, or TRADESMAN.—Address, A. B. Brunner's Library, Bishop's-road, Baywater, W.

TO ARCHITECTS. A PRACTICAL CLERK OF WORKS wishes a RE-ENGAGEMENT. Is well acquainted with the duties of the office, and has had several testimonials.—Address, E. F. 49, Alder-road, Harrow-road, Paddington.

AN Experienced Architect's Assistant, competent to prepare fair working and detail drawings in the Gothic and Italian styles, perspective views, specifications, to take out quantities and survey, is open to an ENGAGEMENT.—Address, H. F. K. Office of "The Builder."

TO BUILDERS AND MASTER PAINTERS. A YOUNG MAN wishes to SERVE either of the above as Writer, Grainer, Sign and Ornamental Painter. Served in last situation eighteen months, where a good reference can be obtained.—Address, F. D. ROGERS, 35, Bedford-street, Woodwich, S.E.

TO ARCHITECTS. A DRAUGHTSMAN, having recently completed his articles, is desirous of ENTERING THE OFFICE of a LONDON ARCHITECT.—Reference allowed to Mr. G. WOODHOUSE, Architect, Bolton-le-Moors.

TO BRICKMAKERS AND DEALERS. WANTED, 140,000 STOCKS, PLACE, BATS, and GIZZARDS, in about equal proportions; also quantity of good old stock BRICKS, delivered at Landing Wharf, Canal Bridge, Mile End-road. Send lowest price to Mr. SWESTON, 10 1/2, Builder, 305, City-terrace, City-road, E.C.

BRICKS by STEAM POWER. The present FAUCES OF BRICKS from the Works of G. CARLBY & CO. (Are of uniform colour, hard, and well burnt, and are of the best quality, and are sold at the most reasonable price for front work. (Vary from the above only in colour, and are No. 2, Minglead, 54, City-terrace, City-road, E.C. Stock Bricks. (Vary from the above only in colour, and are No. 2, Minglead, 54, City-terrace, City-road, E.C. Stock Bricks. (Vary from the above only in colour, and are No. 2, Minglead, 54, City-terrace, City-road, E.C. Stock Bricks. N.B.—A great variety of Bricks in FINE & SMOOTH Shapes always in Stock.

FIRE BRICKS, LUMPS, and TILES of every description. JOHN NEWTON and CO. HONDURAS WHARF, 74, RANKINE STREET, SOUTHWARK, S.E. Begs to solicit the patronage of Chemists, Gas Companies, Engineers, Plumbers, Bricklayers, and all others who may be interested. Duplex for Ramage's Newcastle Fire Bricks, Clay Retorts, Sanitary Pipes, Chimney-lopes, Dutch Chimneys, &c. at the lowest prices. Shipping orders executed with despatch.

CLAUSSEN'S PATENT MACHINES for CUTTING and TRIMMING CLAY for BRICKS, TILES, &c. These machines, which are extensively used by brickmakers on the Continent, are of great simplicity, require but little attention, and by the peculiar motion given to the revolving wheels act so perfectly on the clay, that no clots can possibly escape their action. With one horse power, one machine will prepare six hours capacity sufficient for 6,000 bricks. A machine may be seen working in Mr. VIGOR'S Brickfield, Paddington; and intending purchasers of the Patent may apply to Messrs. WESTON & CO., Brick-makers, 20, Mark Lane, E.C.

HANCOCK'S PATENT VULCANIZED INDIA RUBBER WASHERS for Steam Joints. VALVES for Steam Engines and Pumps. VULCANIZED RUBBER for Rollings Trunks, &c. DROPPING SPRINGS and BLIND SPRINGS. Price Lists on application, post paid. JAMES LYNE HANCOCK, Vulcanized India-Rubber Works, 8, Goswell-road (opposite Spencer-street), London, E.C.

WINDOW BLINDS, FULLER, BROTHERS, MANUFACTURERS OF EVERY KIND OF INSIDE and OUTSIDE WINDOW BLINDS, Warranted of the best Materials and Workmanship, at the lowest Prices, and the Trade supplied. 45, HIGH-STREET, BOROUGH, S.E.

CARTS, VANS, WAGGONS, LADDERS, BARROWS, &c. GEORGE ELL, Cart Wheelwright, Ladder and Barrow Maker, has constantly on hand brick, dobbin, and other carts, spring vans; also a large stock of ladders, barrows, trawls, steps, and other trade implements for builders, contractors, and dealers, on the most improved principles, and at low prices. Standing Ladders, Barrows, Trawls, &c. Sent on Hire. Price Lists on application to G. ELL, 279 and 280, BLOOMING-ROAD, N.W. N.B. Removing to more extensive Premises, situated 368, Euston-road, N.W.

VENTILATION—PURE AIR. Shortingham's Ventilator for the admission of Pure Air through an

EXTERNAL WALL. With single pulley, from 6s. each; with leading pulley, from 6s. 6d. These Ventilators are arranged so that the requisite quantity of air may be admitted for the due ventilation of apartments, without the slightest draught being felt by the occupants, and as they are placed in the exterior walls, their operation is not interfered with when the house is closed for the evening, at which time a constant supply of fresh air is most required.—HAYLER BROTHERS, Manufacturers, 117 and 119, Upper-street, Borough, and Manufacturers, 117, Moorgate-street, London, E.C. Country commissions executed.

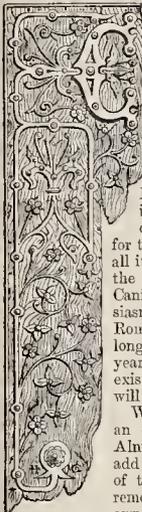

NO MORE SMOKY CHIMNEYS! Builders, Plumber, and the Trade, apply for particulars to Mr. ATKINSON, Patent Chimney For Manufacturer Birmingham. N.B.—The best cure for smoky chimneys.

MONEY—IMMEDIATE ADVANCES on Warrants, Freehold, Leasehold, and Copyhold Property, Bills of Sale, and other approved securities; Advance Stocks prepared, Business disposed of, Partnerships dissolved, and all other matters connected with accountancy promptly attended to, by Mr. CROSSLAND, Accountant and Business Agent, 17, Moorgate-street, Bank, E.C. Country commissions executed. Personal interviews free of charge.

# The Builder.

VOL. XVIII.—No. 915.

The Works at Alnwick Castle.

ONCERNING the works at Alnwick Castle, two striking and important facts combine to give them interest to the professional world. In the first place, two distinct styles of art—the one English, the other Italian, have been blended in the adornment of one edifice.

In the second, because it is asserted that the cinquecento art thus used is now for the first time introduced, in all its purity, into England. As the last work of the great Canina, who, with rare enthusiasm, ventured to journey from Rome to Alnwick after he had long passed the three score years and ten allotted to man's existence, these restorations will have a separate story.

We have already sketched an outline of the history of Alnwick Castle. We will now add an account of the progress of the new works. It will be remembered that the noble owner, his Grace the Duke of Northumberland, had resolved that the external character of the building should be handed down to posterity in all its pride of doujon, towers, barbican, and moat; and that the interior was to present a palatial aspect, with decorations of the cinquecento period of Italian art. To this end Mr. Salvin was entrusted with the exterior. The internal decorations were submitted to the Commendatore Canina, and Mr. F. R. Wilson was appointed to superintend both works. The contract was taken by Mr. George Smith, of Pimlico, who, over a space of nearly six years, including the trying time of the London strikes, successfully carried on this considerable undertaking. Operations were commenced in October, 1854, by pulling down a tower to make room for the main feature of the additions—the Prudhoe tower. The sky line of the castle had hitherto been flat and tame; the new tower was to rise 20 feet above the circle of towers, of which the keep was composed, and form a massive central object. In pulling down the condemned tower, some ancient window-heads were met with between the ashlar and the internal surface; and, soon afterwards, the black glass bottle, containing the parchment scroll mentioned by Professor Donaldson in his paper read to the Institute.

The word was quickly passed among the trades, that the old castle, the pride of every Northumbrian, was to be restored, and applications for employment streamed in,—every local workman and tradesman being anxious to be associated with the repair of the ancient Percy's stronghold. In the course of the excavations for the foundations, the old Norman moat was discovered with which the keep had been defended, in addition to the curtain-wall with its towers and outside moat. It followed a regular curve, and possessed a battered retaining wall. The foundations of the new tower, 15 feet thick, were carefully laid down; and, on the 25th of November, 1855, the corner stone of the splayed base was laid by her Grace the Duchess of Northumberland. This ceremony was marked by the first of a series of annual commemorative dinners given by the duke to the workmen.

The walls of the Prudhoe tower gradually arose. Good freestone was to be had in abundance, in the noor quarries, not a mile distant from the castle; and sand was obtainable from the bank of the river which winds past the

foot of the eminence on which the castle is built. The most particular regard was paid to preserve the character of the ancient masonry in the new work. It frequently happens that the prim smooth stone-work of a modern restoration stands out a gleamish and a patch upon the bold irregular work of the men of old; but in this case, after a careful study of the peculiarities of Edwardian masonry, exact drawings were made giving the dimensions of every stone that was to form part of the new work,—hence we have a faithful reproduction of ancient masonry. The south-west front of the tower is ornamented by a large *alto-relievo* of the Hotspur banner, which has been sculptured by Forsyth; while at the north-east angle arises the new flag turret. Thirteen months after the foundation stone was laid, the flag was lowered from the old flag tower as the standard of St. George was hoisted on the new turret, amidst general congratulations and rejoicings, intensified by the fact that the day on which this ceremony was performed was an anniversary of the duke's birthday. The towers and turrets of the castle reverberated the salute of the cannon, Lurley-berg fashion; and the cold grey town was bright with flags, and hospitable with commemorative feasts.

Meanwhile the Italian studio was in full operation. Signor Montiroli, architect, accompanied by Signor Bulletti, the Florentine carver, had visited the works, bringing with him the designs for the ceilings of the state-rooms as approved by the lamented Canina, and accepted by his grace the duke. He proceeded to make upon the floor of each apartment, to which paper had been previously affixed, full-sized drawings of the carved coffered panellings intended for the ceilings. Thus instructed, Signor Bulletti commenced to carve in wood samples of the decorations determined upon. It was intended that, after inspection and approval of these specimens, he should return to Italy and their superintendent the execution of the quantity required. But a carver, residing in the town, who was temporarily engaged to assist him, was found to imitate the models set before him with so much ease and precision that the first intention was abandoned, and it was resolved that the whole of the carvings should be executed in Alnwick by native talent under the guidance of Signor Bulletti. By the third year, after the commencement of the works, three of these ceilings,—the saloon, the drawing-room, and dining-room,—were perfected and fixed in their places. It was at this season that the lamented Canina visited this remote branchlet of his beloved art. Long will his venerable memory be associated with a sunny terrace walk, sheltered from the north by the castle walls, which he was frequently seen pacing with contemplative mien. With the English architect he could only exchange greetings by signs, neither understanding a sentence of the other's language; but with Professors Cockerell and Donaldson, who were also consulted at this time, he was able to communicate his impressions. Doubtless his sympathies were too entirely dedicated to the glories of the ancient Roman empire for him to feel much for the scenes of the Percy's prowess, although Sir Walter Scott's novels, translated into Italian, have rendered the Border and its history an attractive subject. The Commendatore brought with him, besides Signor Montiroli, Signor Mantovani, by whom the friezes were to be executed,—an artist already favourably known as having been entrusted with the restoration of Raffaello's frescoes, in the famous Loggia, in the Vatican.

In the Italian specification, already published in this Journal, it was proposed to observe a certain progression in the decorations; that simplicity should reign at the entrance and that an increased richness should gradually prevail till it culminated in the state apartments. The grand staircase, 12 feet wide, is wrought of a fine white stone whinned on the craggy hills of Rothbury, where great blocks of it break through the green and purple crest of heather. It was no easy task to bring the first landing-stone, 12½ feet square and 14 inches thick, safely down this hilly country into the valley in

which Alnwick is built; but it was eventually successfully accomplished. The staircase terminates in a vestibule, which is to be paved with marbles and adorned with paintings; thence, an antechamber admits the visitor to the principal apartments. The effect of the decorations is gorgeous: the minutely carved ceilings blazoned with gold and colour, the friezes rich in the ripe warm colouring of the south, the dados of choice woods inlaid in lozenge patterns, the marble mantel-pieces sculptured in Rome, produce a striking result. Looking upon one of the apartments the same flash of brilliant colouring is reflected on the eye as when standing before one of Turner's sea and sun pieces; but no reminiscence of the ancient Percies is recalled to the mind. And herein lies the gist of all that has been said about the re-modelling of Alnwick Castle. The identity of the building as the home of the chivalrous Earls of Northumberland, who fought and bled at Otterbourne, Bramham Moor, Towton, and St. Alban's, has not been preserved. The old Percy dining-hall, the Armourer's Tower, and the Falconer's Tower, have been successively sacrificed. Who cares how many times the gentle ladies of the house of Percy entered the Falconer's Tower on a visit to a pet merlin or a dying hawk? Who cares for the phantom knights who may have watched their disused armour hanging in the groined chambers of the Armourer's Tower? To accommodate the newly-arranged apartments to the Italian interior, the new Prudhoe Tower is built in such a position that the view from the windows would have been blocked out by these old towers: in consequence they are levelled to the ground.

The new range of kitchens is built, in disregard to Mediaeval precedent, without the line of circumvallation. The principal kitchen has a stone gabled roof, rising to a lantern, after the manner of the kitchens at Fontevault, Chartres, and Glastonbury; and the stone fireplace is treated in the same Mediaeval manner. Modern contrivances for culinary operations have been freely adopted; Messrs. Peetham, of London, having furnished stoves, ovens, and gas and steam apparatus of the most approved description. The numerous ladders and sculleries have been conveniently placed on one level; and hydraulic lifts from the kitchen to the principal floor also combine to save unnecessary labour: these latter are the engineering works of Messrs. Easton & Anos.

The decorations of the ceilings of the state bed-rooms are of plaster, cast from models made by Signor Taccolozzi for the purpose. Messrs. Earle, of Hull, furnished the cement used in these and other parts of the works.

The machinery and ironwork required in the building operations were furnished by Messrs. Hawks & Crawshaw, of Newcastle, with the exception of the immense girders and joists for the fireproof floors, which were provided by Messrs. Barrett, of the Adelphi. Some acres of lead were laid on to the roof by Messrs. Wilkin & Dickman, of Alnwick, who also manufactured the scores of copper and iron sashes and casements required. The local tradesmen were further employed on numerous other portions of the work. Mr. T. Robertson constructed the mechanical parts of the ceilings. The works are rapidly approaching completion, of which, when attained, we shall inform our readers in another paper.

## THE ARRANGEMENT OF WAREHOUSES.\*

HAVING seen Mr. Adams's warehouse, and learned his wise arrangements for the good of his hands, I naturally bethought me of looking into the condition of those warehouses in Manchester where females work. I was not previously aware of the great number of women who find employment in our warehouses at frill-making, cap-making, and the like, amounting, I am credibly informed, to several thousands. By the permission of various masters, kindly and frankly given me, I have looked through ten warehouses, employing about 1,100 women, and of these only two can be said to be commodious and well aired. In the work-rooms of four or five, the cubic air space per woman was excessively small, and the

\* By Mr. John Robertson. See p. 459, ante.

atmosphere polluted by gas-stoves and gas-lights. In one of these warehouses I noticed a long low room of less than 4,000 cubic feet of air space, where at fifty women, and in an adjoining room, of not more than 1,800 cubic feet, there worked twenty-four women; and the air space of the rooms in several of the other warehouses, with reference to the number working in them, was little if at all greater. The atmosphere in these was very bad; and when, in one instance, I expressed my surprise that a window was not kept open, my attendant replied that the inmates shut my window he might open as soon as he turned his back. On this I asked one of the women what made them do so; to which she answered, the place was so hot that an open window produced draughts such as nobody could endure. It is hardly possible for any one to imagine the incummodiousness of several of these warehouses, and the bad state of the atmosphere in the work-rooms, without paying them a visit; and a remedy for such evils is by no means easy. The reason is this: nearly all the buildings in Manchester in which women work were originally erected, not for warehouse purposes, but as dwelling-houses; and the work-rooms—once used as nurseries and sleeping apartments, perhaps—are now occupied by nine or ten times the number of persons they were originally meant to accommodate.\*

What, it may naturally be asked, is the physical and moral condition of the women in these, for the most part, badly ventilated warehouses? I do not find that they work longer hours than in Mr. Adams's establishment; and they cease earlier than his hands on the Saturday. With respect to health, I noticed in many that sallowiness of complexion which indicates a depressed state of vitality; but were it found that the health does not absolutely break down, this would make little in favour of the sanitary state of these warehouses. The female sex, when in the spring-time of life—between the ages of fifteen and twenty-five—bear up surprisingly under such causes of physical exhaustion as these; especially when, as in the present instance, they do not sleep on the premises,—the case in many of the London warehouses,—but walk night and morn-

ing to and from their own homes, which lie often at considerable distances.\* Concerning their moral condition, I would speak with caution. Their position in this city is one, doubtless, of great temptation; and I know not that anything hitherto has been done by the masters for their moral or intellectual advantage. A friend, whose official duties make him familiar with the state of our lower classes, tells me that when trade is brisk the women's work-rooms are generally overcrowded; and being in most instances badly ventilated, a state of atmosphere is produced injurious to health, depressing to the spirits, and disposing to the use of intoxicating liquors, as well as to such excitements as the dancing-room and theatre. When work becomes scarce, some of them street-walk—in hard times many do. This, it must be admitted, is not a cheering picture. If lodging-houses, factories, and print-works are thought to require inspection, these work-rooms, it will perhaps be conceded, equally demand it: assuredly this is a form of social evil which ought not to be overlooked.

Dismissing the subject of women's warehouses, I now venture a few remarks concerning those used for the country and shipping trades. And first, with respect to salubrity,—a point of no small importance, when it is considered that in some instances the number of hands, boys and men, in a warehouse reaches 250 and upwards. The build of a warehouse will, of course, have a bearing on the health. If the rooms are well lighted by windows in front and back, or on opposed sides, so constructed as to be readily opened, and which are not very remotely apart, this will be favourable. "Well-openings" of various kinds, now common where the area of the floors is great, assist in giving light, but do little for ventilation in comparison with properly-placed windows. Unfortunately, in a number of structures that have been built for warehouses (of transmuted dwelling-houses I am not now speaking) there are windows on one side only, the opposed side being a dead wall, and proper ventilation, therefore, out of the question; to say nothing of the impossibility of so placing the latrines as to avoid atmospheric pollution. An instance will best explain what I mean. A gentleman in delicate health, on whom I was attending, said to me—"I fear the air in my office is not good: I wish you would look in, and tell me if it could be improved." On calling, I found a warehouse for grey goods, employing about forty hands. It was an extensive structure of four stories, back to back with another warehouse, the windows in one end and side. On entering the ground story, I was sensible of an unpleasant odour, and at the same moment I cast my eye on two doors facing me, near the before-mentioned dead wall. On asking a man what were these, he said they were the closets, one for the masters and the other for the hands. It being early in the forenoon, and the closets, of course, recently used, the atmosphere was a good deal tainted; and as such air will ascend and circulate through a building, I found, on reaching the offices, which were on the first story, that they were not free from taint: this, I may remark, is anything but a solitary case. In some warehouses I found there was no water-closet, the hands having to get accommodated as they best could. In a number of recently-built ones, however, is an outside stair behind, and off the landing for each flat of this stair is a little room containing a water-closet, urinal, and lavatory. Yet even here the latrine might be better ventilated than in any instances I have yet seen. On points such as these architects have something still to learn. As connected with salubrity, it would be wrong to omit the mention of an atmosphere loaded with dust and fine filamentous particles in certain quarters of shipping warehouses, produced in preparing the goods for packing. I know not how the evil is to be remedied; but I am assured that it gives rise to cough and ill health in those—often ladies—who from morning till night are inhaling it.†

The lighting of warehouses by gas is doubtless an improvement upon lamps and candles, giving a brighter and clearer light, and lessening the risk of accidents by fire. But gas used, as is commonly is, without a flue to hear away the heated impure air—the product of its combustion—is

unwholesome, partly from the large quantity of oxygen it consumes, leaving the atmosphere poor, and partly from the flood of carbonic acid it generates. This is especially noticeable in the offices where sit the masters and clerks; and so depressing to the feelings have I known this impoverished air to become, that the gaslight has had to give place to the feeble illumination of the oil-lamp. What is the remedy? I answer, a flue in every instance, opening over the flame, to carry off the heated and vitiated air as it is being produced. I cordially agree with what the editor of the *Builder* says on this point,—“A gaslight without a chimney, or ventilating apparatus, ought to be as unusual as a fire without a flue.”‡

Thus alluding to warehouse offices, I may just observe that, in many instances, to my knowledge, the air in them is sickly and depressing to the spirits, owing solely to imperfect ventilation. Such an office ought to have either a *dead-end* partition, to give it community of atmosphere with the rest of the warehouse, or the partition going to the ceiling, it ought to have windows in the partition opposite those by which it is lighted from without, in order that, when necessary, the air may be speedily renewed by a through current. Rarely do I enter an office of any kind without being at once sensible that I am breathing an impoverished atmosphere; and as the remedy is easy, it ought not to be neglected.†

It will not be denied that mechanical inventions, employed as substitutes for, as well as in aid of man's muscular powers, are beneficial; and nowhere is this more strikingly apparent than in a number of our large warehouses. Formerly (even now, in some instances) tons of goods were brought and laid at the warehouse door, thence to be borne, perhaps to the fourth or fifth story, on the backs of porters; reminding one of the astonishing feats of strength and endurance, told by Humboldt, of the Indians in the Peruvian mines, who not only climb ladders from a great depth, like the Cornish men, but bear the produce of their labour to the surface on their backs. I cannot better illustrate the value of mechanical helps than by referring to a petition of the cotton-ports of Glasgow, addressed to the cotton spinners of England and Scotland, praying them to send lighter burdens. They say, that from the nature of their employment, the manner in which warehouses are constructed in that city, and from the absence of hoists in them, they (the petitioners) are compelled to carry skips to third and even fourth flats, whereby they have sustained serious bodily injury; further, that as all of them are not able to carry the heavy weights which are sent into the market, the few who are strong and young have to do the share of the less powerful and aged of their number, and thus, ere long, are reduced in strength, and become diseased by such excess of labour. We may hope the petition will not be in vain; for, when we notice how rapidly goods in warehouses are packed by the hydraulic press worked by steam power, how easily the heaviest bale, laid on a truck and wheeled to the hoist, is, by this means, carried from any flat to the basement, where, on another truck, it is pushed to the loading door, and with tackle, managed by the band of a mere lad, is lifted into the wagon, it is obvious that science renders now the infliction of bodily injury by heavy burdens laid on porters without excuse.

Leaving what has been said concerning the Nottingham warehouse to produce its effect on humane and benevolent minds—it will not be read without some benefit—I proceed, in conclusion, to say a word or two on the late hours and the night-work in a number of our warehouses. I have reason to believe that late and night labour is losing favour with a few of the more enlightened employers, because it is not found to be, upon the whole, profitable. Even this is encouraging. We must not repine should the majority go on for a

\* See the *Builder* for November 26, 1859, p. 770.

† The close, unwholesome state of offices, law-courts, schools, and places of public worship, is not peculiar to this country. In New York, we are told that the court-rooms are proverbially unhealthy, and valuable lives have been sacrificed in consequence of the bad air which prevails in them during the transaction of public business. The offices attached are equally liable to objection, and the churches, during a crowded service, in many instances, are almost insufferable from the heat and impurity of the internal air. School-houses, also, by the neglect of sanitary science, endanger or permanently injure the health of both teachers and pupils. See the elaborate and most interesting report of a select committee appointed to investigate the Health Department of the city of New York, presented to the Legislature February 28, 1859, p. 19.

‡ This curious petition, which is well worth reading, may be seen in the *Manchester Guardian* for October 31, 1859.

\* This transmutation of dwelling-houses into warehouses in Manchester, is a subject of considerable local interest and curiosity. The following account of it, with the rise and extension of the different branches of our trade, I have from Mr. David Bellhouse, the person, from his great local knowledge, no one is more competent to supply this kind of information.—“The first warehouses I remember being built,” says he, “were in what were then called the ‘New Market-buildings,’ off Cross-street, near to Market-street. What was known as ‘New Market’ had been built by the Lord of the Manor, and had a butchers’ shambles and fish market; but in course of time these were done away, and the land became the site of warehouses. They were all cotton warehouses. At this time (1804) the cotton trade, dealing in the raw material, was a principal trade in Manchester; and the cotton warehouses congregated round, and as near as might be, the Exchange, including Back-square, Bank-street, Half Moon-street, Cross-street, New Market-buildings, and some on the other side of Market-street, leading to Cross-street, New Cannon-street, &c. By degrees the cotton trade declined, just as spinning and manufacturing increased,—the cotton being either imported by the spinners themselves, or brought, as it is now, through the brokers in Liverpool. From about 1804 onwards, the principal warehouses for manufacturers and the country trade were in Hodgson-square and an extensive lot of narrow streets, including the Blue Bear-court district through the heart of which Corporation-street now runs; Cannon-street, New Cannon-street, Duke-street, Peel-street, High-street, Marsden-square, Church-street, and adjacent small streets. These warehouses were originally, for the most part, dwelling-houses altered and enlarged. I remember dwelling-houses in Cannon-street, and in High-street, at the end nearest Market-street, where also was the Bridgewater Arms, then the principal hotel, the site of which is now covered with warehouses. By degrees these warehouses, altered from houses, became inadequate to the requirements of the extending trade of Manchester. A few new ones were built at the bottom of Cannon-street, one—I believe, the first—by the late Messrs. Richard and Thomas Potter; then a new pile, called Cleveland's-buildings, Tipping's court; next, some new ones in High-street, Church-street, Marsden-square, and top of Cannon-street; and, more recently, in New Brown-street, Palace-street, and Spring-gardens. I think this brings us down to 1825 or 1830, from which period the ‘country-trade warehouse’ increased in importance, and even the comparatively recent warehouses became inadequate. The Cannon-street district was completely deserted by the home trade, and the old warehouses fell in value and were used for inferior trades, such as those of the country manufacturers, &c. The country trade, however, began to spread into Fountain-street, where Watts had their first large warehouse,—Church-street, where Phillips's house stood, and is there now, then in Mosley-street, York-street, George-street, Booth-street, Parker-street, Piccadilly, and Portland street, ending in such handsome establishments as Potters and Norris's, McLarens, Bannermaul's, Westhead's, Kersey & Co.'s, Brown & Co.'s, Sam Fletcher & Co.'s, Jackson's, and Messrs. Waits's. During this time another branch has been rapidly increasing—the shipping trade; and for this purpose a great number of new warehouses—some of them magnificent—have been built in streets generally distant from the Exchange; but on a matter so well known, it is, of course, needless for me to enlarge.”

\* I am informed by an experienced upper servant in one of our warehouses, who used to be in a London house, that there a considerable proportion of the hands remain and sleep on the premises, the beds often laid in corridors and other close quarters.

† Perhaps flues running to the roof from each flat or room where this dusty work goes on, and a current maintained up each flue by a ventilating wheel at the top, might be found useful.

while in the old way; for progress, though slow, is sure: long experience has taught me this, and leads me to anticipate that, in time, the interest of the employer will be seen in all cases to harmonize with justice and mercy to the labourer. Forty years ago I remember well the absurd way in which factory labour went on, when even children of six years worked, under the stimulus of the strap, sixteen hours a day; and, through a long subsequent period, how a set of night-hands kept the factory illuminated till morning, and that with the most deplorable consequences to the morals of these workers. All this is happily of the past; for factory labour, thanks to wise legislation, is now as compatible with health and morals as any kind of employment. Another step in the right direction was the Saturday half-holiday, which, however, as many will remember, encountered strenuous opposition, notwithstanding it could not be denied that late Saturday labour usually led to a violation at once of the laws of religion and humanity. A friend told me, during the agitation for this reform, that curiosity induced him to go to an extensive bleacher, whose works lie about twelve miles from Manchester, and ask at what hour on Saturday his carters got home. Pondering the question for a little, the bleacher replied,—"Saturday! No, they usually get home about six on Sunday morning." "And what then," said my friend, "do the men do with themselves when they have unyoked and put up?" "Oh," said he, "they are asleep immediately in the straw-beds beside the horses." All this sounds to us now as something fabulous.

The policy of night-work has always, I confess, appeared to me questionable, and it does so more especially now, when mechanical means enable the packing and loading of goods to be accomplished with such wonderful ease and rapidity. If it be contended that shipping orders have often to be executed with a promptitude which necessitates late, and even night labour, the reply is, that this kind of argument of urgent necessity may be advanced against almost every reform, just as happened with respect to the Saturday afternoon holiday (admitted now to be an unalloyed good).

It is pleasant to be able to report that some of the gross evils connected with late and night-work are being gradually, though perhaps slowly, mitigated. A allude in particular to the substitution now, by some, of tea and coffee for the refreshment of the late and night hands, instead of the old allowance of beer. The extent of beer consumption in late-working warehouses may be imagined when I state that as much as 57, a week has been paid for the beer consumed by the hands in a single house; and I have been told of a more lavish rate of expenditure in some houses than even this. As a medical man, I can say, from personal knowledge, that amongst the clerks and younger hands, the late-hour system—that is, leaving off at ten, eleven, or twelve o'clock—exposes to temptation and immorality. With regard to the masters, especially the younger members of the firm, who usually stay the last, and upper servants, ambitious of making for themselves "a position," I fear the habit of late work, though sometimes disavowed, prevails in busy seasons almost as much as formerly; and that, in the case of not a few, the consequent exhaustion of body and mind (to say nothing of the unseasonable hours and the waiting up they inflict on their households) more than counterbalances the advantage supposed to be gained. Indeed, this too eager pursuit of business,—this lavish waste of health and vigour on the part of very many who have come under my notice,—has often reminded me of what is suggested in the homely adage about burning the candle at both ends; for if we will thus make light of Nature's best gift—"a sound mind in a sound body"—we need not be surprised should she vindicate her beneficent laws by a painful award.

\* It is instructive to read what Mr. Russell, in his "North America, its Agriculture and Climate," page 226, reports of late and night working in the Island of Cuba during the six months of the cane-crushing season. The negroes begin the day's work at half-past four, and at ten have an hour for breakfast, then resuming the work go on till sunset, when they have an hour for dinner; after which they toil till midnight; thus working eighteen hours out of the twenty-four. He was assured by an engineer that fatal accidents, from the labourers being overcome with sleep and falling into the boiling pans, are not uncommon. Happily we have nothing quite so bad as this amongst us. One of our houses, to my knowledge, is setting an example to its neighbours which it would be well were they to follow: the packers give over at nine, come in the morning at six, and at eight o'clock have a substantial breakfast provided at their employers' expense.

#### BRITISH ARCHEOLOGICAL ASSOCIATION IN SHROPSHIRE.\*

THE alternating of wet and fine days gave us our share of rain on Wednesday, the 8th; and although the arrangements comprised the examination of works of great interest, there was a sensible falling off in the number of the excursionists, although there were more than sufficient to cover the guarantee of a minimum for the special trains engaged. On arriving at Shifnal the rain fell in torrents, and some members returned. The programme was involuntarily altered; and, after hastily viewing the church, the Rev. Mr. Petit's paper being postponed, the company, in sections, made their first resting-point at Tong Castle, where Mr. Tucker received the Association (in the name of Captain Thorneycroft, who was absent at a distance), and read a paper chiefly on the lords of the castle (of which he said there had been four). The present building is modern. Thence to Tong Church was a short drive across the park. Mr. R. Norman Fisher read a paper on the subject. He described it as a cross church, although this had been questioned, and that it was almost unique in the general arrangement. The outside is much plainer than the inside.

At the north-east corner he considered there had been a chapel to the Virgin: he came to this conclusion from a statue there. The south aisle was older than any other part. The Rev. J. L. Petit explained his discovery of the earlier and more elaborate label moulding to the south face of the arcade, between the nave and south aisle; but Mr. C. E. Davis thought it not earlier, but a specimen of the more elaborate finish given to the faces of internal walls, where a strong light fell. Both Mr. Gordon Hills and Mr. Roberts thought it was of a different date to the other part of the church, but partly reworked. Mr. Planché gave his opinion on the monumental effigies of the Pembrugge family. He said it was the first time he had seen them. There were some points of interest about them: the date of one was 1408, and would apply to Sir Fowke Pembrugge: it had the same basinet and hauberk as in Henry IV.'s time, and the same kind of japon which preceded the complete plate. The effigy of the lady gave him the impression at first that it was of Sir Fowke's first wife, of the family of Trussell. It is habituated as a widow, with the barbe crossed above the chin. The costume was of the date of 1446, and therefore was not that of his first wife. He thought it must be of his second wife, who survived him. He differed, with great diffidence, from so great an authority as the Rev. Mr. Eytton. The other tomb was that of one of the Vernons. Some of the shields in these monuments were blank, probably left to be filled up afterwards.

The president had arranged to receive the Association at Decker-bill, where accordingly the company arrived, and found that an unfortunate misunderstanding had caused the president to keep to the programme, which the violent weather had induced the members to alter. The reception was not the less cordial for this *contretemps*, and almost immediately an elegant *déjeuner* was laid in two reception-rooms, presided over respectively by Mr. Botfield and his lady, to whom thanks were most sincerely returned; and then a division of the members occurred, part returning to Shrewsbury *vis* Shifnal, and about thirty enlisting the services of Mr. Roberts (who had made a preliminary examination) in an inspection of Lilleshall Abbey. The weather cleared in the course of the drive, and it formed a delightful excursion.

The foundation of this building is of the time of Stephen, by Ethelreda, a daughter of King Alfred, who was subsequently a perfect amazon, and was called the "Lady of the Mercians." There must have been a large guest-hall and extensive dormitories; for, being on the high road, the number of demands by travellers was very great; and the abbots made several complaints of their want of means to supply these demands. It was an abbey of regular canons of St. Augustine. There were several charters by which privileges were granted by Stephen, Henry Duke of Normandy, King John, Henry III., Edward I., Richard II., and even Henry VIII. Amongst the benefactors were Fitzalan, part of whose monumental slab the association had discovered at Buildwas on Tuesday; Le Strange, Dmstanville, Pantolfe, Lezouche, Trusbut, and Erdington.

The buildings consist of a nave, choir, and transept, with, perhaps, a lady chapel; the nave being Early English, the other being Norman. The west doorway displays exquisite Early English

mouldings, with fillets adapted to the circular arch, such as was found in many of the Shropshire transitional works. The great west window has been inserted, and is Late First Pointed. The south aisle of the chancel, or lady chapel, is in effect a separate chapel built against the main building, with a very perfect piscina and credence in one, with a shelf or ambry over one corner of it. The drain from the piscina is horizontal. The north aisle is a separate chapel or chantry, with an ambry remaining. In the choir is a semicircular arch over a recess with Early English mouldings and shafts. The stalls were removed from here to Wolverhampton at the dissolution, and are believed to be in existence now. All these buildings were vaulted. On examining the exterior, Mr. Roberts pointed out the early specimens of buttresses.

The conventual buildings were next examined: they are, unfortunately, desecrated by being converted into stables—the cloister into a pheasantry, and the refectories into refuse yards.

The chapter-house is in the same position as at Wenlock, with a sacristy or treasury on one side, and a scriptorium on the other. The refectory on the south side of the cloister has a very peculiar and beautiful recess; used, probably, as the pulpit, with a quatrefoil in plate to give light, and was most likely inserted afterwards, as the character is later. In two recesses are laid fragments of tombs, one being a knight of the date of King John or Henry III., judging from the armour and shield; and the other of an abbot, apparently, of the earliest Decorated period. In the chapter-house are two coffin-lids, one without any mark or inscription remaining, and the other with a cross calvary, the cross being within a wheel.

At the evening meeting, the Rev. C. H. Hartshorne read an interesting paper on "Powis Land and Powis Castle." That which we referred to last week, read by Mr. Hartshorne, was one on "The Princes of Upper Powis," by the Hon. and Rev. George Bridgeman, — our reporter was accidentally seated in a part of the court where he was precluded from hearing well, and the court is one of the worst possible in respect of hearing. The other papers were by the Rev. George Dod on "Boscohel," and Mr. E. Levison on "The Shrewsbury Book."

This book is so called because it was executed by order of John Talbot, Esq., of Shrewsbury, as a wedding present for Margaret, daughter of René, duke of Anjou and Maupe, and titular king of Sicily, Naples, and Jerusalem, upon the occasion of her marriage with Henry VI., king of England and France, in April 1445. The volume is interesting as an example of the state of arts at the period when it was executed, and on account of the historical associations which it calls up, and the illustrious persons by and to whom it was presented. Margaret of Anjou was an artist of no ordinary degree of merit.

Thursday, August the 9th, was a railway day, but still an early departure was made; and the weather being more propitious, a large party assembled, and, a special train being prepared, no time was wasted. The first stoppage was at Stokesay Castle, of which Mr. C. E. Davis gave a description. The account given by Mr. Parker, he said, was incorrect. He stated that the license to crenellate Stokesay, obtained by Lawrence de Ludlowe, in 1291, could be but little guide in ascertaining the date of the present castle, as it was quite clear that it must have existed previously, as two portions (the two towers) were of earlier date. The southern tower resembles very much the Peel towers of the Borders, and is, doubtless, a complete fortress. The lower story was entered by a large doorway, and all the other stories were approached by a staircase within the thickness of the walls. The story above has an entrance which was approached by a small bridge. These two were, doubtless, ordinarily used; but in case of defence being necessary, Mr. Davis had no doubt that the lower door would be walled up, and the upper one only used. On the story above, singularly enough, one of the windows was inserted in an archway; that is, it had the remains of door-binges, proving most certainly that this must have been an entrance also that might be used, closing both lower doors, and making this tower resemble in all particulars the Border castles. The great hall is clearly the erection of Lawrence de Ludlowe, and is a fine specimen of the architecture of the period.

The party afterwards proceeded to the side of the railway line, and were taken up by a train, and continued their trip to Ludlow, the church of which was described by Mr. Edward Roberts. He said it was a curious specimen of the utter obliteration of the former work by a casing of the walls in a later period. He pointed out several early

\* See p. 507, ante.

parts which still were visible, particularly two piscine in the large south chapel, one of them being semicircular, although, as at Lilleshall, with Early English mouldings, and with a horizontal drain. The Rev. Mr. Hartshorne thought them even so late as Decorated. The glass and rood screens were pointed to as very beautiful.

The castle was examined and described by Mr. Thomas Wright. He said the earliest account was in the history of the Fitzwarines, which is curious and partly traditional. It was stated to have been built by Roger de Montgomery, Mr. Lyton, however, showed that from an examination of all the documents, that could not have been; and one very good reason was, that the land itself never belonged to him. It was probably built by the Lacies, between whom and the Fitzwarines there was a deadly feud, and might account for both families possessing it in the course of warfare. It was founded before the end of the twelfth century; and, by the middle of the thirteenth century, the whole castle covered as much ground as now. It was occupied by the two princes who were murdered. Edward IV. had rebuilt the residence in it, and several times the court was held there. The greatest alterations were made in Elizabeth's reign. The furniture remained in it as late as the middle of the eighteenth century.

After a minute account of the several apartments, the party assembled at the antiquated "Feathers' Inn, a pretty half-timbered house, and accepted a very handsome luncheon at the hands of Sir Charles Rouse Boughton, to whom thanks were given. Some healths were drunk, including Mr. Thomas Wright, proposed by Mr. Mair, of Liverpool, and "The Ladies," proposed by Mr. Pettigrew, in a speech full of humour and spirit.

There was still an hour to spare: this some filled up by visiting Ludford Church, which Mr. E. Roberts described as peculiar in respect of being a very small nave and chancel, with a very large chapel. The west wall is evidently older than the other part, and might be either Saxon or Norman. The tower has been built against it. There are several Medieval tombs.

At the evening meeting, the Rev. J. L. Petit read a paper on Shiffnal Church, an elaborate memoir profusely illustrated.

This was followed by Mr. Thomas Wright's paper on the Legends of Shropshire, from which we must give a couple of examples:—

"Everybody will remember the story of the building of Carthage, how the founders could only obtain as much land as they could encircle in a bull's hide, and how they craftily cut it into slender thongs, and thus contrived to encircle as much land as was sufficient to build a town. Geoffrey of Monmouth tells the same story of Hengist, who, by the same stratagem, obtained from the Britons land enough to build a castle, to which, in memory of the transaction, the Saxons gave the name of Thanester. There are several places in England to which this legend is attached, and among them that of Tong in Shropshire. The same story has taken a very curious form in a legend preserved in the parish of Bromfield, in our county, where they tell of a young lady, whose father would not permit her to marry a gallant knight because the latter was only a younger brother and unable to offer her a sufficient marriage settlement. The young lady, however, persisted in her resolution to marry the knight, and at last one day she informed her father that the ceremony was to be performed the next morning at Bromfield Church. The angry parent told his daughter she might follow her will, but, of all his great estates she should receive for her portion no more land than she could crawl over before morning. She went from his sight, apparently unaffected by this threat, but next day she made her appearance at the breakfast-table covered with mud, and announced that she had secured a tract of meadow reaching about half-way to Downton, round which she had crawled on her hands and knees during the long winter night. The father was so pleased with the spirit displayed by his daughter that he made her the heiress of all his estates, and they remained in the possession of her descendants many years. This ground is still called *Crawl Meadows*."

"There is another legend connected with Shrewsbury, intended to explain the cause of the extension of the trade in Welsh flannel, and it is certainly a curious illustration of the history of the more miscellaneous class of local legends. It is said that the Welshmen took the precaution of measuring their 'pieces' of flannel before they left their homes, but the purchasers in the Shrewsbury market, who bought by the yard, invented a method of measuring which pleased by its quick-

ness and ingenuity, under cover of which was practised a rather ridiculous deception. They made a round harrel or frame, exactly one yard in circumference, on which the parties concerned placed one end of the piece, and went on rolling it until the whole piece was wound up, each revolution counting for a yard. For very obvious reasons, the Welsh seller always found his piece shorter at Shrewsbury than at home, until, having at last discovered the trick, the Welshman refused to attend the Shrewsbury market any longer."

We must finish our notice next week.

#### A LIMP ACCOUNT OF THE SUSSEX ARCHEOLOGICAL DAMP DAY AT PEVENSEY.

THE Sussex Archaeological Society held its annual meeting on Wednesday last week, Pevensey and Hurstmonceux Castles being the points of interest proposed to be visited. A previous attempt, ten years ago, to inspect Pevensey Castle, had been rendered abortive by the very bad weather; and now again the old spell seemed to rest upon the excursion, for the rain descended in a hopeless never-to-be-ended manner. A special train was arranged to start from Brighton at ten o'clock, and it was with an ominous smile of half contentment and pity that the smart young ticket-collector pointed it out to the adventurous archaeologists, as he inquired, "Pevensey, Sir?" The said "special train" was specially late in starting; but doubtless the officials purposely detained it, with the charitable design of keeping its passengers as long as possible under cover, reasonably concluding they would find *such* a day long enough any how. Some of the carriages were unprovided with lamps, the directors doubtless thinking these illustrious *illumina*ti, who can look into the past through the darkness of ages, and make all things clear by the light of their own minds, could not possibly need lamps to guide them through the gloom of merely a tunnel or two. Considering the very settled state of the weather—settled for rain, that is—the society must be congratulated on the enterprising spirit of its members, as evinced by the respectably large gathering of them which congregated within the roofless walls of the picturesque ruins, Pevensey and Hurstmonceux. But the proposition to alight, and view the church close to Pevensey Castle, was, nevertheless, negatived in some of the conveyances, by the majority of the party; so the minority had to content itself with a passing glimpse of the strangely extensive old pile, and to console itself with the assurance that, thanks to railroads, one could easily run over any fine day and inspect the church, which, from the antiquity of its walls, promised many points of interest, in spite of the fearful "Carpenter's Gothic" of its windows.

Another hour of close compression, in tightly packed vehicles, brought the members to the top of the hill, at the foot of which Hurstmonceux stands. Here all who would view the noble ruin were compelled to alight, it being judged, but erroneously so, by the respective Jehus, quite impossible for the carriages to descend the once descending slope. Accordingly, ladies and gentlemen turned out in the pouring rain, raging wind and driving mist, to walk down over steaming grass that covered their feet nearly to the ankles; but the universal good temper that prevailed diminished all difficulties, and the desire to make the best of a bad business was everywhere apparent. One little lady, in our hearing, exclaimed, good humouredly, on being consoled with, "If the day had been fine, where would have been the use of putting on our prettiest petticoats, for we should have had no opportunity for displaying them?"

Umbrellas were all but useless: many of them were turned inside out, and portions of others blown hither and yon; while those that maintained their integrity of shape were altogether unable to afford protection from the pitiless, all-permeating, misty deluge. Nevertheless, one or two enthusiasts, on whose vision the beauty of the pile opened for the first time, actually stood still for some minutes, regardless of discomfort to body, to feast their minds on the grand effect it produced, which effect was doubtless doubled in grandeur by the scar of the storm.

Within the ruin printed descriptions of it were distributed to the visitors, this method of imparting information being thought preferable to the old plan of "reading papers," it having been noticed, on some former occasions, that as the lecture proceeded the ladies gradually melted away from the throng by twos and threes, and as was of course to be expected, their respective escorts of gentle-

men presently followed them, leaving, at last, the worthy lecturer himself, and a few of the committee-men, alone with the learning.\*

Here you have what was said about the building:—

This building was erected in the year 1440, by Sir Roger de Fynes, at a cost of 3,800*l*. A manor-house had previously occupied the site, and been the seat, successively, of the De Mouceux, and the De Mouceux de Fyneses, from the time of the Conquest. To the park which had previously existed, Sir Roger added 600 acres of land. His son, Richard Fynes, Sheriff of Surrey and Sussex in 1452, married Joan, heiress of Thomas Lord Dacre, and was, in her right, summoned to Parliament, and declared Baron Dacre of the South in 1458. Thomas, the second Lord Dacre, distinguished himself as a soldier, and was Constable of Calais. He died in 1534, and was buried under a magnificent altar tomb in Hurstmonceux Church. His grandson and successor, Thomas Lord Dacre, associated this place with a very tragical event. Engaging in the foolish and unlawful frolic of hunting deer in the park of his neighbour, Sir Nicholas Pelham at Hellingly, a fray took place between his companions and the knight's gamekeepers, which resulted in the death of one of the latter. For this Lord Dacre was held responsible, and he, together with three of his gentlemen, Mantel, Frowds, and Roudon, were executed at St. Thomas Waterings, 29th June, 1541, but not married. His sister Margaret espoused the Sanson of Lemard, Esq., and was recognized as Baroness Dacre. They resided much at the castle, and added greatly to its internal decorations. The castle and estate remained in his eventful line of descent until the time of the Sanson created Earl of Sussex by Charles II. He improved the castle by the addition of sash windows on the east; but, losing a great part of his estate by extravagance and gambling, he was obliged to sell Hurstmonceux, the seat of his ancestors from the Conquest. In 1708 the estate became the property of George Naylor, Esq., of Lincoln's Inn, who married a sister of Thomas Pelham-Naylor, Duke of Newcastle. His successor was Sir Francis Kinsman, Dr. Francis Hare, Bishop of Chichester, and the latter left the castle to his son, Francis Naylor. In 1775 it devolved upon his half-brother, the Rev. Roger Hare, but was then considered to be so dilapidated as to be past repair. The interior was therefore demolished, and the materials were employed in adding to the mansion called Hurstmonceux Place. From F. Hare Naylor, Esq., in 1807, the estate passed by sale to Thomas Read Kemp, Esq. In 1819, it was purchased by the Gillon family. In 1846, Jno. Gillon, Esq., M.P., sold it to H. B. Curtis, Esq., M.P., father of Herbert Mascal Curtis, Esq., the present owner. The castle is accounted one of the earliest brick buildings in England. It is also among the latest specimens of a castle, properly so called; possessing much of the grandeur, with little of the strength, of the feudal fortress of earlier times. When in full repair, it was considered the largest house in England belonging to a subject. Addison's comedy, "The Drummer, or the Haunted House," was said to be based upon a tradition connected with this mansion. The room immediately over the Porter's Lodge was known as Drummer's Hall, from the loud "spirit-rapping" formerly carried on there.

After a hurried inspection there came the repacking of damp individuals into very small omnibuses and other conveyances, and then the return to Pevensey. During the retreat animal spirits were decidedly "below proof," doubtless reduced in strength by the involuntary admixture of water from the clouds; and possibly also by the unwonted fasting which, in many instances, extended from eight o'clock in the morning till between two and three in the afternoon. Re-arrived at Pevensey, however, a handsome spacious booth (which the Society is ambitious of purchasing), erected within the ruins, gladdened the eyes of the intrepid voyagers.—I use the word advisedly, this being decidedly *water* excursion,—and a capital dinner, well cooked, well served, and well eaten, brought to a more successful termination than could have been anticipated, a day which had opened upon the Sussex Archaeologists with so little promise, and which had hitherto certainly not belied its foreshadowing.

The Lord Bishop of Chichester presided at the dinner; and, after its conclusion, appropriate toasts were given; but, though the circumstance was once just barely mentioned, all the speakers missed taking advantage of what might have been made a fine point in a speech,—the grand effect produced by the heavy measured booming of the murderous gun, which, as a trial of its own power, was endeavouring to batter down one of the massive Martello towers hard by;—so named, as the *Builder* has before now said, from Martello, or Myrtle bay, in Corsica, whence they were copied, and which were raised on our coast as a protection against the expected invasion of the Corsican, Napoleon Bonaparte.

Mr. Mark Anthony Lower read a verified descriptive account of Pevensey, respecting which I will only say, it was a pity the author had not contented himself with the rich smooth plain of grandly-marching prose, instead of attempting to toil up the steep of Parnassus, only to lose himself in the mist and fog which on Wednesday last enveloped all heights, physical and fanciful.

Subsequently Mr. W. Durrant Cooper read a very curious letter, hitherto unpublished, from

\* Some notices of Pevensey and Hurstmonceux will be found in previous volumes of the *Builder*, especially the volume for 1855, p. 133.

Dr. Andrew Borde,—the original "Merry Andrew."

One idea worth recording was eliminated during the return journey home, to the effect, that archaeological meetings might be rendered additionally interesting and instructive, if arranged chronologically as to periods,—the British, Roman, Danish, Saxon, Norman, &c. And it was suggested that a local museum, illustrating solely the precise period of the building to be investigated, should be collected; and that all papers read, and all decorations used, should be made to bear upon the same point.

A WOULD-BE ARCHÆOLOGIST.

WHITBY.\*

WHITBY occupies a very picturesque position at the mouth of the Esk, on the Yorkshire coast, midway between the Hamber and the Tync. The vicinity is fine, with all the dales and glens connected with the Esk. The town is built on the two opposite sides of the inlet formed by the river in its passage to the sea; and the harbour, above the revolving bridge by which the divisions are connected, is capable of containing 300 vessels of the medium size, the two lighthouse piers shaping the entrance, as well as guiding to the port. The landmarks are, the abbey in ruins, and the old parish church, on the eastern cliff; while, on the summit of the western eminence, the terraces extend in lines of modern construction. The town, with its 11,000 inhabitants, crowds in its central parts towards the water. The alleys or yards stretch from the top to the bottom of the acclivities, and the houses on either side, built tier above tier, are reached by flights of stone stairs; the higher landing-places, above the sphere of roofs, and masts, and smoking chimneys, having their own view of the town, the harbour, and the German Ocean.

"Whitby, and not Scarborough," says White, in his "Month in Yorkshire," "would be my choice had I to sojourn for a few weeks on the Yorkshire coast. What it lacks in the style and show, which characterize its aristocratic neighbour, is more than made up by its situation on a river, and the beauty of its neighbourhood."

The vicinity has its antiquarian and its poetical interest, too. Here the famous St. Hilda dwelt in her abbey of Streonshalh, which she founded in the seventh century. Ages have gone by since Hilda was gathered to her fathers, but posterity still cherishes her memory. A fair is held to this day at Whitby on her birth-day, the 16th of August. The town owns her for its patron saint. Churches are dedicated to her, and miracles ascribed; for in the "olden time" the neighbourhood was cleared of its *snakes* by her power, as the abundance of its Ammonites testifies!

"Then sole amid the serpent tribe,  
The holy abbess stood,  
With fervent faith and uplift hands  
Greeting the holy rood.  
The suppliant's prayer and powerful charm  
Th' unnumber'd reptiles own:  
Each falling from the cliff becomes  
A headless coil of stone."

Hilda was succeeded as abbess of Streonshalh by Elleda, the friend of St. Cuthbert of Lindisfarne, of both of whom, and their friendship, Bede discourses at large.

The town of Streonshalh and its monastic ere were destroyed in 867 by the Danes, and both lay desolate for 200 years. The monastic foundation, however, was re-established in 1074, by Reinfrid, a zealous monk of Evesham, to whom William de Percy granted the conventual ruins; but there are no grounds for believing in the rebuilding of the monastery by its first Norman possessors. However, of this it is certain, that all traces, both Saxon and Norman, have disappeared in the erection of the present fabric, which exhibits the Pointed Gothic in its first, second, and third periods or styles, the first, or oldest, belonging to a date a century later than the life-time of Reinfrid. The town of Whitby, like its predecessor, Streonshalh, arose as a dependency on the abbey.

The abbey-church has been the most stately fabric in the monastic group. The east end, with the walls of the choir and the north aisle; the north transept, and a remnant of the nave, still remain; but the dwellings and offices for the household, as standing on the south and south-west of the church, having all been removed, are known only by name in the records. The abbey is the great historical monument of the district. When entire, the square tower, as marking the centre of the cruciformation, arose on four huge arches opening

to the usual quarters of a church—the choir on the east, the transepts north and south, and the nave, or longest part, on the west. On the site of Hilda's foundation the fabric in length is 310 feet; and, with the south projection of the transept, which is gone, the cross extent would be 153 feet. The main side walls in height are 60 feet. The height of the tower was 10½ feet.

In the earlier eras, the monastic buildings in their character were primitive and unpretending; but an advance in magnificence marks their erection as ecclesiastical splendour grew with an increase of revenue. The choir, in the lancet or Early English style, is ascribed to the abbot Richard of Peterborough, whose administration lay between 1148 and 1175. The eastern front, entire, exhibits six lancet windows in two tiers, with three of smaller dimensions in the gable between the pinnacles, for lighting the roof. Sided by seven pier arches for the ground story, the superlatitudes are the triforium and the clerestory. Within the walls, a passage crossing the lancet lights of the clerestory has communicated with the different quarters of the building, one approach remaining at the west angle of the north transept, and another at the north-west angle of the nave. At the distance of one arch from the east end of the choir the pillars indicate a screen for the high altar.

The south aisle of the choir is gone. The extant north aisle retains a part of its groined roof, with curved bosses at the intersections of the ribs. On one is a lion rampant; another bears the lamb and flag, an emblem of peace; a third has two fishes; and a fourth is a circlet of foliage or flowers. The windows throughout are "single lancets" charged with dental and zigzag mouldings, the arches of those in the clerestory springing from heads crowned and mailed. The body of the choir would be roofed with wood: the side aisles were vaulted in stone. The front of the north transept, still perfect, presents nine lancet windows in three tiers, with a small "Catherine wheel" in the gable. The style is Decorated.

Viewed from within, the windows recede in elaborate undercut borderings, and the capitals of the side shafts, in contrast with the plain round caps of the choir, are an exuberance of foliage and flowers, in which birds and fruit appear and reptile formations entwine.

The tower fell on a calm day, June 25th, 1830. The pillar at the south-west corner had long been cracked; and, as a further weakness, the staircase within it is recollected as approached from the south transept. The top story was panelled on the four sides in window-shaped compartments, three on each side, and a staff with a vane stood at the north-west angle.

The nave has formed a perspective of eight arches, being one arch longer in the parallel than the choir. All that remains of it is part of the north side aisle and a fragment of the west end, in which we perceive the principal entrance to the church, the access in ordinary being by a small doorway, formerly porched, and still extant in the side wall aforesaid.

The west end, by pre-eminence "the front," has been very imposing. In the central space, between pinnacled buttresses, the principal entrance shafted and moulded, and "the great light of the nave" with its variform tracery, stood deeply embayed. The front, in its leading details, belongs to the last variation in Gothic architecture—the Perpendicular style; the indications being found in the window constructions.

The nave is not in a straight line with the choir, but exhibits a deflection at the west end of 9 feet towards the north. The cause is a query, and the solution hitherto given not satisfactory enough to be interesting.

The parish church was originally founded after the Conquest, for the use of the laity. In 1510 it became parochial. Originally Norman in nave and chancel, with the entrance on the south side of the former, the tower at the west end, as well as the transepts, are after additions. The entrance, round-arched, with a pair of "cushion-capped" columns on either hand, was destroyed in 1823, to make the principal porch nearer the tower, where it now is. A line of semicircular-headed windows, each 4 feet high and 22 inches broad, originally encircled the building; and, as an outside example, the one blocked up over the modern porch aforesaid may be cited.

In the modernization of the old fabric, a process which commenced in 1744, the walls were everywhere pierced for the ordinary house sash. The repairs and extension of the structure took place when old church arrangements had not the position in the public mind which they now occupy.

The elevated site of the church, and of the abbey on the eastern cliff, is attained by a hand-mailed flight of 196 steps, termed the church stairs.

Whitby, on the whole, is an interesting place, and the first of the two volumes above referred to, to which we are mainly indebted for those few notes on it, contains a full account of the town and its history, buildings, and neighbourhood. The "Guide" is a smaller work, which, for a shilling, gives a more limited account of all the objects of interest at and about Whitby, with an Essay on Sea-bathing, by Dr. J. Dowson. Both volumes contain maps of the district.

The neighbourhood appears to be advancing. Good free stone abounds, and is in great demand.

LODGING HOUSES IN DRURY LANE AND ISLINGTON.

ALTHOUGH something has been done in erecting proper houses in various parts of the metropolis, there is wide scope for the exertions of private individuals, who,—seeing the sure effect of wise arrangements on health and life, and believing that by conducting such places in the ordinary business-like manner, they can be made to pay a fair per-centage on the money invested,—may be led to build houses for the use of families, and adapt others for single men.

The large cost of ground in the metropolitan districts, and some other reasons, cause difficulties, but in several instances such experiments have been very successful.

Since the establishment of lodging-houses for single men by the two societies for the improvement of the dwellings of the industrious classes, several places on a similar plan have been opened with varied success. We have before referred to some of these, and may now glance at the "Drury Chambers" (Nos. 3 and 4, Pitt-place, Drury-lane). These are old-fashioned houses, of considerable size, which have been put into thorough repair, well ventilated, and opened as lodgings for single men. Under the care of the inspectors of lodging-houses, the beds have been so arranged according to the space, that over-crowding is prevented; and for 4d. a night, or 2s. a week, including Sunday, a man may obtain a wholesome lodging. The bedding is very clean; and at the time of a chance visit the place seemed well managed and cared for. A kitchen or sitting-room is provided for the men, with locked cupboard for each; and it may be expected, notwithstanding the considerable amount which has been expended, that the manager will gain a good income from the speculation.

When we remember the former condition of the majority of the lodging-houses of this class in many districts of the metropolis and in the provincial towns, the contrast is satisfactory. In such places as these men have the opportunity of association without the need of resort to the public house. In winter time there are a comfortable fire and light. The police inspectors of lodging-houses—intelligent men, who, on all occasions on which we have had the opportunity of noticing their operations, have been remarkable for the kindly yet firm manner in which they fulfil their duties—see carefully to the drainage, and by their timely visits enforce a degree of order and cleanliness which is as beneficial to the lodgers as to the keepers of the houses themselves.

Formerly the houses for the reception of travellers in the suburbs, and in St. Giles's and other parts of London, were, in most instances, frightful places, in which either decency or morality was next to impossible. Men with wives, and families of children of different ages—in search of work or from some other causes obliged to take the road—had often no other choice than to resort to those places, where they were forced to associate with the most depraved and profligate.

Barred doors prevented visits of the police, and such was the nature of the people boarded there, that it was a matter of no little danger for those who meant kindness to venture into the neighbourhood. Persons of both sexes, old and young, were huddled together, and the uncommunicated boy or girl was thrown into close co-uection with those versed in vice.

It is difficult to estimate the damage that resulted from such association,—the amount of robbery, and systematic hugging and imposition, which was reared and encouraged by the ill arrangements of these terrible resorts of the poor and depraved. As a contrast to these, we may look at one of the houses for travellers, situated in Islington, which is much resorted to, and is registered, and looked after by the police inspectors of lodging-houses. This is situated in a

\* Whitby: its Abbey and the Neighbourhood. By F. K. Robinson. Whitby: S. Reed, 1860.  
See the Illustrated Guide to Whitby. Sixth edition. Whitby: S. Reed.

narrow court, which, but for care, would be a nursery for fever and disease. The lodgings consist of several houses: by means of many contrivances—which are not very apparent to the eye unpractised in those matters—a fair amount of ventilation is managed; and perhaps, in such conditions, it is as well that the means of ventilation be not too apparent; for those who have been accustomed to lodge in close, impure atmospheres, seem to have a strange aversion to the admission of air, and possibly would keep it out. Doors have, however, been taken off, and panels taken out of cupboards, which answer a good purpose. Some rooms are fitted up with beds for men, which are placed at the distance legally allowed.

No miscellaneous hoarding together of men and women is allowed in these apartments; there are, however, some of the rooms arranged for the use of married men and their families. In these places, a partition is placed at such a height as ensures a certain amount of privacy, and still allows ventilation. It would perhaps surprise some accustomed to affluence, and who have not looked at the condition of the London poor, to see the rough accommodation for travellers who are praising. Great, however, is the improvement which has been made; and it is something to know that, although the arrangements are not of the most refined description, here people, at the cost of about 3d. a night, can sleep without the fear of evil communications, fever and pestilence.

According to the terms on which these houses are licensed, it is necessary to whitewash all the rooms at stated intervals, to prevent damp, and do proper repairs; to change and properly keep clean the bedding; to trap and keep clear the drains. A sufficient water-supply is also required. The opposition will be remembered which was made by even those who were dying by the hundred annually through the ill conditions in which they were placed. Now, however, not only the tenants, but those who let the houses are thankful for the change.

Some of the courts close by, in Islington, are differently managed, and need supervision. In these places there is a large population. We will not just now mention the names. They ought, however, to be well known to the parish inspectors. The closets are insufficient for so many occupants, and the condition of them in the morning on which we called was abominable. The usual complaint was made of short supply of water. Few would think, on first looking at the dilapidated dwellings, that they were uninhabited: it will be found, however, that working men and their families thickly populate the place. In passing through the apartments it is evident that the want of proper closets, conveniently attached to houses which are let in tenements, is the first requirement which should be attended to. A visit to some of these miserable London interiors is indescribably painful. In one room, occupied by a blind woman, there was not an article of furniture: a few dirty shavings in a corner served for a bed. In another room a child lay seemingly at the point of death. Terrible must be a sick bed in such a situation, and sad it was to find a man in the last stage of consumption in a place close by. With several miserable pictures stored in the memory, squalid figures relieved by mouldy, damp, and decaying walls, and other scenes of dirt, confusion, and neglect, we can but wish earnestly for the means of improving such a state of things.

We are told that horse property in these courts is of little value in its present condition. Surely, however, those persons in whose charge the houses are, should see that they are kept in a decent condition. In some courts, small casks, bottles, and a variety of odd vessels were waiting for the water supply to come in. Most inconvenient and insufficient is this arrangement. In another court (Ashley-court) the people can draw water at any time from a tap which is placed in a convenient part of the court. Some of these courts exhibit such different degrees of cleanliness and care, that much evidently depends on the exertions of the persons who own or have the superintendence of the houses.

In some of them, indeed, it is evident that as much is done by the owners as can reasonably be expected, and that the tenants repay the endeavours by decent behaviour and carefulness.

**THE TOMB OF HARVEY.**—It has been determined by the College of Physicians, with the consent of the next of kin of the illustrious discoverer of the circulation, to restore his tomb at Hempstead church in such a manner as to secure his remains from the desecration and destruction to which they are now exposed.—*Lancet*.

#### ON THE MECHANICAL EFFECT OF COMBINING GIRDERS AND SUSPENSION CHAINS, AND THE APPLICATION OF THE SYSTEM TO PRACTICAL PURPOSES.\*

At the meeting of 1857 a paper was read by me on this subject, my attention having been directed to it by being required to investigate, as engineer-in-chief to the Londonderry and Enniskillen and Coleraine railways, the best mode of connecting the railways across the River Foyle, in conjunction with a road bridge. The depth and bad bottom of the river led me to recommend a suspension bridge, combined with a girder; and, in order to investigate the strain and the amount of girder power required to cure the oscillation and wave, the model was made which I now submit to the meeting.

The design, when submitted to the Commissioners of the Road Bridge, was approved by Sir William Cubitt, their consulting engineer; but, some doubt having been suggested as to the fitness of suspension bridges for railway traffic, the question was submitted to Mr. Hawkshaw, who recommended the girder bridge now in course of erection by the Road Commissioners, at their cost.

It is, no doubt, the safest course for an engineer to recommend what has been done before, and to avoid experiments; but this, it is contended, does not render it less desirable that the subject now before you should be understood as a mechanical question, as it is admitted by the strongest opponents of suspension bridges that they are practicable and advantageous when large spans cannot be avoided, and we have as a fact the Niagara bridge of 822 feet span, constructed principally of timber, in a situation exposed to severe hurricanes, which has carried over for six years the heavy goods and passenger railway traffic of the New York Central and Great Western of Canada Railways.

It is not, however, in cases where large spans are indispensable that this principle of construction is alone advisable. In the case of the Londonderry bridge it is not impracticable to construct piers in the river, but they are attended with serious risk and cost and interruption to the navigation, which, in the opinion of Sir William Cubitt, might have been avoided, and a superior engineering work made at less cost.

The same occurs in London. The Hungerford Suspension-bridge has become the site of a railway extension, and it is at once assumed that for railway purposes suspension is inadmissible, and this bridge, so ornamental to the river, is to be superseded by a girder bridge with numerous piers. I believe for no other reason than because the mechanical effect of the combination of chains and girders is not sufficiently understood, and for this reason I desire to press the investigation of the subject. But referring again to the Niagara bridge, which is 822 feet in span, and of which the girder portion is of timber; if this bridge will stand heavy railway traffic, can it be doubted that a bridge entirely of iron of the best quality, or the improved material puddled steel, can with safety be constructed of much larger spans?

But it is not only to avoid the difficulties of rivers that a successful suspension girder bridge would be useful, but in many cases valuable property may be saved, and even the difficulties of dealing with the crowded traffic of the streets of London very much diminished.

A suspension girder bridge of spans of 2,000 feet is perfectly practicable, constructed with superior metal, but 1,000 feet is sufficient to meet the difficulties of the case, and lines of railway can thus be easily carried across a crowded city at less cost and with less destruction of property than by underground railways or any other means than has hitherto been suggested.

I shall speak subsequently more in detail of the cost and practicability of such lines of communication, but it is necessary now to say a few words to justify my claiming the attention of the meeting to the subject.

The principal cost of a structure consisting of a series of openings will be the suspension wires or chains and the towers. The amount of girder power to cure the wave and oscillation will not be found, as my experiments will show, to be a serious addition to the cost, and the item in ordinary suspension bridges which forms the largest proportion, viz., the anchorage, will here be divided over numerous openings.

With reference to the chains or wires, the most ready estimates will be deduced by reference to any existing structure, and I select the Niagara

\* Read at the Oxford meeting of the British Association, by Mr. Peter W. Barlow, F.R.S., as mentioned in our notice.

bridge as the only one tested by railway traffic. Here we have a section of 242 inches of wire with a weight of 350 tons, a span of 822 feet, and a deflection of 59 feet.

In a series of spans the suspension chains, irrespective of the towers, would form fully half the weight of metal in the structure, and assuming a price of 40l. per ton, we have 12,400l. for each opening as the cost, assuming that for the purposes of omnibus traffic we require an amount of strength which has been found sufficient in a locomotive railway of heavy traffic, combined at the same time with a separate carriage road communication.

The rule for ascertaining the sufficiency of railway bridges adopted by the officers of the Board of Trade is to estimate the strain produced by the greatest weight which by possibility could come on the bridge throughout every part of the structure, which should not exceed one-fifth of the ultimate strength of the nettle.

The strength necessary, therefore, depends in a great measure on the mode of traction adopted, and it is therefore a very important question in this case to consider whether locomotive steam engines are the best mode of traction where the traffic will be entirely of an omnibus character, requiring trains as frequently as every four or five minutes to give efficient accommodation and relief but of the lightest character.

Parson's Air Engine may be well adapted to the purposes of such traffic. Although it may be justly condemned as applicable to the ordinary railway traffic, it has advantages where the tractive power required is not such as to exhaust the reservoir of power and require high pressure too rapidly, which will not be the case in the present application, partly because the trains will be very light, and partly because at every pier or tower small stationary engines will be used for the purpose of raising the passengers from the surface of the ground to the platform of the railway, which would furnish a supply of compressed air for the renewal of the reservoir of the iron locomotive. Without entering further at present on the question of the practicability of this suggestion, or whether the atmospheric or any stationary system may be so, as it is assumed that such a system of traction is adopted, or that a locomotive of one half the weight only of ordinary locomotives, such as I am now employing on our railways, is required, and therefore the ultimate weight which might arise on such a bridge would not exceed one half of what might occur on a railway bridge, assuming the extreme case that it be loaded from end to end with locomotives.

It is generally considered that a bridge for ordinary road traffic does not require to be made of the same strength as an ordinary railway bridge, but this I believe to be an error. A railway bridge covered from end to end with locomotives is a possible strain to which it may be subjected, but in a large span it is a less possible or probable contingency than that of a road bridge being densely packed with passengers or soldiers, by which a greater actual weight would arise with a greater amount of vibration, while bridges with a motive power like Parson's engine, or stationary power of any kind, would not be liable to an ultimate strain of one half that of a bridge for ordinary road traffic.

It is true that many failures have occurred in suspension bridges, which fact has much shaken public confidence in them, but it is only necessary to examine the causes of their failure to see that they were the certain results of the defect of construction, and when these cases are examined they become evidence of the advantage of the principle, not of its defects. If road, like railway, bridges had been constructed under the supervision of the Board of Trade, not a single failure would have occurred, and when it is stated that these bridges have been constructed with from one-fourth to one-sixth the section of iron that the Board of Trade would require, and without any means of correcting the wave and vibration, it is not surprising that they have failed, but rather that they have existed so long, and that some of them now exist.

The public may rest satisfied that any bridge which has passed the approval of the Board of Trade is not only sufficiently strong, but much in excess of the necessary strength, and they can as safely reside under such a bridge as under the roof of a house, and it is in accordance with these rules that my estimate is formed.

The section of metal in the suspension chains or wires required for a double line of railway with a span and depth equal to the Niagara Bridge, with girders constructed of good iron to comply with the Board of Trade rule, would not be more than 240 inches, and I propose to adopt this

section; that is to say, to give the same strength to my structure for light railway passenger traffic as has been given to the Niagara bridge, which has a road communication in addition to a heavy railway traffic, in a situation exposed to the most severe hurricanes.

We thus arrive approximately at the main cost of the structure, viz. the supporting chains which will contain 2,000 tons per mile, which at 40l. per ton will be 80,000l.

We have next to consider the cost of the towers or piers, which I propose to construct of wrought or cast iron, and we have the Crystal Palace water towers as an example of a similar structure from which the cost may be deduced. These towers are 220 feet in height and support 1,500 tons of water at the top. The towers required for such a bridge as I have described will not have so much weight to support, and the height will not exceed 150 feet, and allowing the same section of metal and strength, the cost will not exceed 10,000l. each tower.

The next large item is the cost of the girders and the platform necessary to prevent the undulation or wave—a necessary addition to every suspension bridge, but one which has hitherto been generally neglected; and thus has arisen the want of confidence in a mode of structure which admits of numerous applications of great public importance.

The investigation of this part of the subject is the immediate object of this paper, as the strains and necessary weight of metal in the main suspenders has been long calculated and fully established; but for the purposes of the approximate estimates, I shall only here state that a weight of metal equal to the chains will be found to be sufficient at a cost of 60,000l., and thus a total cost, allowing for land and other contingencies, of 300,000l. per mile, would carry such a structure through the densest part of London; a sum small, compared with the object to be obtained, and which will probably be much reduced on further investigation, as it accomplishes the object of railway communication without any interference with the sewers, water-pipes, &c., and with less destruction of property than a tunnel, which will be unavoidably most unpleasant for passengers, and more objectionable for the application of steam and locomotive power, that a viaduct, where if Parsey's system or stationary power does not admit of practicable adaptation, light locomotives may without difficulty be used.

I am, however, dwelling more on this part of the subject than the title of my paper justifies, my object being merely to show that, if a system of larger spans can with safety be established for railway purposes, that there are many instances of useful application to the public.

#### General Remarks upon the Construction of Bridges of Large Span.

Bridges may be divided into three classes:—1st. The arch—a structure in which the supporting material is subjected to compression alone, but which contains no rigidity in itself.

2nd. The suspension bridge, in which the supporting material is subjected to extension alone, which also contains no rigidity in itself; and

3rd. The girder, in which the material is subjected to both extension and compression.

Of these three systems, the girder necessarily requires, from combining compressive and extensive resistances, a much larger amount of metal than either of the other systems.

In an ordinary arch, the compressive force is resisted by the abutments, which in no way add weight or strain to the metal; but if the arch is converted into a girder, it can only be done by adding a tie-bar, the arch having then to support its own tie, or substitute for an abutment, in addition to its own weight.

In a suspension bridge the tensile force is resisted by the anchorage, and if these are taken away to make it a girder, a compression tube or bar has to be used as a substitute for them (as in the Chepstow Bridge), which tube becomes, in large spans, with its supports, by far the largest portion of the structure, and destroys the bridge by its own weight, besides doubling the deflection.

It is thus evident, that if you convert a girder into an arch or suspension chain of the same depth, half the supporting material is at once dispensed with, from the duty being transferred to the abutments or anchorage, and the deflection decreased one half.

Thus, theoretically, an arch will produce the same saving as a suspension chain; but it is not so in practice, because there is much greater difficulty in dealing with compression strains than with extension. In the latter case, the strength

is correctly measured by the section of the metal; but where you have compression strains to deal with, wrought iron is liable to buckling, and you thus cease to have any true measure of its strength and power of resistance, a difficulty which arises not only in larger iron arches, but occurs also in deep girders, and thus limits their extent of application.

Mr. E. Clarke, who published an account of the Britannia Tube, concludes his investigation of the subject by arriving at a similar conclusion, in which he no doubt also expresses the views of Mr. Robert Stephenson. In speaking of the limits to which tubes similar to the Britannia would be carried out, he says:—

"If the dimensions of the section remained constant, and the length only were increased, the tube would break with its own weight when it became about 850 feet long.

But if the dimensions of the section were also increased so that the tube retained the same proportions, becoming then a similar tube to what it is at present, it would break with its own weight when it became about 1,570 feet long. The depth of the tube would in this case be 100 feet; the breadth 45 feet, and the weight 62,000 tons.

Other curious properties of similar tubes may be determined from the preceding reasoning; but in practice these theoretical limits cannot be approached. The impossibility of construction, the rapid increase in the weight of the requisite pillars for any great extension of depth, the necessary additions for preserving the general form of a large structure, considered merely as an edifice, independent of its action as a beam, and the great crushing strain to which the bearings would be subjected, are all elements increasing in a high ratio with the dimensions, and rendering impossible, on similar principles, any structure of much greater magnitude than the Britannia Bridge. This will be evident if we call to mind that in that tube 21 per cent. of the whole weight of the sides is already consumed in stiffening them; and not only would the weight of a larger structure increase as the cube of its length, but it would also require a much larger per centage of stiffening plates in the sides, for as the pillars increase in height, the weight increases as the cube of the length, while the strength is only as the square.

In this respect the ordinary suspension bridge possesses considerable advantages over other structures, for the strain being wholly tensile, the laws of pillars do not come into operation, and such bridges may be safely constructed of magnificent dimensions with little material.

These advantages, however, at once disappear when the horizontal strain is resisted by a pillar forming a portion of the structure itself, as in the case of the Chepstow bridge; and the limits of such a system are nearly similar to those of a tube, the weight per foot run increasing nearly as the square of the length, and therefore the weight of the whole structure as the cube.

The magnitude of the arch is limited, like that of the beam, by the danger of distortion, its stability being dependent on the laws of pillars. The thrust on the abutments becomes, moreover, a formidable difficulty in arches of great magnitude."

These observations, which are, however, much at variance with the arguments which decided that the suspension-bridge of Telford should be superseded, I fully concur in, and they are very important. It must be admitted, at all hands, that a structure whose direct strength depends on the resistance to the extension of iron, is safer and of greater strength than one which depends upon its compressive resistance. Firstly,—because the extensibility obeys known laws, and metal is superior in tensile strength; secondly,—for the reason previously described, that you avoid the necessity of loading your bridge with material to produce compressive resistance; and thirdly,—because the deflection varies nearly as the square of the depth, and you can have increased depth in a suspension-bridge with little additional material and cost.

A comparison of existing structures will at once prove this, and as an example I will mention that the two tubes of the Britannia bridge contain 2,500 tons of supporting material in a span of 460 feet, while the Niagara bridge, of equal strength and of 822 feet span, contains only 350 tons.

In the face of such undeniable facts, it is surprising that a system of parallel girders for large spans has been adopted, the safety of which, as regards direct strength, is not so certain because you depend on compressive resistance, which may suddenly fail from buckling, as you cannot estimate where it will occur from experiments on a

model, and you are therefore only certain of the strength of your structure as far as you actually test it, and have not that margin of the excess of certain strength to allow for deterioration which it is desirable to obtain.

As these advantages of suspension structures must be obvious, the question at once suggests itself, why have they been abandoned for railway purposes, where safety is so important?—the only answer to which is the supposed practicability of curing the oscillation and the wave produced by a passing load; and it is to the investigation of this important subject that my experiment and observations are directed. The first objection of the oscillation or swinging produced by a hurricane is not a serious one, as the force of the wind will only occasion mischief in combination with its action on the timber platform of the bridge, producing undulation and waves, and has been cured by Mr. Rendel by the addition of a girder parapet of iron. It could not occur in bridges with an iron platform, and stiffened by a girder of good iron, presenting comparatively little resistance to the wind; and I have therefore directed my experiments alone to the cure of the wave.

For the purpose of my experiments I had the model made which I now lay before the meeting, which represents one opening of the intended Londonderry bridge,  $\frac{1}{2}$  of the intended size, the length between the towers being 13 feet 6 inches, which it is submitted is of sufficient dimensions to deduce accurate results when large compression strains are not the subject of investigation.

To illustrate the object of my experiments, I will again explain that a suspension chain, *per se*, has no rigidity in itself; a weight placed on any part will instantly distort the figure, and the platform will take the form of the wave; and thus the numerous bridges erected on this principle, without a means of correcting the distortion, are unfit for the purposes of traffic of any kind.

The obvious correction for this undulation, which has been adopted by Mr. Rendel and Mr. Roubin with success, is a girder attached to the platform of the bridge, so that the weight is distributed and the waves diminished to such a degree as to be unobjectionable in practice; and the mechanical question for consideration is the amount of wave which will arise with a girder of a given depth and section of iron.\*

#### THE "IRON HORSE" MAKING A NEW START.

WE see it reported in the Banif and Wick papers that Lord Caithness has had a carriage fitted up on something like the locomotive principle, and has travelled on it with considerable rapidity, up hill and down dale, in the rough and hilly north, as well as along level roads and through crowded market-places; the whole apparatus, it is said, being as completely under the command of the noble driver as would have been a carriage-and-four or a mail-coach. With this carriage the Earl of Caithness and his Countess are said to have paid visits to friends, and completed a journey of some length with the speed of the old "mail;" and with great success. Does not this now at length fore-shadow that the day may yet after all arrive when the horse, being no longer necessary, may become a curiosity, as the skeleton of the mammoth in the British Museum, now is?—that, even in warlike operations, instead of cavalry mounted on horses, and now less efficient on account of the use of "arms of precision," we will have regiments of stalwart men mounted on "iron horses," as our primitive British forefathers had their peripatetic apocryphal iron war chariots, extremes thus meeting, but with a difference, even in the wild and savage war screech with which they will rush upon the foe?—that in more peaceful scenes even fair ladies may call for their steam horse, so tamed, that with it they will fearlessly roam through the streets of the West-end, the parks, and other places of fashion? What will they do with the grimysnoke? may some say; but are we for ever to be unable to consume our own "blacks?" Let us at all events console ourselves with the idea that coal, as a means of propelling the locomotive, may not be always necessary! Electricity would be cleaner: even the German baron's compressed air-hotties of iron, or some still simpler motive power, may one day replace it, at least in the new equivalent for pony carriages, cabs, and riding horses.

The revival of the locomotive carriage for common roads is not so likely now to have its progress checked as it was when the rail shot ahead of it; and it is to be hoped that no renewed infliction of heavy tolls will again stupidly interfere with it.

\* To be continued.

KILMORE CATHEDRAL, IRELAND.

## KILMORE CATHEDRAL, IRELAND.

KILMORE CATHEDRAL, of which we give illustrations in our present number, was consecrated on Tuesday, the 17th of July last, by the bishop of the diocese, in presence of a large number of the clergy.

The old cathedral, whose place it supplies, was a mere square room, with flat ceiling and gallery, quite inadequate for the accommodation of the parishioners.

The new building has been erected from the designs of Mr. William Slater, of Carlton Chambers.

The style selected is Middle Pointed. In plan the church consists of nave and aisles, north and south transepts without aisles, and chancel also without aisles. The tower is central: it is carried up one stage above the roof, and terminated by a four-sided pyramidal roof.

The west door is double, with a carved tympanum. The roofs of the nave and transepts are open, with carved braces supported on columns: in the chancel the roof is panelled. In designing the building two objects were kept in view,—the first, to provide suitable and increased accommodation for the parishioners; the other, to preserve, as far as possible, the distinctive cathedral arrangements. To accomplish these, the nave and aisles and south transept are filled with convenient open seats for the general congregation.

The north transept is occupied by the organ, which stands on the floor, and by the children of the schools. Under the tower are placed the stalls for the clergy and choir, and the bishop's throne: all these are of oak, and richly carved by Mr. Forsyth, of London, from the architect's designs. The chancel proper is left unoccupied by seats, and is thus available for confirmation or gatherings of the diocesan clergy, and the like. The pulpit is placed at the north-west part of the tower, and the font in the nave, at the west entrance. These were executed in Dublin by Messrs. Purdy & Outhwaite, who also carried out the stone carving.

There are at present only three stained glass

windows in the church,—two in the south transept, executed by Mr. Miller, the gift of the Nisbett family, and one in the south aisle, by Messrs. Clayton & Bell. The chancel is paved with Minton's encaustic tiles.

The general works were carried out by Mr. Hague, builder, of Cavan. The materials used are dark local stone for the general walling, and a lighter stone, from Dungannon, for the dressings. The external effect is much increased by the site, which is on the slope of a hill.

The funds have been provided by the bishop, assisted by private benefactors and a grant from the Ecclesiastical Commissioners.

## CONDITION OF THE POLICE COURTS.

In the police-courts of the metropolis, which day after day are crowded, may be noticed examples of the dangerous classes who are to be met with in the dismal and neglected neighbourhoods of London, but who, except in troubled times, are but little known to the more prosperous inhabitants.

Terrible are some of the countenances which may be seen, and so great and singular is the contrast, that the skilled painter might here form impressive pictures. In the waiting-rooms, most of them had in their sanitary arrangements, may be observed all grades of people. Some of these courts are so unwholesome in their arrangements that they cannot fail to shorten the days of those whose duty it is to be in constant attendance there, and are most pernicious to those who have occasionally business to transact. It is singular that, in those places where the law is generally well administered, such ill arrangements should be allowed.

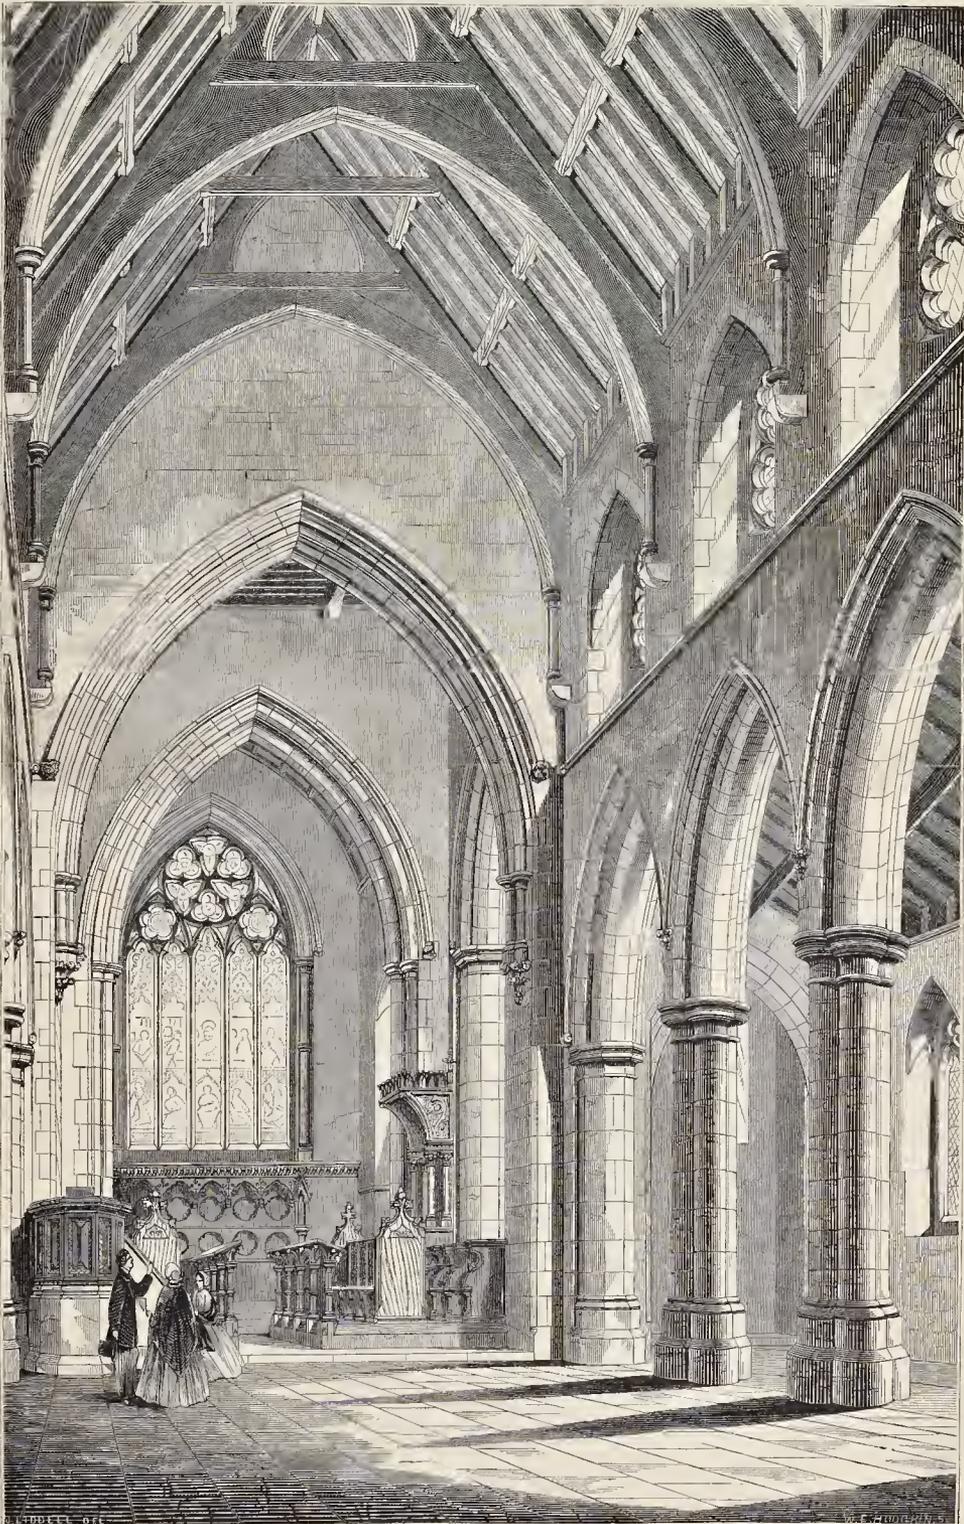

In Clerkenwell Court, a place of but recent erection, striking defects may be noted. In the waiting-room, which is often densely crowded on a hot summer's day, the most simple means of ventilation are neglected. As such a large number of people are often kept waiting here sometimes for hours, there should be, besides

the windows, an opening into the chimney, near the roof; and, as the door-way is usually blocked up by persons, there should be another opening above the door. It might be thought that the fireplace would help the ventilation; but, strange to say, the register of the stove is carefully closed; at least it was when we looked at it.

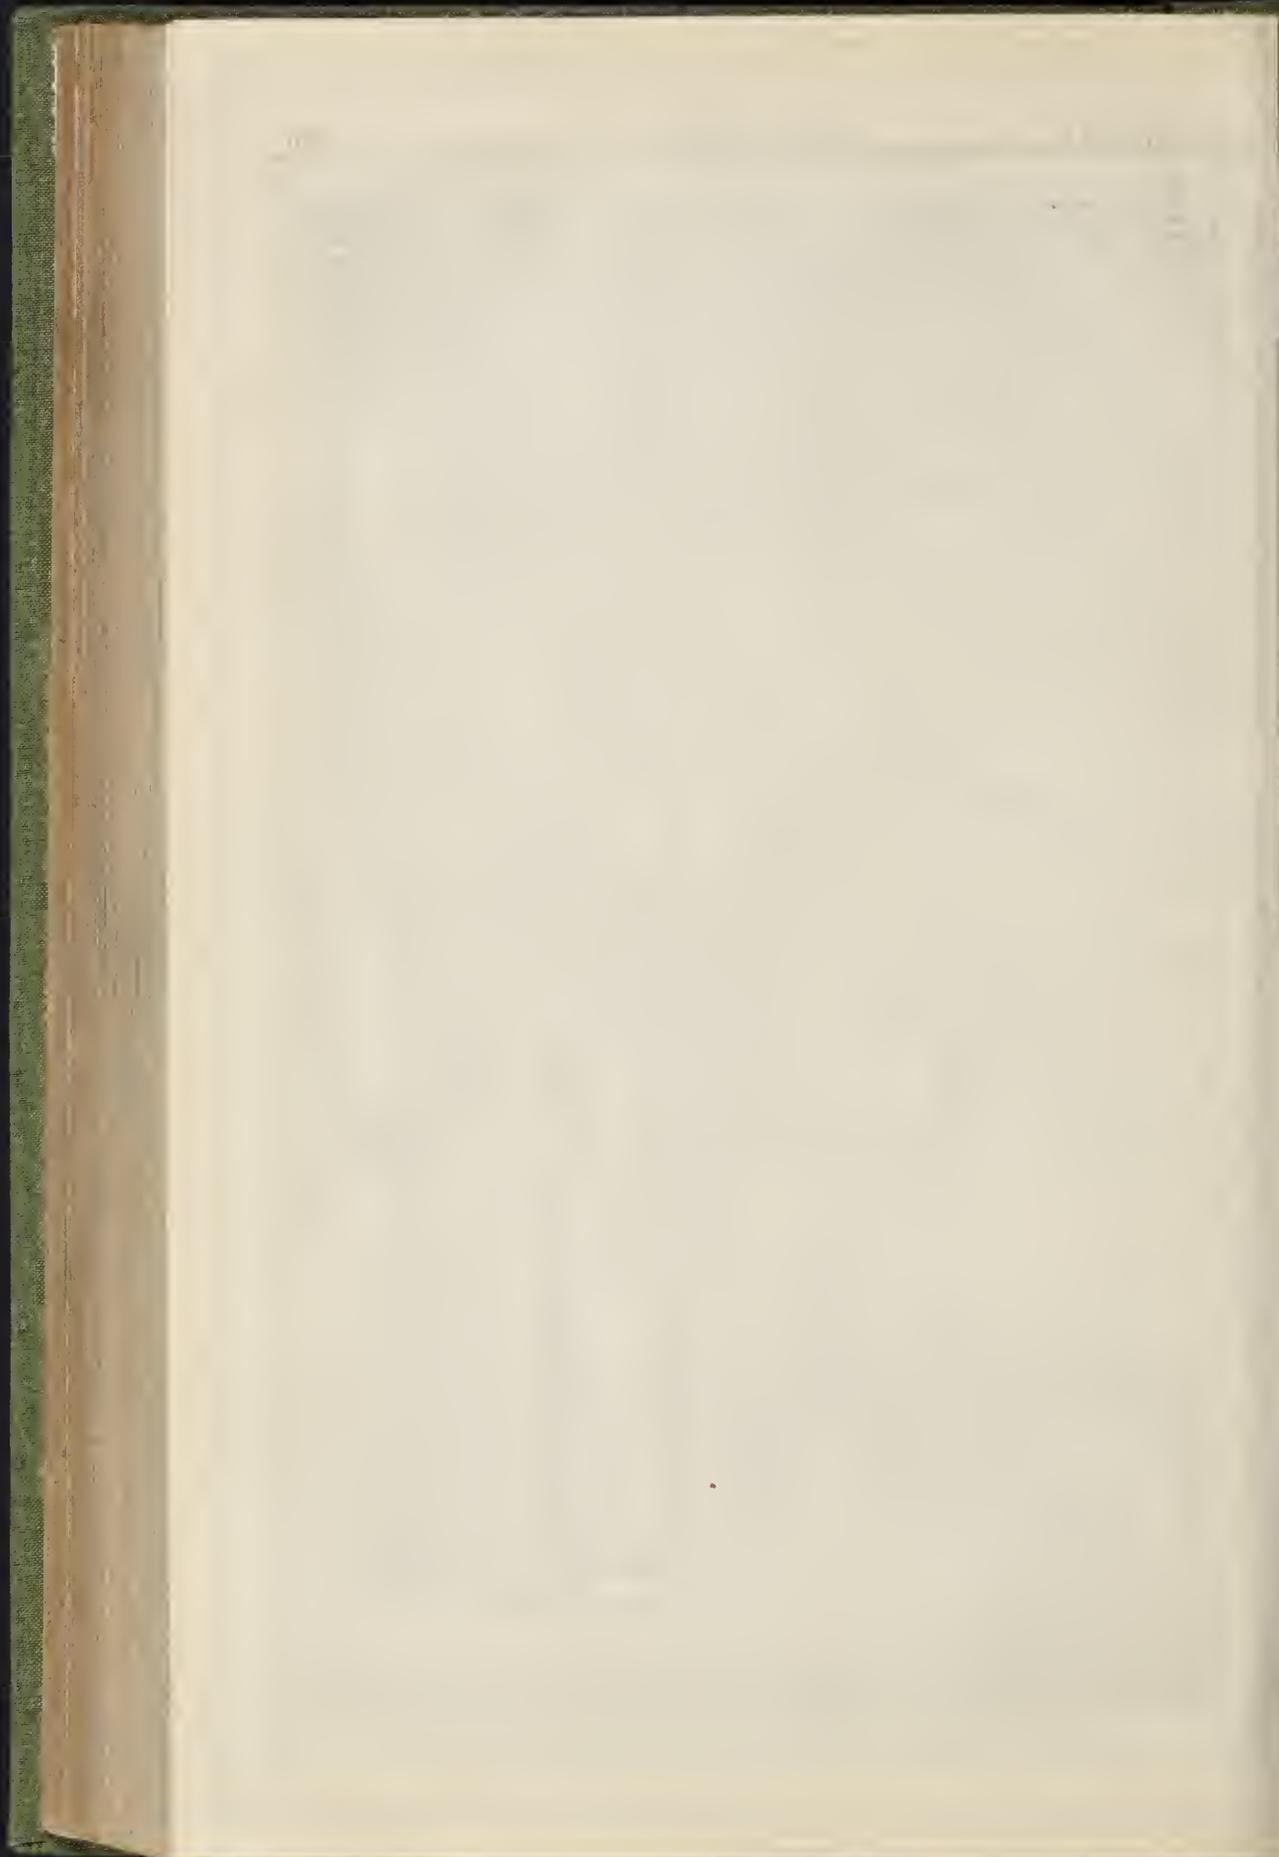

Here were sergeants of the useful sanitary portion of the police, who might give a beneficial hint in such cases. In the magistrate's private room and some of the other offices leading from the long passage which stretches to the court, a little care would improve the ventilation. At the further end of the passage mentioned there is a door, which, during the most busy part of the day, is kept closed. When last there, notwithstanding that the windows which range along one side were open, from the want of vent, at and beyond the door we found the atmosphere stagnant and oppressive. In the seats were women and children, and the place was thronged with other persons who were waiting as witnesses, or had been summoned for other purposes.

Persons unaccustomed to such places complain of the effect which the heavily-loaded air has upon the spirits. Children either doze into an unnatural kind of sleep, or become fractious; and doubtless, besides the inconvenience at the moment, future damage is done. The court here is of fair proportions, and well lighted; but, as we have said, there are needed further means to promote the circulation of air, perhaps more particularly in the winter time, when the windows are kept closed, than in the summer.

In the Guildhall Police-court, which has been altered, the arrangements are now very good. A large space has been provided for the accommodation of the public. The room is large, and the ventilation well managed. This now contrasts agreeably with the accommodation in the Courts of Exchequer, &c., near the Guildhall, and the Lord Mayor's Court at the Mansion House. The latter is even worse than Bow-street, and calls loudly for great improvement.

INTERIOR OF KILMORE CATHEDRAL.—MR. WILLIAM SLATER, ARCHITECT.

## ARCHITECTURAL PHOTOGRAPHS.

MESSRS. THOMPSON & Co., of Pall-mall, propose to publish a series of Architectural Photographs, on the 1st and 15th of each month. They profess that they intend to issue only first-class, carefully-printed, impressions, of really good and interesting subjects, at an unusually low price; and they have engaged the co-operation of Mr. F. Bedford, by whom all the photographs will be taken.

They propose to include, in the series, "Illustrations of Medieval Ecclesiastical Architecture—Exteriors and Interiors; Mural, Monumental, and other Sculpture; choice or remarkable examples of Civic and Domestic Architecture; Picturesque Ruins, and various other noteworthy subjects of a more or less rigidly technical character, interesting to architects, artists, archaeologists, literati, and persons of taste generally."

Each view is to be 11½ inches by 9½ inches, mounted on board, 18 inches by 14 inches, and singly will be sold for 6s.; to half-yearly subscribers, each will cost 5s.; and to yearly subscribers, only 4s. 4d.

We have before us half a dozen of the photographs prepared for issue, including an excellent view of Lichfield Cathedral (and giving the whole height of the spire); the Tower of Wrexham Church; Roublia's Monument to Mrs. Myddleton (not a wise choice); and the monument erected to the memory of the late Venerable Archdeacon Raikes, in Chester Cemetery, from the design of Mr. Penson. Mr. Bedford's name gives sufficient assurance that the photographs will be good as photographs. Everything will depend on the taste and tact employed in the selection of subjects.

## PARIS.

THE deep foundations that are being taken out, in order to continue La Rue des Halles on the site of the ancient market-place, bring to light, every day, a large quantity of human bones, belonging to the cemetery of the Innocents, and which have been carefully collected for re-interment. Now situated in the centre of Paris, the cemetery of the Innocents was primitively established outside the boundary of the town, between the two bourgs of Saint Germain-le-Neuf and Saint Germain-le-Vieux, the Beau-Bourg, and the Bourg l'Abbé, near one of the north of Paris gates, at the junction of the Saint Denis and Montmartre roads.

From the time that Philippe-August had it properly enclosed until its suppression as a burial-ground in 1785, it never ceased to receive funerals from twenty different parishes. The number of persons buried increased extraordinarily every year. The last grave-digger, Nicolas Poutrain, within the space of thirty years, had laid down to rest, according to his notes, no less than ninety thousand human beings. Thus, the number must have been about 3,000 each year, most of whose remains were heaped up in a common grave from 5 to 6 metres deep. It has been estimated that as many as 1,200,000 were interred in this cemetery from 1186 to 1785, or within about 600 years.

The fatal incidents which have occurred from time to time during the last century, in different quarters surrounding the cemetery of the Innocents; the complaints of the inhabitants, who attributed to this focus of putridity the fetid state of the well water; and the disappearance of generations by result of fever from the above emanations, called the attention of the authorities; and the Council of State, by its decree of the 9th of November, 1785, pronounced the suppression of the cemetery of the Innocents. The ancient quarries situated under the plain of Mont Souris, at a place called the Tombe Isoire, appeared the most convenient for the establishment of a subterranean cemetery. Thus originated the catacombs of Paris, which became the depository of the bones of all the churchyards of the capital, not far from the new little square of the Halles, where the restored and repaired fountain of Jean Goujon refreshes the verdure.

A steam fire-engine was tried in the Champs Elysees a few days ago. Placed in communication with one of the water-cocks of the grand avenue, it threw a jet higher than the roof of the Palais de l'Industrie. The advantages of such a machine are incalculable, both from the quantity of water and the force of projection.

The works of the tower in course of construction between the Church of Saint-Germain-l'Auxerrois and the Marée of the first arrondissement are drawing to a close. Already, notwithstanding the surrounding scaffolding, one can form an idea of

the effect of this structure, whose height is not less than 40 metres. It stands on a square base 7 metres on each side, the faces being pierced by trilobed ogival windows. Hexagonal counterforts or buttresses, separated by arches, flank the upper story, and a gallery with open work balustrade runs round the higher story, which is of octagonal shape. Statues of saints and kings will be placed on the different stories, and they are now receiving the finishing touch for the statuary.

The fountain of St. Michel is nearly finished: the bronze statues of the cardinal Virtues have been put in place. These statues, nearly 3 metres high, stand on capitals of white marble, supported by four columns of red Languedoc marble, and placed in pairs on each side of the central niche, to be occupied by the group of Saint Michel, which has been already cast, and is being cleaned up. The two stone figures of the upper façade,—Power and Moderation,—are completely terminated, as are also the different bas-reliefs, bronze shields, marble tablets, and other sculptures and ornaments which enter into the composition of this work. Two enormous eagles, of hammered lead, are being put up at the angles of the pediment, to whose ornamentation they will add, and at the same time mask the house against which the fountain is reared. A number of carvers are finishing off the marble fountain in which the waters are to play on the 15th inst., the *file* of the Emperor. On this occasion the scaffolding and canvass will be removed, and the public will be able to gaze upon this important public work, destined to mark the entrance of the Boulevard de Sebastopol on the left bank of the Seine.

The works of the Cathedral of Notre Dame are drawing to a close. New statues have been placed in the vacant niches of the *Galerie des rois*, on the west front; and in a few days the twenty-eight niches which compose this group will be completed. An immense scaffolding covers, at present, the southern façade of the transept, by means of which the last finishing work will be given to this important restoration. The grand rose on this side is shortly to be demolished and reconstructed, on account of its dilapidated state: all the portions are ready for putting up, so that much time will not be lost. The new central spire, almost clear of scaffolding, now appears with all its elaborate ornamental work. The plumbers are putting the last touch to the lead-work of the base, also to the ornamental ridge fret-work of the roof of the nave. Before the year is out the cathedral will be finished and given up to the parochial authorities.

## ART AND RECREATION IN THE COMMONS.

IN course of an incidental discussion on the National Gallery last week in the House of Commons it was intimated, on the part of the Government, that they approved of Mr. Pennebroke's plan for a new gallery in preference to Captain Fowke's for an alteration of the present building, even although the latter would only cost from 30,000l. to 50,000l., while the former would cost probably 200,000l. Captain Fowke's plan, it was thought, was either too extensive for a mere alteration, or not extensive enough. In course of the discussion, Lord Palmerston said it was desirable, if they could, to make some final and permanent arrangement, to provide for the whole of this subject. The question came to this, whether, by the outlay of some small sum for a short time to come, upon the present building in Trafalgar-square, the immediate want could be provided for, so as to render it unnecessary to embark upon the large expenditure which would be necessary in order to build a new National Gallery on the site of Burlington House. As the matter must come forward again on a future occasion, he would simply point out that that would be the question which would then have to be discussed. In reply to a question put by Mr. Coningham, Lord Palmerston said that in the belief that Sir C. Eastlake was a most proper person for the office of director of the National Gallery, he had recommended her Majesty to re-appoint him, and he had been re-appointed accordingly.

On the supply question of a vote of 100,400l. (which was finally granted) to defray the expenses of the royal pleasure-grounds and parks, a discussion ensued of a miscellaneous character as to the parks, the new ride, &c. Lord John Manners said, as to the ride, the argument in favour of the riding part of the public might be carried too far, because a far greater part of the public rode in cabs and carriages than on horseback, and, to be consistent, the right hon. gentleman (Mr. Cowper) should throw open the road to carriages (omitting

buses and cabs inclusive?) as well as to people on horseback.

With regard to the works at the Serpentine, Mr. Cowper said he had, in conformity with Mr. Hawksley's recommendation, had a well sunk for the purpose of providing fresh water, as he believed the principal evil of the present state of the water arose from stagnation. As to any excess in the expenditure, he had Mr. Hawksley's assurance that it would not exceed the sum of 17,000l. There would be a power of supplying the round pond in front of Kensington-gardens from the well in question, instead of by the water companies.

With respect to the proposed museum in Victoria-park, he stated that the Board of Works had no power to erect any such building, and he was simply asked to do that which he had no power to do.

As to Battersea-park, there was great want of water there, and it was proved to be more economical to have a well sunk, than to take a supply from the water companies. It would cost just as much money to get water from the river as from a well; and he thought that if Thames water were used in the gardens, Battersea-park was likely to be a very disagreeable place. Mr. Joseph Locke thought the economy of sinking the well so near the Thames was very doubtful, and ought to be more clearly shown. Mr. Cowper explained that sinking the well at Battersea-park would save an annual expense of 300l. for watering the gardens, for water for the lodges, &c. Mr. John Locke wished to know why no progress had been made in letting the ground in the neighbourhood of Battersea-park for building purposes. He had no doubt that a great check upon traffic, not only over Chelsea-bridge, but over Southwark-bridge, was owing to the existing tolls. As a matter of economy, it was worth the while of the Government to consider this question of payment of the toll at Chelsea-bridge (particularly as the new railway bridge was nearly completed), in order to make the public property at Battersea as remunerative as possible.

Lord J. Manners said, with regard to the metropolitan parks generally, that, when the parks were established, the metropolis had no special voice in the matter. The legislature made them, and consequently the public, he thought, ought to pay for them.

## THE TOWERS AND SPIRES OF LONDON.

THE churches of London, which give so much beauty to every view of the metropolis, and have, moreover, so many valuable and interesting associations, are threatened by the "Union of Benefices Bill," now before the House of Commons. The Royal Institute of British Architects, as we have already mentioned, have sought, even if they could not save the churches, to obtain protection for the towers and steeples; and, at their inspiration, Mr. Cavendish Bentinck proposed to the House in Committee, on the 8th, to add these words:—

"Provided always, that nothing in this Act contained shall authorize the pulling down the churches of Saint Stephen, Walbrook; Saint Martin, Ludgate; Saint Peter, Cornhill; and Saint Swithun, Cannon-street; or the towers and steeples of any of the churches within the City of London, and specified in the schedule to this Act annexed."

Further, to insert the following clause:—

"In case any of the churches specified in the schedule to this Act annexed be pulled down, the towers or steeples of which shall, under the provisions of this Act, be required to be left, every such tower or steeple shall be considered to form part of the church of the united parishes, and be repaired and sustained in the same manner as such united parish church is repaired and sustained."

That part of the first clause which defends the four churches specially named was carried, but the remainder was not; and some further efforts to preserve our steeples are necessary.

On Monday last a meeting was held on the top of St. Paul's; Mr. Godwin (in the chair), Professor Donaldson, Mr. Norton, Mr. Penrose, Mr. Porter, and Mr. T. Hayter Lewis being present; when the various towers and steeples were examined, with the view of saying which should be preserved. The sight was wonderful, and those present found few spires to the destruction of which they were willing to assent. The following memorial was agreed on; and, being afterwards signed by the president of the Institute and such members of the council as could be found, was presented on Tuesday night:—

"To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned President and Members of the Council of the Institute of British Architects, sheweth,—That your petitioners have learnt with great satisfaction that on the recent discussion in your honourable House of the Union of Benefices Bill, the

church of St. Stephen's, Wallbrook, and three other of the churches built by Sir Christopher Wren, celebrated for their architecture, were expressly exempted from liability to be destroyed under the operation of the proposed Act.

Your petitioners, as architects, beg respectfully to impress upon your honourable House that the appearance and beauty of the city of London arise chiefly from the highly picturesque and beautiful towers and steeples built by Sir Christopher Wren and other architects, which for variety and excellence of architecture are not surpassed by the celebrated campaniles of foreign cities, and which render the aspect of the City from the river and bridges, and other commanding situations, one of the most striking objects in the world, and a just pride to the country and the metropolis.

The City is chiefly composed of brick mercantile buildings of little architectural character, and the loss of some of the towers and steeples which might be of little importance, would detract greatly from the general effect.

Your petitioners beg respectfully to submit, that at a time when your honourable House is voting large sums for the erection of public buildings in the metropolis, it would be a great loss to destroy existing structures of great architectural merit.

Your petitioners trust your honourable House will add to the list of churches already protected some of the other towers and steeples in the city of London.

Your petitioners, therefore, humbly pray your honourable House that the following towers and steeples be added to those exempted from destruction in the Bill before your honourable House, namely:—Saint Alban's, Wood-street; Allhallows, Bread-street; Allhallows, Lombard-street; Allhallows, Thames-street; Saint Andrew's, Holborn; Saint Andrew's, Watling-street; Saint Augustin's, Watling-street; Saint Bartholomew's the Great; Saint Bene't's, Thanes-street; Saint Bride's, Fleet-street; Christchurch, Newgate-street; Saint Dunin's Backchurch; Saint Dunstan's in the East; Saint Dunstan's in the West; Saint Edmund the King's; Saint George's, Botolph-lane; Saint Giles's, Cripplegate; Saint James's, Giltie-hill; Saint Lawrence's, Jewry; Saint Magnus's, London-bridge; Saint Margaret's, Lothbury; Saint Margaret Patten's; Saint Mary's, Abchurch; St. Mary's, Aldermary; Saint Mary's Bow; Saint Mary's Somerset; Saint Mary Magdalen's, Old Fish-street-hill; Saint Michael's, Cornhill; Saint Michael's, Queenhithe; Saint Michael's Royal; Saint Mildred's, Bread-street; Saint Mildred's, Poultry; Saint Sepulchre's; Saint Yves's, Foster-lane. And your petitioners will ever pray," &c.

#### THE MANUFACTURE OF PAVING TILES.

BEFORE conducting the members of the British Archaeological Association over the works at Benthall, as mentioned in our list, Mr. Maw explained the nature of the several processes. He said,—The manufacture consists of two distinct branches, which are essentially different in nearly the whole of their processes. Firstly, the making of encaustic tiles, or those inlaid with a pattern of two colours, which is the re-production of an art limited in Medieval times to church decorations; but now having a much more extended application. Secondly, the manufacture of plain tiles, and tesserae of a uniform colour used in the construction of geometrical mosaic pavements, similar in character to those found in the Medieval buildings in Italy; also mosaic and tessellated mosaics, similar to those occurring in Pompeii, and almost all Roman remains in this country and on the Continent. The materials employed in both processes are nearly identical, and consist for the most part of the clays and marls of the Shropshire coal-measures. These, without any colouring matter, together with clays from the south of England, form the red, buff, and fawn-coloured tiles; and, in connection with different proportions of oxides of iron and manganese, the black chocolate and grey tiles. The white and all the richer coloured tiles and tesserae are formed of a species of porcelain or Parian, the white left uncoloured, and the blues and greens coloured with oxides of chrome and cobalt. The preparation of what is technically termed the body of the tile, which is the first process in the order of manufacture, consists in mixing the constituent clays and other materials with water, and commingling and purifying by passing them in a semi-liquid state through a sieve made of the finest lawn, containing between 10,000 and 15,000 perforations to the square inch. All the coarse particles are by this means removed, and the texture of the clay rendered perfectly fine and even, as well as greatly adding to the brilliancy of the colour. The semi-liquid purified clay is then dried out what is termed the slip-kiln,—if for the manufacture of encaustic or inlaid tiles, to a plastic state; or, for plain or self-coloured tiles, perfectly dry and hard. It is at this point that the two processes diverge and are essentially different. There is also some slight difference in the proportions of the materials used in their composition, but this need not be more than noticed. The encaustic tiles are made of plastic clay; the pattern impressed from plaster of France moulds, and the indented surface filled in with different coloured clays in a semi-liquid state. The tile is then allowed to dry gradually to the consistency of wax, and the inlaid patterns developed by scraping off the superfluous clay. For the manufacture of the plain tiles, of one colour throughout, the material, which has been dried quite hard on the slip-kiln, passes through a

machine which grinds it to powder ready for moulding, which is performed in steel dies under very powerful screw presses, some of which work to a pressure of 30 tons. Both kinds of tiles, after having been formed, are placed for ten days or a fortnight in the drying stove, an apartment heated by fires up to 80 or 90 degrees, and when the whole of the moisture is driven out, they are ready for the burning. This is performed in large kilns, the tiles being stacked in fire-clay boxes, termed saggars. The actual burning occupies four days and nights, during which time they are gradually brought up to white heat by the consumption of from 18 to 20 tons of coals; and during another four days and nights are as gradually cooled, occupying the kiln in a hot state for eight days and nights. Great care is necessary in this part of the process to give the correct amount of heat throughout the kiln: if the firing is not carried sufficiently far the tiles are soft and irregular in colour, which necessitates a repetition of the process; and, if carried beyond a certain point, they gradually decrease in size. They are judged of by long narrow tiles termed "proofs," from time to time drawn out of the kilns during the firing. The whole contents of the kiln may be spoiled in a very few minutes. The great bulk of the tiles are employed in the unglazed or bisquit state, the manufacture of which is complete with the burning. They have merely to be drawn from the kiln; and, as they somewhat vary in size and colour, depending upon the precise extent to which the firing has been carried, have to be passed through a gauge, which divides all the larger forms into four distinct sizes. The process of glazing or enamelling is performed by applying a thin coat of paste, made by vitrifying materials on the tiles that have been previously burned, which is converted into a glaze by subjecting to a low red heat in a small furnace termed the enamelling kiln. Glazed tiles are principally employed for both linings and the sides and backs of fire-pieces, also for pavement in combination with unglazed tiles, with which they form very pleasing contrasts. To those who are interested in statistics, I may mention that we consume every year about 1,500 tons of coal, and from 1,100 to 1,200 tons of clay, and various materials entering into the composition of the tiles, out of which between 20,000 and 30,000 square yards of tiles, tesserae, and mosaics are manufactured, composed of 700 or 800 distinct shapes, sizes, and colours. About half of these are laid by the paviors in our own and our agents' employment. The principal use of our manufacture is for the entrance-halls and corridors of private houses and public buildings; also for conservatories, verandahs, dairies, and internal and external wall decorations. A considerable proportion is sent to America, India, and the Colonies. Among the principal works we have executed, or have in hand abroad, I may mention the pavements of the entrance-hall of the new University of Toronto; also nearly the whole of Osgoode Hall, Toronto, laid by our own men sent out for the purpose; the entrance-hall of the Hong Kong Club; Deck House, and other parts of the steam yacht *Said*, for the Pash of Egypt; Jessore Church, Bengal; the ground-floor of the new General Post-Office, Calcutta; and the Cathedral of the Spanish town, Jamaica.

#### LIFE AND DEATH.

THE Registrar-General's annual report for 1858, referring first, not to England alone, but to Great Britain, states that its estimated population in the middle of 1858 was 22,626,331, and the excess of births over deaths in the year, 246,458. 759,676 children were born alive, 351,316 persons were married, and 513,188 died; so that on an average, upon every day in the year, 2,080 children were born, 962 persons married, and 1,405 died, leaving a gain of 675 as the result of the day. The birth rate for Great Britain was 33·67 to 1,000 living, the death rate 22·68, the marriage rate (persons married) 15·52. For easy recollection it may be noted that rather more than twice as many are born in a year as are married, and the deaths should not be so high as married between those two numbers. To 1,000 people living in the two countries the births in the year were thirty-four in Great Britain, twenty-seven in France—a very striking difference; the deaths twenty-three in Great Britain, twenty-four in France; the persons married 15·5 in Great Britain, 16·9 in France. In Scotland the marriages, if all registered, were not so numerous as in England; the births were almost exactly at the same rate; but the percentage of deaths in Scotland was only 2·047, in England 2·303. Turning now to Eng-

land and Wales only, we learn that to every 1,000 girls 1,045 boys were born, and 102 males died to every 100 females, the average of twenty-one years being 103; but there are more females living in England than males, and out of equal numbers living 105 males died to every 100 females, the average being 107. The births are always most numerous in the first half of the year: in 1858 they were as 2,091 to 1,909 in the two half-years. The mortality of the year was high. The deaths in the chief towns were at the rate of 2·655; in the country districts, 2·006. The deaths registered in the three months that ended the 30th June, were 110,578,—a larger number than was returned in any previous June quarter (1848-59). The annual rate of mortality last quarter was 2·228 per cent. of the population, while the average of ten previous springs was 2·195. It is a remarkable and interesting fact that, if 2,000,000 of acres on which the chief towns of England are situated be distinguished from the remaining 35,000,000 which hold small towns and country parishes, it is found that the rate of mortality on the former (2·305 per cent. per annum) was below the average of last quarter, whereas on the latter the rate, 2·155, was above the average. The average rates were respectively, 2·346 and 2·028. It cannot be questioned that large populations have even now some advantages of a nature favourable to health which villages do not possess. The highest attainable health is probably to be sought in a happy combination of both states—*rus in urbe*. In London 14,894 persons died in the quarter. The metropolis lost about a thousand more lives than in the healthier spring of 1859. Pulmonary complaints were very fatal. The mortality from zymotic diseases generally was comparatively low: in this class measles chiefly prevailed.

#### DRINKING-FOUNTAIN COMPETITION, BOSTON.

TWENTY-TWO designs were submitted in competition for the above, when that by Mr. Sherwin, of Liverpool, obtained the first place, and that by Mr. Charles Phipps, of Bath, the second. Both are Gothic designs.

#### HEREFORD CLOCK TOWER COMPETITION.

THE Hereford Town Council advertised for designs for a Clock Tower and Clock-Tower Entrance. Fifty-eight architects have sent in designs, and these are now being exhibited in the Shire-hall. The decision is to be announced on the 6th of next month.

#### SOUTHMOLTON MARKET COMPETITION.

THE first prize of 25*l.* was awarded to Mr. W. T. Cross, of Exeter; and the second prize to Messrs. Waters, of London and Exeter. Mr. Cross was appointed architect for the erection of the new market, at an estimated cost of 3,000*l.*

#### SCULPTURE AND GOTHIC ARCHITECTURE.

At the *conversations* of the Birmingham Archaeological Association, held in King Edward VI.'s School-room, on the 7th inst. Mr. Chamberlain read a paper on this subject. He said that in the old Gothic times, sculpture and sculptured decoration were of many different kinds, sometimes simple and cheap, sometimes elaborate and costly, now conventional and then natural, now roughly hewn and then smoothly finished, as circumstances might dictate; but that in all good Gothic work sculptured decoration of some kind was present, and that in the best periods it was used most profusely and lavishly. In the minor works of the period as much was given as the builders could afford; but, in the cathedrals and other large works, every feature, external or internal, was wrought by the agency of the chisel and mallet into forms of great and lasting beauty. Although many styles had used sculpture profusely, in no other than the Gothic had it been trusted to so wholly or relied upon so thoroughly. It had commenced with perfectly simple forms and conventional methods of treatment, and had worked its way up to the expression of the natural grace and beauty of leaves and flowers, of the human form in the added majesty of clothing, and the human countenance. The artists who produced this sculpture also knew thoroughly well where it should be placed, and where it would show to the greatest advantage, so that by this means also this work possessed a

charm which modern work frequently is wanting in. Their practice was not to put a public building at one end of a street and a statue at another, but they made their public buildings eloquent with the statues of the saint, the warrior, and the statesman, and thus secured to each part the dignity and the excellence of fellowship. All Gothic sculpture commenced in the decoration of the constructional features of the building, and forms which, by superficial observers, are supposed to be merely ornamental, are full of actual use and real service. The law of Gothic life was, first, truth and use; and then beauty. All that the architect needed in the way of size or of strength, every feature of construction required by his building, was provided first and chief of all; but he did not end his labour there, but by his thoughtfulness and care these necessities of construction were made, each in its degree, beautiful; and, while the usefulness of the building was unimpaired and its strength undiminished, the required beauty was obtained, to the building's great and lasting glory. The Gothic architects allowed the workmen an amount of liberty which was never tolerated in the Classic styles; both the Greek and the Gothic builders knew that only one man here and there was compelled to produce the best work, but that there were a host of men who could produce the minor forms of decoration. The Gothic architect eagerly accepted their help: he asked each man to produce the best work possible to him; and only reserved to himself the right of deciding where it should be placed. The Greek architect, on the other hand, brought down his own ideas to what he conceived as the level of average ability. He set before the workmen some few abstract forms, some few simple arrangements of conventional line, and compelled them to produce these low forms of beauty with mechanical perfectness, no deviation being permitted from the decreed standard. The law of the Greek was copyism and unholly obedience. The law of the Mediaevalist was liberty and law. Consequently, in the best Gothic work the grand spectacle was exhibited of many differing minds, and much varying power, all working harmoniously together, to produce a given and worthy end. Every building became a book, stored with all kinds of lore for all degrees of men; full of all sorts of truths and lessons; written ever with the records of noble and heroic deeds; and eloquent with the great truths of Scripture history. Those who decried this style have found fault with it as being barbarous; but they would see less to blame if they considered the matter more deeply. One part of the grotesqueness was attributable to the state of general education of the people: these buildings were meant to be understood by them, and the grotesque sculpture was exactly fitted to awaken their inquiries and to cause them to think for themselves. One other great part was attributable to the fact that the spirit of the style encouraged rough village masons and carpenters to attempt methods of ornamentation above the mechanical powers of production which they had acquired; but that, however rough and rude their efforts might be, it was better that they thought about leaves and flowers, about saints and angels, than if they had contented themselves, as in the modern classic days, with cutting triglyphs and sinking square channels round stones. The spirit of Gothic architecture always remained the same: the outward characteristics of the style changed rightly with each century. The Middle Ages were the days of Ecclesiastical architecture. This was the period of Domestic architecture. Yet in this, as in the old styles, sculpture ought to form a chief method of decoration. The union of architecture and sculpture was again needed: each was feeble and weak without the other; and true architecture and good sculpture were alike impossible, until the architect and sculptor were really one, and their work recognized as being in all essentials the same. The revival of Gothic architecture became every day more sure in its success, but it still needed the earnest and hearty co-operation of all who love art. Those who oppose barely seem to know what they are doing: they are opposing a style in which progress is possible, and success is sure—a style which can use all the powers of man, which can find room for the most humble work, and which thankfully receives the highest; while the style which they would propose in its stead was weighed long ago in the balance and found wanting,—a style where success means degradation, and whose prosperity entails upon its followers that worst of all servitude—the slavery of the will and the mind.

At the same meeting Sir Francis Scott made

some observations on Limoges enamels (of which specimens were exhibited); and Mr. T. Bunce read a paper, entitled "A Few Words about Antiquaries."

LEEDS SCHOOL OF ART.

A GREAT effort is now being made to raise funds for a new school of art in Leeds. It is to form one wing of the projected Mechanics' Institution, concerning which an advertisement to architects for plans recently appeared in our columns. Perhaps, in proportion to the size of the town, Leeds may at present be said to have the worst accommodation for a school of art of any town in England. Lord Palmerston has consented to preside at a meeting in October, at Leeds, to inaugurate the building scheme of the whole institution, and to bring its claims forcibly before the public. He will also be requested to distribute the medals to the successful students at the school of art. It is proposed to build the school of art wing first.

The increase of work in the latter shows how peremptorily additional accommodation is called for. We quote from the list of successful candidates at the late examination:—

Summary and Comparison of Results for Session ending 15th June, 1860.	
	1850. 1860.
Number of medals awarded.....	11 20
Passed senior examination.....	53 103
Passed junior examination.....	73 150
Elementary prizes.....	75 92

THE PUBLIC BATHS AND WASH-HOUSES OF THE METROPOLIS.

THIS movement progresses in a most satisfactory manner, and the accommodation provided in these places is appreciated by the class for which they were intended. In connection with some of the large swimming-baths, clubs have been formed, and skilful professors teach the useful art of swimming. This is a matter which has for long been too much neglected in the large towns of England, a fact which seems remarkable, when we consider how eminent this nation is as a maritime one.

From inquiries made, it seems that the number of bathers is constantly increasing. In this respect we are, however, only going back to a good practice of days gone by,—to the old Roman and Saxon times of England,—when the use of the bath was common. The wholesome custom, in the Mediaeval and more recent ages, went nearly out of use.

Buckland, in his "Curiosities of Natural History," remarks that the English people have not been for so very long a bathing people, so that bathing-machines on the sea-shore are a comparatively recent invention. The sea was only considered fit for the purposes of commerce, and the coast as the residence of merchants and fishermen.

Bath, and some other places famous for mineral waters, were in use. More than a hundred years ago a physician named Russell wrote a book on the advantages of washing his body in the sea. From that time the pleasant nooks along the British coast have been becoming more and more in request. Brighton has risen to a vast population, and places which were formerly desert spots are now yearly resorted to by thousands for health and pleasure.

THE VICTORIAN TRADES' HALL AND LITERARY INSTITUTE, MELBOURNE.

AN inaugural address, for 1860, was delivered by Mr. John Millar, Honorary Architect to the Institute, on 24th May last, on the presentation of a design by him, gratis, for a permanent hall, to be erected on the Government gift of an acre of ground in the centre of the city for a site, and estimated to be worth 10,000*l*. The extreme measurements of the building will be 340 feet by 135 feet. The site is 400 by 250 feet, bounded on one side by Victoria-street, and on the other by Lygon-street. The building will be placed in the centre of the ground, isolated, and elevated upon a stylobate of 7½ feet above the level of the street, and approached from both fronts by deep flights of steps of 40 feet each in extent. The style will be Greek of the Periclean age, the Greek being regarded by the architect as more appropriate to the climate than Old English, which he should have otherwise, he says, preferred. The great central public hall of the edifice will be capable of accommodating 4,500 persons, and measures 150 feet by 90 feet wide, and 75 feet in height, including the galleries. Various committee-rooms

for the separate trades surround the hall, and there will be a colonnade 130 feet by 20 feet, running parallel with these and the central hall. There will also be a lecture hall, 80 feet in diameter, class-rooms, news-room, and various other accommodation, besides a basement story for stores, &c. The portico is flanked by a campanile tower, 80 feet in height. Nothing is said of the probable or estimated cost. In his address, Mr. Millar particularized the following as a few of the buildings in progress of erection at Melbourne:—

Senate House.....	at a cost of £250,000
Post Office.....	100,000
Custom House.....	100,000
Treasury.....	100,000
Chief Secretary's Office.....	150,000
Free Public Library.....	200,000
University.....	100,000

all connected with the State; besides the numerous banking establishments, including the Savings Bank, and many others, at a cost, he says, far exceeding a million of money.

BATTLE-FIELD CHURCH, NEAR SHREWSBURY.

THE attention of the public having been directed to this interesting relic of past days, by the visit of the archaeological congress to the spot, let us hope some advantage will follow.

Here, where Sir John Falstaff fought a whole hour by Shrewsbury clock—if he might he believed,—this church was erected in memory of the dead who fell in a great national struggle. The building, moreover, is a very good example of a certain style of English architecture. This ancient church—in every way so interesting—has since stated to fall into decay, as we some time ago stated, a large portion of the roof is gone; and, if efforts are not made, the place will become a complete ruin. The population of this parish is very small, and the means available quite insufficient for the restoration of the building.

Some time since it was said that the owner of the domain on which stands the church, being friendly to English sports,—hunting, and others,—it was proposed in his honour to restore it; it seems, however, that a present of plate or something of the kind was accepted instead. The gentlemen of Shropshire are generally remarkable for both patriotism and intelligence; and it may be hoped, therefore, that Battle-field Church will not be allowed to perish.

SURVEYORS AND THE APPRAISERS' LICENSE.

WE were requested last week to publish the following correspondence, but preferred making some inquiry first:—

Sir,—I have to acknowledge the receipt of your favour of 21st instant, and beg to thank the Board for their courtesy.

You say "Every person who exercises the calling or occupation of an appraiser, and who, for or in execution of any gain, fee, or reward, makes any appraisal, or valuation chargeable by law with any stamp duty, requires a license," &c.

Permit me to trespass a little further, in order that I may be informed what is an appraisal or valuation chargeable by law with any stamp duty. I have applied to my legal adviser, who is unable to inform me; and as I am desirous of fully complying with all proper legal requisitions, I should feel greatly obliged by a definite explanation of the terms employed.

For example: If I, in the course of my professional practice, prepare a valuation, that is, a report of my opinion of the value of any property for sale, mortgage, or probate, is a document of that kind liable to stamp duty? If, under ordinary practice, such a document is exempt from duty, but when used in the Court of Chancery, for example, requires by the rules to be stamped subsequently to leaving my hands, ought I to be licensed before making an affidavit on plain paper, for the purpose of having my report so used?

Again: If, in my profession of an architect, I measure and value the materials and workmanship in any building, for the purpose of adjusting the settlement between the proprietor and the builder, ought I to take out a license before acting in that capacity—the documents in ordinary cases never being stamped at all? I am not aware that any court would require such documents to be stamped.

And again: If in a dispute between certain parties I am appointed a referee for the adjustment of their differences by a proper legal instrument, and in that capacity measure and value any artificer's work and material, or value any land or building, making my award upon a proper legal instrument, is it necessary that I should be licensed before acting in that capacity?

Hoping to be favoured with a reply to the foregoing inquiries, I remain, &c.

"Inland Revenue, Somerset House, London, W.C. 1st August, 1860.

Sir,—Referring to your further letter of the 23rd ult., I am directed to inform you that all appraisement or valuation of any estate or effects, real or personal, heritable or movable, or of any interest therein, or of the annual value thereof, or of any dilapidations or of any repairs wanted, or of the materials and labour used or to be used in any buildings, or of any artificers' work whatsoever, is liable to duty. I have also to state that an appraiser is liable to a

penalty of 5s. if he neglects to deliver to his employer, within fourteen days, a duly stamped appraisal.—I am, sir, your obedient servant.

(Signed) T. SARJENT.

It was held, at the Inland Revenue Office a few years ago, and correctly as it seems to us, that a license is not necessary for those who, acting for the builder, prepare his accounts. These are not "appraisements" requiring a stamp, but the tradesman's bills of charges, and the surveyor is simply his clerk for the time, so to speak.

#### A STATUE OF ROBERT STEPHENSON.

A MEETING of noblemen and gentlemen, friends of the late Mr. Robert Stephenson, M.P., was recently held at Fendall's Hotel, Westminster, for the purpose of taking into consideration the most appropriate mode of testifying, in a public manner, the general respect for his memory. Lord Lansdown was unanimously requested to take the chair. In the course of his address the chairman said he would suggest the memorial being a statue, and that application should be made to the Government for permission to place it within the area of St. Margaret's Gardens, Westminster, where, beside that of Brunel, on the way between the scenes of their professional labours, and of the parliamentary contests they had maintained, the effigies of the two men might stand as beacons of encouragement to the younger members of that profession to which great Britain owed so much of her present greatness and prosperity. Mr. Joseph Locke, M.P., proposed the first resolution, which was seconded by Lord Powis. Mr. Hawleshaw proposed the second resolution, seconded by Mr. Fowler; and the third resolution was moved by Mr. J. P. Gassiot, and seconded by the Hon. Robert Grimston. The resolutions were then unanimously passed: they are as follows:—1st. That this meeting, desiring to testify the universal respect entertained for the character of the late Mr. Robert Stephenson, M.P., proposes to erect a statue in his memory. 2nd. That subscription lists be opened for providing the necessary funds. 3rd. That the noblemen and gentlemen present be requested to act as a committee for carrying into effect the foregoing resolutions, with power to add to their number. Subscription lists were ordered to be opened at the banks of Messrs. Glyn, Mills, & Co., and Messrs. Coutts and Co., London; and Messrs. Hodgkin, Barrett, Pease, & Spence, Newcastle-upon-Tyne; and at the office of Mr. J. G. Parry and Mr. Charles Manby, the honorary secretaries, 24, Great George-street, Westminster.

#### THE DRINKING-FOUNTAIN MOVEMENT.

A FOUNTAIN of some cost has been erected by Messrs. Wills, Brothers, in the Strand, close to the Church of St. Mary-le-Strand, and nearly opposite Somerset House. The public are indebted for it to the liberality of Mr. Robert Haubury, M.P. The base of the fountain is composed of polished red granite, above which there are six bronzed pillars supporting a polished marble entablature, surmounted by a dome enriched with water plants, and over all a Cupid without wings or darts, bearing on his head a vase supposed to contain that fluid which the fountain is intended to supply. There is, or is to be, a lamp suspended from the dome. The water flows from two jets out of a bronzed vase in the centre of the fountain. On the east end of the fountain is inscribed:—"The gift of R. Haubury, esq., M.P.," and underneath, and elsewhere are various texts. We are forced to say that the details are very unsatisfactory.

#### SUPPLY TO DRINKING-FOUNTAINS.

RESPECTING the filters in street drinking-fountains, your correspondent justly points out the need of change or the necessity for improvements therein. I have, through practical experience whilst fitting up filters, for a considerable time past also felt convinced of the need of a change, and would therefore suggest the following remedy. In all the drinking-fountains which I have taken notice of, the following plan is carried out:—the water supplied by the company is first introduced to the filter, and, after passing through the best filtering substance or purifying process known, is immediately allowed to flow onward through several feet of metal pipe, pass brass taps, empty into metal cisterns with copper cock, then descend through smaller pipes, and is given out to the people warm in summer time, and generally impure.

I would suggest that in no case whatever should filtered water be allowed to come in contact with metal afterwards. There is no necessity; for, when

the water has once passed through a filter, it should flow on through glass tubes, earthenware pipes, or enamelled iron bore to the outlet. Such tube or pipe may be protected by passing through a pipe of larger diameter, or in some cases through solid stone, or even through the middle of an ice-bank, and thus effectually escape the heat of the sun. But if the filter is fixed in the proper place, which is as near as possible to the outlet, the water will be generally obtained, independently of other means, both pure and cold.

The expense of altering or removing the filters now in use or action would be trifling; and in those heretofore erected the cost would be much less than heretofore. The space required would be less also.

The friends and admirers of this drinking-fountain movement are greatly indebted for the information and suggestions given in the columns of the *Builder*.

WILLIAM EAST.

#### THE SIZE OF RAIN-WATER PIPES.

The formula  $400 a \sqrt{h} =$  discharge in cubic feet per minute, used by some writers, when applied to rain-water pipes leads to very erroneous results, being based upon the assumption that fluids follow nearly the same laws of gravity as solid bodies, which is true only so far as relates to velocity.

When the fluid falls in a continuous stream, the velocity multiplied by the sectional area of the column will be a constant quantity for all heights, the size of the stream diminishing as the velocity increases.

It therefore follows that the length of a rain-water pipe will not affect the discharge to any extent.

In calculating the following table, I have adopted the formula  $q = 5 \sqrt{h}$ ,  $d$  representing the diameter of the pipe in decimals of a foot, and  $q$  the quantity of water discharged in cubic feet per second.

It is applicable to all vertical pipes which receive their supply with little or no pressure or head.

Table showing the Discharge from vertical Rain-water Pipes, &c.

Diam. of stack in inches.	Discharge in cubic feet per second.	Discharge in cubic feet per minute.	Superficial feet of roof, age water pipe, required to lead the water from rainfall being at the rate of 1 inch in 240 per hour.	Diameter of pipe, required to lead the water from the stack in feet.
2	.057	3.42	2.449	3 inches.
2½	.099	5.943	4.279	4 "
3	.156	9.375	6.750	4 "
3½	.239	13.783	9.924	6 "
4	.321	19.250	13.860	6 "
4½	.431	25.834	18.500	6 "
5	.509	33.539	24.250	9 "
6	.711	42.965	30.719	9 "
6	.884	53.033	38.184	9 "

It will be seen from this table that, even in small pipes so placed, the capacity for discharging water is very considerable.

The stack pipes generally used are abundantly large, but the eaves gutters are frequently too small.

Eaves gutters should never be less in width or depth than twice the diameter of the stack pipe: the depth, however, should be reduced towards the end farthest from the pipe, so as to admit of a sufficient fall, the appearance presented by which might be concealed by having a fascia of uniform width cast on the face of the gutter.

J. T. HURST.

#### THE FIRST MAKER OF EARTHENWARE SEWER AND DRAIN PIPES.

In a recent number of your journal, under the above head, are some inquiries as to the comparative novelty in this country of earthenware socket-pipes. I beg to call your correspondent's attention to the following extracts from Heath's "Accounts of the Ancient and Present State of Ragland Castle, &c. Monmouth, 1806."

"The well which supplied Ragland Castle with water . . . is distant near two miles, . . . many of the pipes which conveyed it have been ploughed up in the fields in which they were laid. . . . These pipes were of two sorts, viz., lead and earthenware. Mr. Daniel was so obliging as to favour me with a piece of this pipe, which is made of clay, but so well and judiciously burnt, that, though it has been underground some centuries, it would still defy the injuries of time and weather for ages to come. Judging from the part in my possession, they appear to have been made

with bell mouths, and fixed one within the other. It measures ten inches in circumference, the diameter of the lower two inches, which would throw about 200 gallons of water a minute."

A patent was granted so early as 1619, for the manufacture of earthenware drain-pipes. See the "Abridgements of Specifications of Patents for Drain Tiles and Pipes," published by the Commissioners of Patents.

W. G. A.

#### A PROTEST AGAINST THE RIDE IN KENSINGTON GARDENS.

MR. EDITOR,—Do hold out a helping hand to the nearly vanquished pedestrians who feel themselves failing in their hard struggle to maintain the integrity of their dear-loved Kensington gardens.

We do not wish, as has been asserted, to render the gardens "private," but merely to keep them safe; and every one knows it is positively unsafe for women and children to cross Rotten-row, during the hours chosen by equestrians for their rides. If the same is to be the case in Kensington gardens, a large portion of the community must give up walking in them altogether, for they can neither go to nor return from any part of the gardens through two-thirds of the entrances without crossing the proposed ride, and thus running the risk of being ridden over by "a cavalcade of pretty women bounding along in their breezy gait."

As the writer of the *Times's* leading article is so very philanthropic, how was it the idea did not occur to him that less wealthy persons, who can only afford to ride in Kensington gardens, might also like to take an airing in the park and gardens? They have to bow in submission to a restriction which is made for the good of the many; so surely the rich equestrians, who have so numerous other enjoyments, may well afford to be bound by the same law.

Kensington-gardens is the only place in all London set apart for the use of pedestrians, while every park is open for riding and polo. Surely the suggestion to take it savours somewhat strongly of the old Hebrew story of the "one little ewe lamb."

If the equestrians wanted "air" to gallop on, why did not the petition to have the upward-proceeding slice after slice of grass land taken away from the once broad stretches of green to widen their own Rotten-row? And if it be "shade" they need, will not the trees still standing on the monotonous space suffice for that purpose, especially this very unusual summer, when to feel the heat of the god of day is a treat rather than a trial?

No: there is no good reason of justice or necessity why the beautiful gardens should be thus disordered and rendered useless to those for whom they have been heretofore set apart, or no English Peer- or Mater-families would raise a voice against the appropriation.—I remain, sir, respectfully yours,

THE MOTHER OF THREE LITTLE GIRLS (Who certainly do like to be able to walk in Kensington-gardens twice in the day).

#### TREATMENT OF BUILDERS.

Sir,—In my neighbourhood it is proposed to erect national schools, with residence. Several builders of respectability were invited to send in tenders for the work, and not to receive instructions and bear conditions, by appointment, in the architect's office. It was there stated that the lowest tender would be accepted; but should its amount exceed the sum intended to be expended by the committee, *then* reductions would be made, which would be a matter of arrangement between the successful candidate and the architect.

When the tenders were examined (which, though considerably over goods, did not vary more than 30%), it was found that the lowest considerably exceeded the sum proposed to be laid out; and slight alterations were made in the plans, for which a corresponding reduction was offered on behalf of the contractor whose estimate was the lowest. However, to the surprise of many, the committee (doubtless, from the advice of their architect) have decided on carrying out the works themselves, after professional advice as to building, purchasing materials, and hiring labour.

Would you, sir, kindly offer an opinion as to the legality of such proceedings? Would you also be good enough to say whether such an arrangement as I have described is just to the competing builders, especially to him who sent in the lowest tender. Would he not be fairly entitled to compensation?

I confess myself ignorant of the civil law in this matter, but I am quite sure that "Summum jus summa injuria."

A COUNTY BUILDER.  
\* \* \* Just, of course, it is not. If the statement in the letter can be proved, and there were no contrary condition, the builder who made the lowest tender is in a position to sue for compensation.

#### INSTITUTION OF MECHANICAL ENGINEERS.

The proceedings in connection with the annual provincial meeting of this institution commenced on Wednesday, the 8th August, in the Lecture Theatre of the Midland Institute, at Birmingham. Mr. James Fenton, of the Low Moor Iron Works, near Bradford, Yorkshire, presided, and there was the usual attendance, principally gentlemen resident in Birmingham. The walls of the room, and around the platform, were hung with diagrams illustrating the subjects treated in the papers read.

The Chairman having briefly opened the meeting, called upon Mr. William Mathews, of Corby's Hall Iron Works, Dudley, to read the first paper entitled "The progress of Mr. Mathews's theory presented in his paper, which was 'On the Ten-year Coal of South Staffordshire, and the Mode of Working.'" The remaining papers were read by Mr. Marshall (secretary). The first was by Mr. Charles Goehring, of Manchester, describing a method for taking off the waste gases from blast furnaces.

The next was by Mr. E. W. Siemens, of London, on a new method of insulating electric wires for underground and ground purposes, by the application of India-rubber and its compounds. Mr. Siemens remarked that until lately gutta-percha was thought

to be an almost perfect non-conductor of electricity, but in dealing with long lines of submarine electric telegraph, its conductivity had become a source of painful anxiety to the electrical engineer, who had to look out for insulating materials. Glass and other vitreous substances, which possessed the highest insulating properties, were, of course, inapplicable; and amongst the various insulators, none combined the insulating with flexibility, and other desirable properties, in so high a degree as india-rubber and its compounds. The proposal of Mr. Siemens was based on the well-known adherent property of india-rubber when two fresh cut surfaces were joined under considerable pressure. It was stated that, the advantage of comparative cheapness, and certainty of result, would by this system be combined with that of rendering the application of heat unnecessary. A practical demonstration of the proposed method was given by means of a working model.

The fourth paper read was "On Coal-burning in Locomotive Engines," by Mr. Charles Markham, of Derby. Mr. Markham stated that experiments on the Midland lines had resulted in a simple apparatus termed "a smoke consumption plate," with which all the engines on the line were now fitted, and by means of which the smoke was burnt with complete and efficiency that had never been previously attained. The Chairman stated that Mr. Markham's invention saved the Midland Railway Company 40,000*l.* per annum.

On Thursday's proceedings were resumed, Mr. James Kennedy, of Liverpool, president of the Institution, in the chair. The attendance was as numerous as on the preceding day.

The first paper, read by Mr. Marshall (secretary), was a description of Aert's Water Axle Box, by Mr. Sampson Lloyd, of Wednesbury.

The second was on a new system of Open Coking, by Mr. S. H. Blackwell, of Dudley.

The next was a "Description of a Machine for Drilling instead of Punching Wrought-Iron Plate," by Mr. John Cochrane, of Woodside Ironworks, Dudley. The machine was designed for the purpose of drilling a large number of holes in wrought-iron plates required for the construction of girders for the new railway bridge over the Thames, at Hungerford. In describing the machine, it was stated that the holes were drilled by means of a table, and surrounded by a wrought-iron frame, within which the plate was accurately adjusted to the proper position; water-pressure was employed for raising the table to the drill, and for giving the required pressure in drilling. The machine was arranged so to drill all the holes in one plate simultaneously, and accomplished its work with much rapidity, and complete efficiency.

The next paper was a "Description of the Round Oak Ironworks," by Mr. Frederick Smith, of Briery Hill, communicated through Mr. Alexander B. Cochrane, of Dudley.

The fifth was "On the Application of the Decimal System of Measurement in Boring and Turning," &c., by Mr. John Fernie, of Derby.

In the last paper was a "Description of Machinery for Crushing Stone for Macadamising Roads," by Mr. Charles G. Mounthan, of Birmingham. The writer stated that he believed the machine referred to in the paper was the only instance in which the invention had been found commercially successful. Its origin was due to Messrs. Ellis & Everard, of Leicester, who desired a machine to break stones which would otherwise have been wasted in the Matchfield quarries, near Ashby, in Leicestershire. The design was prepared by Messrs. Ellis & Everard, and placed in the hands of Mr. J. E. Hodgkin, Birmingham, to construct a machine, but Mr. Hodgkin relinquishing business, the design was devolved upon the writer to carry it into effect. The experiments made with the machine completely established its success.

During Wednesday and Thursday afternoon a large number of the members of the Institution availed themselves of the courteous invitation given them to visit the principal manufactories in the town, and from an inspection of which they derived much gratification.

The *entertainment* which took place in the Town-hall, on Wednesday evening, was attended by a large number of persons, including many ladies. In the committee-room was arranged an ample supply of refreshments, and in the hall adjoining there was an exhibition illustrative of art, science, and manufactures, the objects being principally supplied by local firms.

**Books Received.**

*The Illustrated Horse Doctor.* By Edward Mayhew, M.R.C.V.S. London: Allen & Co., 7, Leadenhall-street. 1860.

This is a handsome and ably written volume on a subject of unquestionable importance to all classes, from the highest to the lowest, in the possession of the management of horses, and to building tradespeople fully as much as to any other. It is plainly written, without the use of much technical or veterinary phraseology, which, indeed, has been systematically avoided, in order that the book might become generally useful. It gives a detailed account, illustrated by more than 400 very graphic and interesting pictorial representations by the author himself, of the various diseases to which that poor, faithful, and useful servant of man, the horse, is subject; together with an account of the best mode of treatment, and the requisite prescriptions, written in plain English; so that, in fact, by its means, if judiciously perused, every one may become his own veterinary physician and surgeon, and be able to ward off and prevent many diseases, the premonitory symptoms of which ignorance and harsh usage but too often aggravate and confirm.

There are one or two points, however, on which we would have wished the author to have enlarged a little more than he has done; namely, on the proper construction and the sanitary arrangement of stables,—a subject to which we have frequently

given attention, although the author asks, sarcastically, "How could any architect be so very 'maudin' as to design a stable with the slightest consideration for a horse?" As well might we retort the sneer, since the author himself has done little or nothing to point the way to that proper construction for the want of which he blames "architects," who have but too seldom anything to do with it. Neither has he said anything worth speaking of in regard to the sanitary arrangements of stables, and shows want of appreciation of efforts in that direction while talking of the "great fuss made about sanitary laws" for human beings. Now although Mr. Mayhew is not an architect, surely he is a sanitary officer so far as regards stables and horses, and ought to have discussed the subject of sanitary arrangements, which in truth involves the more architectural department of construction itself. This defect in his otherwise very useful work we hope he will amend in an early one of those many new editions through which it will probably run.

**Miscellaneous.**

**FLUES FOR BOILERS.**—In the course of the last report of Mr. H. W. Harman, C.E., chief inspector to the Manchester Association for the Prevention of Boiler Explosions, he says,—“The necessity of strengthening all boiler flues, by encircling them with hoops of angle or T iron, seems at last to be more generally recognized. Any plan, however, by which the tendency of flues to collapse can be effectually guarded against should be hailed with satisfaction, as rendering explosions of less frequent occurrence, and demanding but periodical and proper inspection to ensure entire safety.”

**PATENT CHIMNEY-BAR AND HEARTH-PLATE.**—The chimney-bar and ventilating hearth-plate, recently patented by Messrs. Edwards & Co., deserve attention. By the introduction of the patent chimney-bar, the flue is at once formed of the required size, 14 inches by 9 inches, thus doing away with the large open space left when the old chimney-bar is used, and which has so often been found not only unnecessary but very objectionable. A register-door is attached to the chimney-bar, arranged so that no space is left for the accumulation of soot or dust. By the ventilating hearth-plate the supply of fresh external air may be brought to the box either between the joists or through hollow bricks, and enter the room through a sliding ventilator in hearth-plate, as shown on plan, and which would be underneath the bottom plate of fender. The expense of the proposed arrangements is comparatively trifling.

**BOYDELL'S TRACTION ENGINE IN BRAZIL.**—The traction engine, which was manufactured under Boydell's Patent, by Messrs. E. T. Bellhouse & Co., engineers, of Manchester, has arrived in Brazil, and is the first steam locomotive in the empire which has ascended to the height of 3,000 feet above the sea. The ascent from the Maua Railway to the city of Petropolis, 3,000 feet in a distance of eight miles, was achieved successfully, we are informed, and the very sharp curves were easily turned. The natives were considerably astonished at its progress and arrival at the city, and seen now prepared to believe any strange tale told by Englishmen, although many doubt the evidence of their own eyes that the engine is in Petropolis. This is the first traction engine which has been sent to Brazil, and it is likely that others will follow, the keep of animals being very costly.

**BUILDERS' CONTRACTS.**—At the Nottingham Bankruptcy Court, a few days back, some curious disclosures were made in reference to builders' contracts. A bankrupt explained an ingenious system thus:—“Suppose eight or nine builders are invited to tender for a job: they meet together, and agree to put so much money, perhaps 200*l.*, on the contracts, which are then sent in in the ordinary way. Whoever is the successful competitor gives a bill for the sum put on, and it is divided among the other builders for their trouble in estimating. The Commissioner said: It strikes me as being a kind of fraud upon the parties who invite the tenders.—Mr. Danks: It is done merely to recompense the unsuccessful contractors for their trouble.—His Honour: They get 200*l.* divided among them, and, as that is put on the estimates, they are to that extent fictitious. The successful one is often enabled to put in a contract which would not have been accepted if the other contracts had been properly estimated. If this is a custom, I think it is more highly honoured in the breach than in the observance.—*Worcester Chronicle.*”

**THE HARROW TONTINE ASSOCIATION.**—We see that a Tontine Association has been established to effect the building of first-class houses, much needed at Harrow. In this Association all the advantages of the system appear to be secured to the shareholders themselves, as the houses to be erected with the capital subscribed become the property of those holding a nomination on the lives of the last survivors when such lives drop to the number of the houses built, the profit rents, until that period, being divided amongst the shareholders.

**MASTERS AND OPERATIVES BILL.**—The select committee of the House of Lords on this Bill have made a report, to the effect that they cannot come to any satisfactory conclusion with reference to the Bill before them without giving to the manufacturing and commercial interests which have not yet been heard an opportunity of stating their opinions respecting it; they therefore recommend that the subject should be postponed until next session.

**CRAVEN HOTEL, STRAND.**—In these times of hotel-building by companies, through whom it may be hoped London before long will be well supplied in this particular, it is but fair to mention what is being done by private owners. Mr. Tapster has enlarged and nearly rebuilt the Craven Hotel, Craven-street, Strand, under the guidance of Messrs. Banks and Barry, and has effected a very great improvement. A lofty coffee-room, of considerable pretensions, has been formed, and the general arrangements for the accommodation of the public appear to be very satisfactory. Messrs. Lucas, Brothers, have executed the works.

**VALUE OF LANDED PROPERTY.**—The Berkswell Hall estate, Warwickshire, ten miles from Leamington, in a favourite sporting country, was submitted to public auction at the Mart, on Wednesday, by Messrs. Chinnock & Galsworthy. The sale attracted a large attendance of gentlemen from the Midland counties, many of them accompanied by their agents, and evidently intent upon purchasing this fine estate. The rental, as stated in the particulars, was 2,350*l.*, including the cottages and 250*l.* fixed as the estimated rental of the mansion. The biddings commenced at 60,000*l.*, and after a spirited competition the price reached 81,000*l.*, at which it was knocked down to Mr. Thomas Walker, of Orgrave Park, near Lichfield, thus realizing thirty-four and a half years' purchase on the total rental, with the addition of timber at a valuation.

**THE ELLESMERE MEMORIAL.**—On the 10th inst. the ceremony of inaugurating the memorial tower erected to the memory of the late Earl of Ellesmere (and of which we have already given an engraved view in the *Builder*), took place at Worsley. Messrs. Driver & Webber, of London, were the architects. The monument, which stands on the west side of Worsley New Hall, is a tower of transition Gothic character, consisting of an octagon shaft, with spiral belt of coloured tiles, rising from a square basement, terminated by a corbelled out-gallery, with iron balustrade, around a central spirelet. The height of the tower is 132 feet, and from the top a view of the surrounding country can be obtained. At the inauguration, suitable addresses were made by the Rev. St. Vincent Beechey and Mr. Fereday Smith, which were responded to by the Earl of Ellesmere and Mr. Webber, the architect.

**LICHFIELD CATHEDRAL.**—The restorations going forward in this cathedral have been the occasion of discoveries illustrating the ancient history of the fabric. Foundations of old walls have been uncovered, which appear to point to the fact that at least two distinct structures have occupied the site at different periods previous to the erection of the present cathedral. Nearly in the centre of the present choir the foundations of a church, with an apsidal termination some 27 feet in radius, are visible. Farther eastward are the foundations and part of the external plinth mouldings of a still larger building. A plan has been made by Dr. Rawson of all that has been found. Numerous other objects of interest have been discovered, such as Norman capitals and arch stones, old coffins, and encaustic tiles. The large spire of the cathedral was struck by lightning on the 29th ulto. It cracked the spire at the base just above the tower, removing a large piece of stone from the window frame: the stone went through the ceiling of the north-east aisle which is under repair. The congregation assembled in the south-west aisle, though much alarmed, sustained no injury. It is said that the spire will have to be taken down as low as the battlement, the top having been injured as well as the bottom.

**FALL OF A BUILDING AT PENDLETON.**—A serious accident occurred a few days ago at Pendleton, three persons being killed and several severely injured, by the fall of the larger portion of the premises occupied by Mr. John Parry, as a small-ware manufactory. The building was in Ford-lane, near the railway station. It was two stories high, and consisted of an old and new part, the latter having been erected within the last twelve months, by Mr. Thomas Valentine, builder, Pendleton. According to the *Manchester Guardian*, the new portion of the manufactory was 70 yards long, and there were fourteen or fifteen persons at work in it at the time of the accident. It seems that, without the slightest indication of danger having been noticed by any of the hands, the whole of this portion crumbled to the ground like a child's house of cards, and so complete was the destruction that scarcely two bricks were left standing together.

**CRYSTAL PALACE.**—The great annual excursion of the Foresters will be held at the Crystal Palace on Tuesday next, the 21st of August. Last year the enormous number of 63,181 persons attended this festival. The Great Summer Poultry Show, which always attracts large numbers of provincial visitors, takes place in the last week in August. This is to be followed on the 30th August by a special day set apart for amusements provided by Mr. Strange, the contractor for the refreshment department. On the 1st September the Hollyhock Show will be held. In the following week the Tonic Sol Fa Association hold a contest of singing societies, a party of Scotch vocalists coming expressly from Edinburgh to sing some of their national airs. On Thursday, the 13th September, the Liensend Victualers hold a great festival for the benefit of their Asylum. A performance by about 2,000 voices of Mr. Martin's glee, which were so successfully produced at Exeter Hall last month, will take place on Saturday, 15th September; and on the 19th and 20th of the same month the Autumn Dahlia and Fruit Show: on two of the last days of September Madame Clara Novello, who is coming to England on her farewell tour, will sing for the last time in the "Creation" and "Messiah," two performances of which will be got up directed by Mr. Benedict.

**THE CHARING-CROSS RAILWAY.**—At the second ordinary general meeting of the company, the report which was read stated that the works connected with the railway bridge across the Thames at Charing-cross were commenced in February last; and the progress already made has been considerable. The principal expenditure incurred has been on account of the purchase of the existing Charing-cross Suspension-bridge, and for the land and premises at Hungerford-market, required for arrangements. The directors have concluded an arrangement with the Clifton Bridge Company to sell them the chains and materials of the bridge (exclusive of the piers) for 5,000*l.*, the purchasers removing them. Steps are forthwith to be taken for purchasing the further property required, in order that the works between the south end of the Charing-cross bridge and London-bridge station may be completed by the time that the railway-bridge and new West-end terminus are ready for traffic. The engineer's report stated that the contractors are making good progress with the Charing-cross bridge. The two cylinders which are to form the first pier on the Surrey side are already sunk to a considerable depth into the bed of the river. Considerable progress is also being made at the contractor's works with the superstructure. The iron necessary for two of the spans is in hand, and about fifty tons have been put together ready for erection. The receipts for the half-year ending June 30th, 1860, amounted to 122,231,129*l.*, and the expenditure to 58,626*l.* 2s., leaving a balance of 63,605*l.* 10s. 9d.

**BUILDERS' DINNERS.**—Sir: As another instance of masters assisting in promoting the social pleasures of their workmen and of good feeling in place of disagreements, I hope it will be worthy of your notice, that on Saturday, the 4th, the workmen in the employ of Dove, Brothers, builders, Islington, went for a holiday in vans to Epping Forest, where an excellent dinner and tea were partaken of. The chair was taken by Mr. Critchett, supported by Messrs. G. Dove, Combe, Stately, Lett, Southam, connected with the firm. The health of our employers was drunk with enthusiasm, in acknowledgment of the very liberal donation given by them towards our enjoyment, and in the evening the party returned to Islington heartily satisfied with the day's pleasure.

—ONE OF THE PARTY.

\* \* \* We have received similar notes as to other firms (Mr. Parsons, &c.), but cannot find room for more.

**NORMANTON CHURCH COMPETITION.**—Competitors, who have received back their designs as "unsuitable," desire to know whose design has been found suitable.

**MOSAIC PAVEMENT.**—We are asked to draw attention to a mosaic pavement, which has just been laid by the Architectural Pottery Company, Poole, Dorset, at their offices, 36, Parliament-street. The design is by Mr. J. M. Lockyer, architect.

**METROPOLITAN BOARD OF WORKS.**—At a meeting of this Board held last week, Mr. DeLith's tender for underpinning the Ranelagh sewer for 2,926*l.* was, upon the engineer's report, accepted. The Board, upon the recommendation of the chief engineer, determined upon taking the contract for the Southern High-level Sewer through the Surrey Consumers' Gas Company out of the hands of the present contractor, the chief engineer and the Board not being satisfied with the manner in which the work was being done.

**DESTRUCTION OF A RAILWAY STATION BY FIRE.** A serious conflagration has taken place at Paisley, resulting in the complete destruction of the goods shed, for the accommodation of the goods traffic, at the railway station, and of a number of vans and waggons filled with a variety of valuable merchandise, which had arrived chiefly from the south. The building was almost entirely of wood.

**TRANSMISSION OF MONEY BY TELEGRAPH.**—The *Progress*, of Lyons, says that the administration of the telegraphic lines has now under consideration a project for affording the public the facility of transmitting sums of money by telegraphic despatch. What, by the way, has become of the English project? The extension of the Post-office order system, we suspect, extinguished it. In the absence of such a system in France, the telegraphic one may have a better chance of success.

**"STEAM SUPERSEDED;" NEW MOTIVE POWER.** A correspondent of the *Siecle*, M. Victor Borie, whose name is well-known, writes to announce to the public that the application of dilated air to the working of machinery, as a substitute for steam, has been discovered by a working mechanic of the name of Leveque, living at 31, Rue Rousseau, who is said to be exhibiting a piece of machinery, moved solely by air, of four-horse power, and in a way so perfectly satisfactory that, according to M. Victor Borie, the days of the steam-engine are numbered.

**THE VICTORIA STATION AND PIMLICO RAILWAY.**—The railway and bridge are now ready for public traffic, and the works of the Brighton Company's station are fast advancing towards completion. The Victoria station is about a quarter of a mile west of Buckingham Palace, on the site of the basin of the Grosvenor Canal, and covers 101 acres. This space is divided in the centre, half being appropriated to the Brighton Company, and half to the Chatham and Dover and the Great Western jointly, the mixed gauge having been laid on this portion of the station, and over the main line. The Brighton station covers 51 acres, having eight platforms of considerable length. The main line passes under the Belgrave-road, is enclosed by walls, and covered by a glass roof for about half a mile. This has been done to protect Mr. Cubitt's property from the noise; and, as a further precaution, vulcanized india rubber is placed between the rails and the longitudinal sleepers. The chief work on the line is the bridge over the Thames, which, including the land openings, extends 920 feet in length. The quantities of materials used in the construction of this bridge have been as follows:—197,800 cubic feet of timber, used temporarily in gables and cofferdams, and 16,800 cubic feet in floors; 10,700 cubic feet of York landings; 4,050 cubic yards of concrete; 6,500 cubic yards of brickwork; 23,857 cubic feet of Portland road stone; 57,205 cubic feet of Bramley Fall stone; 1,295 tons of wrought iron, and 225 tons of cast iron. The total cost of the bridge will be about 90,000*l.*, or 3*l.* per square foot. Its strength has been tested by locomotive and loaded trucks, weighing together 350 tons. The deflection on the centre of the two middle openings was one inch and one-fifth, and the greatest deflection on the two outer openings was 0*·*94 of an inch. The load removed, the bridge resumed its original level. It is expected that the railway and station will be opened for public traffic some time during the present month.

**TENDERS**

For a house at North Bow, for Mr. W. H. Macc. Mr. James Tolley, architect. Quantities supplied:—  
Reed ..... 287 0 0  
Ayers & Co. .... 87 0 0  
Ashby & Horner ..... 8-6 0 0

For two houses, Brick-lane, Spitalfields. Mr. William Reddall, architect:—  
Kebbell ..... 21,930 0 0  
Porrett ..... 269 0 0  
Johnson ..... 775 0 0  
Green ..... 760 0 0  
Pritchard & Son ..... 735 0 0  
Case ..... 747 0 0  
Scott ..... 743 0 0

For taking down and rebuilding front wall of White Lion public-house, and part of the *Sapping Gazette* Office, and other works in Tainton-court, Gracchurh-street, for Mr. William Mitchell. Mr. J. Farring, architect:—  
James & Son ..... 215 0 0  
Ramsay ..... 287 0 0  
Noriss (accepted) ..... 280 0 0

For erecting villas on the Trafford estate, near Norwich. John Daymond Ellis, architect, Norwich:—  
Long ..... 21,375 0 0  
Munro & Foyson ..... 1,455 10 0  
Brooks ..... 1,343 0 0  
Lacey ..... 1,329 10 0

For offices at the corner of Fenchurch-street and Rood-lane, for Messrs. E. & S. Edwards. Mr. Henry Dawson, architect. Quantities supplied by Mr. Richard Roberts:—  
Lucas, Brothers ..... 211,798 0 0  
Piper & Sons ..... 11,448 0 0  
W. Cabitt & Co. .... 11,425 0 0  
Brass ..... 11,284 0 0  
Ashby & Horner ..... 11,240 0 0  
Browne & Robinson ..... 11,089 0 0  
Axford & Co. .... 10,887 0 0

For additions and alterations to house, 40, Wigmore-street. Mr. T. H. Northcroft, architect. Quantities given:—  
Harrison ..... 270 0 0  
Knaapp & Son ..... 724 10 0  
Sauders ..... 788 0 0  
Dennett ..... 776 0 0  
Hyde ..... 612 0 0  
Slipson ..... 610 0 0

For house, 48, Wigmore-street. Mr. T. H. Northcroft, architect. Quantities given:—  
Wilson ..... 2,550 0 0  
Terry ..... 510 0 0  
Knaapp & Son ..... 547 0 0  
Jameson ..... 540 0 0  
Slipson ..... 463 0 0

For Friends' endowed schools, Reeth, Yorkshire. Mr. Peachey, architect:—  
For schools and fittings, master's residence, and small cottage boundary walls. Only. £ s. d.  
Warren ..... 2,101 14 1, 1,331 17 2  
Armitage ..... 2,046 12 4, 1,306 1 4  
Bollock ..... 1,958 0 0, 1,250 0 0  
Kemp & Abdale ..... 1,839 0 0, 1,507 3 0  
Elwin ..... 1,866 16 9, 1,507 3 0  
\* Accepted.

For executing the cleaning, watering, cartage-work, and scavenging of the town of Leamington, for the Local Board of Health. Mr. A. Morgan, C.E., surveyor:—

**TO CORRESPONDENTS.**

Letters on Marble.—Sir: Will any of your multitudinous readers inform me of any preparation for colouring letters in marble, that will resist the influence of the atmosphere? I have been in many countries in different parts of the Kingdom, and very few instances can I see of the colouring remaining unimpaired. It being a universal complaint, a preparation that would remedy the evil is desideratum.—H.  
G. R.—D. T. D.—W. H. W.—J. H.—J. F. F.—W. F.—E. R.—W. B. T. & R. E.—W. P. B. (apply to Mr. Robinson, South Kensington Museum).—R.—R. M.—E. H.—J. L.—J. L. M. (there are half a dozen equally good).—J. W.—T. F. (Britton's "Public Buildings of London").

**NOTICE.**—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and NOT to the "Publisher."

Post-office Orders and Remittances should be made payable to Mr. Morris R. Coleman.

**ADVERTISEMENTS.**

**MR. WILLIAM ELLSON,**  
CONSULTING SURVEYOR, late of STAINBY ROAD,  
Has taken Offices at  
13, FENCHURCH-BUILDINGS, FENCHURCH-STREET, E.C.  
Where he continues to receive BUILDERS  
ON BREACHES OF CONTRACT, DISPUTED ACCOUNTS, &c.

**WANTED, A PARTNER** in an old-established BUILDERS BUSINESS, Sleeping or Active, with Four to Five Hundred Pounds.—Address, A. R. Y. Office of "The Builder."

**STAIRCASE HAND WANTED.**—To a first-class Man, constant employment would be given.—Apply to CLEGG & LASKELL, 1st, Small-st. row.

# The Builder.

VOL. XVIII.—No. 916.

Mr. Ruskin's "Modern Painters."\*

AN author, who lays before us a fifth concluding volume of four hundred pages, of a work which bears throughout, evidence of an amount of labour and thought seldom given to an art subject, at least deserves, at such hands as ours, careful examination and a disposition to appreciate the result. We have, therefore, both carefully read Mr. Ruskin's last volume, and striven to possess ourselves of the meaning and intent of his words. We must say, however, the object is by no means easy of attainment. There is in this volume, as in every work by Mr. Ruskin, much that may instruct as well as delight a certain class of readers,—the more thinking, and we may say conscientious,—of whom our author incidentally laments the paucity or want. But, even for these, the aim or drift of the work,

taken to be the exaltation of a particular artist,—whose exhibited pictures and drawings now happen to stand the best evidence of his wonderful, or we will say, as we have long said, quite unequalled power in landscape,—will not excuse a bulk of digressional and episodal *impertinence*, encumbering the march of an argument; useful though they might be elsewhere, or regarded by themselves. Or, taking the intention to be to inculcate the right perception of nature, and appreciation of what is truly art, there are equally excrescences and inconsistencies in the matter of this book. Perspicuity and precision of style, the latter so much contributing to the former, obviously are what they have been called by the first authorities on language, the first and indispensable requisites to pursuance of a thesis. These essentials, however, Mr. Ruskin does not secure, through having omitted to show plainly the object of so large and varied a work as the "Modern Painters," and through the contradictions and inconsistencies to which he has given utterance. We allow, with our author, that changes must occur in opinions during a period such as that of the seventeen years over which the publication of this work has extended; but what must be the effect on a public, indisposed, as we may think from what our author says, to take any trouble to avoid bewilderment? What the tendencies of that so-called criticism which follows Mr. Ruskin's lead, when views have to be reconciled, like some on the nature and essence of art which we find in this fifth volume, to those, for example, which Mr. Ruskin promulgated at the commencement of a well-remembered pamphlet? In that case Mr. Ruskin, so far as plain words went, seemed to hold that art was only imitation, and not to see that mere drawing, or without invention, could not be art. He also did not see, or did not sufficiently show, that there is a certain opposition, or at least distinction, between nature and art, whilst the creative power manifested in works of art is mind—the greatest of all the works of nature. He now not merely gets to see that invention is the essential ele-

ment of art, but he approves of liberties taken by Turner in giving, as representations of actual scenes, objects arranged in different positions to those in which they were observed. He thus forgets what would seem like a *dictum* of his own, that, whilst there is an aim for true art, there is one also for accurate delineation; or, in other words, that, as in landscape painting and representations of architecture, the aim is both the pictorial and the explanatory. In truth, the proportions of the art element and the delineative, by varying, produce the different gradations of art, and kinds of art-work; and were Turner in one sense the greatest artist that ever lived, landscape works of his which were the result of accurate observation and his power of memory, could hardly be ranked in art with subjects admitting invention prominently in the theme,—however nearly allied, and sometimes practically indistinguishable, the delineative power may be from the power of so-called high art. It is not our purpose to attempt to show what art really is. The difficulty always has been felt, and has been confessed by us on many occasions. We would say, however, with our author, that there is a step gained in showing what a thing is not, and in discovery of an error. Such error we believe there is in his depreciation of particular artists and schools; as, indeed, there is in the tone of criticism both on painting and architecture which is now prevalent. We do not class a Teniers with a Titian,—for the reasons just referred to: but both have their merits; and one of such artists is not to be depreciated for the absence of qualities for which he did not seek, and of which the absence by no means implies negation of art. Mr. Ruskin in his preface, after a long account of his labours during the last four years, to excuse delay in the appearance of this fifth volume, says:—

"It was long before I got quit of a boy's veneration for Rubens' physical art-power; and the reader will, perhaps, on this ground forgive the strong expressions of admiration for Rubens, which, to my great regret, occur in the first volume.

Finding myself, however, engaged seriously in the essay, I went, before writing the second volume, to study in Italy; where the strong reaction from the influence of Rubens threw me at first too far under that of Angelico and Raphael; and, which was the worst harm that came of that Rubens influence, blinded me long to the deepest qualities of Venetian art; which, the reader may see by expressions occurring not only in the second, but even in the third and fourth volumes, I thought, however powerful, yet partly luxurious and sensual, until I was led into the final inquiries above related."

And that we may not do him any injustice by what we have said, we will continue the quotation:—

"These oscillations of temper, and progressions of discovery, extending over a period of seventeen years, ought not to diminish the reader's confidence in the book. Let him be assured of this, that unless important changes are occurring in his opinions continually, all his life long, not one of those opinions can be on any questionable subject true. All true opinions are living, and show their life by being capable of nourishment; therefore of change. But their change is that of a tree—not of a cloud.

In the main aim and principle of the book, there is no variation, from its first syllable to its last. It declares the perfectness and eternal beauty of the work of God; and tests all work of man by concurrence with, or subjection to that."

We have shown that we cannot quite agree with the author in the character here given of his opinions.

We may mention that he had before observed, that the first volume, which was "the expansion of a reply to a magazine article," was not begun because he thought himself "qualified to write a systematic treatise on art;" but because he "at least knew, and knew it to be demonstrable, that Turner was right and true, and that his critics were wrong, false, and base." Elsewhere he says that the work has been written for no object of fame or money, or "for conscience' sake," but "of ne-

cessity;" and that by "a little flattery adroitly used," and "the substitution of verbiage generally for investigation" he could have gained greater circulation of the volumes.

"I saw an injustice done, and tried to remedy it. I heard falsehood taught, and was compelled to deny it. Nothing else was possible to me. I knew not how little or how much might come of the business, or whether I was fit for it; but here was the lie full set in front of me, and there was no way round it, but only over it. So that, as the work changed like a tree, it was also rooted like a tree—not where it would, but where need was; on which, if any fruit grew such as you can like, you are welcome to gather it without thanks; and so far as it is poor or hitter, it will be your justice to refuse it without reviling."

The several parts of the work are divided into chapters, which bear the fanciful headings in which Mr. Ruskin delights, and which have their advantages. In the two first parts he pursues, as in the fourth volume, the minute investigation of the structure or growth of certain forms which are elements of the beautiful in landscape scenery. The fourth volume, of about the same bulk as that before us, related entirely to Mountain Beauty. Two questions, our author says, occurred on arranging his materials preparatory to the production of the fifth volume,—“one in the section on vegetation, respecting the origin of wood; the other in the section on sea, respecting curves of waves; to neither of which, from botanists or mathematicians, any sufficient answer seemed obtainable.” Ultimately, knowing "little of ships" and "nothing of blue open water," the section on the sea was unsatisfactory to him: the "mathematical difficulty lay at the beginning of all demonstration of facts;" and he abandoned the proposed section, at least as regarded the present work. He therefore confines the first half, or two parts, of his fifth volume to the "vegetation question" and that of the nature of clouds, or rather as to the production of the forms regarded as objects of beauty. These two parts of the work, and the two following, are illustrated by plates very beautifully engraved as well as drawn, and by woodcuts,—the latter mostly too bold, or coarse, for the purpose of explanation.

The first chapter, entitled "The Earth-Veil," shows that flowers and trees were intended to render service to man, and greatly through their attribute of beauty. The author thinks that the common usage of words by which an ill-taught person is called rustic, and a gentle one urbane, may one day be reversed. In the second chapter, entitled "The Leaf Orders," he divides plants broadly into "Tented Plants," that is those living in encumbrances on the ground, as lilies, or on surfaces of rock, or stems of other plants; and "Building Plants," or trees, which build or rise above the ground. The Building Plants he divides into "Builders with the Shield," and "Builders with the Sword,"—the former being those with expanded leaves, shielding the young bud; and the latter, or the pines, having sharp leaves in the shape of swords. He proceeds, in the next chapter on "the bud," to examine the *chief mystery of vegetation*, which, so far as respects external form, he says is "among the fair shield-builders." In the next eight chapters he examines with great minuteness every feature of the plant, beginning with the simplest spray or shoot, and showing how the leaves and branches grow, and are influenced one by another, and by such causes as decay and the prevailing winds, to form the future tree. He contrasts the treatment of foliage by Salvator Rosa with that by Turner, Albert Durer, and Veronese; and that of branches by some of the Dutch painters, with the natural form of a branch.

In the chapter entitled "Leaves Motionless," he inquires into reasons of the infrequent treatment of flowers in detail by the chief masters. He discovers that flowers have no sublimity, and that there is a wide distinction between flower-loving minds and those of the highest order; whilst he observes that in good landscape painting, the breadth of foreground, included, implies a distance of the spectator which prevents seeing flower-detail. But the reason he gives in which just now we are most

\* "Modern Painters. Volume V.: Completing the Work, and containing Part—VI. Of Leaf Beauty.—VII. Of Cloud Beauty.—VIII. Of Ideas of Relation—1. Of Invention Formal.—IX. Of Ideas of Relation—2. Of Invention Spiritual." By John Ruskin, M.A., &c. Imp. 8vo. pp. xvi. 384, including indexes.—"Local," "To Painters and Pictures," and "Topical,"—to the whole work: 37 plates; many cuts. London: Smith, Elder, & Co. 1860.

interested is, that "much of what is best in flowers is imitable in painting;" and that "a thoroughly good workman feels the feebleness of his means when he matches them fairly with nature, and gives up the attempt frankly,—painting the rose dull red, rather than trying to rival its flush in sunshine." How different is this from the naught-rejecting, non-selecting course, once distinctly named, and which, therefore, it is Mr. Ruskin's fault if he was deemed to recommend exclusively. That the aim in this particular, whatever merits (and these are great) are to be found in their works,—has been mistaken by the artists lately called Pre-Raphaelites, would seem to be admitted by Mr. Ruskin himself in the following passage, as also in one of the main divisions of his volume. He says:—

"Some beautiful things have been done lately, and more beautiful are likely to be done, by our younger painters, in representing blossoms of the orb and the field in mass and extent. I have had something to do with the encouragement of this impulse; and truly, if pictures are to be essentially imitative rather than inventive, it is better to spend care in painting hyacinths than dead leaves, and roses rather than stubble. Such work, however, as I stated in my first essay on this subject, in the year 1851,\* can only connect itself with the great schools by becoming inventive instead of copyist; and for the most part, I believe these young painters would do well to remember that the best beauty of flowers being wholly imitable, and their sweetest service un-renderable by art, the picture involves some approach to an unsatisfying mockery, in the cold imagery of what Nature has given to be breathed with the profuse winds of spring, and touched by the happy footsteps of youth."

We do not think, however, that he insisted on invention with the same clearness as in the present work. On the other hand, he seeks to show a range of conception in Turner's pictures which is scarcely of the nature of landscape art. The exposition by our author, of the relation of tributary lines and forms to the effect of a picture, may be correct,—though we should like to know how much is the necessary result from *perspective*: but the effort, to discover a profound  *motive*  in the work, which involves so much elaboration of words, often suggests the previous question, whether Turner had a  *motive*  other than the directly obvious one, or any requiring the ingenuity expended by Mr. Ruskin on the search. The sixth part concludes with the following eloquent words on the mosses:—

"And, as the earth's first mercy, so they are its last gift to us. When all other service is vain, from plant and tree, the soft mosses and gray lichen take up their watch by the headstone. The woods, the blossoms, the grit-bearing grasses, have done their parts for a time, but these do service for ever. Trees for the builder's yard, flowers for the bride's chamber, corn for the granary, moss for the grave."

Yet as in one sense the humblest, in another they are the most honoured of the earth-children. Unfading as motionless, the worm frets them not, and the autumn wastes not. Strong in loneliness, they neither blanch in heat nor pine in frost. To them, slow-fingered, constant-hearted, is entrusted the weaving of the dark, eternal, tapestries of the hills; to them, slow-pencilled, iris-dyed, the tender framing of their endless imagery. Sharing the stillness of the unimpassioned rock, they share also its endurance; and while the winds of departing spring scatter the white lawn-thorn-blossom like drifted snow, and summer dims on the parched meadow the drooping of its cowslip-gold,—far above, among the mountains, the silver lichen-spots rest, star-like, on the stone; and the gathering orange-stain upon the edge of yonder western peak reflects the sunsets of a thousand years."

Part VII. treats of the various effects of clouds, under the heads,—“The Cloud-Balancings,” “The Cloud-Flocks,” “The Cloud-Chariots,” and “The Angel of the Sea.” The author shows how little is known to men of science of the nature of the clouds, and of the causes of their changes of form; but these chapters may be studied with advantage for

\* “*Pre-Raphaelitism*—p. 28, and the note at p. 27, compare p. 63. The essay contains some important notes on Turner's work, which, therefore, I do not repeat in this volume.”

information on the perspective representation of clouds. In the last chapter, under the fanciful designation given, effects of rain cloud are spoken of. English wet weather, the author says, is “indeed, one of the things which we should desire to see Art give perpetuity to.” And he ranges the climates or lands of the globe under five heads with respect to their fitness for art, or thus shortly worded:—

Wood-lands..	Shrewd intellect..	No art.
Sand-lands..	High intellect....	Religious art.
Vine-lands..	Highest intellect..	Perfect art.
Field-lands..	High intellect....	Material art.
Moss-lands..	Shrewd intellect..	No art.

In the course of this chapter, a reference to the mowing-machine brings the assertion that this, “in common with all other inventions of the kind,” is likely to “bring more evil upon men than ever the Medusa cloud did, and turn them more effectually into stone.” And he adds in a note:—

“I do not say this carelessly, nor because machines throw the labouring man ‘out of work.’ The labouring man will always have more work than he wants. I speak thus because the use of such machinery involves the destruction of all pleasures in rural labour; and I doubt not, in that destruction, the essential deterioration of the national mind.”

He reasserts this error, and at greater length, in a later part of the work.

In Part VIII. the author reaches the most important section of his subject. In the first division of his work, it had been seen how far art might be, and had been, consistent with physical or material facts; in the second division, how far obedient to the laws of physical beauty; and in the last division he has to consider the “relations of art to God and man.” “to inquire into the various powers, conditions, and aims of mind involved in the conception or creation of pictures; in the choice of subject, and the mode and order of its history;—the choice of forms and the modes of their arrangement.” This whole inquiry then falls into two main divisions, namely, *expressional* or *spiritual invention*, and *material* or *formal invention*,—the former being concerned with choice and arrangement of incidents, and the latter with arrangement of lines, forms, and colours, so as to produce the best possible effect. “Well composed,” as applied to a picture, he says, does not mean composed according to rule, but precisely the contrary,—composed as no other picture is, or can be again. Yet there are certain elementary laws traceable. It is necessary first to understand what composition is. “Composition may be best defined as the help of everything in the picture by everything else.” He therefore gives the first chapter to what he calls “the law of help.” In the course of this chapter it is, that he speaks best on the element invention. Invention is “not only the highest quality of art, but is simply the most wonderful act or power of humanity. It is preeminently the deed of human creation; *ποίησις*, otherwise poetry.” Afterwards he shows that to “create” not only *can* be said of man's labour, but must be said continually. To create anything “in reality is to put life into it.” A poet, or creator, is not a person who puts things together, as a watchmaker steel, or a shoemaker leather.

“His work is essentially this: it is the gathering and arranging of material by imagination, so as to have in it at last the harmony or helpfulness of life, and the passion or emotion of life. Mere fitting and adjustment of material is nothing; that is watchmaking. But helpful and passionate harmony, essential choral harmony, so called from the Greek word ‘rejoicing,’\* is the harmony of Apollo and the Muses; the word Muse and Mother being derived from the same root, meaning ‘passionate seeking,’ or love, of which the issue is passionate finding, or sacred invention. For which reason I could not hear to use any harsh word than this of invention.”

In the next chapter,—“The Task of the Least,” he endeavours to show how the minutest portion of a great composition is helpful to the whole. A great composition “always has a leading emotional purpose,” to which its

\* Χοροὺς τε ὀνομαζίαται παρὰ τῆς χάρᾶς ἐμψυον ὄνομα.—(De Leg. ii. 1.)

lines and forms have relation. “Undulating lines” are “expressive of action,” and “horizontal and angular lines” of “rest and strength.” He proceeds to examine in detail certain subjects of opposite characters, noting the smallest details as introduced with purpose. We have alluded to this above. In the third chapter,—“The Rule of the Greatest,”—he says:—“Greatness can only be rightly estimated when minuteness is justly revered. Greatness is the aggregation of minuteness; nor can its sublimity be felt truthfully by any mind unaccustomed to the affectionate watching of what is least.” But this affection must be accompanied by comparison and reflection. The following, in which the italics are ours, like many other passages, indicates an advance from what the author wrote some time back.

“Here I will only state in conclusion what it is chiefly important for all students to be convinced of, that all the technical qualities by which greatness of treatment is known, such as reserve in colour, tranquillity and largeness of line, and *refusal of unnecessary objects of interest*, are, when they are real, the exponents of an abnormally noble temper of mind, never the observances of a people supposed to be useful.”

In the fourth chapter, he treats “the law of perfectness.” Perfectness, properly, he says, means harmony, not carrying the work up to any constant and established degree of finish, but to a degree determined upon. All great work is to be called complete according as it fulfils the conditions which were chosen at first. The sketches of true painters may be classed as—1. *Experimentals*, which by the greatest men are hardly ever made. 2. *Determinants*, to fasten down an idea. And, 3. *Commemoratives*, being records of facts. The sketch made as a memorandum may, unless the exact purpose be understood, be as unintelligible as shorthand. Such, he says, were some of Turner's memoranda: others were both commemorative and determinant. We will merely mention the sketch of Lausanne, altered in the chief features from the reality, whilst made; because it illustrates some of the remarks we have offered. Mr. Ruskin says a picture may be painted almost any way, as by beginning at one corner and finishing, provided it have been rightly conceived.

The last part,—“Of Invention Spiritual,”—contains some of the best writing, and also some of what we must consider the most fallacious, in the book. Object, however, as one may, the book is full of beauties, full of value. Parts are indeterminate and obscure in motive, filling the mind with a poetic mist, so to speak, very charming and enjoyable, but out of which the striving cultivator must condense his own drops of useful rain if he would have it; while other portions contain teaching with the correctness of which we may be unable to agree: nevertheless the whole exhibits so much thought, inducing thought, and so much heart, inducing earnestness, as materially to increase our obligation to the author.

BRITISH ARCHÆOLOGICAL ASSOCIATION IN SHROPSHIRE.\*

THE course of our report has brought us to Friday, August 10, when, with the exception of a visit to the lead-mines at Shelve, where the old Roman workings were pointed out, the drive was taken direct to Linley Hall, the seat of the Rev. J. F. More, who had prepared for the mental delectation of the visitors by exhuming the aqueducts and other parts remaining of a Roman villa, and exhibiting many antiquities, amongst which was a Roman pig of lead, lying beside a modern one, showing how similar they were in shape. It was stamped IMP. ADRIANI AVG. There were two oak blades of spades, said to be also Roman, and in excellent preservation. They were flat, and something like the blade of a baker's peel, but broader, and with a hole near the short projection on one side.

An excellent *déjeuner* was partaken of, and perhaps not the least remarkable thing seen was the splendid service of old china, which was said to be one of the only two services ever exported from China? The health of the host, and of Miss

\* See p. 523, ante.

More, the hostess, having been given, the company spread themselves through the grounds for a short time, as More Church had been cut out of the programme, apparently with the tacit consent of all, for every one seemed content to remain, and it was late before the departure was effected.

In the course of the day the Rev. Mr. Humphreys read an Etymological paper on the names of the locality, and the Italian Hall was described by the Rev. Mr. More. At the evening meeting Mr. George Maw read a paper on Tessellated Pavements, illustrated by drawings of those in Uriconium.

The Rev. Mr. Scarth read a History and Description of Wroxeter Church, which was visited the next day. Mr. Thomas Wright explained briefly the characteristics and history of flint instruments, and exhibited M. Bouche's collection, and an enormous quantity from the neighbourhood of Bridlington, in Yorkshire. In the course of his remarks, he stated that he did not agree with the generally received division of implements into the stone period, bronze period, and iron period, and believed the time would come when that theory would be overturned. He produced a large number of flint forgeries, which, however, were easily detected from the ignorance of the forgers, who used files in their manufacture. On the great question involved in the recent discoveries of flint instruments in early strata, he had no opinion to offer. The whole subject is to be sifted during the next session of the association.

The greatest attraction of the Congress was Uriconium, which was reserved for the last day, Saturday, the 11th, and fortunately the weather was fine. There was again a large increase of numbers; and, as the programme was not quite so long, the time of departure was not quite so early as on previous days. Hitherto the hour of starting had been nine o'clock, but on this day it was half past ten, and half an hour's drive brought the party first to Hanglamond Abbey, which has been much changed by workmen having for several years been employed to almost reconstruct it.

Mr. E. Roberts conducted the Society over it, and said that it was an abbey of canons of St. Augustine, and, as compared with Welock, was scarcely more than half its value. It was said to have been founded by William Fitz Alein, Earl of Arundel; but, on an examination of the buildings, he agreed with the Rev. Mr. Eytton, who drew his inferences from documents, that at all events none of the buildings remaining were of that date. The endowment and foundation might much precede the erection of the abbey; and this, as well as most abbeys, showed progressive building in its several parts.

The church itself is entirely destroyed, except one doorway, of semi-Norman date, at the west end of the south aisle leading to the cloister. This, and the front of the chapter-house of the same date, have been unnecessarily mutilated at various times, down to the present century. The chapter-house has repeatedly been stated to be entire, whereas the front only remains: the other is not only much later, but considerably smaller, and is of very inferior character. It exhibited a sketch from a drawing made in 1813, to show that since then the aspect is entirely changed. The ceiling is very heavily timbered, in the style of the 15th century, but that and the windows in the bay end appear to have been brought from other buildings of that date, and rebuilt here at some later period. This also is the case with the bay window in the abbot's lodging. The great cloister has only part of one wall remaining, in which are two semi-Norman arched recesses, said to have been for a lavatory; but Mr. Roberts thought he should be able to show that there was a room there, and the arcading was one end of it.

The Abbot's Refectory has window-seats in the recesses, and a large chimney-corner, of late Perpendicular work, probably inserted much later. There are two sepulchral slabs of the thirteenth century, in the place where the choir was, but they were removed from the chapter-house. One was stated to belong to the great-grandson of the founder, while the written account at the Abbey described it as of the great-great-grandson. This would rather lead to the conclusion that the founder was the second Fitz Alein. The inscriptions are in Norman French, as follows:—

VOYS KI PASSE PAR ICI PRIES PYR L'AME  
JOHAN FICALAIN XI GIT ICI DEY DE SA ALME  
ET MERCI AMEN.  
& YSABEL DE MOR . . . R [Mortimer] SA  
FEMME ACOST DE LI DEY LE LVE ALM . . . T  
MERCI AMEN.

There was recently a real found here, which

was said to be inscribed with the words, "Robert de Sherrington, Abbot of Haglamon," but as there was no such abbot recorded, he had looked at an impression, and found it simply, "Sigillum Roberti de Sherringtone," and apparently of the thirteenth century. After inspecting a well house of the fifteenth century in the Abbey Woods, Mr. Roberts concluded by saying that there is scarcely any part of these remains which can be looked upon as in their simply decayed state, every part having been renewed, displaced, or altered in arrangement, and destroyed in detail. The greater part of this was done by the late proprietor.

Battlefield Church was visited *en route*, and was briefly described. It is a simple church, with nave, chancel, and western tower. The date of the grant of the land is 1403; but some of the windows are so clearly of an earlier date, that there must either have been a church there before, or the decorated windows must have been brought from some other building. The church is under restoration, but it is feared that the Doric columns in the interior will not be removed. About three feet below the present surface is an almost entire encaustic tile pavement, and some lead coffins have been discovered beneath. The east window has considerable remains of old glass, but much disarranged. Attention was drawn to a representation of a chalice in the glass, which might give a clue to the subdeacon's slab, examined in the abbey church on Monday. The chalice was surmounted by the wafer, with the sacred monogram as a nimbus, with rays of light spreading from it. Some remnants of indented ridge tiles were dug up, and showed that there had been a crestring.

Wroxeter, the site of the ancient city which has been disintegrated, occupied a considerable time in examination, but it has been so fully and so recently described by us,\* that we need only add, on professional points, that the building now supposed to be the Basilica (as appropriated by the conductor of this journal, at a meeting of the British Archaeological Association in London at the commencement of last year), has been filled in again, for want of space for the soil excavated, and that part of the tessellated mural decoration takes the form of a guilloche-patterned skirting, in two colours. The drains discovered have a drip at each stone with which they are floored, and the so-called gutter is blocked up occasionally by cross pieces of stone, or boulders. When pointing out the hypocausts excavated, he stopped for a moment at a small apartment, which he said appeared to have been the place where the fires were made, and was a feeder to the hypocausts; for here was found a quantity of coal and charcoal. The first and largest hypocaust was then entered. This was 37 feet by 25 feet, having at the north end an apse, and was coloured on the outside, showing that the Romans coloured their walls both outside and inside. The apse was formed of strong masonry, some very large stones being found, and one of them having a piece of iron fixed in with lead. To this probably some ornament had been attached. Mr. Wright mentioned that, when this hypocaust was first opened, it was remarkable for the state of preservation in which the columns supporting the floor were. The floor was for the most part gone in all these hypocausts, with one exception; but when these were opened, 120 of the columns were counted, each about three feet high. Unfortunately, however, soon after the discovery was made, a number of colliers got into the excavations, and, in mere wantonness, broke the columns to pieces. They had, however, been subsequently put up again by Dr. H. Johnson, as nearly as possible in their original state. In commenting on these hypocausts, five or six in number now discovered, Mr. Wright said he thought there could now be no doubt that the buildings which they were surveying were the public baths of the city of Uriconium. Some half-worked stones were found. They were now in the exact position in which they were discovered, as if the workmen had been disturbed in their labours by the attack on the city. This was at a place where one of the walls had evidently been mended after its first construction.

Wroxeter Church was described in the Rev. Mr. Scarth's paper as of Saxon foundation, dedicated to St. Andrew. The Norman part consists of a south door in the chancel, now built up. The Rev. Mr. Eytton states that the earliest portion is of the time of Henry II.; the windows in the north wall are of the beginning of the Early English period. The window on the south side of the chancel, and the chancel arch, are of the Deco-

rated period. Other parts are of Perpendicular. The font he thought was an old Roman column, hollowed out by the Saxons. Mr. Scarth now conducted the members over the church; and, on the conclusion of his examination, Mr. Roberts was called upon for his description. He said that the sculptures showing in the south wall were certainly Saxon in their appearance, but had been built in. The semi-Norman south door of the chancel has a transitional character externally, and even a dog-tooth ornament in the label internally. The depressed chancel, which he acknowledged as having at first puzzled him, was certainly decorated, and the peculiar four-centred shape was due to settlements. The tower-arch was of about the same date, but the impostors were Norman, and well sculptured; these were only seen from the gallery, for which they had been cut away on the face next the nave. He had been given to understand that there was a fine hammer-beam oak roof; and he strongly urged the authorities to have the plaster ceiling removed, and also some high chancel-pews, one of them having a canopy like an Elizabethan hedstead.

Atcbam Church was examined on the road homewards, and was the last on the extensive programme of the week. The church is dedicated to St. Eatta, and is of Saxon origin, although none of the works of that time remain. The east wall has a peculiarity, such as was noticed at Ludlow. There are two chambers of 3 feet or 4 feet square, with small apertures externally. These were, probably, for the administration of the Sacrament to a few confessing lepers.

In the evening the last dinner was attended by an unusually large number, as generally Saturday evening meetings are thinly attended. Numbers had departed, but upwards of forty sat down.

The closing meeting was well attended, and a paper contributed by Dr. Wright, on the distorted skulls found at Wroxeter, was read. Mr. Thomas Wright disputed the conclusions at which Dr. Wright had arrived, and expressed his conviction that there was original uniformation, and that the alteration was not posthumous. Considerable discussion ensued, and the subject was deferred till the winter session.

Some interesting records of Hereford were read, and this closed the business of the congress.

Thanks were warmly voted to the several officers and committees, and finally by acclamation to the president, who, with his lady, had been unflinching in his attendance at all the excursions and meetings of the congress. The president, in returning thanks, gave a *résumé* of the proceedings of the week, and thanked individually every one who had contributed by papers and descriptions to the success of the congress, which had been one of continual exertion, arising from the great distance to which the excursions extended.

ON THE MECHANICAL EFFECT OF COMBINING GIRDERS AND SUSPENSION CHAINS, AND THE APPLICATION OF THE SYSTEM TO PRACTICAL PURPOSES.\*

PREVIOUS calculations and experiments on girders enable an estimate to be made of the deflection of the girder of a given length with a given weight, and therefore the deflection of any girder intended to be attached to a chain can be calculated.

It accordingly occurred to me, that if the relation between the deflection of a wave attached to the chain, and that of the same girder unattached, could be obtained, we should be able to ascertain precisely what girder to allow to a chain, so that a given load would produce a given amount of deflection.

For this purpose I made a series of experiments upon girders of different kinds, attached and unattached to the chain, and the following are the results arrived at:—

Experiments.

The first experiments were made with a model girder to correct scale, but it was found that, when attached to the chain, the deflection was too small to be observed, and it was found necessary, in order to magnify the wave and make its amount more distinct, to have a girder of a quarter the depth of the model girder, which was made of angle iron  $\frac{1}{4}$  inch thick.

The deflection of this girder, without the chains, with a load of 42 lbs. placed in the centre, was 1.2 inches.

The deflections of the wave with the chain attached, and 227 lbs. distributed over the girder,

\* See especially our volume for 1859, pp. 372 and 517.

\* By Mr. P. Barlow. See page 526, ante.

when the weights were placed at  $\frac{1}{4}$  from the high tower, were, with—

lbs.	$\frac{1}{4}$ from high tower.	Centre.	$\frac{1}{4}$ from lower tower.
56	-.10	-.01	+.05
112	-.29	-.04	+.12
168	-.39	-.06	+.16

Experiment 2.—In this case the weights were placed  $\frac{1}{4}$  from the low tower.

56	+.06	-.01	-.13
112	+.15	-.05	-.25
168	+.18	-.07	-.36

The deflections here averaged .32 inches, with 168 lbs. equal to .08 inches, with 42 lbs., or  $\frac{1}{4}$  the deflection of the girder without the chain.

It was still obvious, from the deflection at the centre, and little rise exhibited in the wave, that the stretching of the chain to bring the metal surfaces to bear still sensibly influenced the result; and I had another wooden girder made, consisting of a plank  $7\frac{1}{2}$  inches in width, and three quarters of an inch thick, in order still more to magnify the wave, and to diminish the error from the stretching of the chain.

The deflection without the chain attached was 1.48 inches with 10 lbs.

Experiments with the Chain attached.—With 56 lbs. placed at  $\frac{1}{4}$  from the high tower on the girder, which was previously quite unloaded, the deflections were, at—

| $\frac{1}{4}$ from H. T. |
|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| -.31                     | -.48                     | -.32                     | -.02                     | +.22                     |
| $\frac{1}{4}$ from H. T. |                          | $\frac{1}{4}$ from H. T. |                          |                          |
| +.29                     |                          | +.15                     |                          |                          |

Experiment 2.—70 lbs. being equally distributed over the girder, and 56 lbs. at  $\frac{1}{4}$  from high tower.

Experiment 3.—150 lbs. all over weight in same place.

-.20    -.35    -.20    +.02    +.20    +.23    +.14

Experiment 4.—193 lbs. equally distributed; 56 lbs., as before.

-.18    -.31    +.17    +.05    +.18    +.20    +.14

The deflection here indicated with the model loaded with a weight representing 96 tons on the bridge (which experiment was several times repeated), was .31 with 56 lbs., .055 with 10 lbs., or  $\frac{1}{4}$  of the deflection of the girder without the chain.

This result being so much at variance with the general view of the subject, although very nearly in accordance with my calculations, I determined to verify it by a smaller girder, 6 inches by three quarters of an inch thick, which would render the wave still more visible, the observations being made with great nicety.

The deflection at the centre, when not attached to the chain, was 2.375 inches with 8 lbs.

Girder attached to the chains, 193 lbs., being equally distributed over it. The deflection, with the weight placed  $\frac{1}{4}$  from the high tower, was—

lbs.	$\frac{1}{4}$ from H. T.	Centre.	$\frac{1}{4}$ from L. T.
56	-.01	+.13	+.53

Experiment 2.—With 56 lbs. at the centre of the bridge, the deflection was .30.

The deflection of the wave here exhibited at  $\frac{1}{4}$  of the length with the bridge loaded to a weight equivalent to 100 tons on the actual bridge, which experiment was repeated several times with the same result, was 0.64 inch with 56 lbs., the deflection without the chains being 2.375 with 8 lbs., or 25 times the amount, thus confirming the previous experiment—a result so at variance with the preconceived notions of many engineers, that it is to be expected, in some instances, it will be received with incredulity; but an investigation will show that the result is in accordance with the law  $\frac{1}{2} \frac{W}{b d^3 x} = \text{a constant quantity.}$

If the girder were supported only in the middle, the deflection of the half girder would be  $\frac{1}{4}$ ; but, as one half of the girder cannot deflect without the other half rising from the action of the chain, it is reduced to  $\frac{1}{4}$ ; but the girder is not supported at one point only, but at various points, which will still further reduce the deflection.

Assuming .27 to be the true average result, I have calculated the necessary dimensions of a girder as follows:—It being determined by the Board of Trade what amount of weight should be the test to produce a given deflection on half the girder, we may derive from existing girders the weight which must be given to such a span as the Niagara girder to reduce the wave to a given amount. Let us assume, for example, that 200 tons on one-half the span shall not produce a wave exceeding 2 inches. To deduce the result from the Boyne viaduct, we have the ascertained fact

that in a girder of 264 feet span, the deflection with 540 tons all over was 1 foot 9 inches.

The deflection, if of the length of the Niagara bridge, would have been 26.4 to 283: 1.9: 57 inches  $\frac{27}{100} = 2.11$  inches is therefore the deflection which would have been produced by a weight of 540 tons, and therefore 200 tons would produce .79 inch deflection.

The weight of a girder of the same section as the Boyne Viaduct would be 932 tons, 261: 820: 300: 932 tons, and to produce 2 inches deflection, 368 tons, if made of ordinary iron; but if made of superior metal, the reduction of weight will be in proportion to the increased strength.

To obtain the result from the Britannia Tube, we have as an ascertained fact that its weight is 1,600 tons, and that its deflection with 200 tons all over,  $1.25 \text{ inch } 2.40^3 : 820^3 : 1.25 : 7.04.$

The weight of the tube of 820 feet long would have been 2,852 tons.

The deflection, if attached to a chain,  $\frac{7.04}{21} = .36$  inch.

The weight, therefore, to produce 2 inches deflection with 200 tons, will be 370 tons, which nearly agrees with the calculations from the Boyne lattice bridge.

To compare the Britannia bridge with a suspension end of the same span, and to produce the deflection, we have  $\frac{27}{100}$  weight of the chains equal 500 tons.

Concluding Remarks.

By the above calculation we arrive at the result that spans, much above 820 feet, may be constructed even without improved metal, where girders are not practicable; and that in large spans, where they are practicable, a suspension girder, tested with the same load and to the same deflection, will only require one-fifth or one-sixth of the metal, and will be a safer structure from depending on the extension of the material.

This result is the more important because the advocates of parallel girders have acted on this assumption—that the construction of a platform 450 feet long, sufficiently rigid for railway traffic, almost amounts to the construction of a girder itself.

When my paper was read at the Dublin meeting, there were several girder engineers present, but there was no observation made during the discussion upon the special object of my experiments, except by Professor Rankine, who investigated the subject on the spot, and arrived at nearly the same result.

The only observation made by other engineers was to the effect that there would be some oscillation or motion which could not be arrived at by investigation, but without any denial of the truth of the deductions of my experiments.

Now I venture to contend that the amount of deflection of a given girder with a given weight can as clearly be arrived at by investigation when it is attached, as when it is unattached to a chain.

There may be practical points more in favour of one construction than another, which I am prepared, as a practical man, to discuss; but these are questions rather for the Institution of Civil Engineers. But whatever these practical failures may be, there must be a certain deflection which arises with a given force or weight applied, and it is this—the first and most important inquiry in every mechanical structure, which is alone the subject that I am now desirous should be investigated and understood.

With reference to any supposed practical objection to suspension structures, when applied to railways, even when the wave is cured, I will only observe, having had great experience in railway construction, I am unable to form an opinion, without further explanation, of what is referred to, although some railway engineers adhere to the idea that no weight of girder will make a chain rigid, yet this was the original proposition for the boiler, but some of the most eminent men have expressed a contrary opinion. Telford, with whom I had the honour to serve for a time as pupil, and Sir W. Cubitt, whom I also served several years as engineer on the London and Dover Railway, and who has had great experience in railways, are both fully satisfied that the suspension construction might be adopted to all descriptions of bridges.

Mr. Rendel, who constructed the Inverness bridge, and Mr. Vignoles, who constructed the Kiev bridge, in Russia, have expressed a similar opinion. Both of these bridges had stiffening girders, of small depth, and the effect from observations made on passing loads (the Inverness bridge having had a locomotive over it on a truck) fully bears out my calculation of the ratio of the deflection with or without a chain.

I may add, that in America, suspension bridges have been used for aqueducts with success, as well

as for a railway bridge, and that the wave of the Niagara bridge, which has a girder of wood, is less than my calculation would give; in fact, I should have doubted whether any wooden girder construction could have reduced the wave of a span of 820 feet sufficiently for heavy traffic either for road or railway.

It may be true that public feeling is against suspension bridges, from the repeated failures arising from want of metal, and from no means of curing the wave, which arises, as my model has shown, by the smallest weight applied at any one point; but this is only a reason why men of science should look at the question and correct an error which is a check upon useful enterprise and upon the progress of public improvement.

When alluding to the adoption of a system of large spans for the relief of London traffic, it was not intended to express a decided opinion that this is the best mode of removing the difficulty, although I believe, on mature consideration, it will be found to be so, as the objections to the other modes suggested are very great.

Tramways in the streets will be more beneficial than is probably expected, but as London streets are generally so narrow, little can be done by this system, unless stopping at shops or residences is prohibited, except at appointed places.

The construction of a viaduct consisting of a series of shops, with a railway on the top and a street on each side, as suggested by Sir Joseph Paxton, would be the most perfect arrangement, but the cost would be serious; and the railway must follow the surface of the ground, or nearly so, which would render the gradients unfavourable.

The scheme, however, which contends with the greatest variety of difficulties, although actually in course of construction, is the tunnel under London. It is expensive, not only from destroying property on the surface, but from interfering and disarranging the sewer, gas, and water pipes, &c., under the surface. The passengers will be inconvenienced by travelling in the dark, and in a tunnel in which the atmosphere (being immediately under the surface of a crowded city), must be necessarily very impure.

An underground system has also the objection that the application is limited to the elevated parts of London, as, if below the level of high water, it would be liable to inundation.

The use of steam power is also prohibited by Act of Parliament; and Parsey's air engine, not being applicable, the girder system has, in this respect as well as others, the advantage, as steam power may be employed if necessary.

In conclusion, I will, however, observe that whether suspension girders are applicable or not to the particular purpose of London traffic, there are many cases where the benefit of railways may be extended by a safe and economical system of large spans, where they would otherwise be prohibited by the cost of execution, and I therefore trust not to have been in error, as far as relates to the mechanical points, in bringing this important subject before the British Association.

OUR BLACK DIAMONDS.

JOHN BULL finds a piquancy in panics that is not altogether objectionable to him. Panics are, to his ordinary fare—the roast beef and plum-pudding of the British constitution,—palatable *extremes*, leaving, perhaps, a certain amount of thirst and fever behind them, but still imparting a zest to his diet that plain roast and boiled would not afford. Our forefathers relished the same appetising fare. A mysterious rumble, set down for an earthquake, kept our grandmothers from Ranelagh and *faro* for a whole season; and an unexpected comet in those times made more converts to piety than the most popular preacher. In these latter days the Cherbourg dockyards, under the *nom de cuisine* of *pâtés d'invasion*, were made much of. A certain wedge, newly found in our rivers, and threatening to choke them all up,—so says the *Carle*—has also been served up at the national feast. An *entrée* of more importance and more highly seasoned, known as "the great tribulation coming upon the earth," has been partaken of in fear and trembling; while a still more recent dish has been introduced to our consideration, extracted from the probability of the failure of our coal supply. Making due allowance for John Bull's taste for false alarms, the facts in reference to the last conjured panic remain the same. There is an end to everything, and our coal-fields are not exempt from this universal law. We have used up what were no doubt considered to be our inexhaustible forests, and, seeing that our present annual consumption of coal amounts to sixty mil-

tions of tons, we must in process of time come to the last coal seam. Compare our comfortable fire-sides with the execrable stoves of our continental neighbours, and then let us congratulate one another that the failure will not be in our time. Sufficient for the day is the evil thereof.

We are deeply indebted to the coal trade, not only for our cheerful homes, but for the many remarkable inventions, discoveries, and adaptations, to which the prosecution of it has given rise. But for the coal trade, we should still be burning oil in our streets, as they do to this day in St. Petersburg. But for the coal trade, we should be travelling at the old stage-coach rate still; there would be no return tickets to Brighton for 2s. 6d.; no excursions to Paris for 20s.; no trips to the mosques and pyramids; in fine, this is another instance of great results attending small causes: we should be in a very different stage of progression but for the finding of this fossil.

When was it found? Who found it? "Næboly kens," answer the pit laddies. "Probably," suggests the most competent authority in the north, "if the subject could be fully investigated, we should find that the Chinese were the earliest coal miners; for Marco Polo attests the general use of this substance in China in the thirteenth century." Antiquaries appear to be woefully unconvincingly convinced that coals were occasionally used by the Romans, cinders having been found in Roman *débris* in several Roman stations. That they only availed themselves of coal for fuel when wood was not procurable in convenient quantities is assumed from the fact that great surface seams are still apparent, close to more than one station, which present unmistakable evidence of not having been touched. The Saxons made no general use of coal: peat and timber were in sufficient abundance for their wants. But coal must have been burnt by them occasionally for particular purposes; for we read that in the year 852 Wulfred of Sempringham paid to the Abbey of Peterborough sixty cart-loads of wood, and twelve of fossil, or pit-coal. The proportions of this payment confirm the conclusion that the use of coal was exceptional; otherwise, taking it for granted that the wood was intended for fuel, they would have been reversed—sixty of coal to twelve of wood. Possibly, as the monks are known to have been very expert in the manufacture of elegant metal work for the embellishment of their churches and altars, they may have come to the knowledge of the very superior advantages of coal for this purpose. After the Norman conquest, cart-smiths appear to have burnt coal systematically in the pursuance of their trade. The celebrated "Baldon Buke," (the north-country equivalent for "Domesday Book," which, it will be remembered, does not include the four northern counties), mentions coal several times in connection with smithcraft. The coal trade, however, can scarcely be considered to have commenced before the year 1239, when Henry III. granted a charter to the freemen of Newcastle-on-Tyne, for liberty to dig coals; and, when a regular export trade was set on foot, royalty favoured the new fuel, and ten shillings' worth of it was burnt at Edward II.'s coronation.

No sooner was coal employed by the various manufacturers of the metropolis, than an outcry was raised against it which, with but occasional intervals of quiescence, has lived down to the present day. The nobles and commons sitting in the high court of Parliament formally applied to the reigning monarch (Edward I.) to prohibit the further combustion of coal, as the smoke arising therefrom contaminated the atmosphere and rendered it unfit and unwholesome for his liege subjects to breathe. Their sovereign lord the king immediately issued a commission forbidding the use of the offending fossil, and empowering his officers to destroy the furnaces and kilns of any refractory persons who persisted in burning it. Evelyn, in Stuart times, complains bitterly of the state of the atmosphere from "the hellish and dismal cloude of sea coale." And when, in the Georgian era, a certain Fredk. Hoffman published a work at Geneva in which he attributed the frequency of consumption among the English to the injurious effects of coal smoke, the national consternation knew no bounds. On the other hand, we turn to a letter from Sir Horace Walpole, in which he writes he must leave Strawberry-hill, with all its valued associations, for Berkeley-square, for in London alone can be had health,—a fact he over and over again alludes to in his correspondence as being caused by the numerous fires, which dry the air and make it more fit for delicate people. And in the late revival of the prejudice against London smoke, an ingenious chemist asserted, through the columns of the *Times*, that the consistence given to the London

atmosphere by its fogs and smoke rendered it, so to speak, highly nutritious.

The impetus given to the trade by the royal grant, and perhaps, too, in some measure, by the starch opposition, was evidenced by the opening of new collieries. It is on record that the prior of Tyne-mouth let two new collieries near Elswick; and, what is very interesting to know, that the annual rent of one of them was six marks. In 1351 the burgesses of Newcastle were beholden to Edward III. for a license to dig for coal without the walls; and, seven years afterwards, for leave to dig in additional new places—the Castle moor and Castle fields.

In the fifteenth century, Eneas Sylvius, better known, perhaps, by his subsequent title, Pope Pius II., deposed to seeing lumps of black stone given for alms at the Scottish convent gates; nevertheless, the use of coal was pretty nearly confined to furnaces, forges, and kilns, until the middle of the sixteenth century, when it had advanced so far in public estimation as to be burnt in kitchens and halls. Wood, with its autumn-scented wreaths of mist, arising from the hearth, as from some household altar, was still used in my lady's parlour. Wood was also long afterwards employed by particular trades, or branches of trade, such as smelting iron, glass-making, brewing, dyeing, and chemical operations. Indeed, it was not till timber had become so scarce as to be sold by the pound in some districts that the resources of our coal mines were properly applied by our forefathers. Queen Elizabeth passed four Acts of Parliament to prevent the needless destruction of timber, the effects of which legal hampering manifested themselves in the gradual reduction of the number of furnaces from 300 to 59. The iron trade was most affected by the prohibition of wood fires; for in 1740 not 18,000 tons of pig iron were made in all England. This was 120 years ago. Our present annual rate of production exceeds 2,000,000 tons, and requires 12,000,000 tons of coal to smelt it and convert it into bar iron.

The present paper concerns things that are of the pit, yet not in the pit, otherwise we might tell how there are, to this day, in remote districts of Northumberland, small collieries where the mining operations are nearly as primitive as those of Edwardian times,—where a load still means as much coal as a packhouse can carry on his back, and where the machinery is of the rudest description. We may, however, mention one of the early shifts to obtain light in a mine. The moderns complain of the dim light emitted by their Davys, and deprecate the tardiness of invention that has not yet made gas applicable for mine lighting, but what would they think of fish light? Yet the phosphorescent gleam from dried fish was the only alternative the Mediaeval miner had to pitch darkness in many workings.

Coal was taxed as early as the fourteenth century, when 6d. per ton was levied every quarter of a year upon all ships leaving Newcastle with this freight, the necessity for which innovation was caused by the fact that "Scardburgh" was threatened by the French, and the sinews of war were required to defuse it. Soon afterwards the form of the duty was altered to 2d. per chaldron upon all coals not sold to freemen of the port of Newcastle, to counteract a trick of the trade that heaped twenty-two and sometimes twenty-three chaldrons into a keel that was only charged duty for twenty chaldrons. This impost appears to have been, in great measure, evaded too; for, on the accession of King Edward's sister, "Sweet Sister Temperance," Queen Elizabeth, the arrears amounted to a very large sum, which she claimed. The payment was ultimately commuted by an agreement, which fixed that future duty at 1s. the chaldron; while such coals as were sent over the sea were to be charged a duty of 5s. per chaldron. King James resented a rich harvest from this arrangement; but not altogether content with it, he superimposed an extra tax of 3s. 4d. per chaldron upon the coal intended for home consumption, and exactly doubled the duty originally levied upon coal sent to foreign parts by "our late sovereign lady of famous memory, Queene Elizabeth."

The Great Fire of London was the immediate cause of the exaction of a duty on the coal consumed in the metropolis. A large fund was required for the re-erection of so great a portion of the city as comprised St. Paul's Cathedral and fifty-two parish churches,—a difficulty the Parliament met by imposing a tax of 1s. per chaldron upon all sea coal brought to London. The modest sum raised in this manner proved quite insufficient; upon which the Parliament increased the tax to 3s. per chaldron,—much, no doubt, to Evelyn's satisfac-

tion. The old worthy must have felt mightily content when it was subsequently increased to 8s. In the present century, in the war time, the duty ran up to 9s. 4d. per chaldron; in 1830 it sank to 6s. in 1850 the greatest grievance that remained for the Londoners was a municipal charge of 1s. 1d. per ton.

So late as the reign of George III., when Pitt, Fox, Burke, Wilkes, and Junius, were all preaching universal freedom, serfdom existed in the Scotch colliery districts: when a colliery changed hands, the colliers with their wives and children were sold with the property as part and parcel thereof. These victims of legislative sluggishness were not emancipated till the year 1775. And still more pitiable victims, female colliers, were not protected from underground drudgery, by legislative enactment, till 1840. These, with the sad casualties resulting from explosions, are the dark spots on the picture.

It is noticeable that the superstitious feeling of the dark ages peopled the mines with fairies; and death from noxious vapours was attributed to the breath of a certain pale horse. The means taken for recovering persons whose animation was partially suspended by the phantom's fiery breath was one we should hesitate to adopt at the present day. A clod was immediately dug up in a green place, and the patient's face inserted into the hole left by its removal. After lying with his face downwards for a few minutes he was removed to fresh air. If no signs of life appeared after three or four repetitions of this process, it was concluded there was none left in "the pur body."

The names of some of the most brilliant personages in history flash out from the grim records of the coal trade. In 1529 we have Cardinal Wolsey, in his capacity of Bishop of Durham, regulating the affairs of the collieries in his palatinate. Then we come upon Cromwell as the partner in an undertaking to smelt iron with pit-coal. Alas, for the stanch-hearted pioneer! it failed, and was abandoned as an impracticable scheme. Then court scenes in the reign of the merry monarch pervade the page, where we read that Charles II. settled on his natural son Charles, Duke of Richmond and Lennox, the duty levied on the trade of the Tyne, with conditions that, on his demise without heirs, it should be enjoyed by Louise, Duchess of Portsmouth. Our black diamonds have lent brilliance to many a *bon mot*. One of the lady-wits of George III.'s court remarked, during an interregnum between the dissolution of one ministry and the formation of another, when the Earl of Aberdeen and the Duke of Newcastle divided the chances, in public estimation, of being prime minister, that his majesty appeared not to have made up his mind as to which coal he would burn in his cabinet,—whether it should be Scotch coal, Newcastle coal, or Pitt coal.

WORKS ABROAD.

An interesting bridge is in course of construction at Lyons, formed of rockwork, to afford communication between the great island of the *Pare de la Tête-d'or* and the remainder of the park, and promises to be a most charming piece of work. The first arch on the side next the island is just finished, and forms a vast grotto half buried under the bank of the river and half overhanging. It is to be accessible by three irregularly-shaped arcades, one on each side, approached by footpaths on the banks of the river, and one in front through the very shutment. All this is built with fragments of micaceous schist, cemented together with Roman cement, so as to constitute a monolith. Cavities and crevices have been left for the introduction of earth for ivy and stonework, &c. Another bridge, partly wood and partly rustic stonework, will connect the other side of the island with the terra firma of the *para*. The interior of the island is to be fitted up for the reception of wild beasts in caverns, as in the Zoological Gardens of Marseilles; so that the most easy-going and stay-at-home citizen may contemplate the deserts of Africa or America with the groups of tigers, lions, and pumas, and experience all the *émotions des grands voyages*, without fear of danger.

The Minister of Public Instruction in Modena, having been informed that there existed some pieces of music of the sixteenth and seventeenth centuries, mice-gnawn and worm-eaten, in the Palatinate Library, and that another collection equally valuable was stored in the National Palace, has ordered them to be put together and preserved. M. Angelo Catalani, master of the Cathedral Chapel and conservator of the library, much experienced in bibliography and musical literature, has been recently ordered by the

Government to draw up a catalogue of these musical works, among which are many of the finest Stradella, many having been never published. This catalogue, accompanied by biographic, bibliographic, and historic notes, is to be published to the world.

A great exhibition, industrial, agricultural, and horticultural, is to be held the 5th September next, in the town of Saint-Dizier (Haute-Marne), the centre, and the market, of the most important French metallurgical districts. The departments of the Seine, Aube, Côte-d'Or, Yonne, Haute-Saône, Vosges, and Haute-Marne, are invited to contribute. The ground proposed for this meeting contains 50,000 square metres. It is a magnificent park, round which the Marne winds.

The collections of the medal and antiquities department of the imperial library, Paris, have just been enriched by a bronze group of the Gallo-Roman period. It was found on the 1st July, last, at Loisia near Saint-Amour (Jura), and purchased at a high price by a distinguished connoisseur—M. Prosper Dupré, whose collection of Roman medallions is well known to all connoisseurs. This group, as well remarkable for the rarity of the subject as for its perfect state of preservation, represents a half-naked divinity with a diadem, seated sideways on a mare followed by her foal: on the base of the monument, which is no less than 27 centimetres (about 10½ inches) in height is placed an "offering-box" for the faithful. This divinity is *Epona*, the guardian angel of stables and horse-training, as M. Dupré has judiciously demonstrated in a letter of the 15th ult., in which he announces to the conservator of the cabinet of medallions his generous intentions.

The new buildings of the Imperial Library advance rapidly, and are nearly terminated. These constructions are only repetitions of the principal dispositions of those portions previously raised, with the exception of a sort of round tower.

#### THE WEDGWOOD MEMORIAL.

The committee have resolved upon a second competition for the proposed institute, and invitations have been issued to six of the architects whose designs in the recent competition were most approved. Specific instructions are being prepared by a sub-committee, aided by Mr. Hamersley, of the Manchester School of Art. We have been requested to state, in reply to the letter which appeared in our columns (p. 518, ante), that the circumstance of the designs, No. 18, "*Jus supra Tim.*," being placed second in the report of Messrs. Robinson & Hamersley, was simply owing to the accident of its position in the catalogue. "The whole of the designs were hung for examination in the order in which they were unpacked, and the four numbered 2, 18, 19, and 27, were most approved. The premiums were unanimously awarded to Nos. 2 and 27."

#### RATING OF CANALS.

UNDER a Canal Act the proprietors were protected against too great an increase of rating, by a provision that the company should be rated in the same proportion as the lands and grounds lying near the canal should be rated. Several valuable buildings were erected near the canal, and were highly rated. The company objected to be rated so highly as the nearest land containing these lands, and it was held that the rating of the most valuable and less valuable land should be added together, and the canal rated according to the aggregate value of the whole.—*Re the Glamorgan Canal Company.*

#### WORKS IN IRELAND.

A correspondence between the late Thomas Moore (the Irish poet), whose bronzed effigy now stands in College-street, Dublin, and Mr. George Roe, D.L. and alderman, addressed in his corporate capacity, on the scandalous state of the University (T.C.D.) boundary wall, has taken place recently, and elicited from the latter that the city engineer and the college clerk of works are in consultation on the subject. It would indeed seem to be time.

We understand that Mr. Worrall, C.E., is to be the new county surveyor for Derry, in the room of the late Mr. Stewart Gordon, C.E.

Gas has been recently introduced into Ballina, and is selling at 8s. per 1,000 cubic feet, irrespective of water-rent. The works were erected by Messrs. Donald, Wilson, & Co., of Paisley, chiefly on speculation, the town commissioners guaranteeing 200l. per annum for the public lights.

The Towns' Improvement Act has been adopted in Tullamore.

The new R. C. church of St. Vincent, in Dublin, Messrs. Hadfield & Goldie, architects, of which a drawing was exhibited at the Royal Academy, is rapidly making progress. The choir and transepts are raised to the base of the clerestory, the arcade being completed, and the piers to carry the central tower are now being built. The sacristy is roofed. The materials of which this church is built are white limestone dressings and dark rubble. When entirely finished this will be probably the largest R. C. church in Dublin.

A new convent has just been built at Omagh from the designs of Messrs. Hadfield & Goldie, for the religious community some time settled there. The building, designed in a simple manner, contains numerous rooms, and is pleasantly situated near the station of the Londonderry and Enniskillen Railway. The contractor is Mr. Wallis Dorlin, of Dublin, and the cost of the building will be about 2,500l. It is to be opened on the 13th of September.

The convent at Letterkenny, in the county of Donegal, is being considerably enlarged from designs by Messrs. Hadfield & Goldie. The new apartments consist of chapel, school-rooms, and dormitory. A square tower terminates the façade, which is extremely simple, and constructed of stone of the locality.

#### BELFAST, IRELAND.

THERE is a considerable amount of activity in the building trades here. The only thing which appears to limit its further increase is the price to which bricks have lately risen. Several new companies have commenced their manufacture by machinery; but the season has not been propitious, and bricks cost now double, or nearly so, what their price has been. At least 99 per cent. of all the buildings erected here are chiefly built of brick; and until very lately the whole were made by hand, with only one exception, viz. at Ravenhill, where the proprietor, after repeated failures, at last succeeded in making perforated bricks, of an excellent quality, by machinery. But, as he had a monopoly of the trade, his prices were high, which has induced others to erect machinery, which it may be hoped will shortly reduce the price to what would give a moderate profit to the manufacturer. One brickmaker has engaged to supply 1,800,000 bricks to the contractor for the erection of the Ulster Hall, a building intended to be devoted to musical purposes, the erection of which has been commenced. Two Presbyterian churches are also being built, and two others having large additions made to them; and since January last 200 new houses have been occupied for the first time. Turkish baths are being erected in Donegal-street; and, a few days ago, at about 8 a.m., the cornice in front fell, carrying the scaffolding with it to the ground, destroying part of the boarding along the footpath. Fortunately, the workmen were absent at the time, or they could not have escaped unhurt; and no person was injured on the street. The cause assigned is that the cornice projected too far for the quality of the materials employed. The roof was slated at the time.

The basement story of an extensive warehouse for Messrs. Dunville & Co. has been partly completed opposite the Roman Catholic Cathedral. The town being chiefly seated on ground reclaimed from the sea, piling is the only method which has been found sufficient to secure the structure from settlements in any building beyond a small two-story dwelling. In this case, however, as a basement story was to be provided, the foundations have been carried down eight or ten feet below the level of the street, and will, we think, be at least half that distance below the level of ordinary high water, and are about six feet broad. The first-floor will be fire-proof, and formed of brick arches resting on metal girders and columns. The latter rest on blocks of granite bedded on masonry, formed of slabs of sandstone five or six feet square. The girders are about 18 feet in length, and weigh from 17 to 18 cwt. each. The building is about 100 feet long by 80 feet wide, and will be two stories in height besides the basement.

A new Roman Catholic church has also been contracted for, to be erected on the Falls-road, near the model schools. The style is to be Decorated Gothic, with nave, aisles, porch, and two towers. The amount of contract is nearly 11,000l.

Strenuous efforts are being made to revive the project of railway communication between Downpatrick and Newry, where no conveyance ever has

been save an outside jaunting car to carry the mail, which ran as often without as with passengers. A company tried to get an Act for this line, with others, in 1845, but were defeated by other railway companies opposing.

#### AMERICAN NOTES.

The side walls of the great reservoir at the Central Park, New York, have been built up to the required height.

A new art gallery, 200 feet by 35 feet, is being erected on Broadway, near St. Thomas's Church, New York. A collection of paintings from Dusseldorf and elsewhere will be placed in it.

A new free public library is building at Worcester, Mass., with front towards Elm-street of 60 feet and 75 feet in depth. Externally it will present an elevation with a portico, and surmounted by a French roof, and be two stories in height, except at south-east corner which will only be one.

The import of Canadian timber this season to the United Kingdom considerably exceeds that of former years.

It costs 523,355 dollars weekly to clean the streets of New York.

The buildings at Washington are said now to be noble; that of the "Capitol Extension" nearly completed, the "Patent Office," with pure white marble fronts, and the "Treasury building," almost finished, and having a grand colonnade of thirty marble monoliths, being especially so.

A machine that makes 400 barrels a day from logs has been invented, and is at work at Menasha. It is called the *Livernore* patent.

On the Fox-river Canal upwards of a million of dollars have been already expended in improvement.

#### MR. SPURGEON'S METROPOLITAN TABERNACLE.

On Tuesday last a meeting of the friends of the Rev. C. H. Spurgeon was held in the new "Tabernacle," which is being erected for him opposite the Elephant and Castle, for the purpose of offering up thanksgiving for the success of the undertaking, and making an attempt to raise the remainder of the required funds so as to open the place free from debt. From a report read it appeared that the contributions were 22,196l. 19s., of which the following sums had been expended:—Paid on the contract, 10,000l.; for the purchase of land, 5,100l.; extra building expenses, 77l. 15s.; contract for foundation, 516l. 10s.; law expenses, architect, clerk of the works, and various other expenses, with 4,880l. cash in hand, brought the total up to the other side, 5,000l. more were required to complete the contract, and about 2,000l. more for extras, leaving a total of about 8,000l. still required. We gave an engraving of the design as originally selected; but it would seem, from a statement made by Mr. Spurgeon on the present occasion, that the turrets proposed will not be erected. Mr. Pooock is the architect; Mr. Higgs, the builder. We shall hereafter give an account of the structure.

#### THE SANITARY STATE OF ST. JAMES'S, WESTMINSTER.

THE fourth annual report of Dr. Lankester, the medical officer of health to the vestry of St. James's, Westminster, has been printed. It is accompanied by appendices showing the state of the stables and cow-houses in the parish, the houses drained, &c. Dr. Lankester, in his report, says,—There are 392 stables in this parish, in which are kept 1,057 horses. With many of these stables coach-houses are connected, and, above these, each room is frequently set apart as dwelling-places. The number of persons residing in these rooms is 901, or about a fortieth part of the whole population of the parish. Of the stable-yards, 9 were defectively paved; 5 had imperfect drainage; 7 were in a dirty condition. Of the stables themselves, 41 were defectively paved; 38 had bad drains; and 41 had no drains at all: 71 stables were in a filthy condition, requiring cleaning and whitewashing; whilst 238 (considerably above half) were imperfectly ventilated. Of the human dwellings above the stables, 30 were badly ventilated: in 33, the effluvia from the stables was complained of. By reference to the Sanitary Inspector's report, it will be seen that altogether 268 nuisances were complained of, and that up to the end of the year, 208 had been removed or abated. This investigation has led to a great improvement in the condition of the stables, which cannot fail to have a beneficial effect not only on the health of the human in-

inhabitants connected with them, but also on the health of the animals to which they are devoted." While speaking of the parks, and the recreation of the working classes, the medical officer remarks,—"There are no games allowed, and no means of refreshment of any kind exist. A walk in one of our parks is, after all, a dull monotonous affair for a working man, and no wonder that so few are found there. Certain portions of the park should be raised off, so as to allow of cricket and other games,—and in these games we should find at once the means of attraction and relaxation. In most of the parks of continental cities the sale of refreshments is allowed; and if this was done in our own parks, confining the refreshments to tea, coffee, and unfermented beverages, with bread and fruit, I am sure it would be the means of drawing many from the unhealthy atmosphere of the billiard-room and ale-house. Our English notion of the use of a park is too limited."

**METHODIST NEW CONNECTION CHAPEL, LEICESTER, COMPETITION.**

The successful competitor, in a limited competition, for the above chapel, to be erected in Leicester, is Mr. William Hill, architect, Leeds. The works will be immediately proceeded with under his superintendence.

**HEREFORD CLOCK TOWER COMPETITION.**

On the 15th, in pursuance of circular, the subscribers of 5*l*. and upwards to the Hereford market improvements and clock tower assembled in the music-room of the Shire-hall, for the purpose of making a selection of designs to be submitted to the Town Council. There was a large attendance. After various statements and propositions, Mr. Anthony read a proposition as follows:—"That this meeting proceed to recommend to the Town Council three designs for a clock tower and three for a clock turret entrance; but that they are of opinion that the Council should not proceed with the erection of a clock until after the old Town-hall has been removed."

This met the views of all parties, and, the other propositions being withdrawn, it was unanimously adopted.

The meeting then proceeded to make a selection, and handed in their voting papers to the mayor. The result was as follows:—

*Clock Tower.*

- No. 39 ("Tempus Fugit") ..... 22 votes.
- " 50 ("I make aim for the mark") 20 "
- " 41 ("Push Forward") ..... 11 "

*Market Entrance and Clock Turret.*

- No. 39 ("Tempus Fugit") ..... 29 votes.
- " 56 ("Incognito") ..... 5 "
- " 51 ("Belvedere") ..... 3 "

Mr. Anthony, on looking at the voting papers, observed to the Mayor that he was surprised to find that many had voted for only one design, whereas he understood they were to vote for three; therefore the numbers were not a fair criterion of the judgment of the meeting.

The Mayor.—Well, it cannot be remedied now. Mr. Anthony.—No; but I and several others voted for 39 as well as 50, although we regard 50 as greatly superior to 39; now, had we voted for 50 only, 50 would have had a considerable majority.

More recently the town council have selected for the clock-tower No. 50, "I make aim for the mark," and for the entrance, 39, "Tempus Fugit."

**MANUFACTURE OF ORNAMENTAL TILES.**

The expense of encaustic tiles stands in the way of their use to any great extent, and we would gladly see it lessened. Messrs. T. & R. Boote, of Burslem, claim to be able, by means of their patent process, to supply patterns intermixed with luted tiles "at the same price which is now charged for plain tiles, viz. 6*s*. per yard;" and that they are able, under their patent, to inlay or imbed the ornament any depth required into the body of the tiles, which precludes the possibility of the ornament wearing off, as is often seen to be the case with pavements not manufactured under this process.

That part of the mould which is to correspond with the ground-work of the article to be manufactured is made to rise by springs or other means above the level of the mould to a distance equal to the depth which it is thought necessary to give to the ornaments. Suitable coloured clay is placed in the sunk or hollow parts of moulds thus formed, and the clay which is to form the body

or ground of the article is put in, covering the interior of the mould. The whole is then subjected to the usual pressure, which gradually forces the clay last put in down into the various parts of the mould; and, as the springs yield to the pressure, the body or ground clay is forced closely upon and around the coloured clay, which is thus imbedded in the ground of the article to the same depth as that to which the parts of the mould were raised. The article is then withdrawn from the mould, and presents one smooth surface. Or, instead of the arrangement just described, the parts of the mould corresponding to the ornaments may be raised, and the ground part filled in if preferred.

In some simple specimens which have been forwarded to us, the patterns exhibit great sharpness of outline, and the material appears to be good in texture.

**METROPOLITAN WATER SUPPLY.**  
WATER SPRINGS AT GRAYS.

A PAMPHLET titled "The Water Springs of Grays,—their capability of affording a supply of pure water to the metropolis,"—by Mr. Meeson, of George-yard, Lombard-street, one of the proprietors of chalk quarries at Grays, is in circulation, with the view of pointing attention to certain springs of good chalk water which issue from these quarries, and require to be constantly pumped away by engines, to the extent of about 2,000,000 gallons a day. This water, it is suggested, would form a desirable supply in the east of the metropolitan district, as at Grays, Purfleet, Rainham, Dagenham, Lilford, Barking, East Ham, Romford, and Brentwood. It is proposed that a company should be formed to carry out the project; and, from estimates given by Messrs. Easton and Amos, it appears that a far larger quantity than two millions of gallons a day is fully calculated on. Mr. Meeson's statements are also corroborated by reports of Messrs. Prestwich, F.R.S., and Dugald Campbell, F.C.S. Mr. Edw. Amos estimates that a supply of 2,000,000 gallons per 12 hours might be ensured upon a capital of 220,000*l*. being expended in machinery and erections; 4,000,000 gallons per 12 hours for 268,000*l*.; and 6,000,000 gallons per 12 hours for 475,000*l*. He anticipates a profit of from 10 to 15 per cent.

**TESTIMONIAL TO MR. ROBERT HUNT.**  
MINERAL STATISTICS.

RECENTLY, at the Mining Record Office, Geological Museum, Jernyn-street, a silver tea and coffee service, of the value of 250 guineas, was presented to Mr. Robert Hunt, by gentlemen interested in the mineral industries of the kingdom. It consists of a silver tea-kettle, lamp, and stand, tea and coffee-pots to match, cream-ewer, sugar-basin, and hot-milk jug, *en suite*, the whole very elaborately engraved and ornamented, and bearing the cipher of the recipient. A handsome silver oval silver, weighing 200 ounces, accompanied the service, and upon it was engraved the following inscription:—

"Presented by the subscribers, who are interested in the Mineral Industries of this Empire, together with a tea service and a purse of sovereigns, to ROBERT HUNT, Esq., F.R.S., F.G.S., F.S.S., &c., Keeper of Mining Records, To record their sense of the energy and ability which he has shown in originating and carrying out the publication of the Mineral Statistics of the United Kingdom, and their admiration of his public character and private worth.

*Nil sine magno vita labore dedit mortalibus.*  
July, 1860."

A purse of 200 guineas also accompanied the testimonial.

Mr. Josiah Berry presented it, with some eulogistic observations. In the course of his reply, Mr. Hunt said,—When I commenced the work of collecting the Mineral Statistics of the United Kingdom, in 1848, the whole question was of so uncertain a nature, that I then had little hope of advancing it to that condition which has elicited this substantial approval of my labours. I commenced my work with some compilations showing the state of tin and copper mining in Cornwall. It was then extended to the lead mines of the kingdom, at the suggestion, and by the aid of Mr. John Taylor, and eventually enlarged by the recommendation of a Government commission, consisting of Sir Stafford Northcote and Sir Charles Trevelyan, to embrace the coal mines and the iron manufacture of these important islands. I am bound to acknowledge the great assistance which I have received from all parties who are especially

interested in our mineral industries. But for this it would have been quite impossible for me to have published annually, as I have now for some years been enabled to do, a volume embracing returns of all the metalliferous minerals and coal raised in Great Britain and Ireland. This inquiry has extended itself to the earthy minerals; and within a few weeks I shall place in the hands of the public a volume of returns, obtained by the Mining Record Office, of the production of clay, the manufacture of bricks, tiles, &c., and of our building and ornamental stones. I have thus sought to render the Mining Record Office, established upon the recommendation of the British Association, as useful as possible to the public. I can point with satisfaction to the collection of records obtained and preserved, showing the extent of our subterranean explorations in many of our most important mining districts.

**GLASGOW AND SOCIAL SCIENCE.**

THE National Association for the Promotion of Social Science will hold its fourth annual meeting in Glasgow, on Monday, the 24th September, and five following days. The Right Hon. Lord Brougham is president; the Lord Provost of Glasgow, Sir Archibald Alison, and the Very Rev. Principal Barclay are vice-presidents. The presidents of department are, the Lord Advocate, Sir James P. Kay Shuttleworth, the Hon. Arthur Kincaid, M.P., the Viscount Ebrington, and Sir James Emerson Tennent; the general secretary is Mr. George W. Hastings; and the local secretaries are Messrs. W. G. Blackie, Alexander B. M'Grigor, and J. Wyllie Guild.

Our readers will remember that the Association is established to aid the development of social science, and to guide the public mind to the best practical means of promoting the amendment of the law, the advancement of education, the prevention and repression of crime, the reformation of criminals, the adoption of sanitary regulations, and the diffusion of sound principles on all questions of social economy.

The proposed meeting is beginning to have a good effect in Glasgow. In almost every street which had hitherto been obstructed in some way or other, either by a barricade in front of some new building, or embankments of sand and stones consequent on alterations in draining or piping, operations are carried on with an increased energy. In Albion-street the entrance to the city-hall was some time ago rendered more convenient to the public by the demolition of several old houses; and more recently a considerable improvement has been made in Argyle-street by taking away the old-fashioned stairs from the front of the Buck's Head hotel. There is every reason to expect that the meeting will be one of great interest.

**MEMORIALS AND STATUES.**

THE memorial arch to the Royal Engineers at Brompton barracks is now completed, excepting some of the ornamental work. The spandrels and other portions of the arch are carved, some of the designs being copied from works of art met with in the Crimea. The entire work has been constructed by Messrs. Mansfield and Sons, Gray's-inn-road, from the designs of Mr. Digby Wyatt; and the carving and ornamentations are by Mr. Farmer, of Westminster, assisted by some French artists. The iron work has been cast at the foundry of Messrs. Potter, South Molton-street, Oxford-street, the Government giving the captured Russian guns for that purpose.—The statue of Mr. Frank Crossley, M.P., in the People's Park, Halifax, provided by him, at great cost, to the local public, has just been inaugurated. The statue represents Mr. Crossley sitting on a chair or couch, holding in his hand the deed of gift of the park. The pedestal, which is 3 ft. 6 in. high, weighs 34 cwt., and is of Sicilian marble; whilst the figure, which is of pure Carrara marble, is 6 ft. 6 in. high, and weighs 56 cwt. Its cost has been about 1,100*l*. The artist was Mr. Joseph Durham, of London.

—General Jourdan's statue has been placed on the Petit Place en Louvre, opposite the Pont des Arts, at Paris. It is from the chisel of M. Elias Robert, the sculptor of the frontispiece of the Palais de l'Industrie. The statue is of bronze, and is four metres in height. The general wears the uniform of the first Republic, the mantle being thrown over his left shoulder. The statue being thrown for the town of Bourges.—The Prince Regent of Prussia has allotted a sum of 10,000 crowns for the erection of a monument to Goethe, which is to be similar to that now being raised to Schiller.

DRINKING-FOUNTAIN IN THE GREEN PARK, LONDON.  
MR. SYDNEY SMIRKE, R.A. ARCHTGT.

#### DRINKING-FOUNTAIN IN THE GREEN PARK.

THE amiable donors of drinking-fountains throughout the kingdom have been so loud in their self-announcement that it is quite agreeable to hear of one erected by a lady who specially stipulates that her name shall not be made public.

The fountain in question is that which has been erected in the Green-park, and is visible from Piccadilly. Annexed is a view of it. As we have already mentioned, it was designed by Mr. Sydney Smirke, R.A., and is executed in Koclie Abbey stone, by Messrs. Edwards, of Newman-street.

It is a triple fountain, comprising three basins and three separate jets. The water is laid on by the Office of Works, the filtering apparatus being under the pavement of Piccadilly.

#### ART-UNION OF LONDON COMPETITION.

THE Council of the Art Union have not considered that the statutes sent in would justify the award of the prizes offered. They have, however, adjudged the premium of 30 guineas to the group (several figures), "Alfred in the Camp of the Danes." The artist was found to be "Mr. Thomas Dnebett, at Mr. Thornycroft's."

The premium of 100 guineas offered for the best set of drawings in illustration of "The Idylls of the King" has been awarded to No. 18, marked "Constancy," subject to a satisfactory reply from the author, (who is understood to be a foreigner,) to certain inquiries.

Nos. 22, 24, and 25, were other favourites.

It is to be hoped that artists will now send their names to be affixed to the designs, which will be open free to the public all next week.

#### FIRE! FIRE!

ANOTHER fire, of wonderful fierceness, has threatened the famous old church of St. Saviour's, in the Borough. Within the memory of those living, the extent and number of fires which have taken place within little more than a stone-throw of this ancient building are surprising. One of these destroyed the nave, and the place has been so beset by fires, that it seems almost as if by a miracle that the remainder of the fabric has been saved.

On the last occasion the West Kent Wharf, a building which extended in one direction 160 feet, in another 80 feet, and a range of older buildings running along the river to the extent of 100 feet, were burnt.

Once set on fire—it is said, by the accidental lighting of some rags—in a short time, in spite of the most vigorous exertions of the firemen, the fire obtained such strength that the whole of the City was lighted up. In vain the steam and other fire-engines threw vast quantities of water: the fire raged and roared in a manner which will not readily be forgotten by those who witnessed it

and in a few hours property of the value of probably not less than 200,000*l.* was destroyed.

Shortly after this calamity, another fire, also very destructive in its effects, took place in the Phoenix Mills, when a large stock of manufactured food, ready for exportation to the troops in China, was burnt.

The frequent occurrence of fires in the metropolis, the completeness, when the fire has once obtained any footing, of the destruction; the value of the goods and property annually consumed, give these disasters great importance, and show that measures more adequate than those which have hitherto been taken should be employed for the purpose of rendering safer the national wealth. Such burnings are a loss not only to individuals, but to the whole community.

Notwithstanding the numerous warnings, modern buildings are put up little if in any way different from those which have been burnt. Of late, by means of party-walls and the exertions of the firemen, fires are mainly kept within the extent of particular premises. In the case of warehouses, such is the nature of their construction, and so great is the size of the area which is undivided by walls, that, in nine cases out of ten, when a fire has established itself, it is impossible to prevent the destruction of the premises.

If, in the arrangement of warehouses, &c., the area within the outer walls were properly subdivided by other walls, of sufficient strength to stop the progress of fire, and the area was of such a size that only a moderate amount of flame could be produced, the firemen would be able to operate with more certain effect. The requirements of the Building Act, with this end in view, have been set aside by the decisions of magistrates.

At Messrs. Mandalay & Field's works, as we have before noticed, the place is divided by walls, and the doors are of thick metal; besides, there is a regularly organized band of firemen, composed of the workmen who live near: pipes of large diameter are also carried throughout, from which, at a moment's notice, a great quantity of water can be poured on any part. At the General Post Office the water-pipes are laid in all quarters: besides, there are in all the passages buckets and other means of quenching fire provided. There is also a regular attendance of firemen in the building.

At the Earl of Salisbury's, Hatfield House, since a fire which took place there a few years ago, water-tanks of large size have been placed on the roof, and such other arrangements made, that this stately abode is now comparatively safe. If proper provision were made in the first instance in warehouses and manufactories, a great annual saving would be the consequence. They should be built with little that could burn. If the cost were more, it would be a saving in the long run. We cannot but look with dread to several places in the metropolis in which are articles of priceless value; and it would be well to make a careful inquiry if the best arrangements which experience

could point out have been made to prevent loss. The probates of wills, the loss of which would cause endless litigation and confusion, are at any moment in danger from fire. To what extent are the King's Library and some other parts of the British Museum safe? Underneath St. Paul's Cathedral there is a large collection of seats and other woodwork; and if, by any accident with the gas or warning apparatus, it were to take fire, a great flame would be the result. Probably, however, the vaulting would prevent it from spreading to other parts.

Gas-lighting has been introduced into Westminster Abbey. The pipes are carried amongst the carved stalls and woodwork. Are the arrangements now made, to quench a sudden fire in this invaluable relic of times gone by, sufficient and satisfactory?

There are many other places which might be mentioned. In some of the larger town houses there are rare and invaluable works of art. In these buildings fires are liable to happen, which, before the arrival of the brigade engines, might cause serious damage. The most careful arrangements should be made to prevent such a possibility.

It is to be hoped that the subject will meet with the attention which its great importance demands. In considering the question, the introduction of large quantities of inflammable materials into great cities should not be overlooked. In some warehouses, even in the docks, saltpetre is stored with materials likely to produce spontaneous combustion. Rags and greasy matters are not far from each other; and naphtha, spirit of turpentine, and other dangerous compounds are brought *ad libitum* into the midst of populous neighbourhoods.

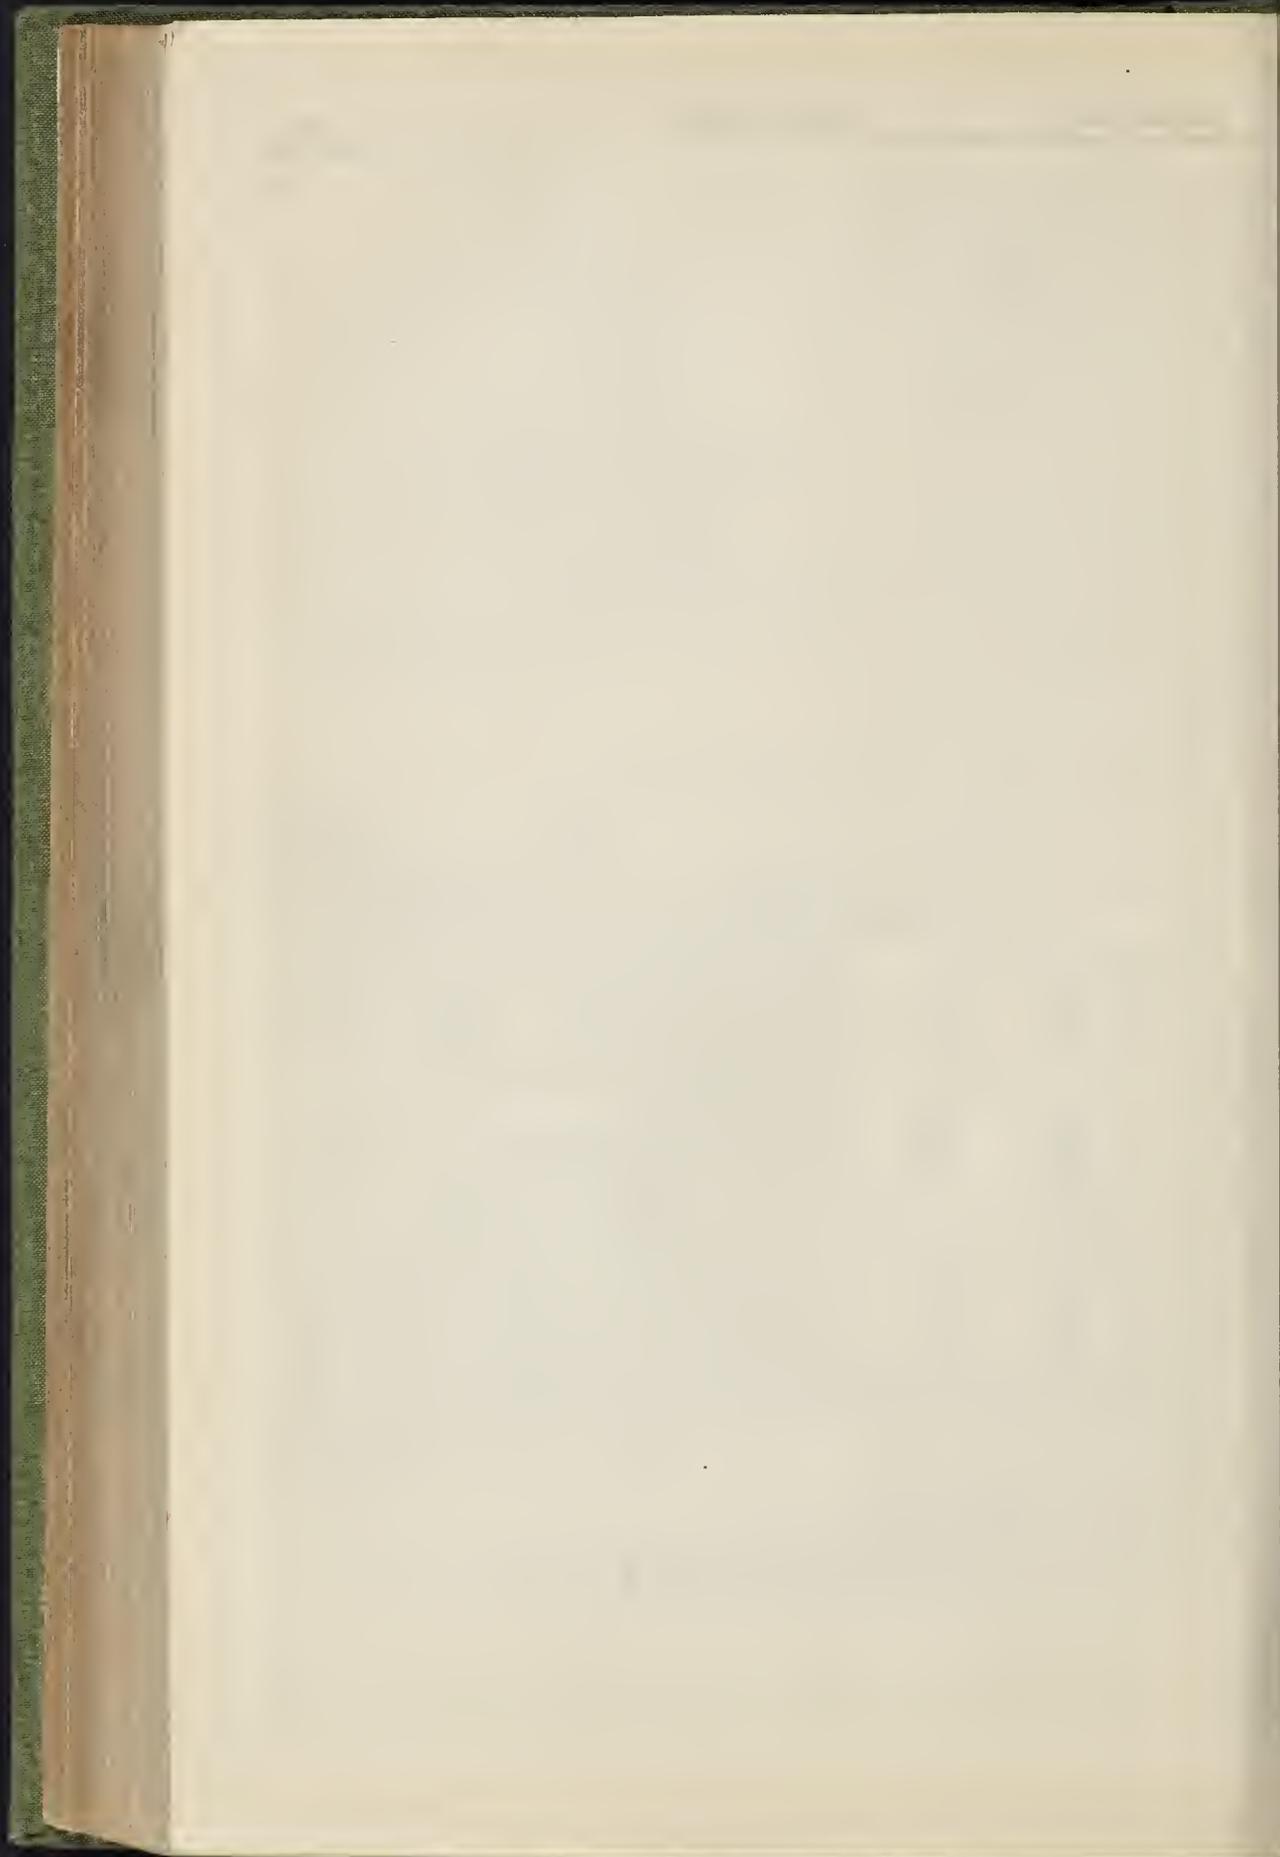

The cause of all fires in large towns should be fully inquired into, with the view of preventing the waste which is caused by the frequent conflagrations which now disgrace and damage us.

#### MESSRS. WRIGHT'S BANK, NOTTINGHAM.

OUR engraving illustrates the banking-house, which has been erected for Messrs. J. C. & J. Wright, in Carlton-street, Nottingham, under the superintendence of Mr. Charles H. Edwards, of London, architect. The front, immediately in connection with the banking-room, is entirely of stone, comprising one large window divided by stone columns, whose proportions and mouldings throughout, with the entablature, are of the Corinthian order, excepting that natural foliage is given for the caps and mouldings, in lieu of that commonly used. These columns stand upon pedestals, forming the base of this front, with moulded caps and bases having large groups of natural foliage carved in each panel. The entablature is adorned with the leaves of trees and flowers. The entrance to the banking-room is in the centre of this front, having two large double lights on either side, with smaller columns of serpentine marble with stone carved caps and bases of natural foliage supporting a circular head, the crest of the firm being carved on and forming the key-stone, above which is a moulded cornice. The glazed windows have mullions formed by twisted columns with foliated caps and bases, all of iron. The other portions of the facade of this building, comprising the manager's-room, &c., are faced with Portland cement; the ground-floor windows having columns circular on plan at top, and octagonal at bottom, whose caps and bases are also foliated, and which rest upon a moulded string. In the circular heads, and also the strings, encaustic tiles are introduced, and the whole is crowned with a moulded and foliated cornice, supported by double-moulded cantilevers. The walls of the interior of the bank are of rough stone, having a dado with moulded coping, neck, and base of polished marble cement. The ornamental architraves to the doors and windows are also of polished marble cement. The ceiling is coved, and divided into panels by ribs, at whose intersections are introduced foliated and moulded drops, the panels throughout being filled with foliated work in high relief. The counter is of oak, divided into panels. The top of the counter is of glass, divided into spaces by brass beading. The gas-fittings throughout are of foliated bronze work, made by Messrs. Tomason, of Birmingham. The floors are of Maws & Bales's tessellated pavement amalgamated. The ironwork is by Messrs. Gilbert & Frasi, Golden-lane, Barbican. The ceiling is of papier maché and carton pierre, executed and fixed by Messrs. White & Parly, of Great Marylebone-street, London. The whole of the works have been contracted for and executed by Messrs. Evans, Brothers, of Whitecross-street, London, at a cost of 3,000*l.*

MESSRS. WRIGHT'S BANK, NOTTINGHAM.—MR. C. H. EDWARDS, ARCHITECT.

PROVINCIAL NEWS.

**Welbeck Abbey.**—A costly range of stabling, coach-houses, fowl-buildings, dairy, laundry, hot-houses, pine-pits, and other offices is now in course of erection at Welbeck Abbey, the seat of the Duke of Portland, at a cost of nearly 100,000.

**Trowbridge.**—The Lord of the Manor has decided to erect a commodious market-house in this town, and it will be commenced immediately. Mr. C. E. Davis, F.S.A., of Bath, is the architect; and Mr. W. Long, of Bradford, has contracted for the masonry work; Messrs. Davis, of Frome, for the carpentering; Mr. Berry, of Trowbridge, for the plumbing, glazing, and painting; Mr. Harris, for the slating, plastering, &c.; and Messrs. Davis & Son, for the iron work. The building will be about 144 feet in length and 80 feet in width, with a frontage of 100 feet, and a considerable elevation. The roof will be of iron frames with a large area of glass, supported by iron pillars similar to the Salisbury market-house.

**King's Weare.**—The prospectus of the South Devon Hotel Company, with a capital of 50,000*l.*, in shares of 5*l.* each, has been issued, the object being to establish a first-class hotel on the King's Weare side of the river Dart, a picturesque locality in South Devon, favourably spoken of by Sir James Clark in his work "On Climate." The directors have entered into a contract with the proprietor of the Brookhill estate for a seventy years' lease of the mansion and grounds, with the option of purchasing the freehold. It is proposed to enlarge the mansion, so that it may contain 150 guests' bed-rooms, and 100 other rooms, including dining saloons, ladies' coffee-room, library, ball and billiard rooms. The cost of the alterations has been estimated at 22,000*l.* by a builder, who is willing to contract for the construction of the hotel for that sum; and the whole cost, including every necessary building, is estimated not to exceed 44,000*l.* The estate is said to be conveniently situated for railway and river carriage.

**Devonport.**—At the monthly meeting of the Devonport Board of Surveyors, five tenders were opened, responding to an advertisement for the widening and other alterations of the Rectory Bridge, at the bottom of the parsonage field, near the Rectory. The tenders were:—

S. Hallett .....	£ 87 18 3
T. Perkins .....	69 0 0
Joseph Tyler .....	64 19 0
Symons & Hoskings .....	63 15 0
W. Smith .....	60 10 0

**Merthyr Tydfil.**—Subscriptions to the amount of 1,150*l.* were collected at a first committee meeting towards erecting the new Town-hall. The Treasury have since promised 2,000*l.*, so that it only remains to raise the remaining 1,000*l.* to realize the amount originally named as being sufficient for the purpose. It is arranged to provide rooms for the Library in connection with the Hall.

**Northallerton.**—The late Mr. Adam F. Weston, of Bombay, has left a bequest of 150,000*l.* to the town of Northallerton, Yorkshire, of which he was a native. The object is to form a botanical museum for the northern counties.

**Middlesbrough.**—The foundation-stone of the new North Riding Infirmary, at Middlesbrough, has been laid with masonic honours, by the Earl of Zetland, grand master of the order of Freemasons. The entire cost of the building is computed at between 3,000*l.* and 4,000*l.* The site has been granted by Mr. Hinstler, of Acklam Hall. In competition twenty-eight designs were sent in, and the plan of Messrs. Oliver & Lamb, of Newcastle, architects, having been selected as the most suitable, that firm was engaged to superintend the erection of the building in accordance with their design. The arrangement of the plan is that of two corridors, open at the ends, of the shape of an inverted T, with wings at each end. The principal wards are designed to hold ten patients each, and the smaller wards four each, 2,000 cubic feet of air being allowed to each patient. The windows are to be placed opposite to each other, with single beds between. The wards will be 16 feet in height, and the building, it is asserted, will be ventilated throughout, by natural means, as recommended by the Crimean Commissioners and Miss Nightingale. In every ward there are to be two large open fireplaces. The wards will face the north-east. The style of architecture will be Italian, and the structure will be of brick, with stone dressings. The house for the matron, surgeon, &c., will be placed in the centre of the corridor, parallel with the road. The operating-room, with a ward for the reception of patients after operations are performed, will be in the middle of the cross aisle, and the extension wards are intended to be built at the end of the cross corridor. The present buildings will comprise the

erection of wards and accommodation for forty patients, out-door dispensary, and surgeon's, and matron's apartments. The building, however, will be so arranged that it can be extended so as to accommodate 120 patients, the maximum number, and the infirmary then will be 200 feet in length.

**Sedgefield (Durham).**—The tender of Mr. Barton, builder, Hartlepool, has been accepted for the erection of Sedgefield Union new workhouse, at a cost of 1,975*l.*

The first contract for the extensive buildings now being carried out for the "Tyneworth Promenade and Assembly Room Company" in this rising watering-place has just been completed and inaugurated by a banquet held in the new ball-room. The block consists of an hotel, and, connected with it by a covered arcade, a range of building, containing the ball-room, reading-room, and billiard-rooms, and a ladies' saloon, with washing-rooms, cloak-rooms, &c. The ball-room is 70 feet long, separated from the ladies' saloon by folding-doors, which, when drawn back, make the ball-room in all 100 feet long. Both rooms are ornamented. The ceilings are divided by curved and moulded beams, with metal scroll-work in the spandrels, and subdivided again into a fretwork of smaller geometrical panels, filled in with fruit and flowers, &c. The rooms are lighted by a chandelier in the saloon, and sunlights hung with crystal pendants, supplied by Messrs. Faraday, of London. Staining and varnishing have been adopted throughout, instead of painting. The principal entrance from the arcade is laid with Maw's encaustic tiles. Underneath the ball-room there is a supper-room of the same size, and on the upper story a suite of sitting and bed rooms, both the lower and upper story being in immediate connection with the hotel. The buildings are carried out in moulded and coloured brick-work, partaking of the character of the brick buildings of Northern Italy, and the internal fittings and decoration are designed in the same style. The architect is Mr. Archibald M. Dunn, of Newcastle. The contractors are Messrs. Wait & Howard, of Newcastle, who have taken the contract for the second block of buildings connected with the scheme, consisting of a range of shops and houses in the front street, with the completion of the arcade, &c.

CHURCH-BUILDING NEWS.

**The Hemans Window.**—By a slip, recently, the window by Mr. Warrington, put up in memory of Mrs. Hemans, the poetess, was said to be in Glasgow. It is in St. Anne's Church, Dublin.

**Aceton.**—The foundation-stone of the new church at Aceton, says the *Lincolnshire Chronicle*, will, it is expected, be laid in a few days. A limited number of builders were some time ago requested to send in tenders for the performance of the necessary work, which were opened on Saturday before last. The one submitted by Mr. W. Huddleston, of Lincoln, which amounted to between 5,000*l.* and 6,000*l.*, was accepted. The architect is Mr. Scott.

**Oakham (Rutland).**—Oakham Cemetery was consecrated on the 2nd of August, by the Bishop of Peterborough. It is situated a short distance from the town, and is 4½ acres in extent. The chapels are approached by a carriage-drive in the centre of the ground, and are midway from back to front. The external walling is executed in dark rubble stone with Bath stone dressings. The chapels are placed with their sides parallel to each other, having the vestries and an open carriage-drive between them. Over this carriage-drive is a groined roof, and tower and spire. At the angles of the tower and chapels there are angle buttresses, with carved and crocketed pinnacles. The gables have perforated ornamental parapets carried out in the Early Decorated style of architecture. The chapels have been executed from drawings prepared by Messrs. Bellamy & Harjay, of Lincoln, architects, and executed by Mr. Robert Young, of Lincoln, contractor. Mr. Thomas Barlow, of Oakham, acted as clerk of the works.

**Moggerhanger.**—St. John's Church, Moggerhanger, has been consecrated. The architect was Mr. Slater, of London; and Mr. Congest, of Kempston, was the builder. It is of Kempston stone, varied with red sandstone from the quarries at Silsoe. The cost has been defrayed by Mrs. Dawkins, of Moggerhanger House, as a memorial to her late husband, the Rev. E. H. Dawkins, whose remains lie under a brass monument in the chancel. She has also given a large burial-ground fenced by a stone wall, and is building a parsonage adjoining. The edifice, according to the *Bedford Times*, consists of a nave and aisles, central tower, and chancel with an

apsidal end. The pillars are of Ancaster stone with carved capitals; the arcades are of the same material, intermixed with Harlestone stone for the sake of variety and effect. The apse is of a more decorated character than the rest of the church, as containing the mausoleum in which the remains of Mr. Dawkins are to rest. The roof is open, and constructed of oak grown on the Moggerhanger estate. The three east windows are filled with stained glass (by Messrs. Clayton & Bell, of London), the centre being the Crucifixion, with the Resurrection and Ascension on either side.

**Landaff.**—From the annual report with reference to the restoration of the cathedral of Landaff, it appears that during the past year the nave has been covered with green Bangor slates, in place of lead, the side aisles of the once ruined portion of the building are being roofed with lead, the windows glazed, and temporary doors provided, so that the whole fabric will soon be covered and enclosed: and it is hoped that ere long the wall which still divides the two sections of the nave, and which is now the last relic of the hideous attempt at restoration in 1752, will be removed, and an uninterrupted view afforded from the western to the eastern end of the cathedral. The floor, however, has yet to be laid, suitable doors provided, and some means adopted for heating this large additional area for the comfort of the congregation. A special fund has been opened for the purchase of an organ, which it is estimated will cost from 800*l.* to 1,000*l.* The bishop's throne and the stalls are in progress of construction; but there is still very much to be done in the work of restoration. The eastern portion of the side aisles require the re-construction of their roofs and the relaying of the floor with encaustic tiles, while there are many other objects which bespeak attention, such as the repair of the monuments, the perforated parapet for the northern tower, the provision of a suitable font and lectern, the substitution of painted windows for those of ordinary glass, and the restoration of the southern tower.

**New Basford.**—St. Augustine's Church has been opened for divine service. The edifice is built of brick and stone in the Decorated style. There is a small tower, with a spired roof of stone surmounted by a stone cross. The east window is adorned at the summit with a vine and grapes, a crowned bend of the Queen, and the head of a bishop mitred, carved in stone. The two next windows (those of the vestry) on the south side have two human heads with a winged dragon in stone. Other carved heads and non-descript animals also decorate the exterior of the edifice. The archway of the western porch is carved, so as to have a lace-like appearance, and rests upon two pillars, the capitals being of carved foliage. All of the windows are of stained glass. Those of the nave are blue cathedral glass. The pulpit is of carved stone. The entrance to the chancel is through an ornamental arch in a carved screen, with metal gates, partly gilt and painted. Over the chancel screen are angels, animals, fruit, foliage, &c., carved in stone. Mr. Arthur Wilson, of Nottingham, was the architect.

**Stanton (Derbyshire).**—Stanton church was reopened on the 11th of July, having undergone a partial restoration, consisting chiefly in removing the inconvenient and unsightly square pews and west gallery, which blocked up the lower arch, taking away a singular wooden division between the nave and chancel, and the very unsuitable communion rail. The whole available space for the congregation has been fitted up with open benches, stained and varnished; a new pulpit, desk, communion rail, chancel door, &c., have also been added; the whole of the aisle and floors relaid with Staffordshire tiles in alternate red and black; the corbels of the tower arch replaced by new ones (the old having been cut away for the convenience of gallery occupants); and a new chancel arch and wall with buttress has been introduced at its intersection with the nave. A memorial window has been placed in the south side of the chancel by the Rev. S. Eversfield, the present curate, to the memory of his mother, and the nave also contains a window in memory of the late Earl Stanhope, given by the present rector. The work has been executed from designs and under the superintendence of Mr. R. Barber, of Eastwood, architect. The contractors were Messrs. Kerry & Allen, of Smalley. The heating apparatus is by Mr. Mitchell, of Lomington. The whole available space for the congregation has been filled up with open pine seats, stained and varnished, and accommodation is now furnished for 100 more than could be seated previously. The work has been executed at a cost of 360*l.* Mr. Howard, the rector, has been at the sole ex-

pense of the works in the chancel, hut the Earl Stanhope was the largest contributor to the general restoration.

**King's Heath (Birmingham).—**A new church has been consecrated at the village of King's Heath by the Bishop of Worcester. The church, which has received the name of All Saints', has been built from designs of Mr. Frederick Preedy, of London, architect, in the early Decorated style, and consists of a nave, chancel, and vestry. At present there is but one aisle, though the plan will allow of the erection of the corresponding aisle when circumstances may require it. The tower is also intended to carry a lofty spire of stone-work, and this is much needed to complete the uniformity of the structure. The roof is open-timbered, stained, and varnished. In the interior the arches are constructed of Bath and Bromsgrove stone in alternate bands. The church contains 430 sittings. The contractor was Mr. Isaac Clulee, of King's Norton.

**Epworth.—**The New Methodist New Connection Chapel was opened on the 25th ult. It is called the Killam memorial chapel, and is built on a site in the centre of the town, of about 1,500 square yards in area. The style is Decorated, modified to suit requirements. The building is about 55 feet long to the apex in front. The plan is a parallelogram, 62 feet by 30 feet. The seats are arranged in three blocks, approached by two side aisles running the entire length of the building. The main entrance is by a porch on the south front, and forms a prominent feature, projecting several feet from the face of the building. On each side of the porch are small windows, over which a string course is placed, directly above which are two large windows filled with tracery, and over these springs a relieving arch encircling a large stone containing a band, on which is an inscription. The gables are surmounted with stone terminals, and the apex with a gilt cross about 6 feet high. The chapel has a very high-pitched roof, surmounted with an ornamental ridge-cresting. In the interior the roof is open to the tie, and celled about 30 feet high, so as to appear octagonal in form, and the bays are divided by circular trusses. The pulpit, which is of stone, is semi-octagonal, with moulded capital base. The new school is similar in design to the chapel: it has a porch, and open timber roof of light and simple character. There is also a superintendent's room and library. The total cost, including land, chapel, and school, will exceed 1,600*l.* The architects are Messrs. R. C. Sutton & H. Paull, of Nottingham, the work being carried out under the superintendence of Mr. Sutton. The contractor for the chapel was Mr. G. Hall, of Nottingham, and for the school Mr. Henry Kelsey, of Epworth; and Mr. J. T. Cockayne, of Nottingham, undertook the stonework for both buildings.

**Hulme.—**The new church of St. Philip is now nearly completed. The church stands at the corner of Chester-street and Newcastle-street, Hulme, and is built of Peel stone, in the Gothic Geometric Decorated style of architecture, from designs by Messrs. Sheldrick & Brown, architects, Manchester. It consists, according to the local *Advertiser*, of a nave with side aisles, and a chancel with a north side aisle. The tower, with spire, stands at the corner, and fronts both Chester and Newcastle-street, and by its breadth the north aisle of the nave is shorter than that of the south side. The total length of the church, internally, is 117 feet 10 inches; the width, 50 feet 2 inches. From the floor to the ridge of the roof of the nave the height is 54 feet. The tower, with its spire (which is crowned with a vane), is 155 feet 3 inches high. The seats are open benches, and free to all comers, the accommodation being for 670 adults. The principal front of the church is that in Chester-street. The chancel, nave, and aisles, are paved with Maw & Co's red and black ornamental tiles. The roof is open timber work, and, like the benches, is stained to imitate oak. The covering is of Welsh slates. Messrs. Ellis & Hitchell have done the masons' work; and Messrs. Boden, Edwards, & Foster, the brick and joiners' work, &c. The gas-fittings, by Messrs. Thomson & Co., of Birmingham, are in design Gothic; and the organ is being built by Messrs. Eccleston & Bowles, of Manchester. All the windows are to be filled with stained glass by Messrs. R. B. Edmundson & Son. The principal chancel window is completed, and has been on exhibition at Messrs. Edmundson's gallery. It is 24 feet by 12½ feet. The three centre lights have for their subject the "Ascension." The light on the right, looking at the window, has for its subjects "St. James the Minor" and the "Last Supper," while the outer light on the left, looking at the window, contains "St. Philip" and "Christ Feeding the Five

Thousand." The tracery is filled with the subject of the "Pentecost," the figures having tongues of fire upon their heads. When completed, the edifice will have cost upwards of 7,000*l.*, nearly all subscribed by the Birley family of Manchester. The incumbent will be the Rev. Robert Birley. On the south side of the church, and fronting Newcastle-street, a parsonage is now in course of erection. The schools belonging to and adjoining the church have been completed some months since, and they will accommodate about 400 children.

**Prestwich.—**The Prestwich parish church has recently been repaired and partially restored. The repairs, &c., have been executed from designs by, and under the superintendence of, Messrs. Travis & Mangnall, architects. The nave and aisles have been repewed, the pews being open and of oak, with carved ends. The stonework round the windows has been redressed, and the windows filled in with diamond quarries, and finished with a coloured margin. The walls and piers have been replastered, and the whole of the nave and chancel ceilings have been repainted and redecored. The panels of the ceiling are powdered with gilt stars and the Tudor rose (red and white), and the beams have upon them imitation diaper work in party colours. The restorations are not quite complete as yet. In the autumn of the present year it is proposed to fill in the chancel end window with stained glass, to the memory of the late Countess of Wilton. The window is to be the work of Messrs. Ward & Hughes, of London. The design contains seven lights (being the number in the present window), the three centre ones being filled with "The Crucifixion," Christ in the middle, with the thieves on his right and left; while the two outer lights on either side have for their subjects the six acts of Mercy, "Feed my Lambs," and the "Good Samaritan." The tracery is filled in with attending angels.

**Kilmore Cathedral.—**The windows in the south transept, we are now informed, were executed by Messrs. Ward & Hughes.

#### SCHOOL-BUILDING NEWS.

**Shrewsbury.—**The opening of St. Chad's Schools has just taken place. According to the local *Chronicle*, the total cost of the buildings exceeds 3,150*l.* The architect was Mr. E. Huxcock, of Shrewsbury, and the contractor, Mr. J. Treasurer, of Newport. The buildings are of Elizabethan character, and constructed of brick, with Gristhill stone dressings. The east end is surmounted by a bell-turret and cross of free stone. The roofs are covered with blue tiles, and ornamental ridge, roll, cross-troughing, and down pipes. All the walls are plastered internally, with the exception of the lavatories, which are whitewashed. The master's house is situate about 22 yards from the street, with boys' play-ground in front, 52 feet long by 26 feet wide. The boys' school is 65 feet long by 18 feet wide, and 14 feet high from floor to ceiling. The class-room is entered from the school-room, and of the same height as the school, 18 feet long by 14 feet wide, fitted with seats on raised platforms. There are four air extracting fans formed in the walls, and ventilating grates in the floors. The floor of each school is laid with red deal boards, with air-space to the depth of 3 feet: there is also an open fireplace, with stone chimney-piece. To the upper school adjoining the master's house is the boys' entrance-porch, from which you enter the boys' school and lavatory. The girls' school is entered by the end of the mistress's house, up a flight of Yorkshire stone steps. The school and class-room are the same size as the boys', and similarly fitted up: the roof of the school and class-room is an open-timbered one, constructed with framed and stop-chimbered circular principals and purlins, plastered between the rafters, stained and varnished, with longes in the gables. The mistress's house is next the street. The girls' play-ground is in front of the schools, and is 66 feet long and 32 feet wide. The boundary-wall is built of pressed brick and Gristhill free stone coping, gate piers with a single cast-iron gate for mistress's and girls' entrance, a cast-iron double gate for boys' entrance, and cast-iron ornamental railing led to same coping.—The new schools, at St. George's, or Pain's-lane, near Oakengates, have also been opened. Earl Granville, who is the principal proprietor in the Lilleshall iron works there, was present, and delivered the inaugural address. The schools have been in course of construction eleven months, and cover one acre of ground. The establishment includes boys' school, girls' school, lavatories, and two residences—one for the master and the other for the mistress. The design was by Mr. Henry Clutton, of London; Mr. Mil-

lington, of the Steam Saw-Mills, Oakengates, being the contractor; whilst the works have been carried on under the superintendence of Mr. John Jones. The general tone of architecture is Gothic, the schools being made with open roofs and lancet arches. The length of each of the schools for boys and girls is 55 feet, or, including the passage, 61 feet 6 inches. The infant school is 42 feet long; the three being respectively 18 feet wide. The contract for construction was 2,000*l.*

**Leeds.—**St. Stephen's National Schools, Burmantofts, have just been opened. The new schools are erected on a triangular piece of land on the north-west side of the church. The buildings consist of two school-rooms, one for boys and one for girls; a sliding screen being placed between the two schools, so that the two rooms can be thrown together for meetings. Each school has a separate entrance porch, fitted up with lavatories. The size of the school-rooms is 36 feet 6 inches by 18 feet 6 inches, and 26 feet by 18 feet 6 inches, and they afford accommodation for 248 children. The rooms are 18 feet 6 inches high to the ceiling, and 13 feet 6 inches to the wall plate. The class-rooms are 20 feet by 14 feet, and fitted up with galleries, and the same height as the schools. The play-grounds and out-buildings are provided at the back of the schools. The building is in the Decorated style of architecture. The principal front facing Accommodation-road combines a centre and two wings. There is also a bell-turret. The cost of the schools, towards walls and out-buildings is about 1,200*l.*, beyond which, we understand, the Committee of Council on Education have made a grant of 559*l.* The schools have been erected from the designs of Messrs. Dobson & Chorley, of Leeds, architects. The contractors for the various works were—masons' work, John Holdsworth; carpenters' work, Charles Dalton; plumbers' work, Messrs. Bradshaw & Myers; plasterers' work, Mr. W. H. Barker; slaters' work, Mr. S. Croft; painters' work, Messrs. Wood & Son; and iron-founders' work, Mr. Green.

#### ECCLESIOLOGICAL SOCIETY.

At a committee meeting held August 1st, amongst other business, Mr. Burges laid before the committee his designs for a small brick church to be built at Fleet, in Surrey. He also described the original purpose of the Maison Dieu, at Dover, and the history of the building, which, after many alterations and mutilations, has been lately repaired, and to some extent restored. Referring, also, to the Liberate Rolls of Henry III., Mr. Burges discussed several questions connected with Medieval domestic architecture, and in particular called attention to the fact that although pine timber was often used in the Middle Ages, no works in that material of that date remained, whence he inferred that our present use of pine, instead of oak and chestnut, in church roofs, was a mistake, inasmuch as it was not likely to last for many years.

Mr. Pritchard, Mr. White, and others submitted designs for works in hand.

The committee, having considered the following extract from a letter from Mr. Robson, agreed that it was impossible to lay down a general rule for such cases, but that it was a right principle to preserve, as far as possible, what was good in itself, or historically valuable, or not plainly incongruous with the rest of a building. The particular case at Durham might depend on the nature of the inserted tracery, and on the extent to which the restoration of the other windows had already proceeded.

I wish to consult you upon the question of restoring First or Second Pointed tracery when inserted in Norman windows. In Durham Cathedral, all the windows on the north and south sides of the nave have had the tracery which formerly filled them removed, before I had any connection with the building. There are, however, yet remaining two or three windows in which the tracery (placed there by the architects of the end of the thirteenth and beginning of the fourteenth century), has escaped, but has recently attracted the attention of the dean and chapter, who propose to take it out as inappropriate.

I have given it as my opinion that preservation, not restoration, should be our object, and that there is at present no ground for destroying the tracery.

But I should very much like to know your views on the question in general, for it is one of no little difficulty. Did the Medieval architects insert it to give a richness to the otherwise bare Norman window? Or did they do so for constructional or glazing purposes? I think the former; and that we, so far from straining after a "purity of style," which they despised to some extent, should even restore First and Second Pointed tracery in Norman windows."

Mr. Clarke having described the present state of the proposed fund for endowing a Travelling Studentship in memory of Augustus Pugin, it was agreed, at the suggestion of Mr. Beresford Hope, that the small balance (of 3*l.* 6*s.* 6*d.*) remaining

from the Carpenter Memorial Fund might most properly be devoted to the Pugin Fund.

Mr. W. J. Hopkins, of Worcester, wrote to say that there was now every hope of the preservation of the Guesen Hall, but that funds were urgently needed for its substantial repair.

THE COST OF CRIME.

AMONGST the estimates granted by Parliament during the present session, we notice the following items in connection with the suppression of crime:—

For convict establishments at home	£368,329
Inspectors of prisons (United Kingdom)	17,000
For the maintenance of prisoners in county gaols, reformatory institutions, and the removal of convicts	159,367
For the transportation of convicts.....	20,671
For convict establishments in the colonies.....	173,000
For salaries, &c., of the metropolitan police	21,337
A further grant for ditto	136,860
For police,—England, Wales, and Scotland.....	223,000
Expense of prosecutions at assizes and quarter sessions.....	100,000
Criminal prosecutions in Ireland.....	64,634
Criminal prosecutions carried on by the authority of the Lord Advocate.....	5,500
	£1,239,793

One million two hundred and eighty-nine thousand seven hundred and ninety-eight pounds! And this is only a part of the formidable account, to which must be added the cost of private prosecutions, the county and other rates for prisons, police, &c., to say nothing of the amount of plunder and the waste of time which might have been devoted to profitable labour! Gradually, it may be hoped, we shall learn how to prevent rather than to punish, and so save part of this frightful expenditure. Schools are cheaper than prisons.

AMUSEMENTS.

Floral Hall, Covent-garden.—The music-loving public left in town have reason to thank Mr. Alfred Mellon for his promenade concerts at this time of the year, when comparatively little is going on. In conjunction with Prince George Galitzin, a great Russian composer and conductor,—in one sense at any rate,—he provides each night a very admirable entertainment, a little less lively, perhaps, than was had from Julien, but more sound. An excellent band, with Miss Parepa, Miss Augusta Thompson, and Mr. Wilbye Cooper, as vocalists, will surely give a good shilling's worth. The building appears to be exceedingly well adapted for musical performances.

St. James's Theatre.—Mr. Barry Sullivan, who has been absent from this country for several years, has improved with time, and is not to be disregarded. He has played Hamlet and Richelieu, and is very well received. Mr. Pianchi's Fortunio has been revived, and is found as sparkling as ever.

The Alhambra.—Mr. E. T. Smith has added, to the horse-riding and gymnastic attractions here, a live hippopotamus, docile as a cat and uglier than a pig. It opens its monstrous jaws to receive its Arab keeper's head, and does not snap it off; and it obeys its master, and ultimately rides off with him in an unnatural and altogether delightful manner. The Brothers Berri are remarkable performers on the flying cord. Horse-riding is looking for its Luther.

ART AND SCIENCE IN THE COMMONS.

THE National Gallery, the Kensington Museum, the British Museum, and the Gallery of Historical Portraits, have been the subjects of a good deal of talk in the Commons this last week or two, mainly on questions of supply.

On the vote of 15,000*l.*, granted, after much discussion, and by a small majority of eight, or thirty-one to twenty-three, for National Gallery improvements, it was explained by Mr. Cowper and Lord Palmerston that the purpose of asking for this sum of money was, that the hall of the picture might be "docked over," in order to provide a spacious saloon, 75 feet by 40 feet, and 35 feet high, giving an additional space of 3,000 feet superficial for pictures, besides a new room of nearly the same size, on the ground-floor, for sculpture. It was also explained that when the Royal Academy was removed, a new staircase would be made and the entrance greatly improved. The removal of the screen dividing the Gallery from the Academy was also alluded to, and the formation of a new facade at the back, the workhouse being removed, was spoken of by Mr. Cowper as a possible though distant future contingency.

On the vote of 17,000*l.* for the Kensington Museum, also granted, it was explained by Mr. Lowe that the present iron building was cold and damp, and therefore

injurious to the articles placed in it, and that the object of the present vote was to enable the Government to give it a space, and to remove the collection contained in the iron building into the building so formed. Mr. Coningham said he believed this vote was a mere drop in an ocean, and that it was intended to enter upon an enormous expenditure at South Kensington.

The vote granted for the British Museum was 89,000*l.* Several members urged the opening of the Museum to the public in the evenings, and others spoke a good word for the officers at the present Treasury, present under consideration of the Treasury. The Chancellor of the Exchequer, while expressing his regret that the Government had been unable to make better use of the site of Burlington House, said it was "owing to the wretchedly inefficient management of our public works, which was marked by vacillation, indecision, nigardliness, extravagance, and every opposite vice. There was no absolute authority, and there was a consequent waste of public money. He should not be sorry to see some sort of revolution overtake this department, for he despaired of ever seeing it brought into proper order by any other means."

On the vote of 2,000*l.* granted for the British Historical Portrait Gallery, Mr. Coningham objected strongly to such a multiplication of establishments, and said this Gallery was another instance in support of the opinion expressed by a great orator that the administration of this country in respect of its art-establishments was marked by vacillation, uncertainty, costliness, extravagance, means, and all the evils which might be enumerated." The purchase of the portraits of eminent persons was an object well worthy of a national institution, and one from which he could not dissent. But he did not think it would be a very desirable or responsible trustees, and he thought there ought to be some means of testing the purchases which were made.—Sir G. C. Lewis defended the purchasing committee, stating that an immense amount of professional knowledge, historical and otherwise, was required for the selection of such portraits, and was possessed by the committee, one of whom was Mr. Carpenter, the custodian of engravings at the British Museum.

A question was asked by Sir W. Gallwey, as to the ruinous state of things in Victoria-street, a site which he said, "presented a scene of ruin and desolation a parallel to which in no country of the world is to be found in any capital of the world. Here were plots of ground selling at prices of which, if a title could be made to them, would be worth a weight in gold, but which were now the receptacles of the filth of the neighbourhood, and the resort of the vice that existed around."

Mr. Cowper said he agreed with the hon. baronet that the present condition of Victoria-street was a most lamentable indication of the mismanagement and misconduct of the building society called the Westminster Improvement Commission; but the Government had nothing at all to do with it. If there were good grounds for appointing a committee, he (Mr. Cowper) for one should not feel disposed to offer any objection to it.

The discussions on art-matters in the House of Commons are seldom very creditable to that body.

THE MASONS' STRIKE.

THE following circular has been issued in connection with the dispute in Leeds:—

Observing that the operative masons in Leeds challenge their employers to a public discussion of the differences which caused the present strike, we think it desirable, while respectfully declining such a challenge, to lay before the public a statement of the case, which we conceive will answer the purpose without the excitement of the disputation sought for by the men.

In March last the masons sent to their employers a "memorial," asking for an advance of wages at the rate of 6*s.* per week, and that the rule of the trade should be signed by the masters. After careful consideration it was unanimously resolved to give the additional shilling per week, but that the hours of labour and the customs of the trade should not be disturbed. The advance was taken by the men, and it was believed that other demands would not be pressed; but it was shortly after insisted that the rules be signed by each employer, or a strike would take place. Such is the nature of the document, and the manner in which it is presented to the masters, that they cannot with any feeling of self-respect submit to it, nor can they agree to allow any irresponsible committee to dictate the manner in which their business shall be conducted.

It was afterwards thought that a deputation of masters and men might, by free discussion, bring about an amicable settlement; but, after three hours' talking, the matter remained as before.

In as brief a manner as possible we beg to draw attention to the rules of the operatives, leaving the public to judge on whom rests the onus of the present strike.

It will be observed that many things already the custom of the trade have been introduced, and we cannot conceive why we should be called upon to sign what has long been acceded. We look upon it as a blind to make the objectionable clauses less "odious."

The following are the rules in question:—

"Rule 1. That the hours of labour commence on Monday morning at seven o'clock, and close at half past five in the evening; and that the other five days be from six o'clock in the morning to half-past five in the evening, except Saturday, to close at four o'clock throughout the year."

The memorial accompanying the rules the men say,—"Employed as we are at a laborious and unhealthy occupation, we have not hitherto had sufficient leisure to enable us to obtain any of the usual recreations, or to visit our friends; and we are shut out on secular days from public parks, libraries, galleries of art, &c. . . . Most of us have long distances to walk to and from our employment, consisting of a low unsheltered street, and must be in the evenings alone for self-improvement, when his physical powers are nearly exhausted." We ask, will the hour required on Monday morning be conducive to the realization of the desire to attend libraries, &c., in the evening? or are the men more unfit to resume their labours at six o'clock than after a Sabbath-day's rest—than on other days?

As to closing at four o'clock on Saturdays, it was conceded to the men several years ago, and no attempt has been made to regain the hour then granted.

It. That, during the winter months, namely, twelve weeks from the first Monday after the 16th of November, to commence work at daylight and close at dark; in no case to work later than half past five in the evening.

III. That nine o'clock be starting time for three quarters of a day during the summer months, and half-past a day's work during the winter months; and one o'clock for half a day's work throughout the year.

IV. That one hour be allowed for dinner throughout the year, and half an hour for breakfast during the summer months.

These rules are the ordinary practice of the trade.

"V. That the summer rate of wages be 4*s.* 6*d.* per day, for forty weeks; and the winter wages be 4*s.* per day for the other twelve weeks in the year."

This request has been acceded to, as already mentioned.

"VI. That sub-contracting and piece-work be abolished.

If the workman cannot make as much or more by piece-work than his rate of wages, he need not enter into a contract; but why should the skilled and industrious be debarred the opportunity of earning as much as they can? Sub-letting is not generally resorted to, but surely a master and his men ought to be at liberty to make any bargain.

"VII. That overtime be not allowed, except in cases of emergency; and not to work more than two hours for a quarter of a day; and to be allowed time and half for all time worked after the first quarter, and double time for Sundays.

No one is required to work overtime except in cases of emergency; it is generally wished for by sensible men, in order to make up the time lost by bad weather, &c. Time and half is always allowed after the first quarter.

"VIII. In yards, or jobs, the nature or extent of which render the demand reasonable, sheds shall be erected. The society, in conjunction with the masters, to have a share in directing, where a dispute exists, relative to the erection of sheds. Any employer not acting in accordance with this rule to pay half the time his men lose in consequence of wet weather."

The masters find it advantageous to erect sheds, and generally do so, as the works now on hand do not, but to require pay for half the time lost by bad weather, under any circumstances, is most unreasonable, while the arbitration demanded in case of dispute is one which no contractor would submit to.

"IX. Walking time in the morning to be allowed to all jobs outside the Parliamentary boundary of Leeds, at the rate of three miles per hour; and any employer having work above three miles from the boundary, to pay 2*s.* per week for lodgings. In cases where lodgings are paid, to work the same hours as in the town, except Monday, when walking-time to be allowed, as above. In cases where men are sent by railway, to have fare and time allowed going and returning."

Walking-time is allowed to men working outside the town, but to grant it because the job is "outside" the boundary of Leeds, is absurd. Do men require walking-time from Leeds to Holbeck? or, if the borough is meant, would the men like to observe the rule, and begin work at six o'clock at Bramley?

"X. Where wages are paid on the Saturday, to commence paying at four o'clock every week; and the men working beyond the boundary to be paid on the jobs, or be allowed to leave work to reach their respective offices at four o'clock. In no case are wages to be paid at a public-house."

If wages were not paid punctually every week, there might be some reason for this rule. Some masters, out of a kindly feeling, pay their workmen when out of town, by the job; but to be compelled to do so, or forfeit the amount of work which might be done in the time calculated to reach the office (at a not over-quick pace), is just the way to lose the present boon.

It appears that the men who receive their wages on the Friday are to work full time; this is unjust.

"XI. That in all cases where disputes arise, a committee be called, consisting of an equal number of masters and men, to settle such disputes."

This rule would create more disputes than it could settle, and entail a vast amount of uncalculated labour upon a "committee," besides interfering with the rights of masters and men to arrange their own differences. We think both would sooner "agree to differ" and part rather than spend their time and patience in altercation with the "committee." It might do for some half-dozen of the "irresponsible," especially if the pay was good; they would then have nothing to do but to walk about in their frock, trying to settle disputes, and so on. It would be easy to multiply until even the former part of the rule would require to be abolished, and the latter clause found very lucrative.

"XII. That these rules be equally binding on both masters and men; and, should any alteration be required, six months' notice shall be given by either party; such notice to expire between the 1st of May and the 1st of August next ensuing."

Here is a fair specimen of the selfishness which pervades the whole. The men dictate their own terms, and finish with the offer of redress, if found unbearable, but fix it at a time "between the 1st of May and the 1st of August," when it will be all but impossible for the masters to alter their position.

In conclusion, we are glad to find that there are men who have the wisdom to discern that the combination for the enforcement of the rules is unnecessary and unreasonable; that there are "other and more solid and practicable remedies for low wages than can ever be effected by a combination;" who have the moral courage to withstand the tyranny of the leaders of the strike. We only wish that others who have similar views had the same moral courage, and would dare to vindicate their right to dispose of their labour according to their own judgment; then would there be hope for a true bond of union between masters and men; then they would never allow one class to trample on the liberties and rights of another class; but would, both by precept and by example, defend their halibut-bright—the freedom of labour.

Signed on behalf of the Leeds Branch of the West Riding Association of Master Builders,

JOHN WOOD, Chairman.  
WM. LONGLEY,  
JABEZ WOOLMAN,  
Leeds, August 10th, 1860.  
DAVID BOOTHEMAN.

Bristol.—At the adjourned meeting of the Master Builders' Association (of Bristol), held on Wednesday afternoon, the following resolution was unanimously agreed to:—"That this meeting does not see any reason to depart from the resolution passed at the last meeting relative to the de-

mands made by the operative masons." The meeting was again adjourned for a week.

The demand, as we understand it, is 4s. 6d. a day instead of 4s., and two hours less labour in a week. The advance does not appear to be objected to so much as the proposed reduction in time. Moreover, some time ago, the "wallers" (less skilled bands), who had received less wages than the free-stone men, struck, and with the aid of the free-stone men obtained an advance, making all equal. These now strike again for the further advance.

#### THE SHORTCOMINGS OF ARCHITECTS.

Sir,—Believing that your pages are open to the opinions of all who may in a friendly spirit think proper to differ either from you or those whose cause you more especially advocate, I am induced to make a few remarks on this delicate subject. In doing so, I by no means intend to disparage that useful and intelligent class of architects who, employing the means which you so judiciously advise and recommend such a building as suits its purpose, as well as becomes an ornament to the district where it is erected, but I find fault with another class altogether, and this is, perhaps, the one which constitutes itself the most revered in ancient as well as modern lore. I mean a no less eminent body than our present church architects! In making the bold complaint, I fear I am laying myself under a charge of something like insensate scolding, or scolding. Nevertheless, let the matter be judged fairly, not by prejudiced professional men, but by the all-important public, and we shall see how much we have to find fault with on this head.

Let us suppose one of the most common of all occurrences, the rebuilding or enlarging of a parish church, for which a reasonable sum is forthcoming. A committee undertakes the duties of arranging with the architect, and one of the highest standing is consulted on the job, and furnishes plans, which of themselves would grace the walls of any one particular church, and which, if they can call them by any other name, are approved of, and the work either contracted for by competition, or by the architect's design, put into the hands of some competent builder, and the work done according to his instructions to the very letter, we may say. Allowing all this to be done, the congregation assemble when it is opened, expecting to find a building adapted to the wants of the present generation; which, alas! the first visit convinces every one that the new edifice is little, if not a contempt of the old one—all the evils of the old one remaining without its benefits. In other words, the architect, in his zeal for antiquarian restorations, had forgotten that people nowadays wear broad cloth, and such delicate fabrics as silk and muslin, instead of sheepskin jerkin, and home-spun linsey-woolsey petticoats, &c., and that no provision whatever was made for the heating of the building, but that the congregation would keep themselves warm by their admiration of the beautiful, such as our professional gentlemen will have them believe the pippit and abstract art. Unfortunately our ancient generation are mortals of a kind accessible to cold, if not to the fire, and a complaint is made that the new church ought to have been heated. Another still more serious complaint is made, that they do not hear the minister so well as in the old building; and many other faults of a similar kind are made.

Now, as a plain unprofessional looker-on, I do not set up myself to be a judge of what a church ought to be; but this I assert, that all of the public buildings adapted for a public purpose, an English church is in general the worst contrivance for the object it is intended for. When we enter a church, it is expected that we must take our hats; but where are they to be put? Under a seat, perhaps, where they receive many kicks and knocks during the service. The fabric also hinders us when we kneel, but the architect has provided no accommodation that way. We complain of not hearing one half of what the minister says; but we are told the design of the building is handsome, and sound being clearly conveyed. And if it be hot weather, we ask why could not some of the windows be opened; but we are told to supply hinges or opening contrivances would mar the beauty of the design, and we must endure the close atmosphere. Whereas in winter, there being no permanent heating contrivance, an Amiot stove is stuck in the aisle, with its long iron tube of a chimney running up to the roof; otherwise I have seen an opening made for it by taking some of the glass out of an ornamental window, and putting it through there. How much the architect might be horrified by this I cannot say; one thing is certain, the churchwardens received credit from their parishioners for the comfort they afforded them, how much soever the self-complacent professional might find fault with the misappropriation.

Now, having taken a view of what architects are doing every day in our churches, let us look at what is done in another quarter. A body of dissenters, by great perseverance, collect a sum of money to build a place of worship; but they do not go to a first-class architect, but consult a well-known practical builder, and explain to him that they want a good comfortable building that will seat the greatest possible number of worshippers in the best manner, and at the least cost—warmth, ventilation, and the prospect of hearing the speaker distinctly, being all considered; and after due consultation this building is erected, and in every respect comfortable to the congregation with its more ambitious neighbour. In the chapel, the windows are to let the light in, and give ventilation; in the church, they are to obstruct both light and ventilation. A row of pews very often surrounds the outer walls, on which hats hang in safety: this homely usefulness would horrify our High Church professional. A useful kneeling-board is also provided in the chapel; whereas the churchman is expected to hang forward on his seat, pressing his forehead against the back of the seat in front of him, until perchance the softened paint or varnish sticks to it, and he has to endure a sort of penance to release himself again. And finally, he quits the church with but a very imperfect notion of what the sermon was upon. The indistinctness in which the sound reached him made it impossible to catch it. Whereas, in the chapel, though containing many worshippers, every one hears distinctly what the minister says; and the shivering in winter, or stifling heat of summer, are alike rectified, much better in the cheaper building than in the more expensive one.

Now I believe there are hundreds who will confirm what I have here stated, that churches in general are not well adapted as places of worship; and, as an English churchman, I say it with regret; and certainly much of the blame lies in our architects, who as a class are more fettered by red tape, and a rigid adherence to certain forms, than any other class; and I feel sorry to see you, as the editor of a paper devoted to building, supporting them in what they call their prerogatives, for assuredly they often fail in accomplishing what the public expect of them. Most callings are the better off by being strictly admitted outside assistance, however derogatory it may seem to be, for a contracted action, like the breeding in and in of cattle, tends to feeblity: let us hope architects will take a lesson, and build us churches wherein we may worship our Maker with the same comfort we enjoy in our homes; and, if they be unable to do that, in their highly ornamented buildings, why, I would advise, where the means allowed, to build a place expressly for worship, and have the fantastic church to look at, or for use on grand occasions: in this they might even have their much-vaunted precedent to guide them, for state coaches and court-dresses are used in this manner, and why not churches.

A LOOKER-ON.

#### Books Received.

*The Uses of Animals in relation to the Industry of Man.* By E. LANKESTER, M.D., F.R.S. Hardwicke, 192, Piccadilly.

DR. LANKESTER delivered a course of lectures on this subject, at the South Kensington Museum, of the animal product and food collections of which he is superintendent; and the present little volume has been prepared from a shorthand report corrected by Dr. Lankester himself. The lectures are essentially contemporaneous and popular, and were designed rather to excite interest in the subject than to exhaust it. Nevertheless they are full of curious and useful information as to various matters, but particularly on leather, bone, hair, silk, wool, soap, and waste.

We shall take a few passages at random, by way of specimen.

Here is an economical view of "shoddy," or new cloth made from the wool of old cloth torn to shreds.

"The cheap clothing of late years has depended upon the introduction of this shoddy; and, provided the price is not larger than gives the fair profit to the manufacturer, we cannot object to it, as it enables many to put on, at least once a week, a decent-looking coat, who otherwise would not have a cloth coat at all; and if the wear only answers to the price given, I do not think any one can find fault."

We recollect an anecdote in connection with shoddy, which shows to what an extent it must be made in some towns, and how universally it must be worn in such places. A gentleman who happened to have "a good coat upon his back," in traversing the streets of one of these towns, to his surprise found himself an object of marked and close attention amongst numerous girls who worked at the factories, and felt, no doubt, a little flattered thereby, till the sentry became rather too close, and too many pairs of eyes were exercised in it to continue at all pleasant; and at length he found, from their whispered *paroles*, that the fact of having on his back a genuine broad-cloth fabric was the sole attraction, as they had never seen such a thing in their lives before, although they had, doubtless, often heard of it.

Passing on from shoddy to leather clippings, I will mention that a patent has been recently obtained for cutting up the clippings of leather, and introducing them into the soles of boots and shoes, rendering them easier to the wearer and quite as durable, thus saving new material.

This reminds us of an attempt, some years ago, by a correspondent, to respond to an idea of ours as to the possibility of producing gutta percha or india-rubber from bituminous or other substances, by chemical means. Our correspondent, misunderstanding our meaning, and having a laudable desire to put waste leather cuttings to use, had reduced some to shreds, and made up a sort of leather shoddy with it, by help of a bituminous cement; but it was quite unfit, in the state we saw it in, to form a substitute for leather. Doubtless, it may have suggested the patented invention, however, mentioned by Dr. Lankester.

The number of uses to which a dead horse is put is really surprising. The only part to which we shall here allude, however, is the tongue, respecting which there was some mystery, till Dr. Lankester incidentally suggested that it was probably sold for export to the doctor of a newspaper, which reported the doctor's lecture, declared to be a libel on horse tongue, as it never was sold for anything so "low;" being "always sold as reinder tongue."

"Gather up the fragments that nothing may be lost" is a scriptural motto peculiarly suitable to many such uses as those to which waste substances are put; but it would scarcely form a decent covering to cloak such a purpose as this.

#### Miscellanea.

**METROPOLIS LOCAL MANAGEMENT AMENDMENT ACT.**—Mr. Tate has withdrawn his bill, adding that he intends to bring in a similar bill next session.

**Gas.**—The Ashford Gas Company have unanimously resolved to reduce the price of their gas from 5s. 10d. to 5s. per 1,000 cubic feet. At Abergaveenny it has been arranged between the commissioners and the company that the latter are to supply all private consumers with good and sufficient gas, by meter, at a maximum rate not exceeding 6s. per 1,000 feet, such arrangement to remain in operation for three years. An extension of pipes through the Grofield district has also been resolved upon.

**ST. SWITHIN DEPOT.**—There is now before the Academy of Sciences at Paris "a wonderful invention" of Mons. Helvetius Ote, of Leipzig, by which he promises to "insure fine weather." He erects a platform at a considerable height in the air, on which he places a "propeller," or huge bellows, worked by steam. With these bellows, which are "very powerful," he blows away the clouds as they gather; and, as rain comes from the clouds, it must necessarily follow that where clouds are not allowed to gather there can be no rain. He maintains that if a certain number of his "Rain Propellers," or "Pluvifuges," as he has named them, are placed at intervals over the city, he can provide for the inhabitants a continuance of fine weather, and a certain protection from sudden showers and muddy streets, so long the terror of fair pedestrians. The poor inhabitants of adjoining towns would be benefited. What would become of them? As for the Pluvifuge proprietors, their motto ought to be "Après nous le déluge." Victims, however, as we in England have of late been to wet weather, still we cannot blame the Frenchman's "Pluvifuges," inasmuch as France itself has been in nearly the same predicament,—at least the northern parts of it.

**RUINS OF AN ANCIENT CITY IN THE UNITED STATES.**—A discovery is alleged to have been recently made some ninety miles north-east of Fort Stanton, a long account of which has just appeared in the *Fort Smith (Ark.) Times*. The city, it is said, is quadrangular, and arranged with skill, many of the buildings on the outer line being pierced with loopholes. Several of the buildings are of vast size, and of massive blocks of dark granite rock, which could only have been brought to their present condition by a vast amount of labour. There are the ruins of three noble edifices, each presenting a front of 300 feet, made of ponderous blocks of stone, and the disparted walls are even now 35 feet high. There are no partitions in the area of the (middle) supposed temple, so that the area must have been vast; and there are also carvings in bas-relief and fresco work. The blocks of which these edifices are composed are cemented together by a species of mortar of a bituminous character, which has such tenacity that vast masses of wall have fallen down without the blocks being detached by the shock.

**TERRA-VOLTAISM FOR SUBMARINE TELEGRAPHS.**—Mr. Septimus Beardmore, C.E., has written a pamphlet on this subject (Stunford, Charing-cross, publisher), in which he gives an account of some hopeful experiments made by him, between Cromer and Heligoland, through a line 300 miles in length, with a simple terra-voltaic apparatus, such as he seems convinced must ultimately be used for long submarine telegraphs, instead of the battery system heretofore in use. The new apparatus consists merely of a couple of earth plates, positive and negative, one at either extremity of the line, no other battery being used. By such means it is anticipated that all necessity for insulation of the wires, or at least dependence on perfect insulation, will be obviated, the electricity evolved by a single voltaic couple, while connected with the respective ends of the wire, having no tendency to escape to earth through transit. The chief difficulty relates to the question of intensity; as, by the single arrangement, increase of surface only affords increase of quantity, and not increase of intensity, as by the battery apparatus. The thickening of conducting wires appears to be a desideratum; and certainly, since the failure of the ponderous iron envelope of the Atlantic line, this would otherwise be an improvement. Mr. Beardmore seems to agree with us in thinking that the present line across the Atlantic is not useless,—at least on his terra-voltaic principle. Surely it will not be finally abandoned without such renewed experiments with it as we have suggested.

**NEW SCHOOLS AT BRIXTON.**—The first stone of Christ Church National Schools, Brixton, has been laid by the Rev. McConnell Hussey, the Incumbent. The buildings comprise school-rooms for boys and girls, and master's residence. It is proposed to lay out about 1,700. The architect is Mr. H. Currey, and the builder Mr. Wm. Downs. The ground was the gift of Lord Holland.

**TRAFFIC RETURNS.**—The traffic returns of railways in the United Kingdom for the week ending August 4 amounted to 588,310*l.*, and for the corresponding week of last year to 549,020*l.*, showing an increase of 39,290*l.* The gross receipts of the eight railways having their termini in the metropolis amounted to 265,236*l.*, and for the corresponding period of last year to 249,727*l.*, showing an increase of 15,509*l.* The receipts on the other lines in the United Kingdom amounted to the sum of 323,074*l.*, and for the corresponding week of last year to 299,293*l.*, showing an increase of 23,781*l.*

**THE DOINGS AT GUILDFORD COUNTY COURT.**—The clearing of the court by Judge Blackburn, against which Sheriff Evelyn protested, arose, it appears, from that rampant evil, to which we have in other cases so often drawn attention, the bad construction of the court-house. "In this most inconvenient court," said the Lord Chief Justice, in his reprimand to the sheriff, "the noise from the street was found by my learned brother to be very much aggravated by that which proceeded from the lower part of the court. It did not arise from the disorderly conduct of the people assembled there; but, as no seats were provided for them, much movement naturally ensued, and a stone floor, as we understand, added to the disturbance. Moreover, the prisoners' bar intervened and separated the lower portion of the audience from the immediate supervision of the court. My learned brother found himself unable to hear the witnesses and prisoners; and from this motive, and this alone, — for the proper conduct of business — he directed the lower part of the court to be cleared. The necessity for that step arose from the defective construction and arrangement of this court. Your representation of the case goes forth to the public with a perversion of the truth, though not an intentional one, I believe, that the whole court was cleared. A portion only was cleared, the rest was occupied by the public, and they were freely admitted."

**THE STEAM PLOUGH.**—The "iron horse" has not only "taken to the road" but to the field; and seems quite ready, in this as well as in other directions, to send his fleshy protuberance quietly and gently down into the lethargic miryams of "utter extinction," along with his respected conductor, Giles Chawbacon, whose "place" is about to be taken by the engineering John Gliese, who tend the iron horse. In full view of this imminent contingency, — and doubtless devoted to the interests of "No. 1." — Mr. John Giles, of Cannon-street, City, has issued to the commercial public an address on "The Steam Plough, and its prospective influence on the Ships, Colonies, and Commerce of Great Britain," in which, recommending the "steam plough" for use in Australia, he says:—"It is the present land system of the colonies, combined with the want of an efficient agricultural engine, that checks the activity of industry and commerce, and which has led the colonies, in many cases, to the adoption of a protective policy, they hoping by the taxing of British manufactures not to provide an extended field for the employment of that industry shut out by legislation from its legitimate channel (agriculture). A steam plough will remove this tendency to a protective policy; will open up the fields of legitimate employment both for capital and industry, and there will be no need to create artificial ones by protective legislation; will result in abundant and cheap staple produce, and will subject its supply to the wholesome influence of free trade in production as well as in distribution. The steam plough, then, is a commercial question; and, unless the colonies can collectively make some effort to give it a practical solution, it will never be effected by the local trade societies which now have it in hand. In conclusion, I beg to call your attention to the accompanying advertisement, and to solicit your interest on behalf of this question, and the endeavour to give it a commercial as well as an agricultural character." The advertisement referred to, of course, relates (and quite fairly, too) to "John Giles's steam horses" and "free trade in agriculture." These horses, he says, are also suited for road transport. Their efficiency, he adds, is based on a newly-discovered principle in locomotive mechanics, and their range of speed, as ploughs, is one to six miles an hour.

**COPPER.**—A reduction of one halfpenny per lb. in the price of copper took place on Tuesday, making the wholesale price of tough cake and ingot 98*l.* per ton; best selected, 101*l.* per ton. The price of rolled brass, brass tubes, and brass wire has been generally reduced also one halfpenny per lb. in consequence. — *Birmingham Daily Post.*

**PAPER AND A DYE.**—Mr. John David Barry, of Thurlow-square, Brompton, announces the discovery of a new material for making paper, by a patented process; and he also states that "the pulp," used for the manufacture of this paper, is produced from the residuum of the plant, after chemical treatment for the production of a colouring matter, susceptible of crystallization, and applicable to the dyeing of silk, wool, and all similar animal substances.

**REMOVAL OF THE EAST-INDIA BOARD.**—The work of removing from the old India House to the Victoria Hotel, in Westminster, will commence on the 1st of September. The rent to be paid for the portion of the hotel to be occupied by the various offices is 6,000*l.*, in addition to one-half of the rates and taxes. Nothing is yet known as to what is intended with respect to the Museum. The furniture for the new offices at the hotel, with the exception of the carpets, which are to be provided by the Company, will be supplied from the present India House. The cost of the removal will be 6,000*l.*

**METROPOLITAN BOARD OF WORKS.**—On the 17th Mr. Lowman Taylor moved that three committees be formed, consisting of fifteen in each, of the members of the Board, viz., "The Finance Committee," "Works and Improvements Committee," "Building Act and General Purposes Committee" (the Main Drainage Committee still continuing a committee of the whole Board). The motion, after a long discussion, was agreed to. Mr. Aird's tender was received for the execution of the works for the southern low-level sewer through the Surrey Consumers' Gas Company's premises at Deptford, at a schedule of prices, or at a lump sum, and to take such steps as may be necessary in order to re-commence the works forthwith.

**THE GATESHEAD MECHANICS' INSTITUTE AND MR. CLEPHAN, LATELY EDITOR OF THE "GATESHEAD OBSERVER."**—The Gateshead Mechanics' Institute has unanimously adopted resolutions strongly expressive of their esteem for and many obligations to Mr. Clephan, who is one of their vice-presidents, and their regret to learn that he is in ill-health and about to quit Gateshead, after resigning the editorship of the *Gateshead Observer*; and also intimating their intention to subscribe for a testimonial which is about to be presented to him. The *Gateshead Observer* has long been celebrated for the excellent manner in which Mr. Clephan has conducted it: indeed, besides its never wanting stores of the freshest and most useful intelligence, to which we, as well as others, have for many years had constant recourse; it was often more like a sparkling repository of wit and humour than an ordinary newspaper; and we cannot help expressing our regret to hear of the ill-health of its very able late conductor.

**HONOUR TO AN ENGLISH ENGINEER IN BRAZIL.** The Emperor of the Brazils has conferred upon Mr. W. G. Ginty, formerly of Manchester, the rank of a knight or Chevalier of the Imperial Order of the Rose, inclosing along with the notification of this honour a jewelled box containing the insignia of the order, to be worn on the breast on public occasions. His Majesty has conferred this honour in acknowledgment of Mr. Ginty's general services, and for the able manner in which he has discharged the duties of Engineer-in-Chief of the new city canal and other important public works of Rio de Janeiro, of which Mr. Ginty has had the superintendence. Mr. Ginty has, during the last six years, been the managing engineer and director of the Rio gas works, and has raised the condition of that enterprise so that a dividend of 18 per cent. per annum is being made on the amount of capital, in addition to the 10 per cent. per annum paid into the reserve fund.

**THE PRAYER OF A TAUNTON BELL.**—Mr. Editor, — Knowing from experience that you take a great interest in matters connected with the "Bell family," you would be conferring a kindness if you or any of your correspondents could prescribe a remedy for my complaint, and to save me from certain death. I am pronounced to be *cracked*, and as I am inclined to believe there is some truth in the statement, I must admit that I am not in a proper state to resume my place as leader to that noble peal of "Old Martin Bells;" but still my motto is "Live and let live."

"TENOR TAUNTONIAN."

**THE COUNTY SURVEYOR FOR TIPPERARY.**—We understand that Mr. John L. Wortall, C.E., has been appointed county surveyor of the South Riding of Tipperary, in the room of Mr. William Henry Deane, C.E., nominated by His Excellency to the county surveyorship of the eastern division of Tyrone.

**NEW MILITARY HOSPITAL AT WOOLWICH.**—Tenders will be received at the Royal Engineer Office, Woolwich, in September next, for the immediate erection of the new military hospital, on a site of Government land for the use of the Royal Artillery, it being intended to convert the present Ordnance Hospital into barrack quarters.

**DEATH OF MR. CHARLES MAY.**—With regret we have to record the demise of Mr. Charles May, C.E., of Great George-street. Mr. May was well known in the profession he had embraced. He was for several years a partner in the Orwell Works at Ipswich, then carried on by Messrs. Ransome and May. He was a Fellow of the Royal and of the Royal Astronomical Societies.

**THE ERECTING OF SCHOOLS.**—It appears from a Parliamentary return that the sum expended in erecting schools since the year 1853, under the minutes of the Privy Council of Education, is 1,137,112. Of this large sum, 632,398*l.* was supplied by local rates, 79,735*l.* by non-local subscriptions, and 424,979*l.* was furnished by Parliamentary grants.

**PROPOSED PEOPLE'S PARK AT GLOUCESTER.**—The town council of Gloucester have resolved, by a majority of twelve to ten, to accept the offer of the Spa grounds, to be devoted, with sixteen acres of corporation ground, to a people's park, provided the incidental expenses, estimated at about 1,000*l.*, be raised by public subscription. About 700*l.* have been promised, but the desirable improvement will in all probability now fall through in consequence of a hitch with the Spa proprietors as to the offer not having been accepted within six months.

**IMPROVEMENTS AT THE GENERAL POST-OFFICE.** A glass flooring has been laid over the Circulation Department, under the superintendence of Mr. Gould, the clerk of the works, and Mr. Williams, the surveyor of the department of the Board of Works. The panel flooring (1½ inch thick), which is intended to give light from this office to the lower apartments, has been protected by iron bars, with a network, to prevent any of the officers from falling through to the adjacent floor, or being otherwise exposed to danger. The roof of the "newspaper office" is being composed of glass.

**THE CO-OPERATIVE NEW MILL AT ROCHE-DALE.**—The large new mill, erected at a cost of 34,000*l.*, by the co-operatives of Rochdale, was recently the scene of an event of some interest to that body. The two new engines erected by the Messrs. Petrie, of Rochdale, at a cost of 2,400*l.*, giving a nominal power of 120 horses, were for the first time set in motion, and one was named the "Co-operator," the other "Perseverance." The large mill is fast being filled with first-class machinery, and it is supposed that in a month or six weeks all will be in working order, when work for about 300 hmds will be found. This body will now have embarked about 50,000*l.* in their undertaking.

**ESTABLISHMENT FOR CONVALESCENT WORK-WOMEN AT VESINET.**—The admission of the public, on Wednesday in last week, for the first time, to a view of the establishment founded by the French Empress at Vesinet, for the convalescent work-women discharged from the hospitals, has given publicity to this foundation. "The benevolence of the undertaking," says the Paris correspondent of the *Star*, "is evident throughout the arrangements, which are all on the most liberal scale, and even carried out with a degree of elegance which cannot fail to be appreciated as the graceful homage of a woman to the artistic sensibilities of women."

**M. HITTOFF ON SIR CHARLES BARRY.**—The Five Academies at Paris held their annual sitting on Tuesday in last week, and many of the most distinguished celebrities in art, science, and literature, were gathered in the circular theatre of the Palais Mazarin. M. Hittoff, the architect, chose for the subject of his reading a notice on the life and works of the late Sir Charles Barry. English excellence is beginning to be appreciated by French artists at length; and as the individual perseverance of the Anglo-Saxon character is being revealed, a new field of art is opened to their view. The origin of Sir Charles Barry, contrasted with his end and burial, amongst the kings and most illustrious men of his country, was warmly dwelt upon, and elicited great applause.

**BOW STEEPLE.**—The statement made in some of the newspapers, that Wren's steeple of St. Mary-le-Bow was injured by lightning, appears, we are glad to say, to be incorrect.

**THE TIMBER TRADE OF BRISTOL.**—Messrs. F. K. Barnes & Sons, in their timbor circular for August, say,—"The importation during the month of July was considerable, but not anything near what it was during the last few previous years. The falling off is entirely in New Brunswick goods, and particularly in spruce deals: only 36,420 pieces were imported, against 288,441, the average of the last three years, while the tonnage from the same ports is only 2,630 tons, against 11,328 for the same period. The arrivals for the past month have been 24 vessels, 13,430 tons register (against 24 vessels, 14,526 tons for the corresponding month last year), and consist of 12 from Quebec, 8,025 tons; 4 from New Brunswick, 1,292 tons; 2 from Memel, 626 tons; 3 from St. Petersburg, 2,934 tons; 3 from Norway and Sweden, 590 tons."

**"THE LONDON REVIEW."**—The public are under so many literary obligations (for pleasure and profit received) to the poetical and political pen of Dr. Charles Mackay, the excellent editor of this new and cheap weekly paper, that we are anxious to do our best, as others are doing, not only to promote its interests ourselves, but to afford the public, as far as the *Builder's* very miscellaneous circulation extends, an opportunity of paying up a small weekly instalment towards the debt they owe Charles Mackay, by taking in his new paper regularly, as one of the best exponents "of politics, literature, art, and society" attainable at any price, much less at 3d. only, which is the price of the new *Review*. The current number (for Saturday, 18th August), like all the six which have already preceded it, is a varied and good one. One paper in it treats of the Thames embankment. The social and commercial leader is on the momentous subject of food and money prospects; and there are various other articles on fresh and interesting topics, besides a little poetry, town and table talk, sketches in Parliament, review of political and other questions of the day, book reviews, &c. &c.; the whole forming an exceedingly cheap and good weekly paper, interesting and useful to all classes.

**THE STRIKE AT COVENTRY.**—Work, it appears, has been partially resumed, although there is said to be, "on the whole, an absence of that cordial good will which should exist between employers and employed;" and the workmen are senselessly rejoicing in the damage they have done to the capital by means of which alone they can obtain employment. The *Steele*, in allusion to some of the proceedings, as reported in the *Coventry Herald*, justly remarks, that instead of denouncing "the atrocious treaty of commerce," and the "want of patriotism" in those who purchase French ribbons, the weavers ought to have been made sensible that "their looms were behind the age, and required improvements." It is only in the perfection of machinery, adds the *Steele*, that the workmen will find an end to their miseries; why, then, should they not be frankly spoken to, and the means of procuring the best and most perfect pointed out? The silk-weavers in Sudbury, Braintree, Coggeshall, and other places, we regret to learn, threaten to strike, in consequence of an intended reduction of wages.

**ELECTRO-TELEGRAPHIC PROGRESS.**—The laying of more deep-sea cables after the failure of the Atlantic one, and before something was done to improve the plan and construction of such cables, has, as we fully anticipated and pointed out, not only been followed by repeated further failures, the last of which are the Red Sea Telegraph, the Maltese cables *via* Sardinia and Corin, and the Channel Islands one; but has completely checked, if not finally destroyed, all chance of the laying of more of such lines, at least for some time to come. Can nothing be done to obviate so undesirable a result? The Government ought certainly to appoint a scientific commission, with power to experiment as well as to examine those acquainted with the subject, and those who pretend to the invention or possession of improved methods. As for those practical men who persisted in the formation of cable after cable after receiving such a warning as that of the Atlantic failure, their evidence is clearly out of court. Both gutta percha and iron, as we anticipated, are in disfavour; and the recourse we advised to renewed experiments with india-rubber as an insulator appears to be likely to be justified by the result of the experiments already made. The non-insulating or terra-voltaic system should also be experimented on; and, indeed, there is much to do before another deep-sea line is laid.

**BRIDGE-STREET, WESTMINSTER.**—In answer to Sir J. Shelley, Mr. Cowper said it was not likely that the houses on the south side of Bridge-street would be purchased for two or three years. It would then be for the House to determine what should be done with the site.

**MAGNITUDE OF THE RAILWAY INTEREST.**—Nothing, says the *Times*, can be more impressive than the magnitude of these concerns, if carefully contemplated. They probably represent at this moment at least 350,000,000l. of money actually invested. There are but 380,000,000l. in consols. Last week the chairman of a company, while performing the grateful task of announcing a large increase of traffic, felt bound to explain that a small fraction of it—some 6,000l. or 7,000l.—was accidental. The fact was that this is leap-year, and the odd day in February had added these four handsome figures to the receipts. One per cent. more or less in a dividend means comfort or pressure in thousands of households: a rise or fall in shares decides the market value of millions of property. Take, again, the people employed on the various lines. It is a new profession, and a comprehensive one too. It has a place for every class, for marquises and earls, for country gentlemen, for professional men, for engineers, for book-keepers, cashiers, ticket-takers, porters, constables, and labourers. The North-Western pays its lawyers (unluckily for it) 30,000l. a year, and took over its counters last week upwards of 13,000l. a day.

**THE ALPINE TUNNELLING AT MONT CENIS.**—The following particulars, from a review of the preliminaries regarding the process of tunnelling now in progress at Mont Cenis, we condense from the *Engineer's Journal* of Calcutta. We have before given some of these details, but it is now several years since, and the works have been for some time in actual and successful progress. The tunnel under Mont Cenis is, without exception, the most gigantic individual work that railways have given rise to. It is about seven miles and a half long, and as the depth of the tunnel is about 2,600 feet below the surface of the mountains, it is impossible to make use of even one shaft throughout the whole length. But a tunnel of seven miles and a half, through rock, and without a shaft, according to the means heretofore used for the excavation of tunnels, would be a task, the completion of which one generation would scarcely see. The longest tunnel yet completed on any railway is not quite three miles long; and that, with the advantage of many shafts, took nearly five years to complete. How long would it take, then, to complete one of twice and a half the length, and attackable only at the ends? Compressed air constitutes a motive power which serves to drive the tools into the rock, and to open out holes for mining by gunpowder. A column of water, of 18 inches in diameter, gives an oscillation about every twenty seconds, and the power it exerts amounts to several horse power. As there happens to be, near Mont Cenis, and at each extremity of the tunnel, considerable waterfalls, this hydro-pneumatic machine is particularly applicable to the tunnel in question. The excavation of this tunnel, through the solid rock, is composed of several different successive operations, which may be resolved into three principles:—to break up the rock; to remove the blocks and broken pieces; and to cut the excavation out to the exact profile of the tunnel. The use of gunpowder accelerates greatly the breaking up of the rock, but in no way contributes to the removal of the pieces. It seems to be agreed that the first operation of breaking up the rock, will be greatly expedited by the use of the mechanical appliances of Colladon, Bartlett, Grandis, Grattone, and Soumeiller. The tunnel is considered certain of being completed in about seven years, at a cost of something under 60l. sterling the yard forward of double line. This figure is very low, and many of our tunnels at home, not a quarter the length, have cost nearly double. The commencement of the works of this gigantic tunnel took place on the 1st of September, 1857. With great pomp and solemnity, the king of Sardinia, the prince Napoleon, and a vast number of distinguished persons, were present to witness the first explosion, which was made by means of electricity. The progress forward at each end seems to be about 10 feet a day, or 20 feet altogether. This gives upwards of a mile a year; and, if this rate be continued, the promised time of completion will be kept. The quantity of air used in the twenty-four hours amounts to 2,792,600 cubic feet, which is, however, compressed to one-sixth of that volume as it is used at a pressure of six atmospheres. The waterfalls are found quite enough to produce this effect.

**THE RAGGED SCHOOL MOVEMENT IN EGYPT.**—The London correspondent of the *Scottish Guardian* says:—"To show how London example and influence act, I may mention that there is now a ragged school about to be established at Cairo, in Egypt, for Moslem children."

**PROPOSED NEW STREET FROM COVENTRY-STREET.**—A plan is under consideration for a new street commencing from Coventry-street, passing south of Leicester-square, and in a south-east direction, and continuing along Orange-street at the back of the National Gallery, and in a line with King William-street. The plan has the support of the parishes of St. James and St. Martin. Funds to carry it out are in hand.

**THE DRINKING-FOUNTAIN MOVEMENT.**—At Aldershot, a public drinking-fountain has been erected by Major-General A. J. Lawrence, C.B. It is placed at the west end of the East-Block Permanent Barracks. The design was by Mr. Pepper, of Brighton. Bas-reliefs, dolphins, &c., ornament the sculpture.—At Sheffield a fountain, in the Italian style, has just been erected by public subscription, and, in great part, by gratuitous production. It includes, besides the fountain proper, a cattle trough, a wayfarer's seat, a barometer and thermometer, and a lamp surmounting the whole. The pedestal bears a medallion of the Sheffield poet and publicist, James Montgomery, the gift of the council of the local School of Art.

**MALVERN.**—Considerable additions are being made to Townsend House, Great Malvern, for Dr. Grindrod, under the superintendance of Mr. E. C. Allatt, architect, of Malvern Link. The works now in progress are a new wing, containing twenty-two additional rooms, with large dining-room (40 feet by 31 feet, 16 feet high); hall, staircase, observatory tower, finishing with a lead flat, piers, and open balustrade, the whole forming part of a plan involving an outlay of many thousand pounds. The contractor for the works is Mr. W. Nott, of Malvern Link. On the 27th ult., the roof of the new wing having been completed, through the liberality of Dr. Grindrod the workmen, to the number of eighty-five, were invited to a substantial dinner, to which they did justice. After dinner the grounds were thrown open, and the band of the Malvern-hill Volunteer Rifles (11th Worcestershire), were in attendance, and played a selection of music. In the evening, the workmen, with their wives, who had been invited to join them, to the number of 150, sat down to tea, after which the Rev. G. Fisk (the vicar of Malvern), with Dr. Grindrod, addressed the meeting at some length, and the vicar, at the request of Dr. Grindrod, presented to the architect a case of mathematical drawing instruments (by Archbutt, of London), in testimony of his satisfaction. A Bible and a waterproof coat were presented to Mr. Freherne, the foreman.

**TENDERS**

For alterations and additions to National School, Sutton, Surrey; Mr. Richard Gover, architect:—  
Ware ..... £127 0 0  
Foster ..... 165 0 0  
Cuff (accepted) ..... 163 0 0

For alterations and additions to Camilla Lodge, Sutton Surrey; Mr. Richard Gover, architect:—  
Giem ..... £790 0 0  
Foster ..... 738 0 0

For Villa, at Sydenham; Mr. Richard Gover, architect:—  
Humphries & Ludford (accepted) ..... £1,600

For enlargement of All Saints' Church, Norwood; Mr. Nash, architect:—  
Dove, Brothers ..... £2,057 0 0  
P'Anson ..... 2,944 0 0  
Ashby & Son ..... 2,855 0 0  
Ashby & Hornet ..... 2,830 0 0  
Nicholson ..... 2,800 0 0  
Jackson & Shaw ..... 2,800 0 0  
Deards ..... 2,750 0 0  
Paper ..... 2,700 0 0  
Mlyers ..... 2,700 0 0

For alterations to Warehouses, 56 and 26½, Milk-street City; Mr. William Nunn, architect:—  
Larke & Son ..... £3,243 0 0  
Gadsby ..... 2,798 0 0  
Todd ..... 2,712 0 0  
Brass ..... 2,700 0 0  
Turner ..... 2,580 0 0  
Day ..... 2,550 0 0  
Wills ..... 2,493 0 0

For the enlargement of St. John's Church, Penze; Mr. Edwin Nash, architect:—  
Rudkin, Junr. .... £1,650 10 0  
Watts ..... 1,525 0 0  
Hollidge (accepted) ..... 1,390 0 0

For Works in the formation of Cemetery, Aldershot; Mr. T. Goodchild, architect, Guildford:—  
Two Chapels, Lodge, Dead-house, and Laying out Boundary Walls, and Draining Martin ..... £1,280  
Swayne (accepted) ..... 1,200 ..... £190

# The Builder.

VOL. XVIII.—No. 917.

The Lambeth Wood-Carving Works.

BEFORE now we have mentioned the Wood-Carving Works in the Belvedere Road, Lambeth, which, now as Jordan's and then as the property of a company, have been carried on for several years without any great amount of success. Carving by machinery, as was professed there, did not commend itself to the artistic mind. In carving we look for heart-work, as well as hand-work,—variety, freedom, and individuality. Carving by machinery could not give these; and implied the necessity for repeating the same form. Had less been claimed for the machinery, or had it better understood that less was claimed for it, especially as it could not produce complete carving, it would have been viewed with more favour. The works are

now in the hands of Messrs. Cox & Son, who seem to take a right view of the matter, and do not profess to produce carvings by machinery, but to execute carving with the aid of machinery.

The longer the results of the application of steam-machinery to works of general utility are studied, the more clear becomes the impression that although, for a time, it may press upon individuals and disturb the current of industry, all that lessens the cost of production is a general advantage, ultimately felt even by those interfered with. Unfortunately, however, it is too frequently the case that classes of persons engaged in industrial pursuits, and even those engaged in pursuits which may be considered more purely intellectual, take their view from one point only, and this leads to much of the misunderstanding which prevails.

From time to time we have shown incidentally what the effect of machinery has been. We have noticed the improved condition of the Lambeth potters and the glasscutters; the vastly increased amount of employment, and more comfortable condition, enjoyed by the cottonspinners; how much greater is the number of persons engaged since the introduction of the locomotive in comparison with the old stage coach days; and how, in our great manufactories, the introduction of the steam-engine, so far from having been the means of destroying the value of the labour of men's hands, has increased the demand, and been the means of raising the social position of workmen and the amount of their earnings.

It is difficult to imagine what would have been the state of this and other civilized countries but for the application of steam,—that vast power which seems to have been put into the hands of man by an all-wise Providence to meet the necessities of increased population, and to advance the position of mankind. But for this, how could we at the present day drain from the bowels of the earth in sufficient quantities the coal, iron, and other minerals, which are the very main-spring of our manufactories and great ministers to our comfort? Every tool is a piece of machinery: the most complicated machinery is, after all, but a more perfect tool.

As it is in certain mechanical trades, so it is in departments of art, that aids which would save a vast amount of labour, and not affect

the artistic merits of a particular work, are objected to. In engraving, for instance, Woollett employed assistance in etching large portions of his plates. By his skill in working on this foundation, or what may be considered the "dead colouring" of his plate, he produced original effects, and so we have prints which, in many respects, have not since been equalled. But for this help we should have had fewer engravings from his hand. Many engravers of eminence have declined such assistance, and spent months on parts of plates which might have been quite as well done by inferior hands, or by a competent machine, tastefully and skilfully employed.

In sculpture, when the model has been created by the artist, to hew it from the solid marble or stone is very hard and mechanical labour, and mechanical appliances are used to bring the block to the shape of the model: meaner hands than his own may carry the work still farther, and then the sculptor adds the finishing touches, which give perfectness and value to the work.

As regards carving in wood, and some kinds of metal-work, the same considerations will apply; and it is on this principle that the machinery is used in Lambeth. A visit to the works is interesting.

In commencing a wood carving, as in stone, a large amount of labour is required to shape the material, and bring the work into such a condition as to enable the skilled carver to produce the greatest effect with the least expenditure of time,—giving those delicate touches which make all the difference between perfection and mediocrity. This preparation the steam machinery founded on Jordan's patent executes. Without entering into mechanical details, we will endeavour to give a general idea of the manner in which the work is managed. On the centre of a metal table is a convenience for fixing either a drawing or model of any description which requires to be copied. Supported by an ingeniously contrived apparatus, is a point which with the greatest facility can be made to move not only in all directions, forward and backward, but also to rise or fall with the various depths and sinkings of the carving. We will suppose that a wood panel which it is required to produce is fixed in the centre of the table below the point mentioned, and that one, two, or more plain panels of the proper thickness on which it is intended to operate are fixed in position on either side. Above each of these panels is a drill or cutter which, in an upright position, moves round with the swiftness of lightning: so rapid is the motion that the cutters make from 6,000 to 7,000 revolutions in a minute—driven by the steam-machinery: the cutters whirl with a whizzing noise; but until the central point is made to touch the model, the smooth wood on either side also remains unmarked. When, however, the manager of the machine, by a particular power which it is difficult in words to describe, passes the movable point just mentioned over the outlines of the model,—at the same moment the whirling cutters move over the wood, all acting in exactly the same way, and cutting; as the central point is passed over the ornament, the exact outline of the tracery. Not only do the cutters follow the lines on the surface, but by raising or lowering it to the different depths of the model, as we have said, the whole of the panels become fashioned in a wonderfully short time. It matters not whether the design consists of foliage, figures, scrollwork, letters in relief, diaper patterns, or what not: by the clever guidance of the workman who has charge of the machine, the seemingly magical operation goes on; and soon the panels, or whatever else may be required, are copied, and, in a rough form, ready for the carver to finish.

On examining a number of preparations made in this way, consisting of pinnacles, stall ends, open tracery work, corbel heads, and a quantity of other ornamentation of both large and small size, it is seen that as a preparation for the hands of the finishing carver nothing could be better: the roughness which is left would be suggestive to an artistic mind.

The operations of the machine are limited to the preliminary preparation of carving: the

completion of the work depends on the skill of the carver.

In this place we noticed works in progress for Limerick, Cheltenham, Hemel Hempstead (under Mr. Christian), the Scotch Church, Regent-square (Mr. Gibson), Barbadoes, and other places at home and abroad. It is asserted that, by the application of the machinery, a saving of from 25 to 50 per cent. is made in the cost of most descriptions of carving. About 100 men are now engaged here, whose wages are said to be more than could be earned by them if engaged on the old method. The process can be applied to stone and metals. The saving of labour, in open and other brass-work, is considerable. It is not necessary that all work should be finished in this establishment. The models of other carvers might be sent, and the work prepared in the rough, to be finished according to their taste and skill elsewhere. Nor is it necessary that forms should be largely repeated, although thus of course the greatest saving can be effected: but traceried panels, for example, all differing, can be produced at comparatively small cost, with the assistance of the machine. By thus lessening the cost of carving for ordinary works, it is calculated to lead to an increased demand for it, and consequent greater employment for carvers, who would thus get the means of improvement to fit them for works where cost is of less consequence.

## MEDIAEVAL SCULPTURE; ILLUSTRATED IN GLOUCESTER CATHEDRAL.

In the notice which appeared in our pages of the Gloucester Congress of the Archaeological Institute, mention was made of an address on Mediaeval Sculpture, by Mr. Richard Westmacott, R.A. Let us return to it.

Some have considered, he said, the Church architecture of particular periods to be the indication of the moral and religious condition—the gauge, as it were, of the degree of goodness or piety of a nation; and thus have begged a question, rather than established a temporary connection between the two. It is extremely difficult to account for any particular mode or form of architecture by a reference to a particular class of feelings or sentiment in a people. No one can for a moment bring himself to believe that religious impressions are of such a nature as at one time to be expressed by the round arch, at another by the pointed, at another by the most elaborately decorated double arch, and so on. And yet we should be obliged to admit something of the kind, if the assertions of some admirers of peculiar styles of architecture were founded on true grounds. This character of the art, as eminently expressive of religious orthodoxy, has been attributed especially to the Pointed and Decorated styles of Gothic, according to the fancy of the admirers of each. They have dwelt upon the peculiar forms of these styles, and seem to have assumed that, as these were departed from, it proved the deterioration of the religious element in society—that the architecture is the expression of the religious sentiment—and that it is owing to the more intensely pious impulse of those ages, that edifices of such magnificence and heauty were erected all over this country; and secondly (and it is a sort of logical consequence), that had architectural design proved the diminution of religion in a people. There can be no doubt that in the twelfth and three following centuries, ecclesiastical edifices were erected of a character that succeeding ages have not approached in beauty and richness of decoration; and, on the other hand, at and for some time after the Reformation similar edifices existed. But it would be exceedingly unsound to found upon these facts an argument to prove that the age of beautiful architecture was *ipso facto* an age of morality and piety; and then, *pari ratione*, that the reformers, even of the most extreme school in England, namely the Puritans, were less moral and religious, because their ecclesiastical architecture was of a very low character. The history of the respective periods, and of individual habits, at once would show how fallacious such a test must be. We know that, narrow as were some of the religious opinions of the more modern period, there was an infinitely wider spread of religious interest in the masses, and a greater craving to be taught what is the truth after the fifteenth century than before it. Prior to this all men howed uninquiringly and mechanically to a system that worked conveniently for particular

interests, and which could only so work through the general ignorance of the community.

The earliest style with which we are acquainted, the solid severe Saxon and Norman, by degrees changed its character—almost Egyptian or Hindu in its heavy sobriety—for a lighter form: this was the Early English or Pointed, which again took another character in the Florid or Decorated style. These seem to have been developments of principles discovered or deduced from practice; but the particular styles cannot be referred to any moral causes, or special phases of religious teaching or feeling. But how, it may be asked, can it be accounted for, that so marked a deterioration or degradation of ecclesiastical art occurred, if there was not a decline of religious impulse as a cause? Simply, that having reached a degree of beauty beyond which it seems the artists of that age were unable to carry it, like everything else it underwent a change, and that change was deterioration; not because the religious sentiment was weakened, but because it is in the nature of man not to be satisfied, and desiring change or novelty, he is too frequently tempted to loosen his hold of what is good in art, and, by straining after new qualities, to fall into whatever is weak and bad. What happened in Greece in the best times of fine art? After Phidias had in the age of Pericles wrought sculpture to its highest excellence, and made the art the handmaid and expression of the most sublime sentiment, a change was required from that which had satisfied, till then, the feeling of the time. Praxiteles then introduced the fascination of the material and sensuous style; and later, in the age of Alexander, Lysippos introduced the energetic and exaggerated style, which referred rather to physical than to æsthetic art qualities. And so it was in the history of Ecclesiastical design. There is no reason to imagine that such change was to be considered a proof that there was less real religion in the world, or that when art was in its full glory, the world was also all religious. Diana was not less fervently worshipped at Ephesus, nor Minerva less honoured at Athens, because the sublime sculpture of Phidias, or the exquisite architecture of Ictinus had suffered eclipse, and had given way for less admirable productions. No; the ecclesiastical art of our middle ages shows the immense force and influence of the church at that time as a body politic. The art expresses a fact; but because the art changes, it is no reason that religion dies.

It is a curious and pregnant fact, that all the earlier monuments bearing effigies are of ecclesiastics. The most ancient examples in this country represent two abbots. One is Vitalis, Abbot of Westminster; the other Crispinus; they are in the cloisters of Westminster Abbey. The earlier monument dates in 1086. There is nothing so early in Gloucester Cathedral, for the monument with the effigy of Osric, which has been referred to the eighth century, evidently belongs to a later date. The first monuments, beginning from the period of effigies, were very simple. Usually the figure was in very flat relief, scarcely raised above the plane of the coffin-shaped slab, which represented the lid or cover of the receptacle which contained the body. The figure was usually dressed in the official garments; if a dignitary, with the mitre on the head, or the pastoral staff in one hand. Sometimes the hand is raised, as if in the act of benediction; sometimes both are in the act of prayer, or one is holding the chalice, or other emblem of church service. The design and relief of the figures is sometimes varied, but the usual type is that above described. As a higher degree of finish was attained, and facility acquired by practice, the execution improved, and the details were more elaborate. The effigy of King John, of 1216, in Worcester Cathedral, is the first instance of a regal effigy. The effigies of knights and others, who exhibit many particulars of great interest as the centuries advance—the details are more studied, and there is considerable variety of action within prescribed limits; for such representations were always subordinate to a fixed idea that the figure should be supine, stretched out in a recumbent position. In the fourteenth century the addition of extensive architectural accompaniments mark a novelty which led to very interesting results. The figure of the person represented was not left simply lying on the tomb, as in the earlier examples, but accessories were introduced, relating either to the personal or family history of the individual. Then, again, in order to do it more honour, to protect it as it were, or to enshrine the monument itself, architectural enrichments grew up around it. Canopies were introduced, and similar architectural details. Within niches around the sides of the tombs figures were introduced, either of saints or ecclesiastics,—members,

probably, of the family of the occupant of the tomb: these exhibit various forms of expression. Some are in the act of offering incense, some in grief. As figures they are always very subordinate in dimension to the chief effigy. Some very beautiful *volutes* are seen in some of the works of this age, in the small accessory figures of ministering angels at the head and feet of the deceased. Sometimes they are introduced in the spandrels and hollow mouldings of the architecture, and Salisbury and Lincoln Cathedrals boast of some beautiful specimens of the kind. In the monument in Gloucester Cathedral, called Osric, the figure scarcely exceeds with the earliest type of such works. From his being represented with a crown on his head, and a sceptre in his hand, there can be no doubt a sovereign is here represented; but the style of the work, and the introduction of angels at the head, establish, I think, the fact of the execution of the monument being of a much later date than the presumed period of Osric. If it were desired to commemorate a founder, there would be nothing remarkable in its being done at a late period, when possibly some repairs or enrichments were being added to the church; and thus an opportunity occurred of doing this honour to a benefactor. The next monument, well worthy of notice, is celebrated as the "bracket" monument, from the effigy being placed on a projecting bracket or corbel, panelled on a hollow or OG surface, which takes from it the appearance of a tomb or coffin. The real person intended to be commemorated is not known. Some have conjectured it to be Aldred, who is said to have died in 1069; others Scro, who died in 1104. The latter re-founded a new church, and this seems implied in the accessory of a church beld in the left hand of the effigy. This monument bears evidence of being of a much later date than Aldred; nor can it be attributed to the later period of Scro. No design of the kind can be referred to in the beginning of that century. The same may be said of that of Corthose, son of William the Conqueror, whose effigy is on the monument, in chain mail. He died in 1134. The figure is carved in wood, and thickly and clumsily painted. He was a great benefactor to the church, and, though he died at Cardiff, after an imprisonment of twenty-six years, his body was brought to Gloucester, and was interred near the high altar, where a "wooden tomb" was erected over him. But the object of paramount interest in Gloucester Cathedral is a monument whose history is well ascertained, and with which are connected many affecting associations. This is the enriched tomb erected by Edward III. over the remains of his unhappy father, King Edward II. This interesting monument comes under the head of highly decorated tabernacle work, and is, perhaps, the finest specimen extant. Its composition is rich, but at the same time light and elegant. The details are of great beauty, and show throughout the most careful finish. Within this elaborate shrine, if it may be so called, reposes the effigy of the unfortunate king. This is equally deserving of attention from the simplicity of its face and the generally calm and tranquil expression that pervades the figure, affording suggestive reflections upon the anxious, suffering life of the subject of the sculptor's art, and the contrast of repose, which could only be had in the silent tomb. There are peculiarities observable in this effigy that lead to the impression it may be intended as a portrait of Edward. This, if so, gives the work considerable additional interest, and one would be sorry altogether to give up that claim to our attention. I would direct your attention to one peculiar characteristic of mediæval monuments, and that is the universality of the design of recumbent figures. It is the sentiment that should pervade a monument of one gone to rest, when the tenant of the tomb is represented dying in prayer, or reposing before death in calm contemplation or devotion. It is an idea with which all persons of feeling must sympathise. It is remarkable that when a more debased style of architecture, and of art generally, came in, there was still sufficient respect paid to this *idea*, originated and established by the mediæval artists to preserve the religious sentiment in monuments. Effigies are still represented recumbent on their tombs, with the hands raised in prayer, though all the accessories may be of a most anomalous and uneclesiastical character. In the next innovation, change producing deterioration, the figure was taken from the quiet, recumbent position, and made to kneel up; but still, whether male or female, the subject was engaged in prayer, sometimes before a lectern and book, sometimes simply praying. In monuments of this time, where there was a family, we often see Hues of sons and

daughters kneeling also, arranged behind the parents according to sex. In the sixteenth and seventeenth centuries a change still further for the worse took place in monumental design. To say nothing of the great beds or catafalcs that had been erected, superseding the beautiful Gothic canopies, the figures now begin to show more movement, and, as if tired of the recumbent attitude, they sit up, lean on their elbows, and seem to look about them. The next still more offensive change is when the figures are represented seated and loling in arm-chairs, quite irrespective of the sentiment that belongs either to their own condition or to the sacred edifice in which they are so indulging. But it is painful to dwell upon this degradation of taste, and I am still less disposed to speak, except in strong reprobation, of another still more offensive style of art, when employed in churches. I allude to the class of personal boasting, or glorification, in figures wielding swords, making speeches, or exercising other common worldly occupations. Of the utter absurdity of some monuments that could be pointed out, in the naked, half-naked exhibitions of the figures, or in the Greek and Roman costumes of the English generals and worthies in our English churches, it will be sufficient to record our dissatisfaction without detaching you with unnecessary illustrations. But permit me to say one word in conclusion. The existence of, and perseverance in, this bad taste, is owing to our own fault. If all each one of us would not only protest against, but discontinue to employ artists to produce such works, there would soon be an end to them, and then probably, nay, certainly, a better feeling would induce a purer taste. Figures brandishing their swords, as if in the thick of battle,—senators and legislators making speeches,—men of science pointing to their discoveries,—or scholars and divines over their books and papers,—may all be well and consistently placed in halls, market-places, libraries, or other public situations; but let our memorials of the dead—of those we have loved and lost—of those who have died in humble hope and prayer—be in character with the sentiment of religious thoughts and reflections. In this respect we cannot do better than follow in the steps of the Mediæval artists. We may avail ourselves of our increased artistic knowledge in all respects; but, though we may justly improve upon their works in form, we should admit our debt to them for the true, deep, and appropriate sentiment of monumental design.

#### VIENNA: NEW OPERA-HOUSE COMPETITION.

THE Council of the Royal Institute of British Architects have forwarded to the members copies of the following correspondence:—

"Office of Committee of Privy Council for Trade, Whitehall, 9th August, 1860.

"Sir,—I am directed by the Lords of the Committee of Privy Council for Trade to transmit to you for the information of the Institute of British Architects the enclosed documents, which have been received through the Foreign Department, stating that it is open to all architects, foreign as well as native, to submit plans for the building of the new Opera-house at Vienna, and explaining the conditions upon which they will be received.

"I am, Sir, &c., J. EMERSON TENNETT,  
The Secretary to the Institute of British Architects."

\* At the same time were issued.—

1stly. A copy of a letter which has been addressed to the Mayor of Hereford, respecting the threatened destruction of the old Town-hall of that city.

2dly. A copy of a letter on the subject of architectural examination, which has been addressed to various architectural societies in the provinces, and which we have printed.

3dly. A copy of the report of the proceedings of the Council in attempting to ensure the safety of certain churches, towers, and steeples in the City of London, which were considered to be endangered by the future operations of the Act for the Union of Benefices.

4thly. A copy of a communication received from the Belgian Government, announcing postponement of competition for the Palais de Justice at Brussels, until the 1st of October next.

The circular said,—

"We beg further to call your earnest attention to the assistance that you may be able to render towards the preservation of architectural work of interest, which so much assist, in the words of our charter, in 'the public embellishment of our towns and cities.' If you will send immediate notice to the Institute of any proceedings, commenced or proposed, within your knowledge, affecting the safety of any such structures.

Any such notice should be given with as much detail as possible, and be accompanied with information as to the proper parties with whom action should be taken, the most advisable course to be followed by the Institute, and the name of any architect or person assuming the name or position, who may be engaged in the works to which the attention of the Council is to be directed."

(Copy.)

"Wiener Zeitung, 15th July.

"A public competition for plans of the new Opera-house, which is to be erected outside the Kärnthner Gate, is hereby announced by imperial order.

The plans for this competition, in which foreign architects may take part, must be handed in before January 10, 1861.

A commission will be appointed to consider these plans, three of which at least will be selected to receive a prize of 1,000 Verein thalers.

Authors of plans so selected will be expected to furnish all practical details and estimates.

When this further explanation of the plans has been submitted to a commission, the latter will distribute prizes of 3,000, 2,000, and 1,000 Verein thalers.

Plans that have received no prize will be returned on application, but all those plans which have received prizes become the property of the Imperial Government, to be by them applied as they think fit."

(Translation.)

VIENNA, NEW OPERA-HOUSE.

"By order of the Emperor, plans are to be prepared for a new Opera-house, in Vienna, and foreign architects are to be allowed to compete.

The building will be in the situation determined by His Majesty, between the Kärnthner Gate and the intended Ring-street.

The site, a rectangle, has a length of 57 and a breadth of 50 Viennese fathoms.

The block plan and section of the ground, and the prospect or programme of the building, together with all the necessary particulars, can be obtained by competing architects at the office of His Majesty's High Steward (i.e. K.K. Oberstbottmeister).

In the first instance, general designs only are to be considered, wherein each competitor will show how he would treat the arrangement of the space and other dispositions required by the programme.

The designs are to be forwarded to the High Steward's office by the 10th of January, 1861, at the latest.

They are to be marked with a device, and to be accompanied with a sealed letter, the cover of which is to be marked with the said device, and in which the name and address of the competitor are to be given. The bearer will receive a receipt worded according to the device. If sent in too late, the designs will not be received in competition.

The designs sent in by the time named shall be publicly exhibited for ten days, and then shall be submitted to a commission, composed of persons connected with the und-r-taking, and of professional men, for examination. This commission will select three at least as the best designs for premiums, or more, according to circumstances. The premium will be 1,000 Verein thalers for each of the designs selected. The devices of these designs so chosen shall be published in the *Vienna Gazette*.

Should any competitor, having gained a premium, wish to receive his premium before the termination of the competition, he must send in his name, address, and the receipt for his device to the high steward's office, where his sealed letter will be opened. Those designs not premiated shall, so soon as the award is made public, be returned with the unopened letters. But the successful competitors shall be bound to deliver detailed plans and estimates. The necessary particulars for these plans and estimates are given in the programme.

The period when these plans must be sent, and when the prizes will be awarded for the selected plans, will be published in the *Viennese Journal*.

The detail plans must be made upon the basis of the general designs.

They will undergo an examination by the adjudicating commission, and the three considered as best will be selected for prizes, after which the sealed letters will be opened, unless previously opened as above mentioned.

The prizes will be of 3,000, 2,000, and 1,000 Verein thalers. The award of the commission will also be made public. Lastly, the detail plans which have not received prizes will be returned to the authors. But the general designs of the premiated competitors, as well as the detailed plans of those who have received prizes, will become the property of the Government, who will have the power of making whatever modification in them they think fit, and of intrusting the execution to whomsoever they please.

Given at the Imperial and Royal High Steward's Office, July 10, 1860.

## EXAMINATIONS INSTITUTED BY THE SOCIETY OF ARTS.

PRIZES.

THE Society of Arts has published their list of subjects for examination in 1861. The primary object of these examinations, it will be remembered, is to encourage, test, attest, and reward efforts made for self-improvement by adult members and students of the Mechanics' Institutions, Athenæums, People's Colleges, Village Classes, and other bodies of the like character, that are in union with the Society of Arts. Such members and students are commonly mechanics, artisans, labourers, clerks, tradesmen and farmers not in a large way of business, apprentices, sons and daughters of tradesmen and farmers, assistants in shops, and others, of various occupations, who are not graduates or undergraduates of any university, nor following, nor intending to follow, a learned profession. To all such, male and female (not being under sixteen years of age), the examinations are open on certain conditions. Persons also of a higher grade in society than those mentioned in the opening paragraph are found to be desirous of having their knowledge tested by the Society's examiners; and it has been decided to admit them to examination on payment of a fee of 10s. 6d. for each candidate. Such persons, however, and also certificated teachers, and pupil teachers, though they may be examined and receive certificates, are precluded from competing for the prizes offered by the Society of Arts.

The following is a list of the prizes for 1861\* offered to the candidates, viz.:

One first prize of £1. and one second prize of £1. in each of the twenty-nine subjects of examination.

No prize in any subject will be awarded to a candidate who does not obtain a certificate of the first class therein.

The prize will be given in money or in books, at the option of the candidate.

The following prizes are offered to the institutions, viz.:

To the institution whose candidate obtains the above-mentioned first prize of £1. in any of the twenty-nine subjects, one prize of £1. An institution can take more than one such prize; but no such prize can be taken by an institution unless the Council of the Society of Arts is satisfied that the candidate, in respect of whom the prize is claimed, has received in a class at the institution systematic instruction in the subject for a period of not less than three months.

The following prizes are offered to the local boards, viz.:

To the local board where the total number of certificates awarded to the candidates at the final examination (these candidates being not fewer than twenty), bears the largest proportion (not less than three-fourths) to the total number of subjects in which they were examined;—one prize of 10l.

To the local board where the total number of certificates awarded to the candidates at the final examination (these candidates being not fewer than sixteen), bears the largest proportion (not less than three-fourths) to the total number of subjects in which they were examined;—one prize of 8l.

To the local board where the total number of certificates awarded to the candidates at the final examination (these candidates being not fewer than twelve) bears the largest proportion (not less than three-fourths) to the total number of subjects in which they were examined;—one prize of 6l.

To the local board where the total number of certificates awarded to the candidates at the final examination (these candidates being not fewer than eight) bears the largest proportion (not less than three-fourths) to the total number of subjects in which they are examined;—one prize of 4l.

No local board can receive more than one of these prizes. These sums may be applied by the local boards to the payment of the expenses of the examination, or otherwise, as the board may deem best for the promotion of the objects for which it was instituted.

## ETRUSCAN ART.

WITH a single exception—some coarse canvas discovered at Volterra—the whole of the Etruscan antiquities with which I am acquainted are made of mineral substances, either directly, as metal, stone, or pottery, or indirectly, as frescoes; these throw considerable light on the customs of this ancient people, for of their literature we have no remains. The Egyptian forms of the earliest Etruscan alabaster gods, no less point to their intercourse with Africa than the exquisite figured work introduced by them from Egypt into Italy, where this art seems to have been preserved up to the present time. By a more thorough and thoughtful examination of their works of art, I

\* The fund for the prizes is raised annually by subscription from the members of the Society of Arts and others interested in the success of the examinations. Annual subscriptions and donations to the prize-fund may be forwarded by Mr. Samuel Thomas Davison, the financial officer, Society of Arts, John-street, Adelphi, London, W.C.

feel persuaded that we might become far better acquainted with the social condition of the Etruscans. A mere glance at the graceful designs and fine features observable in their statues leads one to form a very favourable opinion of the Etruscans as compared with the Egyptians. There is more action in their figures: a fine open brow, a handsome nose and well-chiselled mouth, and eyes which bespeak less of the sensuous and more of the intellectual, take the place of that stern fixedness of expression and the hard features so conspicuous in Egyptian types. In Etruria, too, we never find representations of monsters—half-man, half-beast—such as the Egyptian sphinxes. Many other circumstantial evidences might be adduced confirmatory of this remark. Thus, their mode of writing. In Egypt, mysterious and difficult hieroglyphics were employed, in which, probably, the priesthood and government were alone skilled, while the masses were entirely ignorant of any method of embodying their thoughts in a material form.

I am well aware some might object that this was during the infancy of knowledge and art, no better means of writing being yet known; but I would give a conclusive argument against such a theory, since the Israelites sojourned 430 years in Egypt, and we are acquainted with the simplicity of the characters they employed, so that the Egyptian hierarchy—or, at any rate, the government—must have had great dealings with the Jews, at least during the time that they lived in the land of Goshen, and evidently preferred keeping the lower orders in ignorance and slavery, by enshrouding all knowledge under a veil of mystery. In Etruria, on the other hand, we see how, by the simplicity of their alphabet, they early brought the art of writing down to the level of the people. Finding, as we do, coins struck by numerous cities in Etruria, we learn that these possessed somewhat equal rank, incompatible with the idea that the princes who held sway were under a single despot, such as the Pharaohs. The Etruscans were, however, neither socialists nor republicans, for they honoured certain great individuals, statesmen, and warriors, and were prouder of perpetuating the memory of their virtues on tombs than were the Greeks, who, more fickle, and divided into numerous factions, could allow an unappreciated Solon to be banished, and witness a Socrates perish before their eyes, in the full vigour of his giant mind, without the least remorse. It is, indeed, to the tombs of the Etruscan chiefs that we must have recourse to find their professions, the majority of their best works of art being there deposited, as a grateful memorial to departed worth.

Etruscan art has been divided into three periods, corresponding with contemporaneous phases in their political history.

The first period of art in Etruria points to intercourse with Egypt, but it appears that it was the Pelasgi from Attica and Arcadia, who, leaving Greece and settling in Etruria, gave the inhabitants the idea of an alphabet and the principles of architecture. The statues and bronze work of this time are characterized by an inferiority of execution, though they exhibit an appreciation of beauty. The eyes are raised obliquely upwards, like those of the Tatars and Egyptians.

The second period was inaugurated about the time of Sargon (B.C. 1,000), by the arrival of fresh colonists from Greece. The country became too densely populated, so that the inhabitants divided into two portions. One branch emigrated eastward into Asia; the other remaining in Etruria, along the coasts of the Mediterranean, giving to that country the name of Tyrrhenia. Twelve cities, each governed by a chief, and collectively placed under an elective king, now rose to greatness, and even magnificence, while the arts arrived at a high degree of perfection. Their statues made about this time are recognized by their energy of conception and execution. They had also a custom of representing their deities with wings, by which we are at once able to distinguish them from the work of all other people.

Third period (B.C. 500). Meanwhile the Romans, increasing in power, carried their victorious arms into Etruria, enfeebling the nation, so that a year after the death of Alexander the Great (B.C. 324), it was almost entirely subjugated, and the Etruscan language, after having blended with Latin, rapidly became obsolete. Soon after (B.C. 280) their last king, Etrius Volturrius, was killed in battle near Lake Lucerne, and Etruria was formed into a Roman province.

About B.C. 265 the Romans took Volturnum (Bolsena), carrying away 2,000 statues. Bolsena is situated in the States of the Church, but in all probability other cities on the Tuscan territory

were equally rich in similar productions, since metal statues and ornaments are so abundant in all their ruins. The influence of Greek art on the Etruscans now became apparent from the great similarity of styles and of subjects. Thanks, however, to the Etruscan habit of writing inscriptions on their vases and metal-work, we are thus frequently able with certainty to distinguish these objects from Greek productions, when no other clue can be obtained. Some of the finest known specimens of art relating to this epoch are, the candelabra, formerly held in such high esteem by the Romans; the lamps, often similar to those of the last-named people; and the beautiful metallic mirrors with engraved groups of figures.

W. P. JERVIS.

#### THE ARRANGEMENTS OF THE BRITISH MUSEUM.

THE REPORT of the Select Committee appointed to inquire into the arrangements of the British Museum has been published. The special mission of the committee was—

"To inquire how far and in what way it may be desirable to find increased space for the extension and arrangement of the various collections of the British Museum, and the best means of rendering them available for the promotion of science and art.

The questions discussed were—

I. Whether all the collections in the British Museum should be retained in the present locality, or whether any and which of them should be removed elsewhere.

II. What amount of space is requisite for the proper accommodation and exhibition of the collections proposed to be retained, and of those likely to accrue within such a period as it is prudent to provide for.

III. Whether such space can, with due regard to economy, be contained in connection with the British Museum.

IV. What structural conditions in the buildings provided are indispensable for the proper arrangement of the collections.

1. *Natural History Collections.*—The removal of the natural history collections, from the discussions that have taken place both in Parliament and among the trustees of the Museum, and from the general interest which this question has excited both in the scientific world and among the public at large, primarily engaged the attention of your committee.

The arguments against removal may be summed up as derived—

1. From the central position of the British Museum.

2. From the advantages of connection with the great national library.

3. From the expense involved in the construction of a new Natural History Museum, and the transfer of the collections to it.

4. From the risk of injury to valuable specimens, and the interruption to scientific inquiry consequent upon the time unavoidably requisite for packing, transporting, unpacking, and rearranging the collections.

The evidence taken was almost unanimous against the removal of the natural history collections, which are the most numerously visited. The report asserts the necessity of retaining these different collections in connection with the library; should they be removed, the purchase of a special library of reference would be indispensable. The estimates of the expense of the construction of a new Natural History Museum and the transfer of the collections to it are given. They are the same as those presented separately to the House of Commons in February last. Three sites have been proposed—one, a portion of the land in the neighbourhood of Kensington, belonging to the Royal Commissioners for the Exhibition of 1851; the second, the present site of Burlington House; the third, a plot of ground near Victoria-street, Westminster. The cost of the first site would be £3,750; the site of Burlington House covers an area of only three acres, and the new museum would require five acres and a half; in Victoria-street more than sufficient space might be obtained at the rate of 7,000l. per acre. Ground enough might also be obtained in the immediate vicinity of the present museum, but only at a cost of 240,000l.

The formation of a special library of reference for the natural history collections would be about 30,000l., and the addition of all new works would be constantly required. The nation would have to support two librarians and a double staff of attendants.

#### Ethnography.

"Your committee have received evidence from every witness examined on this subject in favour of the removal of ethnographical collections. Great additional space would be required if it be intended that the British Museum should be the depository of a complete ethnographical collection, and it is probable that a more suitable receptacle might be found for it elsewhere."

#### British and Medieval Collections.

"The evidence received upon the subject of the retention or the removal of these collections has been most conflicting, both proposals having received the approbation of high authority. But, having considered the arguments on both sides of this question, your committee would observe that the British Museum is a repository in which objects of historical or archaeological interest ought to find a place without limitation to any particular time or country."

The committee then state the demands for increased space made by the keepers of the natural history departments. They are largest in the department of zoology, which requires ten rooms and a gallery, the dimensions of which are not stated. For the collection of antiquities—

"The keeper of this department has put in a demand for 61,469 additional superficial feet of floor space for exhibition."

The report continues:—

"Your committee, in contemplating an extension of the Museum, have been disposed, in the Natural History Department, in consequence of the gradual but constant increase referred to, to allow for space likely to be required within a moderate period of time; but in the case of the Department of Antiquities, from not being able to form any idea of the character of the accessions that may eventually accrue, and consequently of the nature of the galleries, and of the light that may be required, your committee would suggest that while ample space should be secured for future extension, buildings should not be constructed with a view to the future, but for the present, and always on such a plan as would admit of easy, cheap, and systematic extension.

The total amount of space, therefore, which would be required, so far as an accurate estimate has been laid before your committee, is 81,268 superficial feet. To this must be added the unascertained space required, as before mentioned, for the department of zoology, and for the studies and working rooms which have been recommended. On the other hand, 10,000 feet would have to be deducted if the ethnographical collection should be removed. At the same time it is obvious that the total area thus required need not be all on one floor.

Whether such space can, with due regard to economy, be obtained in connection with the British Museum?

It appears, from a former portion of this report, that the ground immediately surrounding the Museum, within the adjacent streets on the east, west, and north sides, comprises altogether about 5½ acres, valued by Mr. Smirke at about 240,000l. As the proprietary interest in all this ground belongs to a single owner, your committee are of opinion that it would be a convenient, and possibly even a profitable arrangement, for the State at once to purchase that interest, and to receive the rents of the lessees in return for the capital invested. The State would then have the power, whenever any further extension of the Museum became necessary, to obtain possession of such of the houses as might best suit the purpose in view.

*Prints and Drawings.*—A convenient site for this department would, in the opinion of your committee, be provided by the suggested acquisition of additional ground on the north side. A building might there be erected in continuation of the present east wing of the Museum, to contain on its upper floor the mineralogical collections, and on its lower the prints and drawings, with adequate space both for their preservation and exhibition."

The plans of Mr. Smirke, Professor Maskelyne, and Mr. Oldfield, are adverted to—

"Your committee have reason to think that if any of these plans were adopted, involving the purchase of not more than two acres of land, with the requisite buildings and alterations, the cost would not exceed 300,000l. If, however, only this limited portion of land should be at once required, it is probable that the price of what remains would be enhanced. If the whole were to be purchased, as your committee have already recommended, the cost above stated would be, of course, increased.

The cost of the land and buildings required to

carry out the plan for the removal of the natural history collections to Kensington, according to the estimate contained in the report, of the Special Committee of Trustees, which was founded on the assumption that 5½ acres of land are necessary, would amount to 620,000l.

To this sum would have to be added the expense of a departmental library, of packing and removing the collections, and of the extensive fittings and cases required in the new museum—expenses all forming part of the first cost of this plan, and independent of the additional annual charge for augmentations of the departmental library, and for the maintenance of the requisite staff both for that library and for the greatly enlarged public galleries of exhibition.

If, however, the limited principle of exhibition for the natural history collection should be adopted, less land would be required, and the estimate for buildings might be greatly reduced.

But neither of these arrangements would obviate the necessity of providing the additional space required for the department of antiquities at the British Museum.

Your committee can form no accurate estimate of the cost, if either of the other two sites before-mentioned should be selected.

Under all these circumstances, and upon a full consideration of the evidence adduced, your committee have arrived at the conclusion that sufficient reason has not been assigned for the removal of any part of the valuable collections now in the Museum, except that of ethnography, and the portraits and drawings, as previously recommended."

With regard to the last branch of the reference, namely, the means by which the collections in the British Museum may be made most available to the interest of science and art, the committee look on the British Museum as primarily being a great consultative repository, and are decidedly against the proposal for giving lectures in the Museum.

#### ART-UNION OF LONDON COMPETITION.

The author of the set of illustrations marked "Constancy," to which the premium of 100 guineas has been awarded, is Mr. Paolo Priolo, resident in Edinburgh. The council of the Art-Union, anxious to show their appreciation of the response made to their advertisement, have awarded two honorary premiums of twenty guineas each, one to No. 24, and one to No. 25. The artists were found to be respectively Mr. Alexander Rowan, of Stockwell, and Mr. Edward Corbould, the well-known water-colour artist.

The following names have been affixed to designs exhibited:—

- No. 1. W. Chappell, Holloway-road, London.
  - " 2. R. Jefferson, Lambehth.
  - " 10. B. Riviere, Oxford.
  - " 15. W. G. Smith, Askle-street, London.
  - " 22. (Consuelo) A. W. Rayes, near Manchester.
  - " 28. C. M. Dobell, Cheltenham.
  - " 37. Mary Elizabeth Dear, Camberwell-grove.
- The exhibition has been open to the public, free, without the slightest limitation, during the week, and has been very numerously attended.

#### FOOD SUPPLIES: FISH AND FISHERIES.

EVEN although a favourable change in the weather at so late a period of the season should now happily take place, as there seems reason at last to hope, we may have a somewhat short supply of some of the necessities of life, notwithstanding the splendid harvests elsewhere. Even the slightest addition to present high prices must press sorely on the general bulk of the people, but especially so upon the great masses of the poor. It is, therefore, all the more necessary in every way to economize the principal articles of food, and look in directions not so usual, or so much depended on in ordinary times, for the increase of supplies. Of late years much has been done, by means of steam packets and the locomotive, in bringing fish in great quantities to the metropolis, and the large towns throughout the country; and it seems to us that there is yet a great deal more which might be done, and that the sea, to a far greater extent than at present, might be made a means of feeding the multitude. Thinking of this, and that our supply of this wholesome description of food might by well-directed exertions be vastly increased and cheapened, we may glance at a few statistics which will show the progress, and may give some idea of the extent, of the British fisheries.

In 1578 France had on the bank of Newfoundland 150 fishing vessels, Spain 120 to 130, Portugal 50, and England only from 30 to 50.

The regulation and management of fisheries in times gone by seems curious in these free-trade times.

In 1633 Charles I. ordered an association of the three kingdoms, governed by a standing committee; and, for the better encouragement of the adventurer, enjoined the strict observance of Lent. During the Protectorate little was done, except the reduction of the duty on salt; but Charles II. appointed, in 1677, a council of royal fishery; and, for the encouragement of those engaged in this branch of commerce, a lottery was granted for three years; a collection was made in the churches, and an exemption for seven years from customs, both inwards and outwards, on the sale of fish exported to the Baltic, Denmark, Norway, and some other countries.

Moreover, all victuallers and coffee-house keepers were compelled to take a certain number of herrings each year, at 30s. per barrel, until a foreign market could be established to the satisfaction of the council. Beyond these encouragements, a duty of 2s. 6d. was imposed upon foreign herrings imported, and a promise was made of all such other advantages as experience should discover to be necessary. No advantage seems to have permanently resulted from these stringent and singular regulations. After sixteen years of disappointment a charter was granted to a new fishing company, having a capital of 11,580*l.* This seems to have also ended in failure. In the year 1749, the Society of the Free British Fishery was established, with a capital of 500,000*l.*; a bounty of 36s. per ton on all decked vessels of from 20 to 30 tons employed in fishing, was granted for fourteen years. In 1757 the bounty was increased to 56s. per ton, and in 1759 to 80s. per ton, besides a grant of 2s. 8d. per barrel upon all fish imported. Interest, moreover, at the rate of 3 per cent., was secured to the subscribers, payable out of the customs revenue. This scheme, however, also proved a failure.

In the same year, 1759, the whole of the small fishing vessels of Scotland only brought in four barrels of herrings cured at sea, each of which, in bounties alone, cost the Government 113*l.* 15s., and each barrel of mercantile herrings cost 159*l.* 7s. 6d.

In the reign of George III. (1786) a fresh Act of Parliament was made: a bounty of 4s. per barrel was given on the fish, and the tonnage duty was reduced to 20s. By this regulation, on an average of ten years, 54,394 barrels were annually taken, at a cost to the Government of about 7s. 6d. per barrel.

In 1808, the bounty was again raised, to 60s. per ton, on decked vessels of not less than sixty tons burden: other grants were made, but the old system of forcing trade by such means being radically wrong, each of these efforts ended in failure.

In 1830, the tonnage duty and all protective duties were repealed; and, in the year 1837, the Fishery Commissioners reported that 397,737 barrels of herrings had been cured. In 1832, the average produce of the fisheries of all sorts, carried on by the inhabitants of Newfoundland, is stated to have been then worth 516,417*l.*, and from the ports and harbours of Nova Scotia, Cape Breton, &c., large quantities of fish were brought to England. From the coast of Labrador, the year's produce was estimated, by McCulloch, at 350,000*l.*

In 1836, the number of British vessels engaged in the Newfoundland and Labrador fisheries amounted to 94, with 721 men. The boats employed were in number, 11,427;—fishermen and boys, 49,720; coopers, 1,916; fish-curers, 1,916; persons employed in cleansing, drying, and packing the fish, 26,038; labourers, 7,235; barrels of herrings, 497,615; quantity of cod cured and dried, 38,040 cwt.; pickled, 6,276 barrels.

Large supplies, besides, were obtained from the home fisheries, that of herrings being an important item.

On the coasts of Devon and Cornwall, about a thousand boats are, during portions of the year, engaged in the pilchard fishery, giving employment to about 3,500 men at sea, and 5,000 men and women on shore. The fish are pickled in barrels, and exported to the continent, to the extent of about 30,000 hogheads per annum. Besides, there are the mackerel, oyster, and other shell-fish. The supplies from the British rivers and lakes, &c., are also great. Nevertheless, it seems to be clear that,—considering the increase which has taken place since the trade restrictions of the fisheries have been abolished, and the improved methods of conveyance, &c.,—we should look for a more plentiful supply than comes to market at present.

A few years since we recollect noting in the

*Builder* a hope that a movement then in progress for the working of the excellent and abundant fishery fields on the west coast of Ireland would shortly lead to a greatly increased supply to the metropolis and other towns of England, while providing a profitable field of labour and livelihood to the idle Irish, resident on that coast. We regret to say that nothing has come of this hopeful prospect as yet, so far as we can learn. Can it be that Paddy, with his hands in his pockets, still objects, on moral principle, to "take all the fish out of the sea"?

#### PARIS IN 1860.

THE *Moniteur* devotes several columns to an article under this heading, written by Dr. Veron, and the *Times* correspondent gives a general review of it. Dr. Veron starts across Paris, notebook in hand, on the look-out for novelties, "along streets either paved or macadamized, along roads planted with trees, along promenades and boulevards, and through squares, finding frequently upon our path benches of stone, iron, or wood, offering repose to the idler or the weary, to old men and children." He then gives lists of the buildings that have been constructed, completed, or enlarged, from 1852 to 1860,—religious edifices, schools and asylums, hospitals, bridges,—of gardens that have been planted, and thoroughfares that have been opened,—including among them many works that are not yet finished, but are being actively prosecuted.

"Old Paris now reckons forty-seven Catholic churches (the Assumption included), five Protestant temples, and two Israelite temples. The annexed communes have nineteen churches, but they are much less spacious than those of Old Paris. These latter are able to contain one-eighth of the population, while the suburban could admit at one time hardly a twentieth of the population of the annexed communes."

Barracks are a class of buildings with which the second Empire has largely endowed Paris. Under this reign, besides the two vast buildings near the Château d'Eau and the Hôtel de Ville, there have sprung up the barracks near the Bank of France and in the Bois de Boulogne. These are a species of construction for which London will hardly envy brilliant Paris. You would prefer, perhaps, to be more on an equality with the French capital in respect of fountains. Of these there are eighty-two in Paris, besides an immense number of what are called *borne-fontaines*, equivalent to our street pumps. And everybody who has visited Paris knows how highly ornamental most of these fountains are, and will think, with a smile and a sigh, of the soda-water bottles in Trafalgar-square. Squares, or small public gardens, tastefully planted with flowers, have been made within the last eight years in various parts of Paris, in the poorer quarters as well as in the more aristocratic ones, and the gardens of the Champs Elysées have wonderfully beautified that favourite promenade, which we all remember a barren waste.

Dr. Veron reckons eight new bridges built since 1852, besides that of Austerlitz, which has been almost entirely reconstructed, and the Pont Neuf which has been greatly improved. There are now twenty-six bridges open on the Seine at Paris, at only two of which (those of Bercy and Grenelle), toll is paid. Other bridges are projected, of which the most important, it is said, will be that of Louis Philippe—to be placed opposite the street of the same name—and of the Louvre. The cost of all the great works enumerated and projected has caused some uneasiness with respect to the finances of the city, but Dr. Veron assures us that such anxiety is groundless, and has been completely dissipated. He declines entering into details of the municipal budget, but gives a brief summary, which, I presume, must be taken as official:—

"The receipts of the city of Paris in 1859 amounted, in round numbers, to 100 millions, and this revenue is enough to meet all the indispensable municipal expenses: it suffices for the interest and sinking fund of the various loans made for the expenses of great public works, and for the bakers' fund: in short, it suffices for all ordinary expenses: the annexation of the suburban zone has alone given rise to the new loan. The credit of the city of Paris annually improves: not only have all its loans been eagerly taken, but its bonds, issued last year at 400*l.*, are now quoted at 455*l.* In matters of credit the public is the best judge. Moreover, the great works of the city of Paris have not only a moral and political object, but the expense is productive. The revenues of the capital will increase by the influence of strangers its splendour attracts."

According to the article under consideration the number of paved streets in old Paris (not including that is to say, in the *arrondissements*) is 1,215, and of shingled (*empierreées*) or macadamized streets, 254. In the annexed communes most of the streets are neither paved nor macadamized. A square metre of pavement costs about 12*l.*, and of macadam from 3*l.* to 3*l.* 4*l.*; but the difference of cost is considered to be more than neutralized by the difference of wear and of expense in keeping in repair. The great streets and boulevards opened since 1852 are macadamized. In 1859, 1,126,475*l.* were expended in pavement, and 214,5,597*l.* in shingling and macadamization. There are about 400 kilometres of paved street in Paris and about 100 of shingle and macadam, 390 of flag or asphaltic footpath, and 350 of planted ways, boulevard, promenade, and squares. The sewers are 196 kilometres in length. The expense of street-cleaning in 1859 was about 61,000*l.* sterling, and of street-watering something less than 8,000*l.*, which latter item appears by no means large, considering that this department is now well attended to in Paris. This summer the expense of watering the streets ought, one would think, to be extremely small, seeing that we have hardly ever been twenty-four hours without rain; but the watercarts are extremely zealous in discharge of their duty, and it is curious to observe how, as soon as a shower ends and a faint sun-ray appears, they emerge from their retreats to irrigate the already soaked ground.

Paris has five slaughter-houses for cattle and sheep, and two for pigs, and there are three others in the newly-annexed communes. The Prefect of the Seine has a plan in agitation for uniting all these establishments into one.

The population in Paris, we are told, was, in 1856, 1,174,346, including the garrison. The recent annexation has brought into Paris 395,454 inhabitants, also including troops. This would give a present population of 1,569,800; but, allowing for progressive increase, it is supposed that in 1861 Paris will contain 1,700,000 souls. This does not include the floating population of visitors who do little more than pass through.

#### THE WILTS ARCHÆOLOGICAL SOCIETY.

THE annual general meeting of this Society took place on Wednesday in the week before last, at Swindon, and the proceedings were by no means of an uninteresting character, notwithstanding that the attendance was somewhat smaller than usual. The gathering took place at the Town-hall, which had been converted into a temporary museum. Only a comparatively few relics were exhibited.

The chair was taken by the Right Hon. T. H. S. Estcourt, M.P., and the Rev. A. C. Smith read the report, which was received and adopted.

The Rev. Canon Jackson then read a long paper on "Swindon and its Neighbourhood."

The Society's dinner took place at the Goddard Arms Hotel, and the company shortly afterwards re-assembled at the Town-hall, where the Rev. W. C. Lukis read a paper prepared by Professor Donaldson, on the cromlech known as "Wayland Smith's Cave," near Swindon, a legend respecting which is to be found in Scott's novel of "Kenilworth." In the course of his paper, the learned professor expressed an opinion that the boulders, known as Sarsen stones, so abundant in various parts of Wiltshire, are the result of glacial action. Referring to the cromlech shape of the chamber in the cromlech itself, he suggested that the centre contained the remains of one or more deified persons, and that as there were some traces of a ditch, the whole enclosure was probably once dedicated to public worship, and that the covering stones had served as altars for human sacrifice. Mr. Lukis said he was sceptical as to the sacrifice of victims upon these cromlechs: they were, in his opinion, purely sepulchral. He also thought that the cromlech was originally covered with a mound of earth.\*

\* The cromlech cell, and what is here called the ditch, remind one much of New Grange in Ireland (see article on "Symbols" in the *Builder* of 16th October, 1858). At New Grange, the chamber or cell is not only cromlech, but one branch of the cross is inscribed as "the House of the God," and "dedicated to the great mother Ops," while the other is named "the tomb of the hero." A long low, and narrow passage, tunnel, or "trance," as they might call such a passage in some parts of Scotland, runs along the ground from the foot of the cross to the surface of the pyramidal mound of earth under which the cell was built. The ditch here referred to may be the remains of just such a passage; and the Cromlech, as remarked by Mr. Lukis, may have originally been covered with earth. But the Cromlech was probably only typically, or rather mystically, sepulchral and sacrificial, as shown in the article on Symbols just alluded to.

The Rev. W. H. Jones, vicar of Bradford-on-Avon, then read a paper on Lord Clarendon and his Troubridge ancestry; and Mr. Cunningham offered some observations on the geology of Swindon and its neighbourhood, with particular reference to the Portland and Purbeck beds. He was followed by Mr. Moore, of Bath, who gave an account of some discoveries he had recently made in the dirt beds of the neighbourhood.

By permission of the directors of the Great Western Railway, the immense works connected with their locomotive department at New Swindon were thrown open to the inspection of members of the Society.

On Thursday, there was an excursion to Ludington Castle (visiting Ludington Church by the way), Wanborough Church, Wayland Smith's Cave, and other places. In the evening there was a *conversazione* at the Town Hall, and Mr. Poulett Scrope read a paper on the Roman Excavations at North Wrexhall.

On Friday, the excursion included a line of country rich in churches of more than ordinary character. The route lay through Stratton St. Margaret, Highworth, Hamington, Kempford, Castle Eaton, Chicklade, Purton, and Lidard Tregoz.

After quitting Highworth, the excursionists visited Hamington Hall, the seat of Captain Wilkes Johnson, R.N., who courteously received them. The history of the building of Hamington Hall, in 1653, is curious.

Two brothers, who were perpetually disagreeing and quarrelling, combined to execute one work in concert. Accordingly they set to work to erect a house, and it is supposed that they experienced such unusual satisfaction and cordial brotherly love during the progress of the work, that they resolved to record the fact. They therefore had the following inscriptions carved in large stone characters upon the outside of the house:—"Ecce quam bonum et quam jucundum est habitare fratres in unum. Ps. 133." Then to show how completely they were of one heart and mind, they represented two hands drawing open the same money-bag, and upon the bag two hands holding the same heart, with their own names opposite to each hand, viz., Ranfo and William Freke, and the inscriptions "Quo communis eo melius," and "Semper idem." Their cordiality and kindness of feeling towards one another found expression in other words, and they repeatedly gave God thanks for it in these words, "Non nobis, Domine, non nobis, sed tuo nomini, sit gloria." As soon, however, as the house was completed, and there was nothing else to do, they returned to their old habits, and quarrelled and disagreed worse than ever. Why did not these intuitive freemasons go on with their brotherly love and their building?

This excursion closed the meeting of the society.\*

#### VICTORIA PARK CEMETERY.

The costly monuments of men remarkable for talents, rank, or wealth, have their impressive teaching. So also have the memorials which in a humble way are raised in many a quiet church-yard, to show those natural affections which are as remarkable in this land as in the cottages as in homes of more lofty pretensions.

Ramblers are often struck by the touching inscriptions and simple menus which have been taken to mark the spot where some loved companion has found his rest. In some parts of the South of England wooden rails—more or less ornamented, and inscribed with the name, time of birth and death—contain the "short and simple annals of the poor." Perhaps to this is added a plain text, which improves the circumstances of the death, or suggests hopeful feeling for the future.

In the solemn but pleasant country church-yard, a couple of names may be found marked above one grave: in other instances, the members of the same family lie side by side; but in few cases is that shocking packing of the dead into indiscriminate masses practised, that was and still is the case, to some extent, in certain of the suburbs of the metropolis and in large provincial towns. Where this is done, and from twenty to thirty bodies are hurried in one grave, the practice, so far as we had been able to discover, of placing any memorial on such general graves has been neglected. We lately found that this is not always so, and that in the Victoria Cemetery, although the burials are managed in the old fashion, the graves are decorated in a most peculiar manner. In one part of this burial-place

\* A fuller account of the meeting than we can give appeared in the *Wills Mirror* for 22nd August.

a large space is set apart for the graves of the children of the poorer classes; these pits are made about 10 feet 6 inches deep, 6 feet long, and 2 feet 8 inches wide. As funeral after funeral arrives on the ground on Monday afternoons in an almost constant stream, the funeral service is delivered with considerable expedition. One of these graves, it has been admitted, will hold about twenty bodies, in layers. The long rows of these sepulchres, disposed with geometrical exactness, and numbering to three or four thousand and upwards, give one some notion of the vast number of little children who have there found their last rest. Nor can this be wondered at, when we are told that on some days a hundred bodies are buried.

There are many peculiar and painful sights to be met with in the metropolis, and a visit to this cemetery on a busy hurrying-day is one of them. Two, or perhaps three, clergymen are, in different parts, intoning the solemn service for the dead. "I am the Resurrection and the Life," "I know that my Redeemer liveth," and other passages, mingle strangely together. At one grave Irish mourners are sounding their peculiar dirge over their departed friend: in other places women and children are kneeling on the yellow mounds of earth. Funerals ambitiously performed, with nates and feather-men; and others in different descriptions of mourning carriages, pass on: some in cabs, roll along the broad central avenue. Outside, the dull tolling of the chapel bell, the noise of manufactories, the lowing of oxen and bleating of sheep, with sounds peculiar to the railway, which is nearly adjoining,—cause feelings so mingled that they cannot be well expressed.

On observing more closely the children's graves it will be noted that, on most of those which have been banked up, there is a curious variety of ornament. On many are large shells, on some of which are inscriptions: in one, for instance, is "Rosetta Eliza, aged 2 years." Close by is a little plaster cast of the Virgin and Child, and the popular cast of the infant Samuel. There are also chimney-piece ornaments of various value, which had probably been familiar play-things with a poor child who sleeps below. There are little toys, too, mugs with names on them, china figures, dolls, little china basins and vases, in which flowers are sown or planted. On some graves are little wooden memorials, with epitaphs painted in white and black on clouds or rays. On nearly all attempts are made to cultivate flowers. It seems strange, at a first glance, that in this neighbourhood there should be a fashion in the decoration of graves which is not to be met with in other metropolitan cemeteries. This is, however, not so, when we consider that a large portion of the surrounding population in Bethnal-green and Spital-fields, engaged in the silk-weaving trade, are, as has been before mentioned, of French extraction; and in this way are shown the manners of the land of their ancestors. Many were searching for graves, and difficulty seemed to be experienced in discovering particular numbers. They generally, however, recognized them by the little mementoes to which we have referred. A man and his wife had found "little Charley's glass peacock, which his aunt had given him," and were sowing flower-seeds close by. On this grave there were portions of glass and porcelain vessels, of choice shape and manufacture, probably amongst the last treasured relics of more prosperous days, before persecution obliged many thousands of the French Huguenots to fly for shelter to London.

For a certain money consideration the graves can be tarred and edged with wicker-work. This is often done by subscription. In our matter-of-fact times, such observances as these are pleasant, and it is to be hoped that care will be taken to preserve these memorials which, although they have but little market value, are, notwithstanding, prized by those who have placed them here. Centuries hence, when the present level has been raised, and the appearance of the site changed, antiquaries of that period may find, in the excavation, matters which will cause discussion.

#### SCHOOL OF ART AND SCIENCE AT THE CRYSTAL PALACE.

It was a leading purpose in the first foundation of the Crystal Palace that its courts and collections should be a means of education by the eye, and that the treasures of art and beauty, collected and stored up from every part where greatness and civilization had left them, should here present a new and advanced starting-point for the student. With lavish means the directors have been enabled to bring together the most complete collections of their kind in the world; and now what formerly occupied years of study, and difficult and costly

travel, may be judged of in almost as many hours. This bringing together and into series the great examples of art, so that comparison may enlarge and amend our judgment, is, perhaps, the greatest aim achieved by the Crystal Palace. We have often pointed out the value of the collections, and urged making use of them. In the Crystal Palace has been collected such a complete representation of the schools of antique sculpture as no academy or single collection in the world can show. The same may also be said of architecture; and other arts and sciences could be particularized. It is especially with a view to utilize all these particular advantages for purposes of education that the directors have organized the School of Art, Science, and Literature; while at the same time they have borne in mind the necessity of making the system pursued as complete as possible in all its branches, and capable of every practical development. The directors have also extended many privileges to the pupils, such as the free admission to the Palace on all days when the classes are attended, and the purchase-right to a full season ticket, admitting to the Palace on every occasion when open to the public, with some other rights, for 10s. 6d. Professorships have been arranged to utilize the whole eastern range of Fine Art Courts, and also the series on the western side. The magnificent collection stored in the Industrial and Technological Museum, arranged by Dr. Price, in the galleries at the end of the central transept, and described by us in some detail, may also be particularized as thus available. For the use of these and other collections every practical facility is given. The artistic classes are superintended by Mr. Edward Goodhall and Mr. W. K. Shenton; those for Languages, History, Physical Geography, &c. by M. Roche, Dr. Scudler, Signor Volpe, Rev. C. Boutel, M.A., and Herr Somschenich; the Music and Singing by Mr. J. Benedict, Mr. Lindsay Sloper, Mr. Pratt, Signor Garcia, Mr. Henry Leslie, &c.; and even Dancing is not forgotten. Mr. S. Leigh Sothey has offered a prize to be competed for in the class for figure-drawing, and other similar prizes will, doubtless, be announced.

#### IRELAND.

The Carmelite Fathers at Dublin have built a small church in the rear of their schools in Dominic-street. It is 60 feet by 26 feet, divided into nave and chancel, and has a cloister along the side and back, and serving as a vestry. The ceiling is groined in five compartments, and the interior is lighted by five double lancet Gothic windows at each side. Externally, the walling displays alternate courses of granite and black stone (calp), with a double plinth course of granite, wrought and chamfered, and red bricks are introduced alternately with granite in the window arched heads. A crenellated parapet extends on the top, and the roof has a crested ridge. Mr. O. T. Healey is the architect.

The works on the Athenry and Tuam Railway are in a forward state, and the officers travel on the line as far as Ballyglinnon. This railway will be a great advantage when complete, as the present "carrig" system from the stations of the Midland Railway to the several towns in the counties of Sligo, Mayo, and Galway, is miserably tedious.

The Roman Catholic Cathedral at Armagh has been twenty years in course of erection, and upwards of 30,000l. have been expended thereon, independently of a contract for 15,000l. recently entered into to complete it. The roofing is now being proceeded with.

It is stated that a new town-hall for Sligo is projected. The rising town of Ballina requires some public hall likewise, and a little more energy and earnestness of purpose infused into the Town Commissioners' Councils.

A new church is to be built at Sydenham, near Belfast, according to designs by Mr. W. J. Darro, of Belfast and Newry, architect.

The Police Valuator of Belfast reports that 198 new houses in that town have been occupied for the first time since 1st January last.

A new line of railway, from Downpatrick to Newry, is projected, and will pass within three-quarters of a mile of Clough and Seaford respectively, along the western shore of Dundrum, close to the towns of Dundrum and Maghera, within two miles of Newcastle, 1½ mile from Bryansford and Castlewelan, and crossing the Bann at McComb's-bridge, thence to Rathfriland and the terraces at Newry, which will be in Edward-street, in common with the Newry, Warrenpoint, and Armagh Railway.

Mr. Richard Williamson, C.E. (for many years surveyor for the east division of Omagh), has been

appointed surveyor for the city and county of Derry, in the room of the late Mr. Stewart Gordon, C.E.

Alterations and additions are to be made to Dunamway National School, Cork, by the Board of Public Works. Tenders to 6th of September.

THE LONDON MASTER BAKERS' ALMSHOUSES.

AN addition has been made to the Bakers' Almshouses. When, some ten years ago, a society was established in London for the purpose of endeavouring to abolish the system of Christmas boxes, it was, at the same time, deemed desirable to request the millers, who were in the habit of presenting to their customers, amongst other good and seasonable gifts, whole flocks of Christmas turkeys, to divert the flight of their donations into a new channel; and the millers, entering at once into the spirit of the suggestion, converted the turkeys into sterling value, represented in pounds sterling at the sum of 700*l.* This donation, an annual one, accumulated rapidly; and in 1857 the money was converted into the row of almshouses—fourteen in number—in the Lea Bridge-road, Essex. Each tenement (consisting of a bed-room, sitting-room, and kitchen) is an asylum for a decayed master baker, either alone or with his wife, who is besides provided with fuel and a money-payment of 30*s.* a month. The expenses are defrayed by annual subscriptions and donations. A desire has been a long time existing to extend the advantages of the institution; and the late Mr. Waters, of the firm of Waters & Steel, Bucksidge, having left 1,000*l.*, which the committee came into possession of this year, towards carrying out the design, it was at once determined that a wing (on the eastern side) should be added to the building. Mr. H. W. Nevill, the Welsh bread manufacturer, of Holborn, has contributed the expense of one of the additional tenements,—an example which, it is expected, will be somewhat extensively followed. The architect is Mr. T. Knightley; the builder is Mr. E. Clark, of Tottenham. It is intended that ultimately there shall be fifty-four of these tenements, and the whole will then form three sides of a quadrangle.

VENTILATION.

UNTIL a very recent period the proper admission of the atmosphere to residential or other buildings was but little studied, and it was not until the evils arising from the unwholesome condition of barracks, hospitals, and private dwellings attracted observation that structural improvements were called for in the public as well as domestic edifices of the day.

A very simple and effective ventilator, as patented by Mr. W. Cooke, of Upper Stamford-street, has been exhibited in model at the office of the *Builder*. It appears to be peculiarly adapted for the use of dwellings in which no structural provision had been previously made. It is constructed of wire gauze, or perforated zinc, and is fitted to the aperture of the window above, and to the sash below, folding in widths, and lying horizontally beneath the reveal, and out of sight when closed. The fitting up, as well as the removal of the apparatus, is easily effected, and it can be detached with facility. The intervention of the coarse gauze or perforated zinc breaks the draught, but admits sufficient to sustain the vital current in freshness, and at the same time guards us against too sudden changes of temperature.

There are, however, other objects to which these ventilators are peculiarly applicable, such as the cabins of ships, and to carriages generally, and to stables. The patent we suppose simply applies to the mode of fitting up.

HARBOURS OF REFUGE.

The following is the report of the Select Committee appointed to inquire how far it may be practicable to afford better shelter to our shipping upon our coasts than is at present afforded, by the adoption of some plan for the construction of break-waters and harbours less costly and better adapted for certain localities than the system of solid masonry hitherto in use, and whether any such plan appears likely to be also serviceable for the improvement of our national defence, and to report to the House:—

"The committee have met and considered the subject matter referred to them, and have examined several witnesses in relation thereto, and various designs of floating and other breakwaters have been laid before them.

The committee feel the importance of seeking every means by which harbours and breakwaters of a less costly construction than those at present in course of formation could be placed on various parts of the coast.

They have taken much evidence on this subject, and have had their attention especially called to floating breakwaters, of which several plans have been submitted to them. Upon the advantages to be derived from these constructions the evidence is conflicting.

The committee are not prepared to recommend that the Government should undertake the task of constructing breakwaters on these principles; but, looking to the vast cost of harbours constructed upon the systems hitherto in use, they are of opinion that a moderate sum may be advantageously expended by Government in testing any plans which may offer a probability of important results in great future saving of money, and in giving protection to life and property in various localities.

To carry this object into effect, the committee recommend that a sum, not exceeding 10,000*l.*, be placed at the disposal of the Admiralty.

The committee have received evidence on the question of the deposit of silt in the large harbours now under construction. Some witnesses have stated that these harbours are gradually deteriorating from the accumulation of silt. The hydrographer of the Admiralty has, however, informed the committee that at Dover, Portland, Plymouth, and Kingstown, recent soundings show that there is no deposit. The slight silting of a few niches at Holyhead Refuge Harbour may, it is stated, fairly be attributed to the millions of tons of stone, fresh from the quarry, that have been tipped into the sea in the construction of the breakwaters, and that this cause of deposit will consequently cease when the works are brought to a close.

The Committee further recommend that the attention of the Admiralty and Board of Trade should be invited to this important subject, to consider whether any facilities can be given to public bodies or to private companies who may desire, at their own risk, to improve our harbours, or to give increased priority to our coasting trade.

And the committee have directed the minutes of evidence taken before them, together with an appendix, to be laid before your Lordships.

August 2<sup>d</sup>.

THE "BUILDER'S" LAW NOTES.

**Drinking-Fountains.**—A recently passed statute provides that if any person do any damage, whereby any well, fountain, or pump is fouled, he shall be liable to a penalty not exceeding 5*l.* The same Act provides that all wells, fountains, or pumps, provided for the use of the inhabitants of any place (and not being the property of any person or corporation, other than the officers of such place), are to be vested in the local authority of the place under the Act, who are from time to time to cause them to be kept in good repair and condition, and free from all pollution.

**Family Deed.**—A person, against whom two actions of trespass had been brought, executed, several days before the trial, a conveyance of all his property to his daughter without valuable consideration. The deed was declared to be fraudulent and void under the statute of 13th Elizabeth.—*Barling v. Bishopp.*

**Proof in Bankruptcy.**—A married woman lent a person money out of her own earnings while she was living apart from her husband and not maintained by him. The debtor became bankrupt, and it was held that the wife might alone prove the debt, the husband refusing to join in the proof.—*Ex parte Coles.*

**Landlord and Tenant.**—An owner agreed to grant to a tenant a lease for twelve years of certain lands, on condition that the tenant would cultivate the lands in a good and husbandlike manner. The tenant entered into possession, but the lease was not granted; and, after four years, he received notice to quit, on the ground that the farm had not been properly farmed. He applied to the Court of Chancery for the enforcement of the covenant to grant the lease, and the Court decreed in his favour, as it was not proved that there had been such a departure from good husbandry as would have worked a forfeiture of the lease if it had been granted.—*Rankin v. Lay.*

ARCHITECTURAL EXAMINATIONS.

The following letter has been addressed to various architectural societies in the provinces:—

"9, Conduit-street, Hanover-square, W., August, 1860.

SIR,—We are instructed by the President and Council of the Royal Institute of British Architects, to request that you will be good enough to bring before the notice of your Society the enclosed proposal of the Council for establishing a system of Architectural Examination; and we should feel much obliged if you would, by the end of September, if possible, favour us with the opinion of your Society upon the said proposal, and with any suggestion or modification which may be recommended by its members collectively or individually.

We should, of course, be happy to receive such suggestions in any form which may be considered best by your Society; but we may be allowed to mention that, as there are several societies whose opinions we hope to elicit, it would serve to put the whole matter in a clearer way for working out if your suggestions could be embodied in a series

of resolutions, which should either adopt, alter, or reject those put forward by the Council, and, so far as possible, run parallel with them.

We could then collate together, without much difficulty, the opinions of the several Societies, and ascertain how nearly they coincide, or wherein they differ most importantly.

We annex also a copy of the resolutions passed by the members of the Institute, the adjournment having been agreed to in order to ascertain, if possible, the opinion of those gentlemen whose residence and practice are away from London, and who are no doubt fully represented by your Society and others.

We need scarcely mention that the Council attach great importance to the success of this movement, and would wish to know whether (although perhaps differing as to the detail) your Society would be in a position to assist in carrying it out effectually.

We remain, &c.,  
(Signed) T. HAYTER LEWIS, } Hon. Secs.  
JAMES BELL, }

HEREFORD CLOCK-TOWER AND ENTRANCE COMPETITION.

THE selected design for the clocktower (mentioned in our last) is found to be by Mr. C. H. Edwards, of London; the design for the market entrance, by Mr. J. Clayton, of Hereford.

SIR,—As the author of the two designs, numbered 39, one for the proposed clock-tower, the other for the clock-turret gateway, selected by a majority of votes of the subscribers as described in your last number, allow me to correct an impression which might otherwise prevail as to the correctness of the proceedings, owing to the observations made by Mr. Anthony at the close of the meeting.

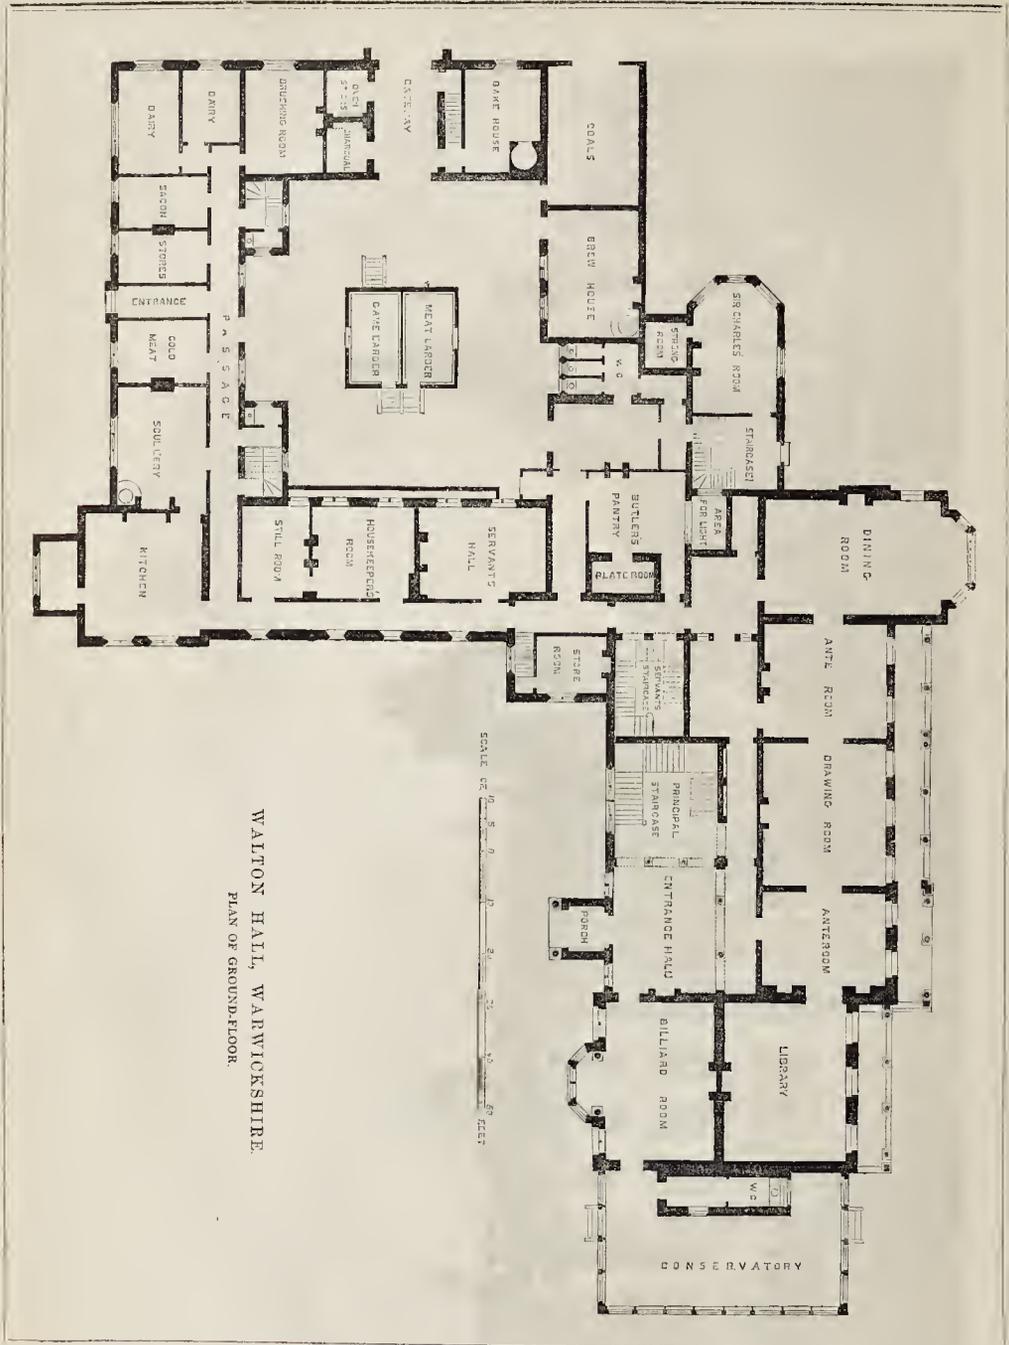

It appears Mr. Anthony observed "on looking at the voting papers, that he was surprised to find that many had only voted for one design, whereas he understood they were to vote for three." Mr. Anthony also gives his impression, that had this been otherwise "50 would have had a considerable majority." From this it may be inferred, that 39 had surreptitiously obtained the advantage by single voting, and that the same was a mode of proceeding not understood or warranted by the meeting. As to single voting, if Mr. Anthony had also taken the trouble to have scrutinized the votes recorded for No. 50, he would have found single votes amongst that list, though, unfortunately, only two! to four! of his opponents, and which, had they all been struck off, would not have given 50 a majority.

As to the general impression of the meeting, it will be at once evident that more than one-half those present must have voted plumpers or single votes for the clock-turret gateway, No. 39, or there would not have been a majority of twenty-four over the other two designs. This having passed unnoticed, your readers will be able to form an opinion of the motive and good taste of the observations alluded to, and also of any subsequent proceedings which may be brought before their notice.

All that I have now to observe, beyond reminding your readers that I hold the appointment of architect, and am now proceeding with the works of the *Hereford Market Improvements*, is, that I could some tales unfold with reference to the proceedings of this competition (in which competitors play their part), not calculated, I should imagine, to increase the zeal of those members of the profession who now so greedily grasp at the paltry bait, and so recklessly enter the unwholesome ranks of competition. JOHN CLAYTON.

P.S. You will perceive, by the resolution relating to clock-tower, that the fine old-timber Town-hall seems doomed to be removed. I should mention, that I had also a drawing of the restoration of this building, without the upper story, giving block at west end, in the Clock-tower Competition.

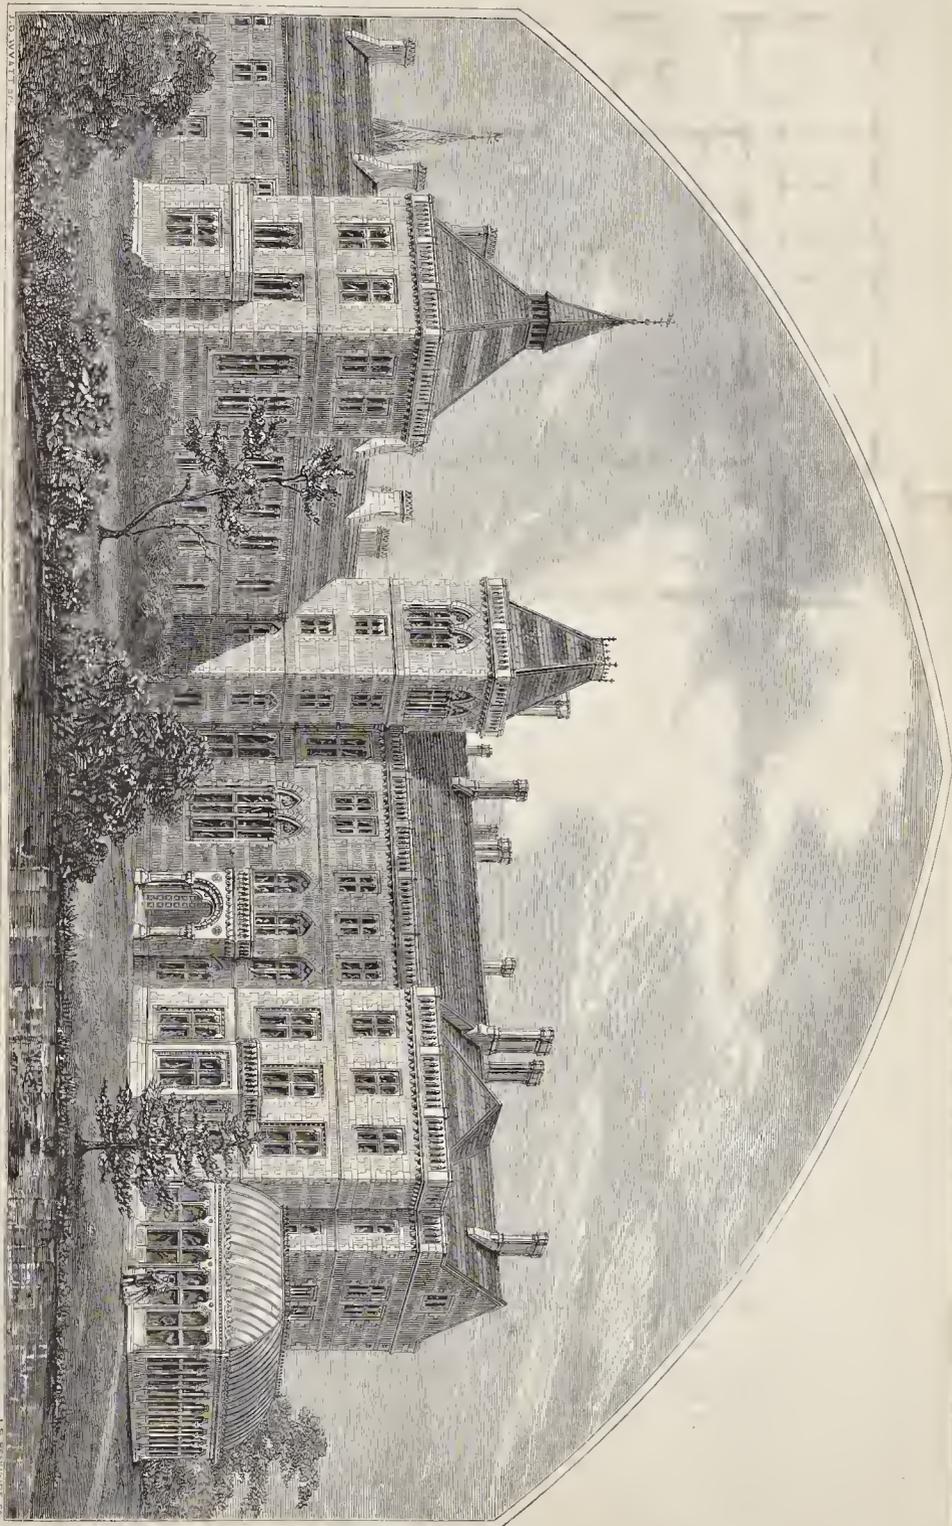

ALL SAINTS CHURCH, KENSINGTON-PARK, NOTTING-HILL.—There is again a report that the works at the above church (of which we gave an engraving in 1855) will shortly be resumed, with a view to its consecration on the 1st November next. 3,500*l.* are required for fittings and debt. The Rev. John Light, M.A., of Ashton-under-Lyne, has been appointed the first incumbent. A daily cathedral service will be performed morning and evening. Dr. James Peel, of New College, Oxford, and Mr. William Sudlow, are the organist and choirmaster.

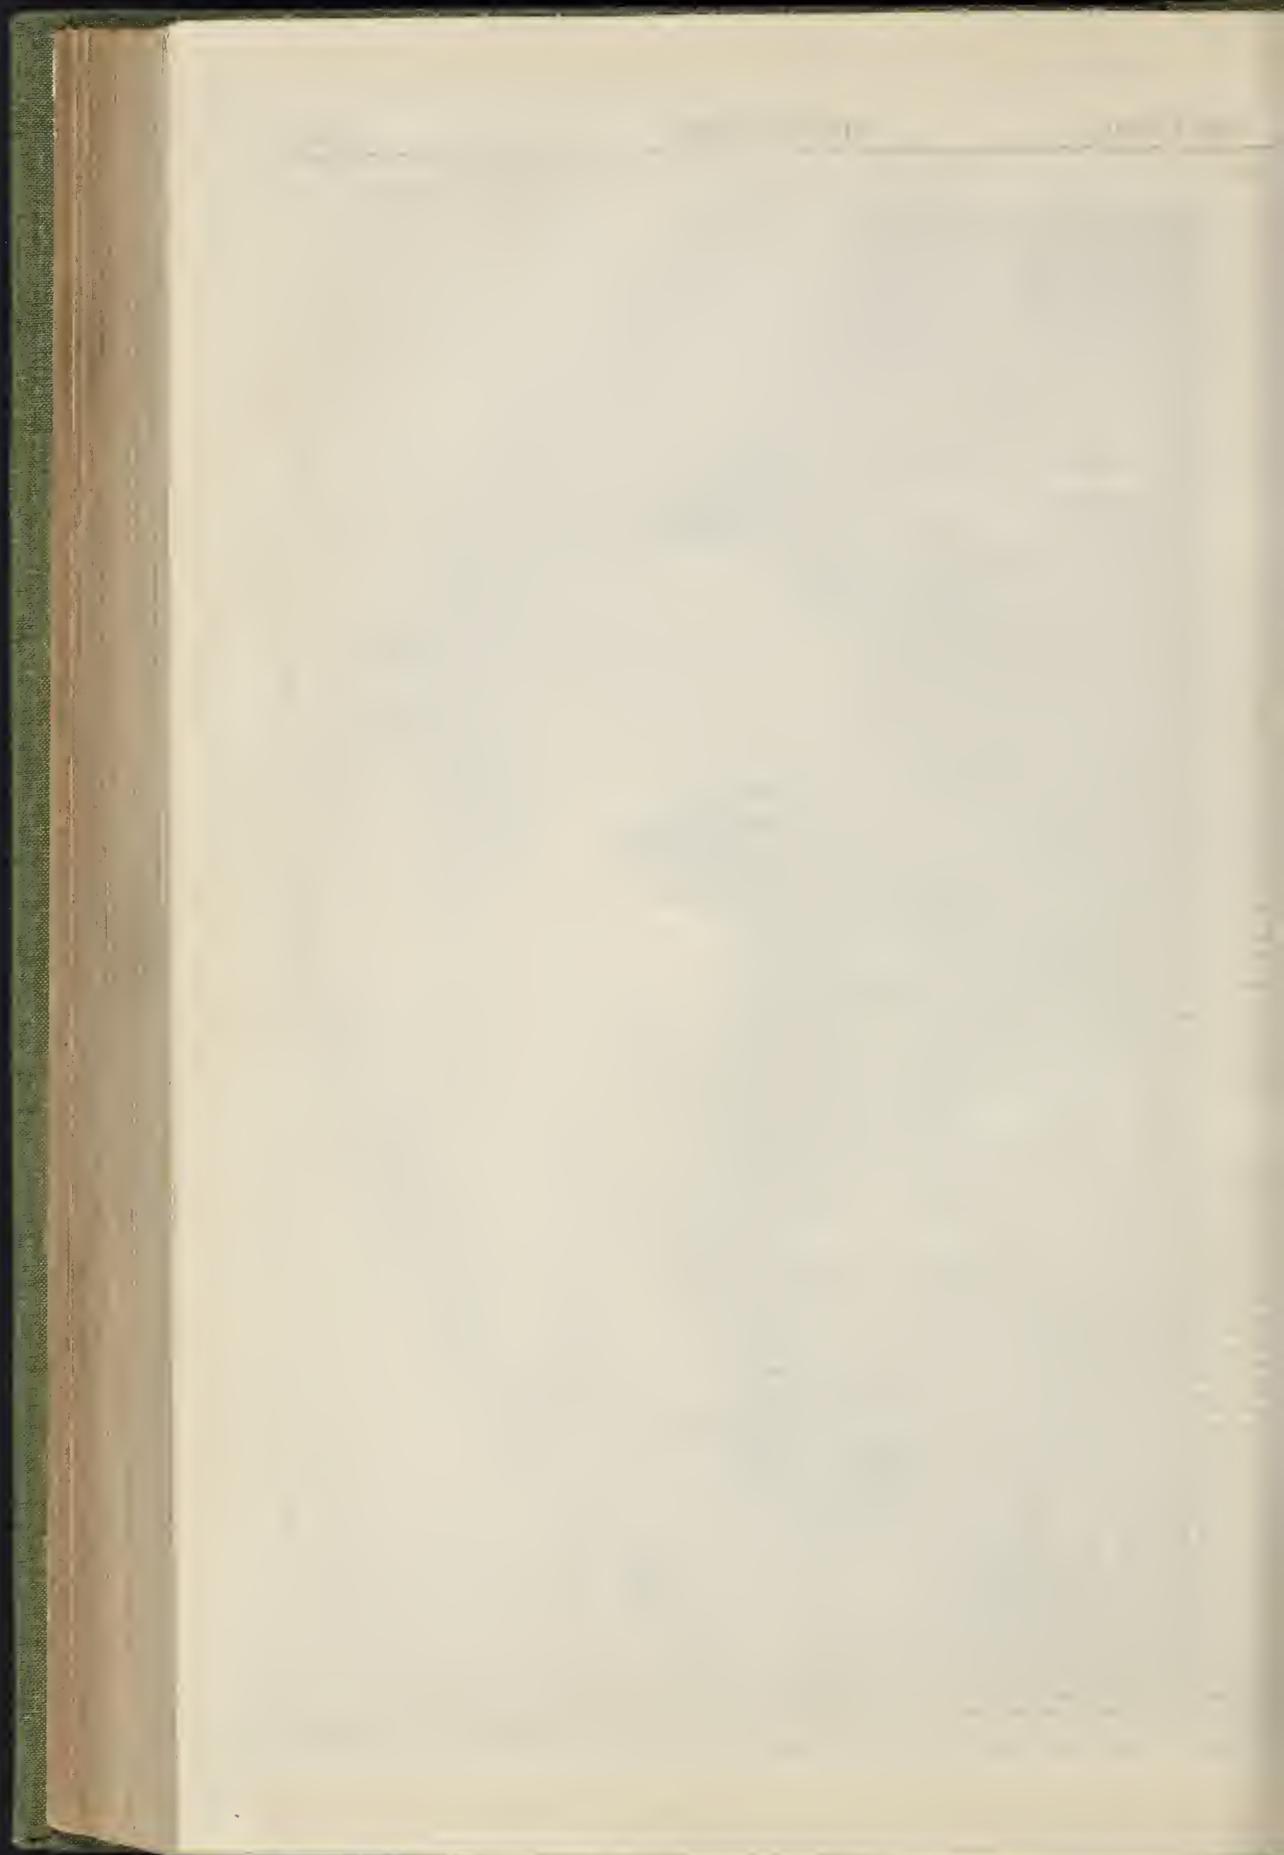

**WALTON HALL, WARWICKSHIRE.**  
 WALTON HALL, situate about eight miles south of Warwick, and the seat of Sir Charles Mordaunt, Bart., has been undergoing considerable alteration and enlargement during the past two years, under the direction of Mr. Scott, and our engraving shows the present appearance, now that it is nearly completed. The buildings occupy a considerable space of ground, as may be seen by referring to the annexed plan, and each elevation of the principal mass possesses architectural features. A spacious conservatory, too, forms an important addition to this portion of the house, of which most of the old walls remain.

The entrance-porch, hall, and principal staircase are, however, wholly new. Considerable attention has been paid to the arrangement of the several offices, which are planned in a quadrangular form. The kitchen occupies one of the angles, and the larder a detached building in the centre.  
 The walls are constructed of local stone, with Bath stone for the dressings. The roofs are of green and blue slates, used alternately. The metal work has been chiefly supplied by Potter, of South Motton-street. The general contractor is Mr. Norris, of Henrietta-street, Cavendish-square, and the clerk of works is Mr. Walter Scott.

**KETTERING CEMETERY COMPETITION.**  
 SEVERAL architects replied to the advertisement of the Burial Board. Recently the Board selected the design marked "Dum Spiro Spero," which proved to be by Mr. R. W. Johnson, architect, of Melton Mowbray, under whose superintendence the works will be at once carried out.  
**CITY AUTUMN EXHIBITION.**—Messrs. Hayward & Leggatt have opened an exhibition of modern paintings under this title, in their gallery, 28, Cornhill. It includes several well-known excellent works.

WALTON HALL, WARWICKSHIRE.—ADMITTED BY MR. G. G. SCOTT, ARCHITECT.

MESSRS. EVANS & PULLAN'S DESIGNS  
FOR LILLE CATHEDRAL.

The design for Lille Cathedral submitted by Mr. G. G. Evans and Mr. R. Popplewell Pullan was not amongst those rewarded, but it was warmly commended by some from this country who viewed all the drawings sent in, and this has led the architects to publish it by means of photography.\* The design is set forth on thirty-one sheets in a portfolio, with some printed observations inscribed to Mr. A. Beresford Hope. The drawings show considerable acquaintance with Mediaeval models, and a ready pencil.

We may mention that progress is being made with the cathedral for Lille rather by preparing stones, for columns and other parts, than by setting them. A lottery is on foot for 18,000*l.*; the sum of 3,200*l.* is to be distributed in prizes. Meantime service is performed in the crypt under the Lady Chapel.

## ELECTRO-TELEGRAPHIC.

As was to be expected, it now appears that the iron covering of the Red Sea telegraph was quite rotten, like that of the Atlantic telegraph, and in course of a single year. The gutta-percha covering is also said to have been defective; but is it not quite likely that the rusting iron will eat into the gutta-percha itself, and destroy it as an insulator? Ship timbers, at least, become curiously changed and blackened where iron bolts pass through them; and this appears to arise from the catalytic action of the oxygen, which rusts the metal, and is transferred to the adjoining material, and replaced by new oxygen in the rust, by a now well-known chemical action. This will only form an additional reason for rejecting iron as a covering to telegraphic lines. Copper, as we have ere now said, would be better and cheaper in the end, were any such ponderous covering still held to be essential; and, indeed, this is now suggested in the *Malta Times* for a new Red Sea cable. Iron, too, being a positively electric metal, and copper a negatively electric one, may not the insulating material, thus placed between two fires as it were, in iron covered cables, be actually destroyed by electrical action? In every way iron ought to be rejected; and, if the telegraphic wires were made of greater calibre, as they really appear to require to be in long lines, the only additional strengthening, besides a good insulating material, such as India rubber, if it can now be rightly and economically applied, would appear to be an outer covering of tarred rope-yarn. The French threaten to cut us out as layers of an Atlantic line, but are they properly prepared with a really improved cable?

## CHURCH BUILDING NEWS.

**Edenbridge (Kent).**—The church here has been restored and reopened. The old pews have been removed; the gallery at the west end, in which the organ stood and the choir were seated, has been taken down; the partition in the south-west corner, which rudely served the purpose of a vestry, has disappeared; the chancel has changed its appearance considerably; a fresh pavement has been laid throughout the church; a vestry has been added on the north side; and the pulpit, organ, and baptismal font have changed their positions in harmony with other alterations. The whole restoration has been effected by the application of the voluntary principle, which has lately been so greatly developed throughout the country. The sittings consist of open benches, providing accommodation for upwards of a thousand persons, a large proportion of them free. In the body of the church they are made of deal, stained and varnished; those in the chancel being of varnished oak. In the chancel, Mr. W's hand have been used for the flooring. The altar, in all its appointments, is entirely new, the cloth of red velvet; and there is a new pointed window, the gift of Mrs. F. R. Gore, which makes a graceful addition to the ornamental part of the chancel. All the doors of the church are new, and amongst other additions is a window at the south-west end, where the partition used as a vestry originally stood. There is a new apparatus for the heating of the church.

**Marborough.**—The cemetery chapel has been commenced. Mr. J. May, builder, has taken the contract for 610*l.*, including the lych gate, of which sum, in addition to the presentation of the land, the Marquis of Ailesbury has contributed 200*l.*

**Guernsey.**—A small chapel in St. Peter's Port, Guernsey, hitherto known as Bethel Chapel, has been reopened, after enlargement and decoration, under the dedication of All Saints. In spite of difficulties of site and space, says the *Dorset Chronicle*, a chance has been won from the adjoining house, small indeed, yet proportioned to the size of the chapel, which will accommodate about 330 worshippers.

**Worcester.**—A rectory-house for St. Nicholas is about to be erected. A suitable site, says the local *Herald*, has been purchased at Lansdowne-crenset; and, by an advertisement, builders' estimates are to be sent in at once to the architect, Mr. William Jeffries Hopkins.

**Bristol.**—The foundation-stone has been laid of a new church, to be added to the list of sacred edifices with which the extensive parish of St. Philip and Jacob abounds. The building will be in the Early Gothic style, and consist of a nave and two aisles; and it is proposed to add a chancel at a future time, while a portion of the ground adjoining the site is reserved for a school. The length of the church will be 86 feet, with a breadth and elevation of 50 feet, the material employed being Hanham stone, with freestone dressings. The aisles will be divided from the nave by rows of pillars, with ornamental stone capitals, and the church is laid out for 700 sittings. The principal entrance will be at the west side of the building, facing the New-road, the porch being on the south. Space will also be left for a gallery.

**Cardiff.**—The foundation-stone of the new Roman Catholic Chapel, in Pucca-lane, has been laid. The architect is Mr. C. F. Hauson, of Bristol, and Mr. Webb, of this town, is the builder. The size of the chapel will be 140 feet by 70 feet. The style will be Gothic; and, when the necessary funds are raised, a tower will be built.

**Welby.**—The church belonging to this parish is undergoing a thorough restoration, including re-roofing the whole and re-building a portion of the south wall, together with a new porch, &c. Situated in an obscure position, at some distance from the lodges which constitute the parish, this church is almost unknown to the public. It has, however, some points of interest to the antiquary, and will doubtless be brought into notice by the effort now being made to render it fit for divine service. The works are being carried out under the superintendence of Mr. R. W. Johnson, architect, of Melton Mowbray.

**Calderbrook (Manchester).**—The foundation-stone has been laid of a new church, to be dedicated to St. James, on the hill-side, within a short distance of the entrance to Summit Tunnel, near Littleborough, in the township of Calderbrook. The new church will have a spire 155 feet high; it will contain sittings for 500 people. The style of architecture will be the Decorated. The edifice will have a chancel, nave, north aisle, and a chapel for the family of the Deardens, similar to the Trinity Chapel in Rochdale parish church. The seats will be open stalls, the roof timbers visible, and the chief windows are to be filled with stained glass.

**Whitwell (Yorkshire).**—At Whitwell, near Malton, a new church has been erected at a cost of several thousand pounds, and also endowed to the amount of 150*l.* per annum, by Lady Lechmere, the wife of Sir Edmond A. H. Lechmere, Bart., of Rhydcourt, Worcestershire. Lady Lechmere devoted 3,700*l.* for the purpose of building the church, but this sum is exclusive of the cost of the site, which contains between two and three roods of land, the greater part, of course, intended for a churchyard. The architect selected was Mr. Street. The style of the building, says the *York Herald*, is Geometrical Middle Pointed. Its extreme interior length is 80 feet, the breadth of the nave 18 feet 6 inches, and of the chancel 17 feet 3 inches. It will accommodate 180 persons. The church is built of Whitby stone of two colours, the dark colour being inserted as bands. There is a lych gate at the principal entrance, and the yard is entirely enclosed by a stone wall. The tower is on the south side of the chancel, and the height from the ground to the top of the spire is 113 feet. The tower contains a peal of six bells, which were cast by Messrs. Warner & Sons, of London. An apparatus has been fixed under the central passage of the church for warming the building. The floor of the nave is laid with Milton tiles—black, red, chocolate, and buff. The chancel is laid with figured encaustic tiles of various patterns, and the walls up to the string course, internally are also laid with coloured tiles and encaustic figured bands. The reredos is by Mr. Earp, of London, and is composed of Mansfield yellow

stone, Staffordshire alabaster, rouge Royal, Languedoc, Galway, Devonshire red marble and pebbles, and Derbyshire spar. The east window is a three-light, presented by Sir E. Lechmere. This window, which cost 140*l.* and is by Messrs. Clayton & Bell, of London, represents the crucifixion in the centre, with St. John and the centurion on one side, and the mother of our Lord and the two Maries on the other side. The two side windows of the chancel were presented by A. Stephens, esq., of Postyn Hall (late of Whitwell Hall), and Mrs. Stephens, Lady Lechmere being the daughter of the latter. These windows cost about 50*l.* The west window, representing the four evangelists, is the gift of the tenantry. This window will also cost about 50*l.*, and it, as well as the windows just mentioned, is the production of Mr. Wallis, of Newcastle. The seats are composed of movable open oak benches. The font is of Caen stone, inlaid with discs of coloured marbles and spars. The pulpit is of Caen stone, with red Mansfield steps. The carving, both in the interior and exterior of the church, is by Mr. W. Pearce, of London. The roof of the building is open timbered, and covered with red tiles, manufactured by Mr. Shafroe, of York, the contractor for the work. The organ, supplied by Mr. Willis, of London, is placed under the tower. The woodwork was executed by Mr. W. Cook, of York; and the sconces and other wrought iron work were supplied by Mr. Lever, of Maidenhead. The clerk of the works was Mr. J. Chick, agent of Sir E. Lechmere, in Worcestershire. The church has been dedicated to St. John the Evangelist, and consecrated by the new Archbishop of York.

**Howsham (Yorkshire).**—Mrs. Cholmley, of Howsham Hall, has caused a new church to be erected at the pleasant village of Howsham, which is only three or four miles from Whitwell, where Lady Lechmere's church has just been opened. Mrs. Cholmley's church has been built in memory of her late husband, Col. Cholmley. Like Lady Lechmere, she has also endowed her church, the entire cost of which will amount to between 2,000*l.* and 3,000*l.* The church is dedicated to St. John the Evangelist. The style of architecture is Geometrical Middle Pointed. The nave is 40 feet, and the chancel 29 feet in length. The breadth of the nave is 20 feet 9 inches, and of the chancel 15 feet. Accommodation has been provided for about the same number of persons as in Whitwell church. The porch occupies a portion of the extreme west end of the building, the remainder of which is occupied by the tower, which has a pyramidal capping, supported by Mansfield stone and marble columns. In the tower are four bells, which were cast by Messrs. Warner & Son, of London. The church is built of Whitby stone, from the quarries of Mr. John Bolton, similar to that used at Whitwell, and it is relieved by coloured bands. The chancel terminates with an apse in the wooden groined roof of the same, which is in seven compartments, and has been painted in varied colours, by Mr. E. O. P. Harrison, of London. The remaining portion of the roofing is open timbered, and of stained deal. The three apse windows contain six lights. The one to the north represents the Last Supper and the Agony in the Garden; the centre one contains the Crucifixion, and the Taking-down from the Cross; and the next represents the Resurrection and the Ascension. The south window of the chancel is of three lights, and represents the Six Acts of Mercy, as recorded by Christ, in the twenty-fifth chapter of Matthew. The two easternmost windows of the nave are of two lights each, and represent the Four Evangelists. The third window is of three lights, representing the Baptism of Christ, Christ inviting little Children to come unto Him, and the other represents Him as Feeding the Lambs. The circular west window represents Christ Judging the World, and six lights contain the evangelistic symbols. The window in the chancel, representing the Six Acts of Mercy, was given by the tenantry on the Howsham estate. The whole of the stained glass windows were supplied by Messrs. Clayton & Bell, of London. The reredos is in three compartments, and is of Caen stone, inlaid with marbles and spars. The centre compartment contains a Maltese cross, which is composed of Languedoc marble. This reredos was supplied by Mr. Earp, of London. The paving of the floor of the church is the same as at Whitwell, being composed of Milton tiles; and the chancel is figured with encaustic tiles and white marble. The pulpit is at the north-east corner of the nave, the base and steps being of red Mansfield stone, and the remaining portion of Caen stone, with inlaid patterns of various coloured marbles. The sconces and other wrought-iron work were supplied by Mr. Lever, of Maidenhead.

\* Published by the Authors, Winborne Minster.

Mr. G. E. Street was the architect, and Mr. Shaftoe, of York, the contractor; and the seats and other woodwork being supplied by Mr. W. Cook, of York. The edifice has been consecrated by the Archbishop.

**Barnby Dun (near Doncaster).**—The church of Barnby Dun is about to be restored. Messrs. Harbald & Goldie have been called in by Mr. J. H. Newsome, who proposes to restore thoroughly the chancel: the nave and aisle have already been repaired to some extent; but it is intended to complete the good work to well begun. The church is of the thirteenth and fourteenth centuries.

**Dewsbury Moor.**—The *Leeds Intelligence* states that the whole of St. John's Church, Dewsbury Moor, has recently undergone some necessary repairs. The roof of the tower has been entirely renewed. It had been for some time in a very dilapidated condition, owing to the decayed state of the woodwork. The exposed parts of the exterior of the church have been pointed with mastie, to exclude damp. The interior of the building has also been renovated. The ceiling has been coloured in panels with a brown mather, and the ribs or spandrels are thrown up in white. The walls are done a warm stone colour. The heating apparatus has also been renewed.

**Bradford.**—That portion of the borough cemetery at Solenemoor appropriated to the Church of England has been consecrated by the Bishop of Ripon. The works have been executed under the direction of Mr. Gott, the borough surveyor. The twenty acres of ground already appropriated appear to form almost a square. The entrance boundary in Necropolis-road consists of palisading and entrance gates. A large house, the residence of Mr. Scanton, the registrar of the cemetery, stands near the entrance. Two sides of the ground are enclosed by high stone walls. A low boundary wall divides the cemetery from the unappropriated ground at the bottom. A carriage road, running from the entrance gate to the bottom, divides it, nearly in the centre, into two portions; one, on the western side, being intended for the Episcopians, and the other, on the eastern side, for the Nonconformists. The two portions of ground are crossed near the middle by a broad terrace. On each side of the terrace is erected a chapel. The registrar's house and the chapels were erected from the designs of Mr. E. Milnes, architect. The style of architecture is the Geometrical Decorated. The cost of the building and the boundary walls was about 2,500*l.*—St. Thomas's Church, designed to accommodate 750 people, will shortly be commenced. The site has been presented to the committee, and plans have been prepared by Messrs. Lockwood & Mawson, of Bradford. The estimated outlay is 2,500*l.*

**Harrogate.**—A short time ago several architects were invited to furnish designs for the new Independent Chapel proposed to be erected at Harrogate. London, Bristol, Leeds, Bradford, Cardiff, and Darlington, responded to the call. The designs sent in by Messrs. Lockwood and Mawson, of Bradford, were selected. The building will occupy a prominent position at the entrance of the Victoria Park. The style is Geometric. A tower and spire rise at the south-east angle to a height of 150 feet. The estimated outlay is 4,000*l.*—Christ Church, High-Harrogate, is also to be considerably enlarged, by the addition of new transepts, chancel, organ-loft, and vestries, and by other alterations, also under the direction of Messrs. Lockwood & Mawson.

**Hull.**—The foundation stone of a new Wesleyan chapel has been laid on the Beverley-road, by the mayor, Mr. Z. C. Pearson. The edifice will be in the Gothic style of the Decorated period. The internal dimensions of the chapel are 90 feet by 54 feet, and accommodation is provided for about 1,200 persons. On the sides of the main buildings in front are projecting wings, with stone staircases to the galleries. The principal front has a large four-light tracered window in the centre, and the gable is finished with an ornamental stone turret. The design was furnished by Mr. W. Botterill, of Hull, architect, and the edifice will be erected under his superintendence. The walls externally are to be of white brick, from Wallingford, with dressings of Bredsworth stone. The contractors are R. Bailey, bricklayer and plasterer; Simpson & Malone, stone-masons; James Jackson, carpenter and joiner; P. T. Harrison, plumber and glazier; Pearson, Dannatt, Kruger, & Co. ironfounders; Dawber & Son, slaters; and W. Wardale, painter, all of Hull.

**Ryth.**—The foundations of a large Roman Catholic church for the Benedictine order have just been commenced, upon a site close to the railway station. It will consist of near 120 feet in length, and transepts, with a bell-turret, and when

completed will contain about 1,000 sittings. The plans have been prepared by Mr. Archibald M. Dunn, of Newcastle, architect, under whose superintendence it will be carried out. The contract has been taken by Mr. James Howe, of Cowpen, for 2,200*l.*

**Walker.**—Another R. C. church at Walker, to contain 700 sittings, from the designs of Mr. Dunn, is about finished and will be opened this month.

#### THE FOUNTAIN MOVEMENT.

SIR,—As an admirer of all modern embellishments in our fair metropolis, and above all of that philanthropy which induces the wealthy to devote their substance to the public good, I approve the Samaritan virtue that founds and dedicates fountains for the relief of all who are athirst; but, in common with all with whom I have conversed, having an artistic tone of thought, I cannot but deplore the paltriness of design which characterizes the majority of these monuments.

Look, sir, at this marble tablet of sable hue and gilt letters, enframed with the same material, varicoloured,—is it not the repetition, only slightly diversified, of the dismal mementos of a country church? It is true there is a living dribble of a pint per minute, and two cups inviting way-farers to toast the founder or each other; but where is munificence fled—such munificence as in bygone days led the really benevolent to found hospitals and charterhouses?

One hundred pounds sterling is about the average cost of these pious consecrations generally: some are much less: we shall soon have model castings in iron at the standard price of 20*l.*, pipes and all; and yet the name of the donor, as you have rightly observed, is ostentatiously emblazoned, perhaps with his arms, as the preeminent benefactor of his fellow-citizens! Here is the fountain of health, the purchase of so great a popularity is cheap, and the smallness of the gift is well contrasted, and at the same time delicately satirized, by that lady (we may guess her name) who benignantly placed a really tasteful fountain in the retirement of the Green-park, containing to arrogate to herself the credit of being the fountains.

The fountain of honour was in past ages supposed to have its seat on a throne: in A.D. 1860 every aspirant to public fame can originate glory for himself. Would it not be in accordance with the system of ancient monumental inscriptions to place on the marble or casting, "Sacred to the memory of" my Lord, or Baron, or Sir James So-and-So? Or if men will seek popular recognition, with the fame of a name, let them erect something respectable, although it be neither colossal nor pyramidal; let them give a bench where the weary may rest while they quaff; let them place over it a friendly shade, and thereupon inscribe, "Stat nominis umbella."

HABITANS INTRA FONTES.

#### WALL PAINTINGS: WEST HAM CHURCH.

I HAVE lately seen in your interesting journal some remarks on the decorating of the walls of public buildings in the city of London. If you will allow me a portion of your space, I will give a description of the decorations on the walls of All Saints' Church, West Ham, Essex. This church being under repair a few years ago, the workmen, in washing off the old whitewash from the walls, discovered they were painted, from the organ-loft, north and south, above the gallery, to the end of the building, in the most showy and beautiful colours and gold. I was sent for to examine the pictures, and intended to have traced the whole of them, if there had been sufficient time; but, being afflicted with giddiness, I could not stand on the scaffold. The ultimate design and purpose of them, however, is quite manifest, by an exhibition of sensible figures to inculcate the doctrine of Purgatory. Over the pulpit, in front, are several figures of females in full length, half naked: they are descending, and seem passing onward to a certain point. Further on are a great many entering the door of Hell: it appears to represent a long river of fire. Further on still are many persons in it, tormented in the flames, all sad and in extreme distress, looking upwards, and their hands folded. One chief figure seems to represent a friar: he has a long, thick beard. Another tall, handsome figure seems to represent royalty, having a gilt crown on his head; the others, a general class of figures, all in torment and fervent prayer. In the upper part of the picture there is represented the exterior of a

noble edifice or temple: at the entrance is one person half-way in the doorway, and guarded by a second person, who has him in custody, and forcing him in, but he appears reluctant to go in. Near the door is another figure, attired in a grave costume, who also appears to be an officer, to execute the will of the judge, who is richly attired with a sort of turban on the head, and his countenance serene and happy. There are two figures, who appear like angels, as porters of the gate. In a line with the door, in the interior of the temple, is a grave person, seated in majesty, with a desk before him, like our courts of justice. On his right is another person to assist in judgment. Beneath these figures is seen the place of torment, all along the lower part of the picture. Extending to the end is continued the place of torment. About midway is a very graceful figure, of a heavenly countenance, and with a gilt crown on her head, who appears as if moved by compassion and tenderness. She is leaning forward and helping one out of the lake of fire by the hand, and another by the arm, as if she would succeed in delivering them from their deplorable situation. This figure I suppose is intended for the Virgin Mary. At a little distance is another figure of consequence, a female, probably an angel, as if assisting the Virgin in her work of mercy, and raising another out of the burning lake. There are some at the entrance of the dreadful cave: these look rather pleasant, and seem as if their punishment was but slight. On a noble figure that spans the north and south walls of the building is represented the bottomless pit, with vivid flames and smoke. On the edge of the pit are two devils, or demons: they are standing one above the other. They are made like brutes, having long horns growing upright, large ears, wide ugly mouths, very large glancing eyes, and cloven feet. One has a person in his arms, lying crossways, and looks in extreme misery, while they are grinning at having gained their prey. There were a great number of figures defaced by the plasterer's trowel scraping off the whitewash to recolour the walls; but the colours were as brilliant as at first executed, and the gliding in good preservation. The large Gothic arches stand on the pillars were painted in stripes, crossways, zebra-pattern. There was a motto in old English characters, as follows:—

"Wisdom's ways are ways of joy."

These paintings were well executed, and must have been done by first-rate masters of the art; the colours have stood well for hundreds of years.

JOHN WILSON, C.E.

#### THE PROMOTION OF SOCIAL SCIENCE.

SIR,—“Social” science is yet in its infancy, and the laws and principles which influence the condition of human kind generally are but imperfectly understood and as feebly enunciated. The Social Science Association which has been recently established may be a step in the right direction, but is not calculated to effect any great advantages to society. The very fact of its meetings taking place only once in the year is an evidence that little good can be expected to result; yet the “social” economy of the human race is, it can scarcely be gainsaid, the most important of all the sciences that can engage the attention of the world. In order that a knowledge of social economy may be attained and disseminated by and amongst the community, every city and principal town in the United Kingdom should have its social science institute, where lectures may be delivered by its members or others; having also its discussion-class or classes, and a library of works relating wholly to social economy. The subject is by far too important to be treated as an amusing and interesting adjunct for the occasional delectation of the members of our various literary institutions, whether supported by the aristocratic or democratic portions of society, as is now most undeniably the case. As a powerful auxiliary to the institutes now suggested to be established, the Government could give effective aid by granting or giving copies of the “blue books” published under its auspices, many if not most of them containing much valuable information in relation to “social economy.” They must not take as their standard of faith the dogmas of the “economists” of the old school, who are now seen to be unsafe guides in many instances, leaning too obviously to the side of wealth or power; nor indeed holding by the creeds of any particular writer, but eulging from all matter worthy thought and discussion. It may be incidentally observed, that the study of “social” economy *per se* is one that should have a place in *all* schools, and indeed a foremost rank

therein. The subscriptions to such institutes now suggested should be very moderate, so as to be accessible to those of humble means, who form a majority in the community, assisted, it may be, by the voluntary aid of the wealthier classes. Already there is a *Journal of Social Science*, and one or two others more or less directly bearing upon the subject, whether able or feeble exponents of the cause: were such institutions organized upon an efficient basis, we might hope eventually to see most if not all of our cities and large towns having their own local "journal of social science," distinguished by the name of the city or town being prefixed to it. E. A. I.

JOHN BUNYAN IN THE LONDON GUILDHALL.

For some days past the model for a statue to this worthy has stood in the Guildhall for the purpose of view. The famous author of the "Pilgrim's Progress" is represented about life-size, seated, the countenance raised upwards. The expression of the face is good. There are books, a broken chain, and other accessories, but as a whole it is not quite satisfactory. The model is placed on the ground near the Pitt monument, with which it does not interfere.

With one exception, the monuments in this place are to the memory of statesmen and warriors. Many would like to see added memorials of men who have been connected with the City, and have distinguished themselves. Daniel de Foe lived for long a city life; Hervey, the discoverer of the circulation of the blood, died within the City bounds; John Bunyan, who often preached within those limits, and died there. There are others of note who might most worthily find a place within the walls of the Guildhall, and the model which has thus been temporarily set up shows that the introduction of statues of a smaller size than those which are already there would vastly improve the appearance of the hall, be honourable to the City, and interesting to numerous visitors who call here. Honest John Stowe should not be forgotten in any such arrangement. AN ARTIST.

VENTILATION OF WAREHOUSES.

SIR,—Having read the interesting paper "On the Arrangements of Warehouses," by Mr. John Roberton, in your valuable periodical of the 18th ult., I am led to call your attention to the following quotation:—

"As connected with salubrity, it would be wrong to omit the mention of an atmosphere loaded with *dust* and *filamentous particles* in certain quarters of shipping warehouses, produced in preparing goods for packing. I know not how the evil is to be remedied; but I am assured, that it gives rise to coughs and ill health, in those (often ladies), who from morning to night, are inhaling it."

Mr. Roberton suggests a way, by means of flues in the wall, and a current maintained by a ventilating wheel at the top. This would be of very little use employed in an atmosphere like that of the Manchester warehouses; and the quantity of air carried off by the ventilating wheel would be a drop in the ocean, in comparison to that required to purify the rooms, and carry away the *dust* and *filamentous* particles.

What is required in these warehouses, where the outward and inward atmosphere have little or no circulation, is a powerful system of *mechanical ventilation by propulsion*, without which you may as well try to find the perpetual motion as to obtain perfect ventilation and remove the filamentous particles contained in the air.

I might bring forward a great many examples, where mechanical ventilation by propulsion has been employed with great success in buildings similar to those referred to in Manchester; but I will content myself with the following one:—

"A great complaint was made by the printers of the daily paper, *Le Moniteur Belge*, for want of ventilation in their printing-office, where some fifty men were assembled daily, with a cubical space of not more than 700 cubic feet per man; the atmosphere was so foul, and the circulation being impeded by the dense outward atmosphere, which always surrounds densely populated quarters, that the men were generally in a bad state of health. Their petition having been agreed to, a mechanical system of ventilation, by propulsion, conducted with warmth, was adopted."

It proved a perfect success, the office being perfectly ventilated and cooled during the summer, and agreeably warmed in winter, and that at a very little cost. Since then no complaints have ever been made as to the ventilation, which, when I visited the office, was perfect.

I inquired whose plan had been adopted, and found that it was that of Dr. Van Hecke. This

system you gave a description of in your number of June 2, 1860.

May we hope that our great manufacturers will not be slow to follow so good an example, and thus alleviate, as far as in them lies, the sufferings of mankind. M. G.

"THE STEAM PLOUGH."

I THANK you for drawing attention to my circular on this subject, and agree with you that it savours strongly of the predominance of No. 1 interests. But even supposing this to be true in its strictest sense, it is only in accordance with the healthiest expression of commercial principle. However, if my object had been merely to say something on this subject, merely to complain of an existing evil, I should have been satisfied with having had my say without suggesting a remedy; but I believe that a great material result is within the scope of accomplishment; therefore, with the statement of the evil, I thought it best to set aside appearances, and plainly state my belief in the existence of a remedy. You are aware, no doubt, that "authorities" on this point say, with much confidence, that steam will never take entire control over all the various operations of the farmer, and that a hilly, soft, and uneven surface presents obstacles to the application of steam-power which mechanical science will never overcome; it would be useless, therefore, for me to complain against those efforts which are being made, unless I was prepared at the same time to point to a more effectual method of attaining the same end. Now I do affirm, with all the modesty with which such a statement should be made in the teeth of "scientific dictum," and yet with all the confidence and boldness that the statement (if a truth) demands, that as the tractive power of the quadruped (which at the present time is the chief agent in agricultural labours) is based on *mechanical principles*, and subject to absolute and definite law, the same principles, if applied to the same purpose through the medium of iron and by the agency of steam, are equally sufficient and equally capable of contending with every difficulty of soil or inclination. These principles have never yet been embodied in an engine, and they consist in developing the tractive power which is due to *gravity directly*, in contradistinction to the present system, which gets all its tractive power from *friction*. Neither a biped nor quadruped could exert a tractive force if the centre of gravity was forcibly kept directly perpendicular to the resting point of the foot; but in drawing, the body is instinctively thrown forward, and both the muscular power and the friction is *subservient to the direct* development of the tractive force due to gravity. Friction, which is most efficient on a hard and smooth surface, and will yield only 20 per cent. of power to the weight it carries, cannot be relied on for half that under unfavourable circumstances. Gravity, however, is more efficient on a soft or impressible surface, and will yield a tractive power from 50 to 100 per cent. of the weight it carries, according to the condition of the soil.

Having spent a great portion of my life in America and the British colonies, I have been struck with the immense extent and fruitfulness of their agricultural resources, and with the immense contrast that is exhibited between the progress of this branch of industry in America and in the British colonies. In India and Australia every effort of legislation and other influences is used to check the flow of enterprise and industry to this legitimate channel; and, as there is no other employment except that offered by manufacture which will absorb the industry of the population, efforts are constantly being made to tax the importation of British manufactures; whilst, at the same time, an irritating social and political agitation is kept up, which is simply due to the absence of a legitimate field for remunerative employment. Now I contend that a steam plough put into the soil of India and the colonies would at once develop the most accessible of their resources, give abundant employment to all, give to industry a natural channel for its energies, and do more to promote internal security and commercial prosperity than 300 years of legislation, while at the same time the vast increase of material wealth, and its distribution, would yield abundant employment to the shipping interests, and a cheap and reliable supply of raw materials to the manufacturing interests of home.

Many seasons of commercial depression, of high-priced food, and of general distress, have afflicted our country; yet all have led to some great and good end by drawing attention to the elements of commercial and social disease, and by concentrat-

ing the efforts of society towards their removal; and if the disasters which in a ruined harvest and a decreasing export trade now seem to hang over us should be the means of drawing the attention of the *commercial community* to the vicious influences which are now at work in every part of British territory, either by legislative restriction or by the creation of social disorder, to check the abundance of staple produce (with no other object but that the antiquated rotten and artificially sustained *prestige* connected with the land here should not be encroached on, or its fictitious sanctity invaded), we shall in a few years look back to the present with a feeling of gratitude, conscious that, although bitter to the taste, it was but a blessing in disguise.

I will conclude by stating that, as the industry of man has three eras of progression, so has steam power, *viz., manufacture, transport, and agriculture*. The third has not yet been accomplished. *Before it* the fetters of negro slavery will fall, and the darkness of superstition and barbarity, now protected by the forest and the jungle, will disappear; *with it* will come the advance of commerce, industry, civilization, and constitutional freedom; and behind it the bright noon of Christian light. With such a prospect, who would not shout with the full force of his lungs, "Help! Help forward! a steam plough for the idle soil of the world." JOHN GILES.

THE SALTING OF BRICKWORK.

THE question was, I think, asked some time since in your paper, whether any means could be adopted to prevent the salting of brickwork. In a building to which I was architect last year, we tried, by the advice of a chemist, oiling the facing bricks with linseed oil. The oil was applied with a brush to one face and one end of each brick; and, as no salting has appeared on any part of the brickwork, which was finished about twelve months ago, the experiment seems to have been in this case successful. I have found the same kind of facing-bricks become salted considerably where they have been used without oiling; and, from the appearance of the mortar joints in the case in question, think that the same would have occurred in the present instance had the oiling not been adopted. The salting of brickwork is so detrimental to its appearance that any means of preventing it is of value; and I therefore send you the result of my own experience on the subject. The oiling rather improves than otherwise the colour of the brick. JOS. A. DAVIES.

TO PREVENT ROT IN DWELLING-HOUSES.

Make two or more openings in the external walls, and put gratings on them to keep out vermin, from below the basement floor. Insert a tile pipe into the fire-wall, with one end open to the space below the floor, and carry the pipe up the centre of the fire wall as close as possible to the fire-flue, and out at the chimney head. The air in the pipe will be rarefied, being in close contact with the fire-flue, thus causing a continuous upward flow, sweeping the space below the floor of all the foul air, which, in my opinion, is the chief cause of dry-rot. The whole of the apartments in the house may be ventilated by means of this pipe, by inserting a tube into it at the level of the ceiling, with a valve in it to prevent down-draught. I have adopted this system for the last ten years, because I know of no better. A WORKING-MAN.

STAINED GLASS FOR ST. PAUL'S CATHEDRAL.

MUCH having been said and done lately tending to increase the funds necessary for putting St. Paul's Cathedral in an efficient and suitable state for public worship, it may not be amiss to offer a suggestion relative to the adornment of the windows with stained glass.

Surely there could scarcely be a more fitting way of settling this desideratum than by the Corporation of the City of London giving one large window or series of windows in the choir-end of the cathedral: if this were done, there is no doubt the great City companies would not be backward in filling several more.

Supposing they each gave a window, it would not only do a great deal towards satisfying the present much-felt want, but would give to the building the character that it should have, of not only being our great national church, but of being in spirit and motive the Cathedral of the City of London. Typical designs might of course be chosen by the respective companies which would thus symbolize the idea. P. H. N.

## AMUSEMENTS.

*The Adelphi*.—The powerful drama of "Jaquet Pride" has been revived here, and the public have fully recognized its merits as a striking picture of life, and the excellence of the acting in it, especially on the part of Mr. Webster, Miss Woolgar, and Mr. Toole. There are others engaged who also efficiently aid in carrying on the story, but with those named rests the burden. Of Mr. Webster's *Richard Pride*, one of those minute and elaborated delineations in which he excels and delights, we have before now spoken. The Greeks who made slaves drunk before their children to disgust and waru would have seen in this remarkable personation a lesson of no trifling value.

*The Princess's*.—"Macbeth," the first of Mr. Kou's archeological and architectural revivals, has been produced here, with the original scenery and accessories: Mr. James Anderson playing the tyrant, and Mr. Weiss and Miss Rebecca Isaacs setting forth the middle Frenchman in "The First Night" with great vivacity and humour, to introduce Miss Maria Harris as his daughter, a promising very young *débütante*.

PROCEEDINGS UNDER THE METROPO-  
LITAN BUILDING ACT.

## ROOF-COVERINGS: ASPHALTE.

At the Wandsworth Police court last week, *Mr. Henry Boughton*, of Mendip-wharf, Battersea, the works of the Asphalt Company, was summoned before Mr. Ingham J. by Mr. Henry Taylor, district surveyor, for covering a certain building upon his premises with asphalt instead of slates, tiles, metal, or other incombustible material, contrary to the provisions of the Act.

The question in dispute was of considerable importance to the company.

A gentleman present said he had been in the business a number of years, and could state that asphalt was incombustible. He stated that Mr. Taylor was a practical man in the case of asphalt, and therefore he was unable to give an opinion. Asphalt was now used for covering the roofs of gunpowder magazines at the Tower of London and other public buildings. He then instructed a case to show its incombustibility. At the late fire at Harley's wharf, London-bridge, the flames spread rapidly throughout the building until they came to a roof which was covered with asphalt, when their further progress was stopped, and in fact the roof extinguished the fire.

A piece of asphalt was produced, and his worship thought it would be desirable to try whether it was combustible or not.

All the parties, with the magistrate, proceeded to the reserve-room of the station, where there was a fire in the grate. The fire having been poked, Mr. Ingham thrust the piece of asphalt into the burning coal, which it immediately bore away, to use the words of a constable who was present, like a rindie. Upon the asphalt being picked out of the fire the flames instantly went out.

The gentleman interested contended that on a roof the fire would burn to the asphalt covering, and would go no further.

Mr. Taylor was unable to make out his case in consequence of his not being able to prove the service of a notice.

On the part of the defendants it was stated they were ready to waive that informality, and to have his worship's decision upon the merits of the case.

Mr. Ingham said that, with the experiment just made, he should rather decline to say whether asphalt was combustible or incombustible within the meaning of the Act, and he therefore dismissed the summons on the grounds of the informality in the proof of the notice.

Mr. Taylor said he should serve the parties with another notice.

## Books Received.

*Notes on Nursing; what it is, and what it is not* by FLORENCE NIGHTINGALE. New edition, revised and enlarged. London: Harrison, Pall-mall, 1860.

FLORENCE NIGHTINGALE is no less distinguished for her intellectual ability, and originality of thought, than she has long been for her benevolence, her moral energy, and her enthusiastic devotion to the good cause to which she has so disinterestedly devoted her life, and so unmercifully sacrificed her health. She is moreover one of the most animated and skilful of writers, as the public have now the advantage of knowing through the publication of her very valuable "Notes on Nursing." Yet she is by no means what is commonly called a "strong-minded" or "masculine" woman; none was ever more womanly in every turn of thought and act—in every sense of the beloved and beautiful expression. This leading feature of her character shines out everywhere throughout her work, but one can especially perceive it in her occasional exhortations to those for whose benefit she designs her "hints," as she modestly terms them. Thus, at the very close of her volume, she says,—

I would earnestly ask my sisters to keep clear of both the jargons now current everywhere (for they are equally jargons); of the jargon, namely, about the "rights" of women, which urges women to do all that men do, including the medical and other professions, merely because men do it, and without regard to whether this is the best

that women can do; and of the jargon which urges women to do nothing that men do, merely because they are women, and should be "recalled to a sense of their duty as women," and because "this is women's work," and "that is men's," and "these are the things which women should not do," which is all assertion, and nothing more. Surely women should bring the best she has, whatever that is, to the work of God's world, without attending to either of these errors. For what they should do (the one just as much as the other, but listening to the "what people will say," to opinion, to the "voices from without"? And, as a wise man has said, no one has ever done anything great or useful by listening to the voices from without.

You do not want the effect of your good things to be "How wonderful for a woman!" nor would you be deterred from good things by hearing it said, "Yes, but she ought not to have done this, because it is not suitable for a woman." But you want to do the thing that is good, whether it is "suitable for a woman" or not.

Oh, leave these jargons, and try your way straight to God's work, in simplicity and singleness of heart.

It requires very little examination of the book to convince any one who does not already know the fact, that Miss Nightingale is no mere dilettante nurse, with an imaginary mission to carry out, but a most skilful, common-sense, enlightened, and experienced mistress of the ministering and angelic office, to which nature has in every way adapted her,—unless it be on the point of physical strength, which she has so overtasked; but where is the woman who could have made with impunity her superhuman exertions during the late war? These exertions, nevertheless, and their laudable result, have by no means diminished her enthusiasm in the cause which she advocates. Its prosaic repulsions are still completely obliterated in her estimation by its poetic attractions. "This book," she remarks, in a supplementary chapter, "takes away all the poetry of nursing it will be said, and makes it the most prosaic of human things. My dear sister, there is nothing in the world, except perhaps education, so much the reverse of prosaic, or which requires so much power of throwing yourself into others' feelings which you have never felt; and, if you have none of this power, you had better let nursing alone." And this Samaritan power, we may add, combined with a vigorous and penetrative intellect, constitutes the chief secret of her own genius and talent for nursing the sick.

The "Notes on Nursing" contain not a few "hints" of importance to architects and builders. Indeed, as respects the right construction of hospitals and dwellings for the promotion of convalescence in the sick, the whole work is well worthy of their perusal; but especially so where the distinct and separate sections in which the author treats of "Ventilation and Warming," and of "Health of Houses."

In the following remarks on pure air to a dwelling, Miss Nightingale, while stating what is otherwise perfectly true, hints architects for that of which they have, but seldom an opportunity of being guilty. This arises, however, simply from her adoption of a popular use of the word architect,—all builders, in that sense, being dignified with the (very erroneously applied) name of architect:—

To have pure air, your house must be so constructed that the outer atmosphere shall find its way with ease to every corner of it. House architects hardly ever consider this. The object in building a house is to obtain the largest interest for the money, not to save doctors' bills to the tenants. But, if tenants should ever become so wise as to refuse to occupy unhealthily constructed houses, and if insurance companies should ever come to understand their interest so thoroughly as to pay a sanitary surveyor to look after the houses where their clients live, speculative architects would speedily be brought to their senses. As it is, they build what pays best. And there are always people foolish enough to take the houses they build. And if in the course of time the lambs die off, as is so often the case, nobody ever thinks of blaming any but Providence for the result. Ill-informed medical men are in sustaining the delusion, by laying the blame on "contaminated air." Badly-constructed houses do not for the healthy what badly-constructed hospitals do for the sick. Once insure that the air in a house is stagnant, and sickness is certain to follow.

Drainage, slugs, papering, light, noise, draughts and many other points of importance, come under the author's careful and all observant notice. In her remarks on drainage, she says,—

It would be curious to ascertain by inspection, how many houses in London are really well drained. What people would say, surely all or most of them. But many people have no idea in what good drainage consists. They think that a sewer in the street, and a pipe leading to it from the house, is good drainage. All the while the sewer may be nothing but a laboratory from which epidemic disease and ill health are being distilled into the house. No houses with any untrapped ventilated drain-pipe communicate immediately with a ventilated sewer, whether it be from water-closet, sink, or gully-grate, can ever be healthy. An untrapped sink may at any time spread fever or pneumonia among the inmates of a palace.

The ordinary obliging sink is a nuisance. That great surface of stone, which is always left wet, is always exhaling into the air. I have known whole houses and hospitals smell of the sink. I have met just as strong a

stream of sewer air coming up the back staircase of a grand London house from the sink, as I have ever met at Sutar! and I have seen the rooms in that house all ventilated by the open doors, and the passages all ventilated by the closed windows. In order that as much of the sewer air as possible might be conducted into and retained in the bedrooms. It is wonderful!

Another great evil in house construction is carrying drains under the house. Such drains are never safe. All house drains should begin and end outside the walls. Many people will readily admit, as a theory, the importance of these things. But how few are there who carefully trace the consequences of such causes! Is it not a fact that, when scarlet fever, measles, or small-pox appear among the children, the very first thought which occurs is "where?" The children can have "caught" the disease? And the parents immediately run over in their minds all the families with whom they may have been. They never think of looking at home for the source of the mischief, if a neighbour's child is seized with small-pox, the first question which occurs is whether it had been vaccinated. No one would undergo vaccination; but it becomes of doubtful benefit to society when it leads people to look abroad for the source of evils which exist at home.

On the subject of servants' bedrooms, — a too much neglected one, certainly, — Miss Nightingale remarks, —

I must say a word about servants' bedrooms. From the way they are built, but fewer from the way they are kept, than from the intelligent inspection that never been exercised over them, they are almost invariably dens of foul air, and the 'servants' health' suffers in an 'unaccountable' way, even in the country. For I am by no means ignorant of London houses, where no other servants are put to live under the ground and over the roof. But in a country 'mansions', which was really a 'mansions' (not after the fashion of advertisements), I have known three maids, who slept in the same room of scarlet fever. 'How catching it is!' was of course the remark. One look at the room, one smell of the room, was quite enough. It was no longer 'unaccountable.' It was a fact. It was a small one, and it was a fact. It had two large windows—but nearly every one of the neglects enumerated above was there.

As to healthiness of site,—

There is a great difference between Hampstead, Camberwell, and Belgravia. The most densely populated and most filthy parts of a town are not the best neighbours to windward. The most elevated and exposed positions are generally the healthiest; the lowest to leeward of nuisances, under the shelter of the more elevated parts, generally the unhealthiest.

The low western districts, under the lee of London nuisances, are the recipients of foul air from the less healthy districts of London, whenever the wind comes from that direction; and yet people like to live there, because it is the "west end."

A house in the country, isolated in healthy and pure air, defies almost any amount of ignorance to malt unhealthily (and often one sees no little), but in the atmosphere of London very little indeed will do.

Houses generally are not built to be ventilated. There is no way for the foul air to go out, and there is no way for fresh air to get in. The best popular test, because almost universal, of the healthiness of a house, is the number of times which most houses retain the smell of dinner: some houses are seldom without it in the garrets. The only place where the air of many a house is drawn is the basement and the kitchen.

The air both of basement and kitchen should be so pure as never to be offensive. Nothing offensive has any right to be there. Keep the air inside your house as pure as the air outside, by all means; a proper use of windows will enable you to do this, but never think of ventilation as a substitute for cleanliness.

A dark house, as the author remarks, "is always an unhealthy house, always an ill-odoured house, always a dirty house. Want of light stops growth and promotes scrofula, rickets, &c., among children. People lose their health in a dark house; and, if they get ill, they cannot get well again in it." And this she proceeds, with sagacious hints and advice to her sister nurses, through the whole range of sanitary science, so far as it directly or indirectly bears upon the recovery of the sick, or indeed upon the preservation of health as well.

The only other quotations we need present by way of showing how the author deals with her many-sided subject relate to house papering and painting, and these we confess we select partly as an acknowledgment of the compliment she is therein pleased to pay the *Builder*.

In the supplementary chapter she says,—

I wonder whether many housekeepers' experience is the same as mine—viz. that in London houses "newly papered" and "newly painted" means putting a fresh paper atop of a dirty one, and tacking a fresh chintz atop of a dirty one,—aye, to three and four deep! No wonder some London houses are always musty, if cleanliness has nothing to do with it. This clearly affects all the inmates: children only suffer in a greater degree.

Again, under the head of "Cleanliness of Rooms and Walls,"—

As for walls, the worst is the papered wall; the next worst is plaster. But the plaster can be retouched by frequent lime-washing; the paper requires frequent re-papering. A glazed paper gets rid of a good deal of the dirt of the ordinary bedroom paper is all that it ought not to be.

A person who has accustomed her senses to compare atmospheres proper and improper, for the sick and for children, and for babies, means putting the difference of the air in old-painted and in old-papered rooms, *ceteris paribus*. The latter will always be musty, even with all the windows open.

The difference between ventilation and cleanliness is shown in this. An ordinary light paper will last clean much longer if there is an Arnett's ventilator in the chimney than if otherwise would.

The best wall now extant is oil paint. From this you can wash the animal exuvia.

These are what make a room musty.

The best wall for a sick-room or ward that could be made is pure white non-absorbent cement or glass, or glazed tiles, if they were made slightly rough.

"That excellent paper, the *builder*, mentions the lingering of the smell of paint for a month about a house as a proof of want of ventilation. Certainly—and where there are amule windows to open, and these are never opened to get rid of the smell of paint, it is a proof of want of management in using the means of ventilation. Of course the smell will then remain for months. Why shouldn't it go?"

### Miscellaneous.

**LIVERPOOL SOCIETY OF FINE ARTS.**—The annual exhibition of this flourishing society has been opened to the public. The different London societies have contributed largely to the collection, and many good names in English art are represented. Specimens of the French, Belgian, Prussian, and Dutch schools are also in force.

**NEW BUILDINGS AT CHATHAM BARRACKS.**—A lecture-theatre, schools of design, class-rooms, and rooms for the instruction of the officers and men of the Royal and Indian Engineers, are to be erected at the Brompton Barracks, Chatham, by the Government. The entire work is to be completed by February next, at a cost of several thousands of pounds, which have been voted by the House of Commons.

**THE ELLACOMBE TESTIMONIALS.**—A pair of silver candlesticks were recently presented to the Rev. H. T. Ellacombe, the rector of Clyst St. George, as from "every householder in the parish." The churchwardens, in their address to the rev. gentleman on the occasion, said,—"We have witnessed and admired the great skill, taste, and exertion on your part, under which the body of our parish church has been substantially rebuilt and greatly beautified; under which, also, the school, with a master's residence attached (which has lately been opened for use), has been erected. We are, moreover, mindful of your earnest and judicious efforts to promote our temporal as well as our moral and spiritual welfare. We desire, therefore, to testify to you, by this slight memorial, our sincere gratitude and affectionate esteem and respect." The gratitude and regard of the subscribers were also expressed towards Mrs. and Misses Ellacombe, for their kind and active interest in the well-being of all around them, and their exertions on behalf of education, their attention to the church music, and in many other respects; and small mementoes were presented to the young ladies. The children presented to their worthy rector a silver pencilcase, and the parents an inkstand to the schoolmaster, and Prayer-book to his wife. It is pleasant to note so much unanimity and good feeling between pastor and people. Clyst St. George seems to be a model parish in these respects.

**CARTOON BY KAULBACH FOR BERLIN MUSEUM.**

—Kaulbach has completed the cartoon for the last of his frescoes in the hall of the new museum at Berlin. After some difficulty and discussion, the subject given to the painter was the age of Reformations, and the general reawakening of the intellect and heart of Europe. A correspondent of the *Telegraph*, in describing the cartoon, says it is "a collection of individuals—contemporaries brought together by no tie of mutual action, and having nothing in common, save, indeed, that they lived in the same era, and worked in the general direction of their age. Thus we get Luther in the centre, though not in the foreground of the fresco. On either side the reformer Melancthon and Zuingle are imparting holy communion of both kinds to imaginary communicants. Behind Melancthon, the old and morose-looking Copernicus, in the act of drawing planetary rings, may be noticed; whilst, as a counterpoise to the dry study of mathematics, Albrecht Dürer takes up his position in the rear of Zuingle, painting—luckily behind the iconoclast's back—unarmored saints. Round about these prominent personages are grouped hosts of others. On Dürer's side of the canvas appear Michelangelo, Leonardo da Vinci, Raphael, and Pope Leo X., the latter the Mæcenas of his time. The space in front of Copernicus is taken up Gutenberg, with a crowd of Protestant students, as if they were of his own creation, and two sovereigns, Gustavus Adolphus of Sweden, and Queen Elizabeth of England, nearest to the spectator. The centre of the foreground is taken up by a warrior in full armour, cutting asunder with his sword a parchment scroll, tremulously held by a Roman Catholic priest. The two latter figures are purely symbolical, and may be interpreted as the bold emancipation of the Protestant mind from the fetters of priestly tradition."

**A NEW KIND OF BRONZE.**—We learn from the *Manchester Guardian* that workers in metal are finding good uses for a new kind of bronze, made by melting together ten parts of aluminum with ninety of copper. It is described as being tenacious as steel, and well adapted for the bearings of machinery. A polisher, who used it for bearings in his lathe, which made 2,000 revolutions a minute, found it last six times longer than bearings made of other kinds of metal. Is not this the bronze with which some ancient nations made their cutting tools?

**THE DRINKING-FOUNTAIN MOVEMENT.**—At Chatham, the Government has given a portion of land in Military-road, near the first drawbridge, as the site for a public drinking-fountain, which will be erected as soon as the necessary funds have been obtained. The present fountain in High-street, erected through the liberality of Mr. E. Winch, has already proved a great boon to the public. Steps are being taken to erect another at the lower end of High-street, Chatham, and also two in Rochester.—At Gravesend, another fountain has been placed at the bottom of Windmill-street, in front of the Alms-houses, so as to face High-street and the New-road. The design is the figure, in bronze, of a Naiad, pouring water from an urn.

**EXTENSIVE FIRE AT LONG-ACRE: DESTRUCTION OF ST. MARTIN'S HALL.**—Mr. Hullah's fine hall and lecture and singing-class rooms were almost completely destroyed by fire on Sunday morning last, the 26th August, together with an extensive carriage factory at the corner, erected, if we mistake not, under the late Mr. Bezley's direction after the fire which destroyed its predecessor about nine years since. Many other houses besides have been damaged, and flying fragments of burning timber were scattered over the back premises of others along to Great Queen-street. The carriage factory presents a singular appearance, having been entirely gutted, so that nothing remains but a gaunt skeleton of great height and circumference, without a morsel of internal wall or structure. St. Martin's hall, as seen from the back of the block along which it runs, has a scarcely less desolate aspect, although the fireproof structure of the lower portion has partially protected the basement. The hall took fire from the roof, after originating, it is thought, in the painters' shop of the carriage factory, and extending its ravages over the latter building. Both the hall and the factory, it is said, were insured. The cause of the fire was probably what is called spontaneous combustion, arising from such substances as greasy or oily rags, which, as we have occasionally shown (and, indeed, no longer ago than in our impression of the very day before the fire, in the warning article titled "Fire! Fire!"), are apt to take fire if allowed to lie about, as also lamp-black, of which we have also repeatedly spoken as a cause of fire.

**ROYAL ACADEMY FINANCES.**—The receipts at the door during the season which has just closed are said to be 11,600*l.* In an article on the Royal Academy last week, the *Athenæum* says,—“The maintenance of the schools is, of course, dependent upon the receipts at the doors of the exhibition. What these are is stated in the report. From this we condense:—Total sums received from the Annual Exhibition, from 1769 to 1859 (inclusive), less the expenses attending the same, 267,583*l.* 15*s.* 5*d.*—sums received by dividends on stock, &c., 91,567*l.* 8*s.* 9*d.*—sums received from His Majesty's Privy Purse, from 1769 to 1780, 5,116*l.* 2*s.*—Turner bequest, 20,000*l.*—sums expended by the Royal Academy, from the commencement of the institution, in the gratuitous instruction of the students, general management, &c., 218,469*l.* 5*s.*—paid in pensions to distressed and superannuated members and their widows, from 1802 to 1859, 28,739*l.* 0*s.* 7*d.*—donations to distressed and superannuated artists and their families, from 1769 to 1859, 32,772*l.* 5*s.* 10*d.* We may state, that we never met with a finer example of the truth of the old adage, that 'charity begins at home,' than this statement. The Royal Academy has taken care of its own, for the former period is shorter by thirty years than the latter; yet the sum distributed at home is but some 3,000*l.* less than that given to the incalculably more numerous body. Yet we find Sir Joshua Reynolds regretting that the institution could not insure the building it gratuitously occupied, because so doing would deprive the poor and needy of their mite. A system of professional and not Academic charity was one of the most frequently advanced claims to public support made by the early Royal Academicians. This statement does not look as if these promises had been fulfilled. To resume.—The balance in favour of the Academy is 104,499*l.* 19*s.* 8*d.*”

**SCOTLAND.**—A design for a public hall for Galashiels, by Mr. Lessells, of Edinburgh, architect, has been exhibited at the office of the *Zorder Advertiser*. A contract has been entered into with Messrs. Herbertson & Son, to carry out the design, minus the porch and spire, which would cost 250*l.* to 300*l.* The building is to be erected for a company.—There is a renewed movement at Hawick for the erection of a new public hall and corn exchange.

**TRANSPARENT METALLIC COLUMNS.**—According to the invention of Mr. G. K. Geyelin, the metal, either solid or in tubes, is twisted in one or more threads round a mandril, which can then be withdrawn. The ends can be fixed in a plate by casting or otherwise. For ornamental or strengthening purposes, the centre of the column can be filled with a coloured glass tube or other materials, and the outside with a reversed thread. The same principle may be adopted for twisting glass.

**RESPONSIBILITIES OF EMPLOYERS.**—Mr. Bedford, the corner, has instituted a lengthened investigation at St. George's Hospital into the circumstances attending the death of Thomas Sandler, a teamster, in the employ of Mr. Gamon, of Lambeth, builder. At Westhill, Wandsworth, while driving a waggon, loaded with timber, deceased, who was driving up the hill, was suddenly knocked down, by a rope apparently giving way, and the load of timber falling upon him, thereby inflicting dreadful injuries, from the effects of which he expired, four days afterwards. The evidence was conflicting, the point at issue being whether the deceased had made choice of the defective rope, or whether it had been supplied to him by his master's foreman. The coroner dwelt upon the responsibility attached to employers in such serious cases as the present, if defective materials were known to have been supplied to those in their employ, and the jury returned a verdict of "Accidental death."

**THE CHANNEL ISLANDS.**—The brick-manufacture of Jersey has of late largely developed itself, says the local *Times*, the exports of bricks having greatly increased. Mr. John Moiss n, shipbroker, has already shipped half a million for Portland, and holds an order for the shipment of another half-million, as speedily as possible, for the same destination. They are of course for use in the public works in progress there.—The Hanois Lighthouse, at Guernsey, of which the first stone has just been laid, will have a height in masonry of 92 feet, its height above high water at spring-tide being 80 feet. The diameter of the base course will be 32 feet 7 inches; its least diameter, 17 feet; the diameter of the gallery course, 20 feet 6 inches. Ascent to the summit of the tower will be gained by means of a spiral staircase of 7 feet diameter. The whole structure will be of dressed granite, from the Crnsev quarries, near Penryn, in Cornwall. The stone is supplied by Messrs. W. & J. Freeman in rough blocks, and dressed at St. Peter-Port. The designing engineer is Mr. James Walker, C.E.; the superintending engineer, Mr. W. Douglas.

**THE BUILDING TRADES MOVEMENT.**—The master joiners and builders of Blackburn and its vicinity have received from their workpeople a circular, of which the following is a copy:—"We, the operative carpenters and joiners of Blackburn and its vicinity, assembled at a general meeting, desire to inform you that, according to a resolution passed at the above meeting, we apply to you for an advance of one shilling per week on our present wages, or a reduction in the hours of labour of two-and-a-half hours in the week, to come into operation on the 23rd of March, 1861."

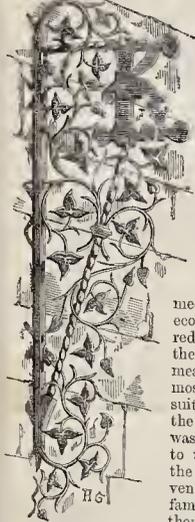

—A misunderstanding has lately arisen between Mr. Darby, the contractor for the new Union Workhouse, at Swansea, and the masons in his employ, the differences have been amicably adjusted. The men contended for the same hours as worked by the London operatives, whilst the contractor required the men to work the hours of the town, which, according to the *Cambric*, are about one hour per diem more than in London. The men, refusing to comply, were suddenly discharged in the middle of the week; and on Wednesday they applied en masse for a summons against Mr. Darby, for having suddenly discharged them. The men, however, were strongly advised to go to work at the usual hours of the town; and, when they accepted a job for the future, always stipulated at the commencement what the hours of labour should be. They ultimately gave in upon this point; and some other matters, with reference to the contractor providing sheds in which the men should work during the wet weather, having also been satisfactorily arranged, the whole of the men consented to resume work on the following morning.

# The Builder.

VOL. XVIII.—No. 918.

History and Construction of the Pianoforte.

KNOWLEDGE of music, however slight, has of late years become as essential an item of a liberal education as any other of the numerous studies and accomplishments that have gradually been added to the time-honoured indispensables,—reading, writing, and arithmetic.

Improvements in mechanical science, by economising labour and reducing cost, have put the possession of this most captivating pursuit within reach of the many, where it was formerly limited to the few; and, as in the sixteenth and seventeenth centuries no family of consideration thought its establish-

ment complete without a "set of viols," so now, in the nineteenth century, but few families, however limited their means, consider their comforts even provided for without the possession of a pianoforte of some class or other, from the Grand to the Piccolo. But of those who possess one how few know, or care to know, the history of the origin and gradual development, or nature of the mechanism of an instrument whose vast compass, adaptation for brilliant and varied display, and general utility constitute it emphatically and literally the "household orchestra." The want of a convenient and easy road to such knowledge is now, however, supplied. In 1855 we called attention to the work of Dr. Rimbault and Mr. Hopkins, entitled "The Organ, its History and Construction," wherein the antiquarian learning of the one and the constructive knowledge of the other had found a congenial task in a valuable historical and critical account of that noble instrument. We now have to speak of a new work, by Dr. Rimbault, upon "The Pianoforte, its Origin, Progress, and Construction,"\* wherein this most useful, universal, powerful, and, in many respects, most perfect of instruments, receives that amount of critical and historical investigation which the importance of the subject so well deserves.

There are few sciences more illustrious in pedigree, more remote in origin than music. Pythagoreans, Platonists, and Peripatetics—in fact almost all the Greek philosophers—either wrote treatises upon it, or alluded to the subject more or less in their writings, but the greater part of them are unfortunately lost: unfortunately, we say, on account of their antiquarian interest, but not for any benefit they might have conferred upon the science. In tracing its first beginnings we find ourselves bewildered in their speculations, and, accepting their assurances for our safe guidance in our search, we are persuaded to abandon the

realms of reality for the fields of fiction, and undertake a journey into the clouds with Aristoxenus and Aristotle, Plato and Pythagoras, Apuleius and Athenæus, Pausanias and Plutarch, and other celebrities, as our travelling companions. Having made the round of the heathen mythology, listened to the rival claims of Egyptian, Greek, and Indian deities, to the "invention," and ascertained to our own satisfaction that Ostris and Isis, Hermes, Brahma and Vishnu, Apollo, Mercury, Minerva, and Pan had an equal share in it, we feel a particular desire to descend from our uncomfortable elevation, and throwing out our grappling-irons to the tones of Burney and Hawkins for aid in our perilous descent, with thankful hearts find ourselves once again on terra firma.

The beautiful myths that entwine their graceful flowers of fiction round each page of the legendary history of ancient Greece, investing each hero with the attributes of a demigod, covering each ruin with an undying verdure, and endowing each event with a charm unspeakable, constitute a halo of glorious uncertainty, to probe which too closely is a task the scholar shrinks from undertaking, lest, by exposing the frail foundation upon which the beautiful fabric of the Classic is erected, his reliance on the faith of ages might be shaken, and, its gorgeous imagery removed, the poem of his admiration be reduced to the unadorned simplicity of sober prose. With quiet enjoyment, therefore, albeit with certain mental reservations, does he listen to the speculations of Plato and Pythagoras, Varro and Lucretius, upon the philosophy of sounds, and with them detects the first beginnings of the science of music in the noise occasioned by the revolutions of the planets, or the rustling of the wind amongst the trees and hal-rushes, or the mighty rushing of the torrent, or the silvery murmur of the stream, or the sweet melody of the birds, or other sounds occasioned by the agency of natural causes, and is satisfied. The antiquary, on the other hand, finds his keenest enjoyment in the task of penetrating mystery and removing error; and rejecting the myths and fallacies that form the scholar's happiness, and abandoning theory in his search for truth, he concentrates his energies in unravelling all that relates to mechanical contrivance, relying more upon one actual specimen, however mutilated, than upon fifty descriptions, flowery, but fallacious. Thus does the fact of many figures of ancient Greek lyres hearing the form of a tortoise bring more conviction with it than the account of Apollodorus, who attributes the invention of the art (he meant the form of the instrument) to the cucumber of Hermes with the shell of that animal: thus does the actual form of the Egyptian harp, as shown by their paintings, betray more indubitably its type in the form of the bow, than the classic story of the adoption of that form by Apollo, upon hearing the twang of the how-string of Diana; and the more so as the Greek and Roman monuments do not bear that form, whilst the Egyptian invariably do.

Music is an art that, disconnected from spoken language that it may serve to illustrate, receiving no aid from anything tangible or defined, appeals more to the imagination of those to whom it is addressed to adopt, embody, and mould into material form the picture intended to be conveyed through the medium of melodious and harmonious sounds alone, than any other of the circle of the imaginative arts. A statue, or a painting, or a building appeals to the heart through one sense—the sight, and presents the same appearance to all who behold it, and it is but in our different powers of appreciation, or our different degrees of cultivation, or of taste, that the impression conveyed by it will vary in character or intensity. A musical composition appeals also to one sense,—the hearing; but its form is immaterial, and cannot be defined, its visit is instantaneous, and cannot be prolonged, its beauties are a mystery, and cannot be explained. There is nothing positive in its construction, yet we seem to grasp it; it speaks a language we have never learnt, yet we comprehend it; it bids us follow it, we

know not why or whither, yet we obey it. Our imagination completes the form it shadows forth, and fills in the landscape presented to us hot in outline; and with every phase of difference in our mental conformation, so do we contribute more or less reciprocity of intelligence to its action, and reap more or less effect from its cause. Fortunate are we, in the nineteenth century, in the possession of a musical wealth that cannot be exhausted; a musical knowledge that cannot be disputed; when the compositions of the ancients have become matters hut of history, and their speculations have succumbed before the light of true knowledge and real science. For whether we look at the subject of music as scholars, or antiquaries, or musicians, no amount of argument can hide the fact from us that it is to the three last centuries that we owe the development of the power of sound as a medium for the soul's expression, as mighty in its operations as the painter, or sculptor, or architect's art, or poet's pen. When, with the ancients, poetry, painting, sculpture, and architecture had attained a high perfection, music was but in its infancy; and the reason was simply that the latter is an art dependent upon a particular branch of manufacture, requiring a technical knowledge and mechanical skill with which the ancients were totally unacquainted. What representations of Greek musical instruments have come down to us betray a means so totally inadequate to its end, that we can but wonder how the art became of such national importance, that to attempt to improve the cithara was considered a capital offence.

Greek instrumental music was but of two kinds, ἀόλιος and ἀόλιος, and the imperfections of the ἀόλιος, a pipe pierced with holes, must have been as great as those of the αἰθάρα, or χάλος (in Latin, *testudo*), an improvement upon the original λάρνα, or lyre (in Latin, *fides*), the varieties in the forms of which latter defy classification. These primitive instruments seem to have been the only medium to which music looked for its expression; and thus we can scarcely wonder that harmony was unknown, rhythm not observed, and the two grand distinctions of major and minor not discovered. Their abstruse calculations, as set forth by Aristoxenus, Euclid, and others, produced most un satisfactory results. Some specimens of Greek music by Kircher and others, are given by Burney, with an imaginary rhythm and in modern notation; but nothing satisfactory can be gained from them; and, as old Roger North observes in his "Memoirs of Musick," "for want of real or practicable specimens, it is not understood what their music was, nor yet, by means of all the pretended discoveries, can any piece he accordingly frauded that mankind will endure to hear, although Kircher hath vainly attempted it."

The Romans, though they did not advance the science, yet invented a new notation, and improved the construction of their instruments. The flute was held by them in most esteem, and its players most honoured, but the

\* *Decus Phœbi, et dapibus supremi Grata testudo Jovis*

is equally sacred to classic Rome as to classic Greece.

Abstract calculations were with the ancient Greeks the point to which their musical studies were directed; and, in the pursuit of the phantom they lost sight of the true principles upon which as a science it is founded, as an art it is developed. "Thus," says Macfarren, "the Greeks had their three genera and their six modes; thus these latter were adopted in the Christian Church; thus a knowledge of the ancient rules, as transmitted by Boethius—not a practical capability in composition or performance,—became the acknowledged test of musicianship; thus when, some six centuries since, the combination of sounds inducing harmony was first practised, the purely artificial rules of counterpoint were invented; and these retained their despotic authority to stifle the imagination, to limit the means of expression, and so to contract music within the arbitrary bounds of scholastic contrivance, from which, about two hundred and fifty years ago, scarcely an effort was made to emancipate it.

\* "The Pianoforte, its Origin, Progress, and Construction, with some Account of Instruments of the same Class which preceded it, viz. the Clarichord, the Virginal, the Spinet, the Harpsichord, &c. To which is added a Selection of Interesting Specimens of Music composed for Keyed Stringed Instruments, by Blytheman, Byrd, Bull, Frescobaldi, Dumont, Chambonnières, Lully, Purcell, Muffet, Couperin, Kuhnau, Scarlatti, Seb. Bach, Matthieson, Handel, C. P. Emanuel Bach, &c." By Edward P. Rimbault, LL.D., Member of the Royal Academy of Music in Stockholm, &c. &c. London: Robert Cocks & Co., New Burlington-street, Regent-street, W. 1860.

Greatly as we must admire the ingenious labours of that galaxy of musicians, the brightest star among them still shines the honoured Palestrina, it is for their ingenuity—for the studied research they evinced,—and not for their power over our feelings, nor for any token of inspiration they present, that we admire them."

The descent from the primitive lyre of all those instruments which preceded the invention of the key-board, including the ancient harp and Medieval psalter, dulcimer, and citole, is a subject of much antiquarian interest, as showing the progressive steps that led to results so inestimable; but of far greater interest is the history of those instruments which succeeded that invention, and which, embracing the successive varieties of the clavictherium, the clavicord, the clarichord, the virginal, the spinet, and the harpsichord, finally resulted in the pianoforte. "And here I may remark," says Dr. Rimbault, in his preface, "that a much greater antiquity is assigned to instruments of this class than has hitherto been accorded to them; although I do not go the length of the learned Abate Pietro Giannelli, who, in the article 'Cembalo,' in his 'Dizionario della Musica,' says 'that King David knew something of this instrument, is apparent from the 130th Psalm, where occurs the expression, *Laudate eum in cymbalis jubilationis*, which is, of course, to suppose that King David wrote and spoke the Latin language; for 'cymbalum' is but the Vulgate translation of a Hebrew term!"

The *clavier*, or key-board, having been applied to the organ at the close of the eleventh century, the adaptation of so great an improvement to stringed instruments would probably soon follow. The clavictherium, or *keyed cithara*, was the first simple result: a small oblong box containing the strings, of catgut, which were sounded or snapped by quill *plectra* attached to the keys.

The clavicord, or monochord, or clarichord, was the next phase of the instrument, and the engraving from Luscinus—the earliest extant—conveys the type of the square pianoforte. Its strings were of brass, and its action simply a piece of brass wire, placed vertically at a point where it could be either struck or pressed against its proper string, and where it might be retained at pleasure by the firm pressure of the finger. The affection of the elder and younger Bach for this instrument is well known, and Mozart himself, when travelling, always included one in his baggage. Dr. Rimbault hazards a derivation of the term clarichord, and its probable point of difference from the clavicord. The clavicymbal was another variety of the same class, and was probably, as Hawkins considers, the origin of the harpsichord. It was sometimes upright, sometimes horizontal, with strings of steel wire, struck by quill-*plectra*.

Dr. Rimbault has diligently collected his authorities upon these various instruments of a common type, and learnedly helps us to make the best of them; nevertheless, the perplexities of the *monochord*, the *cembalo*, and other obscure points, still leave a wide field for future explorers. "The last maker of the clavicord in Germany, of any note, was Krämer, of Göttingen, some of whose instruments may still occasionally be met with in the old baronial residences with which that romantic country abounds." Contemporary with the clavicord, though not superseding it, as it continued in use up to the introduction of the pianoforte, were the virginal and the spinet. M. Fétis, in a "Sketch of the History of the Pianoforte," from the *Harmonicon*, thus describes their peculiarity:—"When the defects inherent in the construction of the clavicord were discovered, a plan was devised of striking the strings with small pieces of quill affixed to minute springs, adjusted in the upper part of small flat pieces of wood termed *jacks*. These jacks were directed perpendicularly upon the key, and when the jack had made its escape, after the string had been struck, the jack fell in such a manner as to be able to reproduce anew the sound at will."

The virginal was of a rectangular form, like a small pianoforte; the spinet was of the

form of a harp, laid horizontally, and both were much in vogue towards the close of the sixteenth century. The etymology of the virginal seems probably derivable from its use by young ladies; but a modern writer, with refined taste, has referred its name to the conventional custom of accompanying hymns upon it to the *Virgin*. The etymology of the spinet is from *spina*, a thorn or quill, the tone being produced from a crow's quill inserted in the jack. Its chief difference from the virginal was in form, and certain alleged differences of construction Dr. Rimbault has not been able to recognise, at least, in any that he has examined.

The next and most perfect of the progeny of the key-board, and the immediate precursor of the pianoforte, was the harpsichord. Its form was precisely that of the grand horizontal pianoforte, and its origin suggested by the harp, from which instrument it derived its name. In the spinet and virginal there was but one string for each tone; but another was added to the harpsichord, the mechanism of the jack remaining the same. At length, Hans Ruckers, of Antwerp, effected an important reform in its construction. "He gave his harpsichords a more powerful and connected tone, by joining to the two strings in unison a third range of shorter and finer strings, tuned to the upper octave of the others, and which could be intoned at pleasure, either together with them or separately. He mounted his harpsichords partly with catgut strings, and partly with steel wire. In imitation of the organ, he added a second key-board to his instruments, the object of which was to allow three strings to be heard at once, or only a single one, at pleasure. In fine, he extended the compass of his harpsichord to four complete octaves (from C to C), by adding four grave sounds to the forty-five which existed before." It was towards the close of the sixteenth century, about 1590, that Ruckers first began to manufacture his harpsichords, and a prodigious number of these instruments, by himself and his sons, were sent into France and Germany.

Many were the varieties and improvements afterwards effected in the seventeenth century. In Italy, Farini produced an instrument to which he gave the old name of *clavictherium*, then long obsolete, wherein he employed catgut strings instead of wire, which gave them a more mellow and soft quality. His example was followed by several German makers. Rigoli, of Florence, invented the vertical harpsichord, taking the idea from the earlier clavicymbal,—an idea since imitated in all pianofortes of the upright class; and Richard, in France, improved the tone by substituting small slips of cloth in the place of the quill for producing the sound. Instruments, too, were constructed, with various modifications, to imitate the tones of the harp, lute, mandolin, violin, &c., wherefrom tones were elicited for which no analogy could be found, and which were honoured with such new and fantastic names as *jeu céleste*, *angélique*, &c.

The result of these various experiments led to the invention of the stops, and from them the *pedals*. Shobert, the composer, was the inventor of a harpsichord with a double bottom, in which was placed, above the first sounding-board, a range of strings of two octaves, of considerable size and length, to strengthen the bass, which were sounded by mechanism, acted upon by a range of pedals. Others followed. Hopkinson, of Paris, substituted metal tongues for crowquills; Sillerman, of Freyberg, invented the *claviccon d'amour*, and Stein, of Augsburg, the *vis à-vis*,—a harpsichord with a key-board at each end, by which means two could play at the same instrument. "But perhaps," says the author, "the most extraordinary invention of the time was that of Louis Bertrand Castel, a Jesuit of Montpellier. This worthy monk, whose 'Physical System' ranks among the best philosophical works of the early part of the last century, and whose 'Optics of Colours' is still esteemed, studied vision and the nature of colours, as blended or contrasted with each other, till his imagination getting the better of his understanding, he confounded the eye with the ear, and associated the harmony of tints with that

of sounds. Infatuated with this idea, he invented what he called an *ocular harpsichord*, which was strung with coloured tapes instead of wires; and, being placed in a dark room, when the keys were touched, the transparent tapes which respectively corresponded with them became visible; and the various successions and combinations of colours, consequent to this operation, produced effects on the sight which his fancy assimilated to the impression made on the ear by melody and harmony."

The inherent defect of the instrument—its affinity in tone to the class of instruments struck by the finger or *plectrum*—had long occupied the attention of three men of different countries, and a threefold claim was almost simultaneously made to the invention of the Pianoforte.

We have thus far very briefly followed Dr. Rimbault, in the leading phases of that class of musical instruments which finally resulted in so marvellous a triumph; but must reserve our remarks upon the history and construction of the perfected instrument itself for another occasion. To examine all the works, or passages from works, that might throw light upon his subject has been the author's aim; and as he himself observes, "the task has been one of no small difficulty, the materials being widely scattered, and in some cases almost inaccessible. The amount, too, of miscellaneous reading required, was almost enough to deter the most ardent explorer after hidden treasure, from pursuing his labour." A rich mine of entertaining anecdote is presented to the reader, and the sources of the author's information are freely exposed for the benefit of those whose love of the antiquarianism of the art may prompt them to inquire into the subject more deeply; whilst for those who desire to study the mechanism of the pianoforte itself, the second division of the work is specially reserved.

The account of the ancient Egyptian and Greek stringed instruments is short, but sufficiently comprehensive for its purpose as an introduction to what follows, and some interesting discussion upon the harp, from the accounts of Bruce, Rosellini, Wilkinson, Layard, &c., is of value. The Biblical instruments of the Hebrews are wrapped in still greater uncertainty, the various translators of the Bible all differing as to the nature of the terms there found, and the Jewish rabbins themselves knowing no more of the matter than those least acquainted with Jewish matters. Thirty-four different instruments are there enumerated, supposing that the titles of several psalms, as *Michlam*, *Syriam*, *Sheminith*, &c., indicate the names of the instruments used in performing them. But the authority for this is very doubtful. The "Harmonicorum Libri xii." of Merseennus, a Frenchman, and a great Hebrew scholar of the seventeenth century, and the "Musurgia Universalis" of Athanasius Kircher, a German Jesuit of the same period (much referred to in the work), to describe these instruments; still their interminable details only perplex still more the question, and it is to the wonderful discoveries in Egypt that we must now look for information.

The Medieval instruments that preceded the invention of the key-board, receive much assistance from the "Musurgia, seu Praxis Musica" of Ottomarus Luscinus, 1536,—a valuable work, from which numerous illustrations are copied.

Mr. Hendrie's well-known translation of a manuscript of the thirteenth century, by the monk Theophilus, "De Diversis Artibus," has afforded Dr. Rimbault a valuable chapter on the subject of "cymbal-making for the use of the church," which he has transcribed entire.

The nature of the cymbal has never been properly understood. It is generally considered as simply rhythmic, producing sounds unappreciable by the ear; but this was not the case with those of the Middle Ages. From the treatise of the monk Theophilus, we now for the first time learn that they were capable of being tuned to the various sounds of the scale.

The psalter, the dulcimer, and the citole, and twenty more obsolete instruments of the Middle Ages, all bearing some affinity

either in name or character to those of antiquity, and alluded to in the romances and ballads of the fourteenth, fifteenth, and sixteenth centuries, are brought to our notice in the introductory portion of the work of Dr. Rimbault, and many valuable illustrations from books and rare manuscripts render it more intelligible to the general reader.

THE ROYAL ACADEMY AND THE NATIONAL GALLERY.

THE National Gallery is closed to admit of the proposed alterations being made in the building. A return to the House of Commons, moved for by Mr. Adderley, has been published, giving the correspondence between the First Commissioner of Works and Capt. Fowke, relating to his plan for alteration of the National Gallery. This plan, we may mention (which has since been much talked of), was briefly described in our pages as long ago as April, 1855. When it was received by the First Commissioner, he sent it to the council of the Academy for their observations. In reply the council returned a long list of comments, in the course of which they said,—

"It will be at once evident from even a cursory examination of these plans, that Captain Fowke has not made himself acquainted with the requirements of the Royal Academy. No offices are provided for the secretary, the clerk, or the porters. No separate access is afforded as at present for the keeper to his apartments, for the students to the schools, and for the public to the exhibition galleries, but all will have to enter by one great hall, common to the National Gallery and to the Royal Academy, this arrangement would be quite inadmissible, and productive of the utmost disorder and confusion, rendered all the greater by the very imperfect lighting of this hall."

These important defects having been pointed out to Captain Fowke by the president and treasurer, he first proposed a supplemental plan, which is annexed to his first plan, but this suggestion the Council has been appropriated to them for so many years, although it is certainly very insufficient for the great objects of the Royal Academy, viz., 1st, The gratuitous instruction of students in the fine arts; and, 2nd, The annual public exhibition of works of art.

A separate entrance and a separate hall are absolutely necessary for each of the two Institutions; for the Royal Academy especially; and a hall is necessary for the reception of their large collection of casts and models. Unless, also, a separate entrance be provided for the students, any rooms that may be appropriated for schools could not be used during the period of the exhibition, and they would thus be rendered altogether useless during that time."

Capt. Fowke replied at some length, expressing his surprise at starting that—

"The Royal Academy should have felt themselves at liberty to put a veto upon any alterations being made in a public building, in which they are only tenants on sufferance, more especially when such alterations are proposed with a view to remedy the inconveniences and expense which their continued occupation will entail upon the public;"

but he did not succeed in removing the First Commissioner's objection to adopt the plan.

The plan which is about to be acted on is Mr. Pennefather's, and includes flooring over the central hall at the level of the galleries, and an alteration of the staircases which, in the case of the Royal Academy, will, if we understand rightly, come up into the middle of the "Miniature-room," somewhat awkwardly. We have reason to believe that the council of the Academy are far from satisfied, and that some of the members are most anxious that Government should postpone what seems to be mere patching, and give the Academy a proper site whereon to erect, at the Academy's own cost, a fitting building for their purposes,—the instruction of students, and the public exhibition of works of art.

The report recently issued by the council of the Royal Academy shows that the secretary's salary is increased from 140*l.*, with 150*l.* per annum in lieu of apartments, to 250*l.*, and the same allowance for apartments. That of the keeper is made 200*l.* in place of 160*l.* The treasurer remains at 100*l.* per annum. The librarian has had his salary doubled, being originally 60*l.*, but now 120*l.* The clerk is paid 150*l.*, and has an apartment provided for him. The housekeeper's salary, for herself and assistants, is increased from 70*l.* to 100*l.* per annum. The two porters receive 60*l.* instead of fifty guineas, each, and the assistant 50*l.*, in the place of 40*l.*

The allowance of pensions now stands thus:—1. To an Academician, a pension not exceeding 150*l.* per annum, provided the sum given does not

make his annual income exceed 200*l.* 2. To an Associate, a pension not exceeding 75*l.* per annum, provided the sum given does not make his annual income exceed 160*l.* 3. To a widow of an Academician, a pension not exceeding 75*l.* per annum, provided the sum given does not make her annual income exceed 160*l.* 4. To a widow of an Associate, a pension not exceeding 45*l.* per annum, provided the sum given does not make her annual income exceed 100*l.*

THE CAMBRIAN ARCHÆOLOGICAL ASSOCIATION AT BANGOR.

At the Bangor Congress of the Cambrian Archaeologists, Mr. Charles G. Wynne, M.P., presided, and delivered an interesting opening address. In the course of it he said,—I shall endeavour to show that archæology, far from being a mere unprofitable dilettantism, has a positive value, one appreciable not only by the literary or scientific mind, but even to those who look exclusively to material interests—that commerce, in a word, no less than history, or art, is under obligations to archæology. I allude to the case of our pottery and earthenware manufacture, which is now an important branch of our national trade. At the time when Wedgwood first began his operations, England was an importing country with regard to this article of trade, drawing her supplies from the Continent, from Holland, from France, and from Germany. About the year 1760, Wedgwood established himself in Staffordshire. The models which he selected for imitation were all taken from the antique, from the Portland vase—Greek vases, cameos, and old coins,—but above all from the magnificent collection of Etruscan vases and earthenware, which were purchased about that time from Sir William Hamilton, for the British Museum. Such was the immediate improvement in classical elegance and purity of design which the manufacture derived from these sources, that, within a very few years, England became an exporting country in this article, and the trade in it has been steadily developed since, until, in the year 1857, the declared value of the earthenware exported from the United Kingdom was 1,488,688*l.* Wedgwood's own sense of the obligation under which he was to his imitation of his ancient models, was marked by the name he gave to the new village, formed round his works in Staffordshire, which he called Etruria in honour of them. More recently still, the collection of Etruscan antiquities made by Prince Caiano, and brought to England by Signor Campanari, has marked another stage in the progress of this branch of industry; and it is a fact that at this moment the best silversmiths and jewellers in London resort constantly to the British Museum to study these models, and copy them for reproduction. The well-known Minton ware—to which belong the most beautiful specimens of fictile art in the present day, are either copied from, or due to the study and imitation of, the Majolica ware of Medieval Italy; whilst the smaller objects of Assyrian art, brought from Nineveh by Mr. Layard, are extensively copied by artists, and reductions of them made, on a smaller scale, in Parian, in marble, or in bronze.

The first paper read was on "The Military Architecture of Wales," by Mr. G. T. Clark.

"The greater number of the existing buildings," he said, "are probably of the reign of Henry III., or early in that of Edward I. Some of the grander examples, such as Caerphilly, Kidwelly, Beaumaris, are regularly concentric, and quite equal to anything in England. Others, as Conway, Caernarvon, Caldeot, are a mere inclosure, divided into courts, and contained within curtain walls thickly studded with towers, and broken by regular gate-houses, and having the hall and other buildings disposed against the curtain along the sides of the principal court.

The smaller castles of this type, as Dinas Powis, Penard in Gower, perhaps Whitecastle, and many others, seem to have been a simple inclosed court, with walls from 10 to 30 feet high, mural towers, and a gate-house, but with small permanent accommodation within. The dwellings were chiefly structures of timber placed against the walls, and have in consequence long disappeared.

When a castle, as Neath, Caernarvon, Newport, and Cardiff, was placed close to a town, it usually formed a part of the circuit of the walls. At Chepstow this does not appear to have been the case."

On the second day an excursion was made to Beaumaris, where the castle was specially illustrated. In the evening the Rev. John Griffith, rector of Merthyr Tydvil, read a paper, entitled, "The Diary of John Taylor, Water Poet to his Majesty King Charles I., through Wales in the Year 1652, in the place of 1604."

The Rev. H. Longueville Jones delivered to the meeting the result of his summer's study of the "Ineised Stones" with which Wales abounds, and which are most important to the proper and correct study of archæology. They had very few

old MSS., but they were exceedingly rich in these stones—richer than most part of the countries of Europe, of which they ought to feel very proud and do their utmost towards their preservation. The rev. gentleman pointed out to the audience by means of diagrams, several inscribed stones some of which had been only recently discovered. Amongst the most remarkable were those of Llansawdn and Llangadwaladr: the latter, in his opinion, could not have been so early as the former. He pointed to others of a very early date found at Penmachno, preserved through the exertions of the president (Mr. C. Wynne) and his family. One of them had the Greek monogram, and the following inscription:—

CARAVSIVS  
IHCICACIT  
INHOCCON  
GERIESLA  
PIDVM

It means that "Caravus lies here in this heap of stones," that is, in a carned. It was rescued by Mr. Wynne, but was well known to Pennant, who met with it in going from Penmachno to Ffestiniog. The other stone had the following inscription:—

CANTIORIHCICACIT  
VENEDOTISCIVEFVIT  
CONSOBRINO  
MAFILI  
MAGISTRATI—

which showed that he was a Venedocian (Gwynedd) citizen. The last word "Magistrati," was never found upon any other stones, and it must carry them back to a very early period. It is hoped now that those stones are going to be placed in the new church at Penmachno, they will be handed down unimpaired to future generations. He (the rev. gentleman) had himself found one some few weeks ago at Spittal. It commemorated the burial of a man and his mother, and was very ancient. The emblems and the Christian characters which the stones bear, formed a very important link in the history of the British church, and established its independent existence, not by theory, but by facts. He next called attention to the Irish oghams found upon the stones, which were the work, no doubt, of Irishmen who came over and marked those they met with in this country. He hoped that some Irish scholar would ere long come over to decipher these characters, which to them was still a mystery. The following inscription is from a long rounded water-stone along the pilgrim road going to Bardsey Island, which Mr. Westwood thinks is of a late period, but which he (Mr. Jones) thought was rather early:—

MERACIVS  
PBR  
HIC  
IACIT

That meant "Meracius the Presbyter lies here." He next came to the famous Frondeg Stone, in Anglesey, which still, he was sorry to say, served as a gate-post, and was certainly not safe in that position. It bore the following inscription:—

N NII FILLVS CUURI CINI EREXIT  
HUNC LAPIDEM.

He alluded to another stone from Pentrevelas which bore a very early inscription, commemorative, some say, of Prince Llewelyn, which might be; but he thought it was much older. However, the inscription could not be read. The rev. gentleman concluded his very interesting and instructive address by impressing upon the minds of his audience, and especially those concerned in the restoration of churches, the importance of preserving from obliteration such ancient monuments of the past, which indicated to them the early national history of the country.

On Wednesday there was an excursion to Plas Newydd, Llanidan, &c., in Anglesey.

On Thursday the places of interest in Bangor were visited. Bangor, the *North Wales Chronicle* remarks, is a compound Welsh word—*Ban* signifying high, *gor*, choir. It was formerly known as Bangor-fawr-yn-gwynedd. Leland says that Condate, a British prince, erected and dedicated here a temple to Minerva. A stone, 3 feet 3 inches long, was discovered at Tyeoch, with an inscription:—

N.V.MN.C  
IMP. CAESAR.M  
AVREL—ANTONINUS  
PIVS. PIX—AC—ARAB.

Cressy says that Malgo Conant built a city called Bancor. On a rocky eminence, about a quarter of a mile east of the city, are to be found the remains of a castle built by Hugh Lupus, Earl of Chester. At the cathedral, Mr. Kennedy officiated, and

pointed out the principal architectural details and history of the edifice. It appears that the cathedral church of Bangor is dedicated to St. Daniel, by whom it was first founded, about the year 525. He was elected the first bishop about 550 (but according to Usher, 522), and was the son of Dunawd Fyr, or Dinotus, abbot of Bangor Isoyd, in the reign of Maelgwyn Gwynedd, Prince of Wales, who was the founder of Penmon and patron of Taliesin. He is said to have been the most liberal prince of his time. The cathedral was destroyed in 1071, by the Saxons, but was rebuilt by King John in 1212. It suffered greatly, as did the cathedral church of St. Asaph, in the wars between Henry III. and the Welsh, about 1247. During the rebellion of Owen Glyndwr the cathedral was destroyed by fire, A.D. 1402, and rebuilt in 1492 by Bishop Derwis or Dennis, temp. Henry VII. The tower and nave of the cathedral were added by Bishop Skelington, in 1532. The ground plan of the cathedral church is cruciform, and comprises the following,—a nave, 138 feet long from the eastern side of the western wall to the western side of the archway of the chancel, and 25 feet wide between the inside of the arcades, which are 3 feet thick, and 34 feet high, including the clerestory, north and south aisles to the nave, extending to the transept, 110 feet long, and 15 feet wide, from the outer sides of the arcades to the north and south walls, which are 4 feet thick and 20 feet high; north and south transepts, each 34 feet long, 25 feet wide, and 34 feet high. The choir or chancel, from the outer or western side of the eastern arch to the inside of the eastern wall, is 55 feet long, 27 feet wide, and 34 feet high, the walls being 3 feet 6 inches thick. The tower at the west end is 18 feet square, and 61 feet high. The pinnacles are 7 feet 6 inches high.

Penrhyn Castle, Llandegni Church, and Ponaemaunawr were visited in the course of the week, and various papers were read besides those already mentioned.

The next meeting of the association (for 1861) will be held in Swansea.

#### STEAM PRINTING.

The great lesson of the rights and duties of labour and the working of commerce is yet to be taught to the great masses of the population. We, therefore, continue to direct attention to circumstances which show the advantages which have resulted to all classes from the introduction of steam power.

To set forth a fresh phase of the subject let the mind's eye penetrate the precincts of Westminster Abbey, where Caxton first in England used type to supersede the pen. It is not precisely known in what part of the Abbey this important event in the world's history took place. Nevertheless, from that time to this, printers meet in "chapel"! Of course the process found opposition on the part of the comparatively small number of persons who were engaged in the production of books by hand. It may be that the clever penmen in "cloisters grey" looked upon Caxton's introduction with objection, and upon that worthy with anger and distrust, saying that no good could come of such new-fangled ideas. This is the kind of treatment which has been received by some of the world's best benefactors.

For long after Caxton's application of types in printing the onward progress of the art was not great. Useful and glorious ideas were, however, spread abroad; intelligence advanced, and a portion of the multitude were, although at a distance, put into communion with men of learning and intelligence. The demand for printed books and papers was great. The energies and skill of several persons were directed towards increasing the producing powers of the old-fashioned printing press.

For centuries after the introduction of type-printing, but little if any change seems to have been made in the construction of the machines. At length, various improvements were effected, chiefly by the Earl of Stanhope; Mr. Ruthven, a printer of Edinburgh; Mr. G. Clymes, of Philadelphia, who invented what is called the Columbian press. Then followed the invention of working a press by steam-power, which, in contradistinction to the old process, was called steam-printing. On the 20th of April, 1790, Mr. William Nicholson, a gentleman well known in the literary and scientific world, obtained a patent for a machine for printing on paper, linen, cotton, woolen, and other articles, "in a more neat, cheap, and accurate manner than is to be effected by the machines now in use." It does not appear that his plans and experiments ended in any practical results. Another machine for printing was

invented by Messrs. Bacon & Donkin, for which they obtained a patent in the year 1813. This machine was so far different from that of Mr. Nicholson, that, instead of requiring the types to be cast so as to arrange on the surface of a cylinder, they were firmly fixed in pages on the face of revolving prisms, having four, five, or any required number of sides. The structure of the machine, however, proved too complicated.

After this, M. König, a native of Saxony, and a printer, introduced another machine. For some years this ingenious inventor had directed his attention to the subject, but his endeavours in the first instance were chiefly to accelerate the motion of the common press. Perhaps in some measure guided by the experiments made in England, M. König's labours were the first that produced any useful fruit. Requiring means to carry out his experiments, the German printer applied without success to many eminent printers in several of the continental capitals. He then turned his eyes towards this country, and arriving in London about 1804, he submitted his scheme to several printers of repute, who were not disposed to incur the risk of expenses: finally, he was introduced to Mr. Bensley, who speedily entered into an arrangement with him.

After a short course of experiments on the fabrication of a press which should have accelerated motion, and, at the same time, render the work of the man who inks the type unnecessary, the above gentlemen were joined by Mr. G. Woodfall and Mr. R. Taylor, both printers, the former of whom, however, soon retired. After great perseverance on the part of the remaining partners, it was discovered that the intended improvement of the common press could not be brought to bear, and that much labour and expense would be incurred, unless some radical alterations were invented. Cylindrical printing was then thought of, and after two or three years of renewed exertion, a small machine was produced, the characteristics of which were that instead of the printing being produced by a flat impression, similar to the ordinary press, the sheet passed between a large roller and the types still flat, and in lieu of the old-fashioned balls used by hand to heat over the types, so as to communicate the ink to their surface, skins were strained round smaller rollers, on which it was contrived to spread the ink, and under which the frame in which the types were fixed passed in its way to the printing cylinder. So much promise of success was given by this machine that it was deemed advisable to construct one on a larger scale. In order to carry out this idea the model machine was shown to Mr. Walter, the proprietor of the *Times* newspaper, and after settling what further improvements were contemplated, an agreement was made with that gentleman for the erection of two large machines for printing his journal. So secret had been the operations of the patentees, that the first public intimation of their invention was given to the reader of the *Times* of Monday, the 25th of November, 1814, who was told that he then held in his hand one of many thousand papers thrown off by steam.

The next advance in improvement was the manufacture of a machine for Messrs. Bensley, distinguished from those before mentioned by the mode of printing on both sides at once. Amongst other improvements was a method of register, which caused the pages to fall precisely on the back of each other. Deficiencies were now discovered in the inking: the strained skins were found to be uneven on the surface, and attempts were made to clothe the rollers with an elastic preparation of glue, treacle, &c., which has at length been brought to a certain perfection.

Another improvement which followed this was the mode of inking the types invented by Mr. Cowper, which was so superior, that Mr. Bensley adopted it for the use of his machines. Together with the successful application of steam machinery to this work, books and other publications for the use of the multitudes, rapidly increased, and printing establishments on a scale which had not before been thought of, sprang into existence. In 1827, Mr. Applegarth, of the Belvedere-road, in his machine printing-office, employed upwards of 100 persons. Here were carried on typesetting, stereotyping, composing, and printing: here were printed extensive works for Government and private individuals. Amongst them may be mentioned the *John Bull* and *Examiner* newspapers, the "Encyclopædia Metropolitana," and "The Every-Day Book."

Since the last-mentioned date the extension of the use of printing has been enormous; newspapers and other serial publications have multi-

plied, and so vast is the circulation of some, that the copyright of a penny journal has been sold for 20,000*l.* Other improvements have been made, and the speed of printing is constantly increased.

Again, we have been indebted to America for improvement in the steam-printing, and by means of an American machine, 12,000 copies of the *Illustrated London News* can be thrown off in an hour. For the purpose of printing this paper and its supplements, there are besides the large machine just mentioned, about a dozen others of various sizes and construction, to drive which requires four steam-engines, altogether of a nominal power of about forty-eight horses. It is almost needless to say that, but for the application of steam, the production of this and many of the other serials would be impossible: besides the general advantage, the application of steam to printing has created a vast demand for various descriptions of labour. These machines, so beautiful in their construction, that their working seems almost like the effect of magic, must have for long kept busy many hands in the making of them. To work and attend to the engines some fifty or sixty persons are required: more employment is given in dampening and preparing the huge stacks of paper for printing. The manufacturing of the paper, too, has been another means of providing labour. Then there are the compositors, numbering over thirty; preparers of box-wood, artists, and engravers. As regards the latter, although a number are employed on the premises, so many of the blocks are cut by various engravers at their own homes that it is not easy to get the exact number who are in this way employed; but we think that it is far within the mark when we put the number of draughtsmen and engravers at 20, who are required to produce each week's illustration. Besides these are editors and writers, a large staff for publishing, and other business arrangements; preparers of printing ink, electrotypers, &c.

If we glance at other great printing establishments of the metropolis,—at the *Times* and the Queen's printing-houses, the offices of the various daily and weekly newspapers, at the office at which this journal is printed, for example (Messrs. Cox & Wymau's), which is amongst the oldest of the printing establishments; the printing offices of Messrs. Petter and Galpin; at Mr. Stiff's—the place where the enormous impressions of the *London Journal* are thrown off,—at the great towns of the provinces, where also printing operations are going forward which are extraordinary for their extent, and which are constantly increasing;—we shall find that the immense army of workers who are in this way engaged are paid good wages, which with care enable them to support a respectable position; and contrasting the wonders which have been done, the present great and constantly increasing numbers who in this way find employment, and the early condition of the art, it must be plain that the application of steam power to the printing press, while it has been a blessing to the world at large by the dissemination of knowledge and the cultivation of mind, has provided fresh means of remunerative employment for thousands.

#### ETCHING.

ORNAMENTATION on metals, glass, and porcelain, has come into considerable use; and, believing, as we do, that such work would not only be pleasant to amateurs, but might also be useful to others, we think that a few brief and practical notes on the subject may not be out of place.

First, as regards copper-plates—which in many respects have an advantage over steel for the use of amateurs,—procure a thin plate, properly polished on the surface, at any of the regularly established copper-smiths. These can be had of the size of several feet down to a few inches. The surface of the plate being bright and free from tarnish, remove all grease with great care by washing with spirit of turpentine and then rubbing with very fine whitening and wash-leather. Care must be taken not to scratch the plate.

Having got rid of all grease, fix a hand-vice to one corner or some other convenient part of the plate; it is then ready for the reception of the etching-ground—a preparation chiefly composed of asphaltum, pitch, and virgin wax: there is, however, a great art in making this sufficiently plastic, so as to admit of its being properly spread upon the plate when heated. It is better for ordinary purposes to purchase it at the copper-smith's or tool-shop, where a supply can be had for about 1*s.* A dabber, for the purpose of laying the ground on the plate, is also necessary. This

is of a mushroom shape, and composed outwardly of very fine silk or kid leather, free from grease: the inside is padded with wool. This can be readily made by any person who has seen one of them. In order to prevent any grit or impurity which may chance to be in the etching-ground, it is better to tie it in silk. For the purpose of beating the plate, a hot iron, or a spirit-lamp, placed below an iron frame on which the plate may rest, or other contrivance, may be used. Care is to be taken to make as little dust as possible. The metal must not be allowed to get too hot, for that would burn the etching-ground, and prevent it from sufficiently resisting the acid. The plate being of a proper heat, by drawing the etching-ground over the face, a small quantity will be lodged upon it. This in the first instance is uneven; but, may be spread in a flat, thin, even manner. Every part must be covered by the ground, or else the acid would leave such places as are bare liable to be corroded into holes. The ground, when this is spread on the surface, is of a light brown colour, so delicate, that it is difficult to see any pencil outline which might be transferred, or properly to see the scratches made by the etching needle. In order to darken this, it is necessary, while the plate and etching-ground are still warm, to smoke it by the flame of a wax-taper or candle. The flame must be kept moving about, and not allowed to touch the plate so closely as to burn the ground.

These operations, although simple, require some little practice and experience; and it is, perhaps, a good plan either to take a lesson or two in ground-laying, and the other parts of this process, from an engraver, or else to get one of this profession to lay the ground, and bite in the plate when etched.

The ground having been made ready, and the plate cold, an outline of the subject, prepared on ordinary or tracing paper, should be damped and transferred by means of pressure. The best way to manage this is to take it to a copperplate printer, who will do it effectually for a few pence: for those living in the country where such convenience cannot properly be had, this transfer can be made by one of the ordinary letter-copying-machines, or by going very delicately over the back of the outlines with a pencil or other instrument which is not too sharp.

This having been done by means of an etching-point, which can be had at the tool-makers, the design can be readily scratched upon the plate. Attention is needed to mark the lines quite through the ground. The hand should also be prevented from coming in contact with the ground, and all unnecessary scratches be carefully avoided. This may, to a considerable extent, be done, by forming a bridge of a flat ruler, supported by pieces of card-board or folded paper.

Wherever the etching-ground has been passed through by the etching-needle, that part is liable to be eaten into a line by the application of acid: on no other portion, however, if properly done, should the acid work.

It being necessary to cover the etching with an even depth of diluted acid (from a quarter to half an inch), in order to produce equality in the biting, it is needed to form a wall of wax round the margin of the work. The best material for this is bees-wax, with a small part of Burgundy-pitch added, and then the mixture boiled until the whole is well mixed. This, when needed for use, should be put into warm water, and then it can be readily raised round the plate and pressed down by the fingers, and after that more firmly by the handle of the etching-point, so that a sort of tank is formed, which will contain the acid as long as it may be necessary.

With the greatest care scratches may be made, or it may be necessary to erase parts, or the wax-wall may not be sufficiently tight. In order to remedy this, turpentine-varnish, or the ordinary "Brunswick black," used for stores, may be employed, thinned to a proper extent by turpentine, and applied with a black-lead pencil.

For the purpose of "biting in" the plate, as the engravers call it, nitrous acid of the purest description should be mixed—one part of acid, and three parts water—which should be stirred up with a feather or pencil: soon the lines will be covered with minute globules; and, in proportion to the time the acid is allowed to remain, the etched lines will become thicker and deeper.

As a matter of course, in order to produce a delicate and refined effect a variety of thicknesses of line is desirable; and, although much can be done by the pressure of the point, by hatching, doubling lines, &c., it is in most cases necessary to allow the acid different times of action: for instance, it will be desirable to keep distant moun-

tains and landscape thin, and to bring out the foreground by bold and deep lines. In order to manage this, the acid must be poured off into a vessel for further use, and then the plate must be well washed with clear water, and afterwards dried with a bellows or other means; then such parts of the etching as are of sufficient depth should be covered with the varnish in the same manner as the blemishes to which we have referred. This operation may be performed any number of times, each time washing and drying the plate: this must be also done when the biting is completed; and then, by gently heating the back of the plate, the wax may be drawn off, and by means of a little spirit of turpentine and oil the surface of the plate may be cleared of the etching ground. There are other operations, such as re-biting, re-etching (by touching with the graver), and by working with a point without the use of acid, &c. &c.: these, however, would require much space to describe, and this we will not just now do, as it is more particularly our object in mentioning the above to make operations which might be useful in many manufactures more readily understood.

In the same manner, but with the use of different acids, and on any scale, etching may be applied to steel, iron, brass, glass, and, lately, we are told, to porcelain. For steel, nitric acid very largely diluted with strong vinegar, is best. On brass we have seen deeper and other ornaments produced with great clearness and rapidity in the following manner. On large works, such as monumental brasses, experience has shown that in the biting, either by nitric or nitrous acid, before a great depth is got the biting of the lines is stopped by the formation of a black oxide, which it requires a very strong preparation of nitrous and sulphuric acid to remove and keep in solution; and this after a time proves too strong, and tears up the ordinary etching-ground: it has, however, been found that turpentine varnish, if allowed for a few days to harden, has a great resistance; and by the use of this when diapers, &c., are outlined, the raised parts may be painted with the varnish; and, when hard, the acid applied; and it is astonishing what good effect may be produced by these means. Large surfaces for the relief of foliage, figures, letters, &c., may, by this means, be executed with rapidity, either for filling in with coloured shellac or pigments.

The painting of these ornamental plates with varnish might be the means of affording employment to females, and probably the preparation of cubbing, and otherwise ornamenting glass to be bitten by fluoric acid, might also be brought into far more extensive use than it is at present, and would also provide a certain amount of respectable labour for females.

#### AMENDMENT OF THE METROPOLITAN BUILDING ACT.

THE following is the whole of the "Act to alter and amend the Metropolitan Building Act (1855)," 23rd and 24th of Victoria, cap. liii. It refers, as will be seen, simply to the size of manufactures:—

"Whereas certain rules of 'The Metropolitan Building Act, 1855,' have been found to operate prejudicially by limiting the contents of buildings to be erected as workshops for the manufacture of the machinery and the boilers of steam vessels, and as the increased and increasing size of such machinery and boilers for the royal and commercial marine of this country requires larger areas for their manufacture than are allowed by such rule, it is expedient to amend the said Act: he it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may be cited for all purposes as "The Metropolitan Building Act (Amendment), 1860."

2. The rules of "The Metropolitan Building Act, 1855," limiting the cubical dimensions or contents of buildings used either wholly or in part for the purposes of trade or manufacture, shall not after the passing of this Act apply to any building to be used wholly for the manufacture of the machinery and boilers of steam vessels beyond the distance of three miles from St. Paul's Cathedral: provided always, that every such building shall consist of one floor only, and shall be constructed of brick, stone, iron, or other incombustible material; and it shall not be lawful for the owners, lessees, or occupiers thereof, or for any persons interested therein, to use such build-

ing for any other purpose than the manufacture of the machinery and the boilers of steam vessels, until all the rules and provisions of the said Act, as to party walls and other matters which are applicable to buildings of a similar character, shall have been duly complied with: provided also, that every such building, if of greater dimensions than 216,000 cubic feet, shall be subject to the approval of the Metropolitan Board of Works, in the same manner as iron buildings or buildings to which the rules of the said Act are inapplicable as set forth in the fifty-sixth section of such Act."

#### EXHIBITION OF MODERN PICTURES, MANCHESTER INSTITUTION.

THE annual exhibition of works of art in the Manchester Royal Institution is now open. The collection is one of average merit, including works by F. W. Hulme, Cobbett, Edward Davies, Lane, Hook, Egley, Duffield, Anthony, and Kennedy; and from many local artists, particularly Bestock, Brodie, Crozier, Henry Calvert, Duval, Gibson, Hayes, Keeling, Percy, Shields, and Whitte. The Exhibition further contains nearly 250 pictures by foreign artists, French, German, and Belgian. Amongst the artists contributing these we find Meissonier, Decamps, Chavet, Contare, Freer, Bossuet, Achenbach, Jordan, Steffeck, Becker, and others. We should like to know under what circumstances these foreign pictures are obtained.

The council of the Royal Institution have left the management to the local artists, and Messrs. W. Percy, J. Keeling, R. Crozier, H. C. Mitchell, and H. Calvert have hung the pictures.

The general price of admission is, as usual, 1s.; but two new features have been introduced into the arrangements, one day per week (Thursday) having been set aside for the wealthier class of society at 2s. 6d., while strangers coming to town on the other days by railway excursions are to have admission at half-price.

What has become of Mr. Fairbairn's projected public gallery for Manchester?

#### WORKS IN FRANCE.

THE works of the first pavilion of the second block of the *Halles Centrales* are nearly finished, and it soon will be open for the sale of butchers' meat, by wholesale and retail, for which this compartment is specially reserved. Shortly the scaffolding will disappear from around it, and also the wooden sheds now standing on the site of the second pavilion. The second block is to be similar to the first, and will contain six pavilions connected by covered passages. A boulevard, planted with trees about 32 metres wide, will separate the two blocks which will cover in all a surface of 40,000 square metres. If we add to that all the passages and outlets, the whole area of this public market will be 80,000 square metres, 8 hectares, or about 19.75 British acres.

The painter Decamps was killed by a fall from his horse on the 22nd ult., at Fontainebleau, and buried at the picturesque cemetery of that town on the 25th, with military honours in the form of a salute from the troops. He was an officer of the Legion of Honour.

The Solferino-bridge has just received its finishing touch of decoration. On the twelve blocks of Jura stone, which are spaced along the parapets of this bridge, are capitals likewise in Jura stone consisting of inverted consoles, surmounting a small frieze. The tablet, or shield, of the anterior portion of each capital, contains the names of the different victories obtained by the French army in the last French campaign.

The bridge constructed over the Garonne, at Bordenaux, by the "Midi" company, to connect it with the Orleans line, has been just terminated. On Sunday, the 5th August, a train starting from the "Midi" terminus, containing M. Surell, director of that company; M. Duvidant, engineer-in-chief of government superintendence (*contrôle*); and Messrs. De Laroche, Tolay, and Regnault, engineers, who projected the structure, and under whose immediate superintendence it was executed, made a trip over the bridge, and came to a stand at the Orleans station. The aspect presented by this bridge is most noble. It crosses the river about 1,000 metres higher up the river than the old bridge of stone, constructed under the First Empire: its length is about 500 metres. The superstructure consists of boiler-plate, top and bottom webs, with diagonal bracing for the panels, resting on six piers, the bearings being about 75m. for the five middle spans, and 56m. 50c. for the end ones. Each pier consists of two hollow cast-iron columns, filled with concrete, and forced into the ground by compressed air. One of

these has been embedded to the depth of 22 metres below the bed of the river, and stands 6 metres over it, thus making a total height of 28 metres. These cylinders are 3m. 60c. diameter. The apidity with which this immense structure was erected has not been equalled in Europe, it having been finished in two years. The old stone bridge of Bordeaux took ten years to build, with the assistance of the most experienced engineers of the Ponts et Chaussées, all whose talent was required to overcome the extreme difficulty of the foundations, hitherto considered unsurmountable.

The town of Moulins (Allier), has been authorized to raise the sum of 100,000 francs, to be repaid by voluntary taxation in eight years, for the completion of the church of Saint Nicholas.

#### IRELAND.

THE inhabitants of Derry complain that the site of the new bridge has been removed, at a great expense, from that of the old bridge, for the reason that at the former place a rocky bottom had been discovered by the engineer; but that now the contractor can find no trace of those rocks formerly discovered, and has been obliged to purchase a very expensive pneumatic apparatus, which gave promise of enabling him to put down the foundations of the bridge.

One of the principal engineering establishments in Belfast is the property of the Messrs. Rowan, whose father was a native of Drough, where the establishment was formerly located, and whence, in the year 1835, was sent out, on an excursion to Belfast, a locomotive for common roads, which passed through the streets of that town; but, like all the others which have hitherto been invented, was found useless. Perhaps the Scottish nobleman who is now experimenting in the north may succeed better.

It appears, from the half-yearly report of the Belfast and County Down Railway Company, recently submitted to the shareholders, that the gross earnings of the railway for six months was 16,047. 8s. 3d., and expenses 7,357. 0s. 9d., leaving a sum of 8,712. 7s. 6d., of which 6,628. 16s. 6d. were required for payment of interest and preference shares, leaving a balance of 2,087. 11s., which the directors recommended to be carried to the reserve fund. The works on the line from Newtownards to Donaghadee were reported to be progressing favourably, and that it would be opened for traffic early next spring. Also that the railway from Castledouglas to Portpatrick is being carried forward with the greatest possible energy, and will be opened for traffic in August next, and that the Government is proceeding with the improvement of the harbours of Portpatrick and Donaghadee, so as to render them suitable for passengers and mail-packet service.

The directors of the Banbridge and Lisburn Junction complain of the slow progress of their contractor.

The directors of the Dublin and Drogheda, and of the Dublin and Belfast Junction, are taking preliminary steps for the amalgamation of their lines, a matter which the shareholders in both should see carried out at the earliest possible moment. The amalgamation of Irish railways in the north would promote all interests.

The Church of St. Nicholas, Dundalk, is a new edifice, in the Early English style of architecture, consisting of nave and aisles, chancel and sacristy, having on the south side of front a bell tower 40 feet high, surmounted by a broached spire 80 feet in height, terminating with a Mediaeval cross. The external walling is built with local granite—the cut stone dressings of white limestone. The internal arrangements consist of five bays of arches at each side, separating nave from aisles. The chancel has a five-light window. The roof is open timbered. The chancel floor is laid with encaustic tiles.

The loans and grants issued from the Exchequer for public works, drainage, and land improvement in Ireland, amount to no less than 10,036,071.2. Nearly half this amount was advanced for county relief works during the famine, but that was remitted. The sum of 3,556,619. for principal and interest has been repaid to the public purse, and there remains to be repaid 4,832,864.7. The chief public works now being carried on in Ireland, under the supervision of the Board of Public Works, are, Kingstown Harbour, upon which 817,786.1. has been spent, and Donaghadee Harbour (opposite Portpatrick), upon which 160,804.4. has been spent, but both these works are nearly completed. There is also a female convict prison in course of construction, a new Landed Estates Court and offices, and the extension of the Four Courts.

#### REFORMATORIES AND REFUGES.

THE last report of the Reformatory and Refuge Union shows that there are now in Great Britain and Ireland no fewer than 172 reformatories, refuges, and industrial schools, more than 40 of which have been established since the committee commenced upon their labours in 1856. These institutions are capable of accommodating 15,000 inmates; and, from careful calculations lately made, aided by the Government inspectors' returns, it appears that there are, not including the institutions in Ireland, upwards of 11,000 boys and girls under preventive and reformatory treatment. These returns are exclusive of the penitentiaries and homes for females, of which there are more than 60, providing accommodation for 2,300 inmates.

The testimony of the Government inspector of certified reformatories is to the effect that there has been a reduction of 26 per cent. in two years in the number of juvenile offenders committed to prison, and this testimony is confirmed by the reports of the various institutions throughout the country.

But it is not alone amongst the criminal class that this progress has been made. The refuges and industrial schools for the outcast and the destitute, which led the way to the establishment of reformatories, have advanced with the same rapidity, the one acting on the other, and both in their places tending to the accomplishment of the one great design.

One thing is to be noticed in connection with the present working of refuges and industrial schools,—more attention is paid to fitting the children for their future occupation in life than, as formerly, to the mere amount of work.

#### SOMETHING REQUIRING EXPLANATION.

WE find the following in the *Nottingham Courier*:—"A recent case in our local Bankrupt Court illustrated, as we took care to show, the custom of the building trade. It will be found, from the subjoined report, that the Nottingham builder was more fortunate than his Lancashire brother:—

**BANKRUPTCY COURT.**—John Pooley, contractor and builder at Liverpool and Birkenhead, came up on Monday to receive judgment on his application for a certificate. Amongst the objections urged by Mr. Martin on behalf of the assignees, was one that the bankrupt had, at the instigation of an architect in this town, added the sum of 100l. to his original estimate for building a church at Birkenhead, and had thus been a party to defrauding the trustees for the erection of the church. Mr. Evans, who appeared for the bankrupt, said if there was really anything in the objection he thought the court should be in possession of the particulars of the case, as what had been done by his client, he was informed, was almost a universal practice, and he contended that the transaction, if it had taken place, had nothing whatever to do with his conduct in that court. If the bankrupt had knocked a man down and robbed him of 100l., that court could take no cognizance of it. Mr. Martin said that certainly would not be "conduct of a trader," but in the case before them he could clearly show that the bankrupt's creditors were defrauded by the transaction, and he should now ask the court for an adjournment, to have the architect present and examined. His Honour adjourned the sitting till the 11th September.

#### THE ARRANGEMENT OF A KITCHEN.

Now that gastronomy is carried to a state of great perfection in this country, and we may fairly vie with our Gallic neighbours in the art of dining, I venture to trouble you with a few remarks on the proper arrangement of kitchens and the offices connected therewith.

In first-class buildings, whether for public or private occupation, the kitchen often has not sufficient of the architect's care in its details. It is generally too small, ill ventilated, and totally inefficient to meet the ordinary requirements. Let me now briefly describe what, in my opinion, is necessary to complete a first-class kitchen. The chief thing to consider, then, is situation. A kitchen should never be constructed in the middle of the basement, but always built out from the principal walls, so that a large skylight may be placed in the ceiling, and which should be constructed so that it may be opened or shut at pleasure.

Large air-drains should be built under the stone-paved floor, with iron gratings for the admission of air, which air should be in all cases taken from the external wall, to ensure a free circulation. The doors leading to the main building should be made with springs, to swing, so that they may always be kept closed, and prevent any unpleasant smells from penetrating into the house, and the walls should be covered with plain white tiles, from the ground to the height of 8 or 9 feet. Of course the size of the kitchen must depend entirely on the space at disposal; but the

height should never be less than from 15 to 18 feet.

Presuming that we have a building of the kind described, let us now consider the cooking apparatus. In the first place, it is highly necessary to have a good open roasting-range, with a smoke-jack over it. Much controversy has taken place as to the relative merits of roasting by gas; but I am quite satisfied, from experience, that the so-called roasting by such means is not to be compared with the old-fashioned plan. Meat cooked in a gas oven becomes highly impregnated with the carbonic acid, however much the oven may be ventilated, and is not to be compared, for flavour, with meat cooked by an open fire. The roasting-range should be situate in the middle of either of the walls which may be best adapted for carrying up the flues; the flue for the range-fires should not be less than 18 inches square, and invariably carried to the highest point of the main building. A range 6 feet wide, and 3 feet 6 inches high, is a very good size, and ample for all purposes. The back should be built of fire-bricks (Newcastle bricks are the best), and should not exceed 7 inches in depth from back to front. This will ensure a good bright fire, giving an intense heat with a small consumption of coal.

On one side of the range, the broiling-stoves, 2 feet 9 inches to 3 feet wide at top, should be placed, one, two, or three in number, as circumstances may require. These should have a separate flue to the top of the house, to ensure a quick draught. At the end of these stoves, a Bainmarie, heated by steam, for gravies and sauces, and next to this a good-sized hot closet, also heated by steam, for the reception of the viands after being dressed at the stoves, and to keep the plates and dishes hot while waiting to be served up. On the other side of the roasting-range there should be a large baking-oven of cast iron, and not less than 1 inch in thickness, for pastry, &c., with a good-sized wrought-iron closet over, heated from the same fire. The flue for this oven might be taken into the roasting-range chimney; but where there is convenience, a separate flue is preferable. Against the opposite wall should be fixed a series of three or four charcoal stoves, for preparing the lighter and more delicate ingredients. Here a good gas-burner may be introduced to advantage: those which burn atmospheric air with the gas are the best, as they give an increased heat without soiling the steppans. This gas stove may be used, among other purposes, for preparing the stock for soups, as the heat can be regulated so that the stock-pot may be left on all night. A steam Bainmarie-pan, for sauces and soups, is requisite at one end of this series. As near as convenient to these a good substantial hot-plate, with an oven on the top, heated from the same fire, should be placed. This and the charcoal stoves would be chiefly under the control of the principal cook. When the dining-room is on the floor above, a lift to wind up the dinners, joints, &c., is a most useful adjunct, as it saves a great deal of labour in carrying dishes up and down stairs. The lift should be as near as possible to the kitchen, but not in it; and a steam table, with closet under, should be near the lift, to keep the prepared dishes hot previous to their ascent.

In the middle of the kitchen there should be a large table, with a good oak top, 3 inches thick, with drawers under for general use: one or two copper kettles, heated by steam, for boiling fish, and, conveniently situated, will complete all that is really necessary here.

The scullery should open into the kitchen, and should contain a hot-plate for boiling and preparing the vegetables, steam-kettles for meat, potatoes, &c., and double troughs, with hot and cold water laid on for washing plates, dishes, preparing and cleansing vegetables, &c., and a sink. Here, also, the boiler for generating steam might be fixed. The size, of course, depends upon the quantity of work it may have to do, and which, in addition to the steam fittings in the kitchen, might be used to keep a closet hot just outside the dining-room. This latter is a most necessary article; for, with all the pains the cook may take to send up the dinners hot, if they have to wait for five or ten minutes before they can be served, they soon become cold, and give dissatisfaction. An abundant supply of hot and cold water to kitchen and scullery is most essential, and for the former a large galvanized iron tank should be placed near the ceiling, with a coil of pipe inside, through which steam passes from the boiler.

In the pastry-room great attention should be paid to situation. It should, in the first place, be as cool as possible, with a window having a north-easterly aspect, and freely ventilated. This should contain a large marble slab, good pestle and

mortar, ice-drawers, and cupboard for sundries. The larder may be next to the pastry-room, should he lofty, with a rack and hooks dependent from the ceiling, for hanging joints, a table in the centre for prepared meats, and a large wire-work safe for protection against flies in summer, a good-sized weighing-machine, an ice-safe, and plentiful supply of ice, &c. Of course, in the foregoing arrangements, considerable modifications and alterations may always be made. Club-houses or large hotels require more fittings of one class and less of another than a gentleman's mansion; but what I wish chiefly to call attention to is this,—that in the latter, in nine cases out of ten, the cook is expected to perform wonders in a small, dark, ill-ventilated kitchen, where a little oven and boiler-range, and perhaps a very small hot-plate, complete the usual amount of apparatus in what are called first-class mansions. I think a little more care in the arrangement, and a few extra pounds spent in this department, would not be altogether money wasted. The cook would be better able to keep his or her temper, and the major domo would get a better dinner. J. D. A.

#### NOTES CONCERNING THE ORIGIN OF PARISHES AND PAROCHIAL CHURCHES.

PARISHES were first distinguished in England under Honorius, Archbishop of Canterbury, about the year of Christ 636.—"Camden's Brit." clix. ed. 1695.

Ridley, in his view of the civil and ecclesiastical law, tells us that fountains, in the primitive times, were not in churches, but the custom of those elder ages was to baptize in rivers and fountains; and that custom being discontinued through persecution, fountains were erected in private houses; and in more peaceful ages they made bold to build their fountains at a little distance from the church. Afterwards they obtained leave to set them in the church porch. At last they got them into the church. But they were not placed in every church immediately; for at the first they were found only in the cathedral church, where the bishop resided; and, though service might be said in the lesser ministers and rural churches, yet the right of sepulture and baptism belonged to the cathedral church, unless it were a case of necessity. It was therefore called the *mother church*.

In succeeding ages, when it was found that the mother church was too far distant from some villages, and so situated that in the winter the people could not repair thither, consideration was had of this inconvenience. The bishop took occasion hence to transfer the right of baptism and sepulture to the rural churches; and this, together with the right of tithes, made it a parish church of that kind which we have now. But, because also in some parishes many families lived so remote from the church that they could not conveniently frequent the same, it was indulged to such that they might build a private chapel or oratory in or near their mansion-places, reserving for the most part the right of baptism and sepulture to the parish church, which, in respect to these lesser oratories, was to be accounted the baptismal or mother church. It was also provided that these families (notwithstanding their grant from the bishop for a private oratory) should, upon more solemn feast days, repair to their parish church. These private oratories were afterwards called *capella*, chapels.—(Thus Ridley).

Now the word "*capella*," *quasi* "*capella*," is a derivative from *capra*, which signifies a chest, or coffer, because the relics of saints and holy persons were kept in such chests; and the places where such chests were kept were also called *unde nomen capella, capellanus*, &c. So Spelman in his glossary upon that word.

Dr. Prideaux says, "none might of right build oratories without license of the bishop; at least, none might administer divine service there without the bishop's special license."

Oratories erected in the houses of great persons I should call domestic chapels. When built by one or several persons in some convenient place for the use of several families, or of a township or townships, not having liberty of baptism or burial, I call such chapels of ease.

When built by a more numerous multitude of the neighbourhood, consisting of one or more villages, having got liberty for baptism and burial, with consecration thereof by the bishop, and sometimes an allowance in money or tithes from the mother church, I call such parochial chapels; for these have all the rites and ceremonies as the mother church or parish church hath, except the tithes; so that, indeed, they are lesser parishes, created within the greater, for the benefit of the neighbourhood."

As to the consecration of churches, we find that the Jews had their feasts of dedication of their temples (John x. 22; Maccab. iv. 59). But there is no dedication of our Christian churches to saints until praying to saints was in use; and after churches began to be dedicated to saints, their dedication feasts were usually kept on that day which was the feast-day appointed in the calendar for commemoration of that saint to whom such church was particularly dedicated. This time was called by us the wakes, from waking, because at such times the people prayed most of the night before such feast-day in the churches.

The saint's bell, as many admit, was not so called from the name of the saint which was inscribed on it, or of the church to which it belonged, but because it was rung out when the priest came to that part of the service, "Sancte, Sancte, Domine Deus Sabaoth," purposely that they who could not come to church might understand what a solemn affair the congregation were at that instant engaged in; and so, even in their absence, be once at least, moved to lift up their hearts to Him that made them. For this reason the saint's bell was generally hung where it could be heard the furthest, sometimes in a lantern at the top of the steeple, or in a turret at one corner of it, if a tower; and sometimes in an arch or gallery, on the outside of the roof, between the church and chancel. This last sort was so placed, that the rope might come down into the choir, and so being near the altar, the bell might be more readily rung out as soon as ever the priest came to the sacred words.

As regards the position of churches, Dr. Plot believes, that in the setting of their churches due east and west, all the direction which people had in former times (till the compass was discovered), was from the sun itself, which rising in summer more or less northward, and in winter proportionately to the southward of the equinoctial east, in all likelihood might occasion so many churches not to respect the due east and west points, but to decline from them more or less according to the late or early season of the year wherein they were founded. A. B.

#### BATTLEFIELD CHURCH, NEAR SHREWSBURY.

MORE than once we have mentioned the deplorable condition of Battlefield Church, near Shrewsbury, and the claims it has to attention. We are glad to be informed that the church is now undergoing complete repair, under the auspices of Mr. Pountney Smith, architect. A considerable sum having been subscribed by the county towards the restoration, Lady Brinckman, of Sandore Castle, Shrewsbury, has undertaken the remaining expenses, and her ladyship has further instructed Messrs. Lavers & Barraud to fill the windows with painted glass.

#### RE-DECORATION OF ST. PETER'S CHURCH, MANCHESTER.

THE interior of this church has undergone a complete re-decoration, and was opened for Divine service on Sunday last. The body of St. Peter's Church, as it now stands, was erected in 1794, from a design by James Wyatt, and is a modern example of the Tuscan or simple Doric order of architecture. The steeple, which was added about thirty years later, was designed by Goodwin, the architect of the Manchester Townhall. In the new decorations Christian symbols (the Cross, the Lamb, the Dove, the Trinity, &c.) have been introduced into the ceiling and other parts. Texts of Scripture, in the English and Greek character, have also been inscribed on the frieze. The altar recess is elaborately treated, and, in addition to other improvements, the hitherto empty niches, four in number, have had statues placed in them, executed by an Italian sculptor, of St. Peter, St. Paul, St. James, and St. Andrew; whilst the eight oval panels on the side walls over the niches and the galleries are filled with paintings in monochrome, representing scenes in different periods of our Saviour's life. These are studies from pictures by various masters, and comprise "The Infant Saviour," Murillo; "Christ Blessing Children," Overbeck; "The Raising of Jairus's Daughter," Von Holst; "Christ Weeping over Jerusalem," Eastlake; "The Transfiguration," Raffaele; "Christ's Agony in the Garden," Le Jeune; "Bearing the Cross," after the celebrated altar piece at Magdalen College, Oxford; and "The Comforter," Ary Scheffer. The propriety of introducing colour and ornament in buildings of this kind is now generally admitted. The altar piece in St. Peter's is by A. Carracci, or of that

school, and is said to have been bought in Paris at a cost of 1,000 guineas. The organ case, designed by Mr. E. Salomon, of this city, has had the mouldings and enrichments brought prominently out in gold, and the front pipes, which are of pure tin, highly lustrated, have been decorated about the mouths in gold and colour. One of the semicircular windows has been decorated with stained and painted glass by Messrs. Edmondson & Son. The subject represents Christ's charge to Peter.—"Feed my sheep." The whole of the details and decorations of the church have been effected by the firm of Messrs. Samuel Bottomley & Sons, of Crosshills, Craven, Yorkshire.

#### SCHOOL-BUILDING NEWS.

**Twyford (Hants).—**A range of buildings, embracing schoolrooms for boys and girls and a teacher's residence, are being erected by Mr. C. Fielder, of Bar-end, Winchester, at this village, on a piece of ground forming an eminence in the lower part of it, the gift of Couway Sulpley, Esq. The buildings, which are in a forward state, include, according to the *Hampshire Advertiser*, a school-room for each sex, the dimensions of either being 30 feet by 17 feet, and adjoining these are classrooms. The portions dedicated to educational purposes form the wings, the centre of the erection being the teachers' residence. The roofs are of high pitch, and are to be covered with slate and ridge tile of a geometrical character. The materials used are flint with blue mortar, and red and black bricks, with Bath stone window (in the Gothic style), copings, corbels, &c. The open timbers of the roof in the schoolrooms, &c., are to be stained oak colour. The architect is Mr. W. Coles (city surveyor, Winchester). The cost will be somewhat under 1,000*l.*, and is to be defrayed by voluntary subscriptions and a government grant.

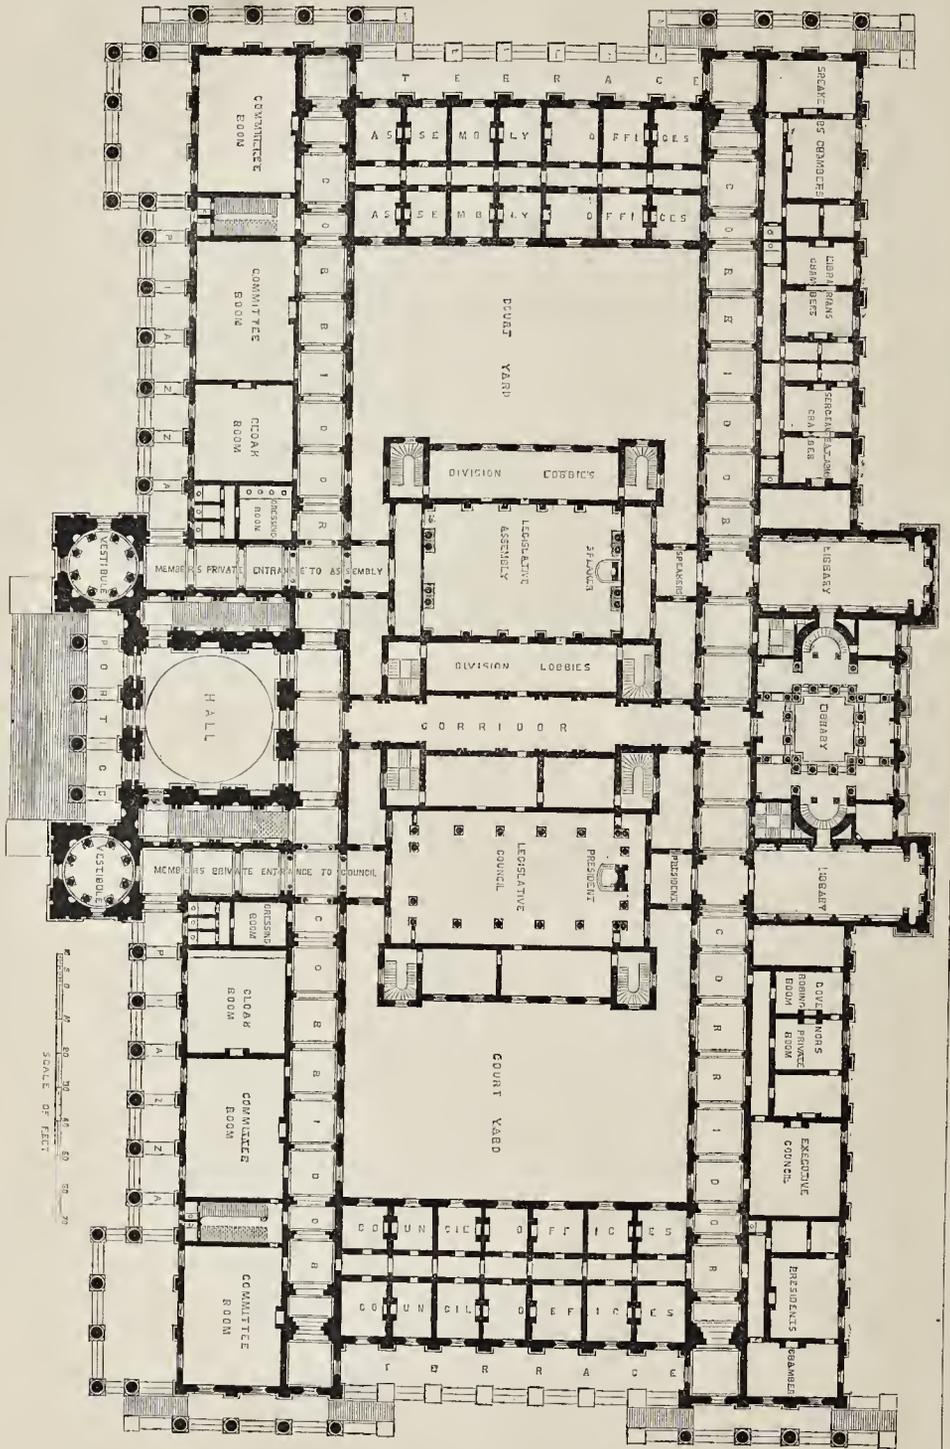

**Driffield.**—The foundation stone of New National Schools, &c., has been laid at Kirkburn. The schools are from the designs of Mr. G. R. Smith, of Hull, architect, and Messrs. Malone & Simpson are the contractors. They include a master's residence. The buildings will cost about 800*l.*, of which 200*l.* will be contributed by Sir Tatton Sykes, the lord of the manor; 50*l.* by Archdeacon Long; 305*l.* by the Committee of Council of Education, and the remainder will be raised by the landowners and parishioners.

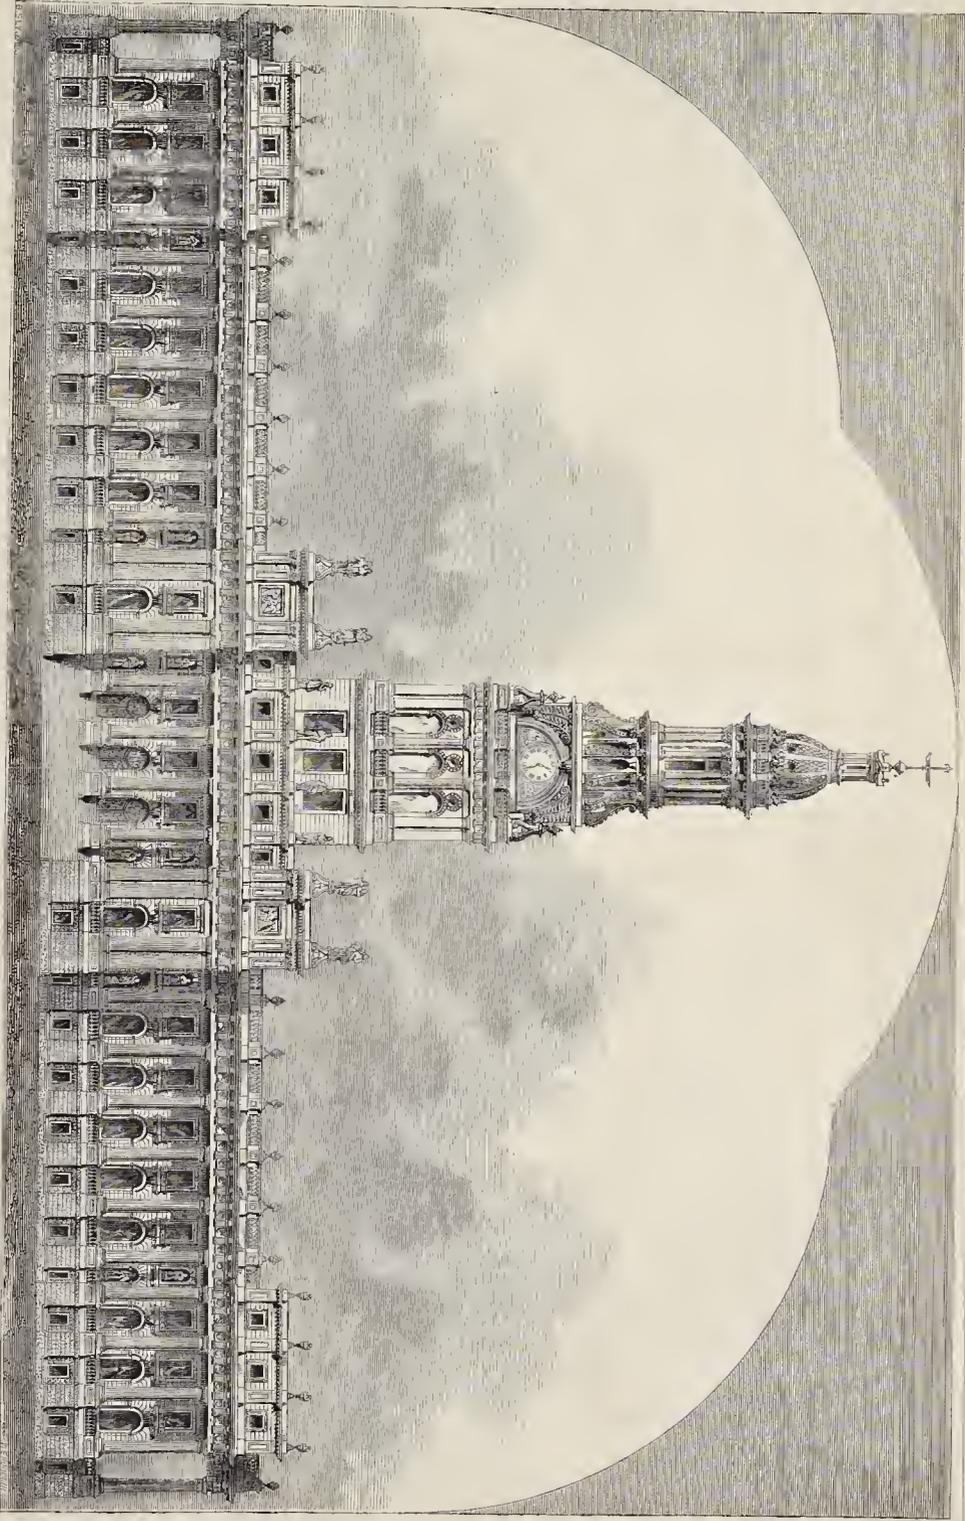

**Manchester.**—New Wesleyan schools have been opened at Newton Heath, according to the *Manchester Advertiser*. The building in style is plain. It consists of one large room on the ground floor, and open to the roof, through which the principal light is received, while on each side a smaller or anteroom is constructed, on the second floor. The estimated cost of the building alone was 700*l.* There is said to be an absence of all proper means of ventilation,—an indispensable requisite, especially where a large number of persons are congregated.

**Kirkdale.**—The first stone of the Kirkdale Industrial Ragged Schools and Church has been laid by the Earl of Derby. The exterior fronts of the building are to be plain brick and stone. The basement floor is planned for a cooking kitchen, which can be used for a soup kitchen during the winter months, and has a separate entrance from Major-street. Adjoining this kitchen is a flagged cellar, intended as a playroom during wet weather, or for workshop when required. The main entrance to the ground floor is from Major-street, to a schoolroom 80 feet long, 25 feet 6 inches wide, and 18 feet high; intended also to be used as a free church for the poor of the district. From this room there is a class-room, large workshop, and store-room, covered lavatories, urinals, &c., and a large play-yard. The upper floor, which corresponds with the ground-floor, and which has also a separate entrance from Major-street, is intended for girls' schoolroom, class-room, printing-shop, and large workshop. The buildings and yard walls occupy an area of about 1,300 square yards, and as it is intended to erect them in as plain a manner as possible, the estimate for the same, exclusive of land and general fittings, will not exceed 2,000*l.*

**A MAN'S HEAD SAWN IN TWO.**—On Monday Mr. William Payne, the coroner for Southwark, received information of the death of Jeremiah Kellimer, aged twenty-seven, who had lived at Deptford. It appeared that the deceased was stooping down to collect some wood dust at a steam saw-mill there, when the circular saw completely cut his skull in two. He was taken to St. Thomas's Hospital, where he expired.

HOUSES OF PARLIAMENT, MELBOURNE.—Plan of principal floor.

HOUSES OF PARLIAMENT, MELBOURNE.—MESSRS. KNIGHT & KERR, ARCHITECTS.

HOUSES OF PARLIAMENT, MELBOURNE.

THE site selected for the erection of the Parliament buildings is at the eastern end of the city, and commands a fine view of the town, suburbs, and adjacent country. The Blue Mountains of Dandenong and the shipping in Hobson's Bay are plainly seen from the upper windows, while the entrance at Port Phillip Heads can also be discerned through the clear Australian atmosphere. The new Treasury, a costly and elaborate building, is in close proximity to the Houses of Parliament. Extensive offices for the chief secretary and executive, the foundations of which buildings have cost 32,000*l.*, are also in the vicinity of the senate house; the eastern end of Melbourne will, therefore, in antipodean position, agree with the western end of London.

The spirit of "fastness" which characterises most of the colonial proceedings does not apply to the progress of the building in question; the portions at present erected are the two Legislative Chambers and the Library, which occupies about a third of the eastern elevation.

The Legislative Chambers are each 72 feet long, 40 feet wide, and 40 feet high. Division lobbies are attached, but the number of members—seventy-eight for the assembly and thirty for the council—being comparatively small, the lobbies are also used for committee rooms. The Corinthian order has been employed for the "Upper" and the Ionic for the "Lower" house; both Chambers are elaborately decorated.

The style and treatment of these apartments have received commendation. The building, when complete, will be about 400 feet long, 220 feet wide, and 74 feet high. The principal order employed for the exterior is the Roman Doric. The Library, now in course of completion, contains a central hall 40 feet square and 40 feet high; two reading-rooms, each 50 feet by 25 feet; and numerous private rooms. The refreshment-rooms are in this part of the building, and comprise two saloons, each 50 feet and 25 feet; smoking-rooms and other accessories.

Messrs. Knight and Kerr are the architects appointed by the Government to carry out the work.

It is understood that the urgent necessity for new executive and treasury buildings referred to above has caused the commencement of the grand front to be postponed longer than was at first intended. It will now, however, we believe, be commenced immediately. The material to be employed is a Colonial stone, called New Darley, and is somewhat of the colour and texture of that used in our own Treasury buildings. The part already completed is of basalt, termed in Australia, "blue stone."

Mr. Knight, as president of the Victorian Institute of Architects, last year, read a Treatise on "Colonial Building Stones," which was afterwards published, and was noticed by us at the time. In this he speaks as follows of the blue stone:—

"Basalt is spread over a large area of the country, and is the most abundant of all the minerals. The stone is too well known to need any technical description; its durability is unquestionable, but its suitability for works of much architectural pretension is generally doubted. In my own practice I have been a great friend to blue stone, but the result of my experience has somewhat altered my opinion of this material, and I am now inclined to the belief that it is unfitted for any public edifice where the design entitles a moderate amount of architectural embellishment.

I fear there is a disposition to tax blue stone beyond its capacity, to produce architectural effects. In Melbourne, thousands of pounds are almost wasted in working delicate mouldings upon this material, such details in many instances being scarcely visible. I have not been free from the committal of this error, but hope to avoid falling into such mistakes in future. I hold it to be an anomaly to spend 10*l.* worth of labour in working a moulding or enrichment which does not pay for the outlay in gratifying the taste to a proportionate extent. We attach a certain idea of beauty to the form of a particular moulding, which beauty is derived partly from the contour of the figure, and partly from the play of light and shade upon it. Now, the colour of blue stone destroys the proper effect of shadows: they are to a great extent absorbed by the stone, instead of reposing distinctly upon it; and, as a natural result, the beauty, proportion, and character of minute enrichments in basalt are comparatively lost, when compared with those of more appropriate colour. While suggesting the exceptions to be made in the use of blue stone, it must be admitted that for ordinary purposes, both in architectural and engineering works, this material could be so generally employed; for foundations it is eminently suitable; for stores, its sombre hue imparts an appearance of commercial as well as structural solidity; for ecclesiastical buildings, it relieved by freestone dressings, it can be used in a cheap and most effective form; while, for engineering works, its moderate first cost, and the facility with which it may be cut into plain forms, leave no occasion to wish for a better material. There is absolutely no waste on blue stone; the smallest chippings are valuable for road making; and, when we further consider the abundance of the supply, and the trifling cost of quarrying it, for ordinary purposes, we may safely say that

blue stone is one of the most useful of the mineral products in Victoria.

It may be asked, if I think so much of basalt, why seek to employ another stone in the erection of the Houses of Parliament?

I confess to feeling very great reluctance in making any exceptions to the employment of blue stone; because, from the nature of its formation, there can be no doubt of its durability. It is more indestructible than granite, not one-third as costly, but, perhaps, not a third so beautiful as that material. In instance of the durability of blue stone, I know of no steps in the entrance to the Government Offices, in William-street, where they will be found to be less affected by time and wear than those which are of colonial granite.

My principal reason for objecting to adopt blue stone for the external elevations of the Houses of Parliament I have already given in the form of a general proposition—that the colour of the material is unequal to the production of those ordinary effects of light and shade which are essential to realize the spirit of classic architecture; and, if the utilitarian proposition be not regarded as untenable, that the money spent upon the execution of architectural details should produce a feeling of satisfaction or pleasure in the mind of the observer proportionate to the amount of the outlay incurred; then I say that ornaments wrought in basalt will not come up to such a standard of

comparison; and, under these circumstances, the expenditure of large sums of money in attempting to delineate minute features is a waste of capital and a misapplication of the abstract forms of beauty in architecture.

If the known durability of blue stone is to be regarded of greater moment than any objections to its colour, let us use it with discretion; let the treatment of the orders be simplified to suit the material; and although such an innovation would detract from the acknowledged standard of correctness, the loss in this respect will be compensated by the saving in cost effected through the omission of those enrichments which show but vaguely on such a gloomy stone.

STRENGTH OF BUILDING STONES.

THE following table (showing the specific gravity of colonial and other building stones, the force required to crush 1 inch cubes, the amount of disintegration caused by the action of sulphate of soda, taking 1,000 as an indication of perfect resistance, and the weight per cubic foot, is from Mr. Knight's treatise mentioned in our notice of the Melbourne Houses of Parliament:—

Colonial Stones.	Specific gravity.	Crushing force per square inch.	Amount of disintegration.	Weight per cubic foot in an ordinary state.	
				In lbs.	In lbs.
Darley sandstone	2,350	2,118	'800	124 7-16	132
Bacchus Marsh sandstone	2,218	1,949	'200	123	133 5-16

Table showing the Weight required to crush inch Cubes of the four Building Stones principally used in Melbourne:—

	Crushing force per square inch when dry.		Crushing force per square inch after four hours' immersion in water.
	In lbs.	In lbs.	
Pitfield's new quarry at Kangaroo Point	2,056	1,919	313
Pitfield's old quarry at Kangaroo Point	2,881	1,428	594
Darley	2,118	1,260	351
Bacchus Marsh	1,949	1,073	45

The above results are derived from the average of four samples of each stone in a dry and two of each in a wet state.

Experiments to prove the fitness of the following stones to act as lintels, &c., tried on scantlings 4 inches by 4 inches, having a span of 4 feet, and the entire weight suspended from the centre:—

	Breaking Weight, cwt. qr. lbs.
Fifehire (Scotland) sandstone	1 1 26
Bath oolite (England)	2 2 20
Kangaroo Point white sandstone (from Pitfield's new quarry, Tasmania)	2 2 20
Kyneton (Victoria) sandstone	2 2 21
Kangaroo Point sandstone (Pitfield's old quarry)	2 3 20
Bacchus Marsh sandstone (Victoria)	2 3 24
Darley sandstone (Victoria)	3 0 2
Bulleen sandstone (Victoria)	3 2 9
Doncaster sandstone (near Bulleen)	3 3 20
Geelong (Barrabool Hill) sandstone	4 2 20
Portland limestone (English)	6 0 20
Park Spring sandstone (from Quinn's quarry, near Leeds)	9 3 6
Adelaide marble	10 1 11
Colonial marble	13 0 2
Mount Moriar (near Geelong)	4 3 16

Table showing the comparative Cost of certain Descriptions of Masonry.

Description of Stone.	Price per Foot.	Price of Labour per Foot.		
		s.	d.	q.
1 Granite	8 0	11	2	6
2 Marble	10 0	0	8	6
3 Mount Sturgeon freestone	7 10	0	6	10
4 Bluestone	3 6	0	9	9
5 Bacchus Marsh or Darley stone	6 6	0	4	5
6 Portland from England	5 6	0	5	6

Memo.—The prices of all these materials include delivery at Melbourne. The prices of labour provide for the same amount and description of work being put upon all the different stones. The various prices of labour (with the exception of granite) are taken from actual tenders. The price of working granite is founded on the ascertained cost of dressing samples of that material. All the prices are calculated for large-sized blocks.

PROVINCIAL NEWS.

Northampton.—There is no no doubt, says the local Herald, that a new townhall will be built. Ample premises in St. Giles's-street have been secured for a building worthy of the town and equal to its requirements; but, before the plans are decided upon, it is requisite that a clear understanding should exist as to what those requirements are. The writer then points attention, amongst other requisites, to the importance of making provision for the adoption of the "Free Public Libraries and Museums Act."

Nottingham.—We are asked to state that the carving at Messrs. Wright & Bank, recently illustrated in our pages, was executed by William Sheriton, of that town.

**Derby.**—The following particulars relate to tenders received by the local committee for works connected with the formation and completion of the proposed new cattle-market in the Holmes, and published in the local *Advertiser*. It was agreed that the tenders here specified should be recommended to the council for their acceptance, viz.: Division No. 1. Bridge over Canal, &c., 720l.; by Mr. W. Hyslop.—Division No. 2. Iron Castings, &c., 764l. 13s.; by Messrs. J. and J. Cliff, of Bradford.—Division No. 3. Materials and labour in constructing and completing market, &c., 3,021l. 16s. 9d.; by Mr. Jos. Tomlinson. The above form a total of 4,506l. 9s. 9d., being 37l. 1s. 9d. under the estimate (4,561l. 4s. 6d.) of Mr. Thorburn, the borough surveyor. A further tender of Mr. Hyslop's for Division No. 4, being for the making of the road on the north-east side of the river, amounting to 554l., was also recommended to be accepted. The whole of these tenders make a total of 5,060l. 9s. 9d.

**Ashbourne.**—The committee of the Market Hall at Ashbourne had six tenders sent in for the projected market hall: Robinson, Belper, 1,625l.; Humphreys, Derby, 1,600l.; Thompson & Fryer, Derby, 1,557l. 15s.; E. Thompson, Derby, 1,500l.; Brinsley, Ashbourne, 1,480l.; Cooper, Ashby, 1,151l. Mr. Brinsley consented to reduce his contract to 1,435l., and an agreement was made with him for that amount. Instructions were given for the immediate commencement of operations, under the superintendence of Mr. Wilson, the architect.

**Birmingham.**—The Corporation Baths in Woodcock-street have been opened to the public. The building is of red brick, and the elevation fronting to Woodcock-street has courses of various coloured bricks in the arches, corncices, and piers. There are separate entrances for men and women. The baths comprise, on the men's side, one hot and one cold first-class plunging bath, sixteen first-class private baths, and the same number in the second class. There is also a swimming bath, 80 feet long and 35 feet wide, with a depth of water of 3 feet 4 inches at the top end, 4 feet 6 inches in the middle, and 5 feet 6 inches at the lower end. On the women's side there are six first-class baths, and one first-class plunging bath, with eight second-class private baths. There is a waiting-room on each side, and the ticket-office is so arranged that persons of both sexes may apply at once, and yet be invisible to each other. The cold water comes from the pipes of the Water Works Company, and the hot water is supplied direct from the boiler, by a contrivance patented by Mr. Purnell, the superintendent of the Kent-street and Woodcock-street baths. Attached is a house for the resident engineer, and at the back are the necessary offices for washing towels, &c. The plunging and swimming baths are lined with Rufford's white glazed bricks, and the private baths are also of Mr. Rufford's manufacture. The margin round the swimming bath is laid with lime and red quarries, arranged in patterns. The want of the place seems to be a first-class swimming bath. The original plan, it seems, provided for such an arrangement, as well as for thirty-five more private baths. The architect is Mr. E. Holmes; and the contractors were—for the building, Mr. C. Jones; for the plumbing, &c., Mr. Whitworth; for the cisterns, boilers, and machinery, Mr. Middleton; for the engine and pumps, Mr. Dean.

**South Shields.**—The works for the building of seventeen additional cottages for the trustees and committee of the Master Mariners' Asylum, have been let to Mr. Hoppell, of North Shields. The buildings have been commenced under the superintendence of Messrs. Oliver & Lamb, of Newcastle-on-Tyne, architects.

**Shotley Bridge.**—A townhall is about to be built at Shotley Bridge, and the directors have appointed Messrs. Oliver & Lamb, architects. The style of architecture adopted is Gothic. The building will be formed entirely of stone; and the centre projection will be surmounted by a clock turret, with a slated spire roof.

#### CHURCH-BUILDING NEWS.

**Bromley (Middlesex).**—It is proposed to erect a Congregational chapel and schools in Wellington-road, Bow-road. The style is to be Decorated Gothic, in white Suffolk bricks, and Bath-stone dressings, and coloured arches. The chapel will accommodate 780 adults, with galleries. There will be a tower and spire at the north end of the east aisle. Messrs. Morris & Son, of London, are the architects.

**Eccles.**—The first stone of the new church of St. James, at Hope, near Eccles, has been laid. The new church is intended to accommodate 640

persons, and is in total length, 132 feet; breadth, 57 feet; and height, 43 feet. The style is Gothic, of the thirteenth century. The plan consists of a chancel and a nave, with clerestory, and north and south aisles, divided from the nave by a double row of seven arches, deeply recessed on circular pillars. The chancel is one quarter the length of the whole, having the desk and pulpit on either side of its arch. It is flanked by an organ chamber, and by the vestry on the north and south sides, and, rising three steps from the nave, terminates with a case window, of five lights. The font is at the north-west door. The chief feature of the building will be a tower and spire, 160 feet high, disengaged from the church, except at the base, where it is joined to the north porch. The roofs of the church are open, with the rafters exposed; and the ceiling is of wood, covered with slates in alternate courses of blue and red. The main walls are Yorkshire pierpoint, with dressings from the Storton quarries, Ceshire. The architect is Mr. Walter Scott, of Liverpool.

**Birmingham.**—The chief stone of the place of worship now in course of erection for Dr. Brindley, in Lower Gooch-street, has been laid by Sir J. Ratcliff. The building is to be erected by Mr. Griffiths, from designs by Mr. S. Henning, and will stand at the corner of Gooch-street and Conybeare-street. It will be 86 feet by 60 feet; and, by arranging the pews in the fashion of an amphitheatre, space will be obtained for 1,000 persons. The plan includes school-rooms, arranged under the raised seats, and there will also be a vestry. The cost will be about 1,340l.

**Bilbrough.**—The parish church of Bilbrough, the last resting place of Thomas, Lord Fairfax, the Parliamentarian, has been re-opened, after a renewal of the inner fittings and furniture. The old pews have been replaced by stalls. An oak pulpit and lectern replaced, in new situations, the former pulpit and reading-desk. The total cost will be about 200l., to be defrayed wholly by subscription. The designs were supplied by Messrs. Atkinson; the wood-work executed by Mr. Cook; the stonework by Mr. Wilson; and the painting and staining by Mr. Perfect and Mr. Poulter.

**Halfax.**—Several statues have arrived towards completing the decorations of All Saints' Church, Hales-hill, built by Mr. E. Akroyd. They are all for the exterior.

**Tynemouth.**—A correspondent informs the *English Churchman*, that three new churches are to be built in the parish of Tynemouth, Durham, in addition to the three already existing, so that the parish will comprise six incumbencies. The five new parishes will be endowed with 200l. per annum each. To carry out this plan, the Duke of Northumberland contributes the sum of 30,000l. The Ecclesiastical Commissioners will make a grant of a similar amount.

#### STAINED GLASS.

**St. Mary's, Eynesbury.**—A window, to the memory of the late Colonel Humbley, has been erected at the west end of this church. The window consists of three lights, with a figure of a Scriptural personage in each; and below each figure is portrayed an incident in the life of the person represented above. The figures represent David, Joshua, and Cornelius. Under the figure of David is David slaying Goliath. Under that of Joshua is represented an angel delivering his commission to that leader. Under the figure of Cornelius appears an angel speaking to the centurion. In the tracery, above the figures, are the three emblems of the Christian faith—the Shield of Faith, the Helmet of Salvation, and the Sword of the Spirit, each borne by an angel. This is the third memorial to this officer, which appears in this church. The execution of the work was intrusted to Messrs. Clayton & Bell.

**Oldbury Church.**—The parish church of Oldbury has had several memorial windows lately erected. The large east window is dedicated to the memory of the late Mr. William Chance, of Birmingham, who was a partner in the Oldbury Alkali Works, and represents the entombment, resurrection, and ascension of our Lord. The window is erected by Mr. Chance's family and the inhabitants of Oldbury. The ten clerestory windows have been similarly dedicated by Mr. Dugdale Houghton, of Birmingham, to the memory of his father, and represents the four Evangelists, together, with other designs. The whole of the glass is from the glassworks of the Messrs. Chance, at Spon-lane, and from the designs of Mr. S. Evans, M.A.

**Gloucester Cathedral.**—We stated some time ago (says the *Gloucester Chronicle*) that the Dean and Chapter contemplated the restoration of the magnificent east window of the cathedral, and

with that view had obtained designs from several of the most eminent manufacturers of stained glass. The designs were exhibited at the cathedral, and naturally excited considerable interest. We now learn, however, that the intention of carrying out either of these plans has been abandoned, we believe at the suggestion of the *savans* who lately visited this city, and who stated that the window contained one of the largest collections of ancient glass to be found. A scaffolding has been erected, and the window will be repaired, the old glass being preserved in its present state.

**Church of St. Peter-Port, Guernsey.**—The Lieutenant-Governor Slade's gift of stained glass for the St. Peter-Port Church has been inserted in the oriel of the south transept. The subject is the Lamb, surrounded by six angels, and by the twelve apostles seated on thrones. The artist was Mr. Gibbs, of London. The glass has been fixed in the window by Messrs. De Patron, of Guernsey.

#### CHEAP SCHOOL-CHAPEL.

A SCHOOL-CHAPEL has been lately erected at Crampmoor, in the parish of Romsay, Hants. The building is used as a school during the week, and for church-service on Sundays; and the school-mistress occupies rooms on the south side. The external walls are built of brickwork, 14 inches in thickness, and hollow. The floors are boarded. The roofs are covered with plain tiles. There is a bell-turret, of wood. The nave is 27 feet by 16 feet; the chancel, 10 feet by 9 feet; porch, 5 feet by 4 feet. The living-rooms (two, and a scullery) are plastered, and fitted with range and iron chimney-pieces. The cost of the whole, including frames, seats, and lectern in the chapel, and a well in the garden, was about 225l. Mr. E. W. Lower, of Guildford, was the architect; Mr. T. Hill, of Romsay, the builder.

#### ARCHITECTURAL SOCIETY OF ARCH-DEACONRY OF NORTHAMPTON.

A COMMITTEE MEETING was held on August the 13th; the Rev. Lord A. Compton in the chair. Plans for the re-seating and enlargement of Ketton Church, by Mr. Scott, were examined. The form of heath proposed was disapproved. Plans for re-building Sutton Church, near Harborough, by Mr. Goddard, of Leicester, were examined, and generally approved. A design for the restoration of the chancel of Kilworth Beauchamp, by Mr. Slater, was approved; and also, by the same architect, plans for the National Schools at Islip. Plans of the re-seating of Wallingborough Church, by Mr. E. F. Law, which had been formerly approved, were re-submitted to the consideration of the committee. After some other procedure, the subject of the mode of grants made to new and restored churches by the Church Building Societies was considered, and a memorial unanimously resolved on, to be communicated to the Society of the Archdeaconry and the Incorporated Society in London, and which stated, *inter alia*, that "by the rules and practice of this, as of most, if not all Church Building Societies, the increase of accommodation, upon which grants are made, is estimated by the number of sittings shown on the ground-plan; and this, without any reference to their convenience of site, and only partially with regard to convenience of occupation. The result is, that the architect, in order to gain for his employer the largest amount of grant, is led to reduce his seats to the very narrowest measurement allowed, to cramp his passages, crowd in seats into the most inconvenient places for hearing or seeing, and occupy spaces (as for instance, close to the reading-desk, round the floor, or in the chancel) which the order of the Church service almost demands to be left open. In many cases, for the sake of showing a greater increase of sittings, the whole are spoilt, and kneeling almost prevented. We should respectfully suggest, if the grant were made according to the available ground area, these evils would be avoided without any attendant disadvantage." The annual meeting was decided on for Tuesday, the 11th of September, when Mr. Poole will read a paper "On the Round Church."

The Architectural Society of the Archdeaconry of Northampton purpose to hold their annual meeting in conjunction with the committee for the Restoration and Enlargement of St. Sepulchre's Church, with the view of bringing its claim more prominently before the public. Of the four remaining Round Churches of England, this is the only one allowed to remain in the desecration and em-

brouness which years of carelessness have brought upon it: so unruled and mutilated has it been that it is difficult, on entering it, to detect its circular form, and strangers have left it under the impression that they have mistaken the Round Church. The extended claim which it has upon the antiquarian world of England, seems to have chilled and paralysed local efforts. Of its proposed enlargement, the foundations have already been commenced. The contractor for the work became bankrupt at an early stage of the undertaking; but the committee have persevered in carrying on the work.

WITTON CEMETERY COMPETITION: BIRMINGHAM.

At a meeting of the Birmingham Town Council on the 4th instant, the report of the Burial Board Committee was read by the Chairman, Alderman J. H. Cutler. The following is an abstract:—

"The designs, ten in number, for laying out the grounds at Witton, in the County of Warwick, twenty in number, for the erection of the chapels and other buildings had, since their reception, been suspended in the Borough Surveyor's office for inspection by members of the Council. The committee, after carefully considering the respective merits of the architectural designs, reduced their number to one-half; and, impressed with the importance of the duty entrusted to them, resolved to call in Mr. Stevens, a gentleman whose knowledge of ecclesiastical architecture, and high repute in his profession, fully entitled him to the confidence of the committee, to give an opinion in writing as to the merits of the remaining ten plans, and to state whether in his judgment they could be carried out for the sum specified in the printed instructions issued to the architects—5,000l. Mr. Stevens reported in favour of the designs of Messrs. Clark, Naden, of Nottingham; and Holmes, of Birmingham, without expressing any opinion as to their relative merits; but he also reported that according to his calculations the cost of the buildings, if erected, would exceed the amount to which the architects had been limited. Upon this the committee required the authors of the three selected designs to guarantee the erection of the buildings for the sum specified, to which regulation they replied by referring the committee to estimates obtained from them by builders willing to enter into the contracts for less than the amount named. Mr. Stevens was then called in again to advise the committee as to the relative merits of the three selected plans. The result of a long personal interview with that gentleman was an opinion formed by the Committee that the premium of 500l. should be awarded to Mr. Clark, of Nottingham, and that the prizes of 300l. and 200l. should be awarded respectively to Mr. T. Naden and Mr. E. Holmes. The Committee also recommended that the prizes should be thus distributed, and that the designs of Mr. Clark should be those adopted by the Council, while their author should be appointed to superintend the erection of the buildings in accordance with them. They further recommended that they should be empowered to advertise for and accept tenders from builders for the erection of the buildings, and that, in the event of all such tenders exceeding the proposed outlay, the designs should not be carried out nor the premium be given to their author, but that the designs of Mr. Naden and Mr. Holmes should be taken in their turn. From the ten designs received for laying out the grounds the committee had selected those of Mr. R. Ashwell, of Coventry (estimated cost, 3,610l.); Mr. G. H. Stokes, London (estimated cost, 3,136l.); and Mr. W. Davidson, London (estimated cost, 2,860l.) as being the most satisfactory, entitled to the premiums of 300l., 200l., and 100l., offered by the committee. The accepted designs became the property of the Council; and, as there was no agreement with the competitors as to their employment in any other work, the committee recommended—on the ground that while the three plans were capable of adaptation, none of them were entirely fitted to the purpose—that they might be empowered to amalgamate the designs of the managers as to them might seem expedient. The selected designs were lying in the council-chamber."

After much discussion, and the loss of two amendments, the report was adopted.

VENTILATION OF GAS. CONDITION OF LILLE.

I HAVE for many years lived during seven months of the year in a house composed of a great number of small rooms, lighted with gas. With only a few friends falling in of an evening, the temperature was found very uncomfortable. I set about to find a means to remedy the defect, and employed the following. Over the lustre of three or more burners, and even a single burner, I inserted in the ceiling a cast-iron, ornamental, and very open rosace; and, in the thickness of the joists, a sort of hopper, in zinc, with a pipe of the same, leading therefrom into a flue, or, if below stairs, carried through into a passage and up to the roof, and I have found it peculiarly efficacious, in making a cigar in the room, even at a distance from the centre, the direction of the smoke towards the light and the upward current, is very observable. It is an easy, and not expensive alteration to make to any room. I had a room (bed-room) at the back, to which I was forced to take the dust and dirt of the neighbourhood) to place double windows. The renewal of the air by opening these was very difficult; but, by means of a pipe under the floor, in the thickness of the joists, fresh air was brought in from the street

as you would bring in hot air from a calorifere, with a sort of throttle valve to close when not wanted. It answered remarkably well.

This town of Lille has gained for itself great notoriety: great numbers of the inhabitants live and die in cellars, the arch of many of them being below the level of the street. I have frequently thought of you, Mr. Editor, when seeing the inmates of these subterranean abodes shutting themselves in for the night. A commission was named by the Republican Government in 1818, to visit the dwellings of the poor in Lille. Victor Hugo was one of the commission. He made a report which caused great sensation, not only in Paris, but in the provinces: he drew it and coloured it in the distal style he delights in; but the people still live in cellars and garrets: many prefer the former.

A photographer on the part of Prince Albert, I learn, had been here taking impressions of the greater number of sketches of old masters in the Wicar Collection.

The Picture Gallery in the Town-house is being extended, and will, in a short time, be of great interest.

STABLE FITTINGS.

SIR,—Iron is rapidly and deservedly taking the place of wood for the fittings of stables; but I think it only right to caution the trade and the public against the danger of iron mangers and racks, as they are very generally made. The plate which forms the top should be curved downwards, not only in front, but likewise all round the insides of the manger and rack, and should not offer, in any part, the abrupt edge of the iron plate for the horse to lay hold of. A bad accident has just happened to a horse of ours from this cause. He laid hold of the front of the manger (as horses generally do when being harnessed): the teeth of the upper jaw got under the projecting edge above described: the groom was unable to release the horse's mouth; and the result was that, in struggling to get free, he broke some of his teeth, and has seriously strained, if not dislocated, his upper jaw. A moment's inspection of these fittings, supplied by an eminent firm, will at once show how easily this accident may occur.

A BUILDER.

ILLUMINATING CLOCKS.

THE present mode of illuminating ( ) our public clocks is unsatisfactory, all must admit. Why attempt the lighting of the whole dial? Why not rather point the hands with an electric star, by means of a wire or wires edging the two hands, meeting and producing combustion at each point? The intelligence that will seek the time on a dark night will be satisfied by the relative situation of the two star points of white light so produced, even though the whole dial be utterly invisible. I merely suggest this as probably within the capabilities of science.

C. DENT.

PREVENTION OF FIRES.

THE recent fire at Frost Brothers' rope-work, near the Commercial-road, impels me to revive a recommendation strongly urged years since,—the importance, by the appointment, through the Government or otherwise, of a well-qualified, practical man, as an inspector, to see and report upon the safety of the pitch boilers; also as to the quantity and disposition of the full and empty tar barrels in such works.

I have no hesitation in saying these fires could be made preventable, as they mostly originate in the pitch-boiling.

I have had the misfortune of seeing many destructive fires in London, and was an eye-witness of this at its commencement. In less than five minutes it ran like a train of gunpowder, firing buildings nearly a quarter of a mile in length, and in parts vast sheets of flame ascended a great height: fortunately it was eight o'clock, a.m., and no wind.

Had it been night, with wind, the chances were that the backs of houses to two streets, more or less, would have been destroyed, housing at least from 2,000 to 3,000 souls: even as it is, the fright to hundreds of the women will take a long time to tranquillize.

As a matter of course it is beneath the notice of our M.I.B.A.: as one of the workers, I say it boldly, in these matters it is their duty to suggest plans sufficiently stringent to prevent suffering to hundreds. I should hope the Metropolitan Board will look into this matter; and, if they have the power, they must at once see the importance of appointing such an officer to examine and report

upon the way in which destructive fires may be made preventable, by not allowing the cupidity of large firms to put in jeopardy the lives of persons residing in the localities of such factories as use combustible materials. C. V. BERNARD.

THE WINDOWS OF ST. PAUL'S CATHEDRAL.

I SAW with much pleasure your proposal respecting the filling of the windows of St. Paul's Cathedral with suitable stained glass, suggesting that the Corporation and great City companies should take the lead in so desirable an undertaking. The proposition is "Good! very good!! excellently good!!!" and it is much to be hoped that it may be acted upon. One thing is quite certain, that until the cathedral is relieved from that dreadful chalk-pit effect produced by its present unadorned walls, and gaunt white windows, little can be done to give that solemn grandeur which ought to strike every one on entering the cathedral of the great and wealthiest city in the world.

Something is now being done to remedy the former of these evils, by gilding the four large arches of the dome; but all the gilding in the world cannot compensate for the want of the "dim religious light" which we are accustomed to look for in our cathedrals.

A commencement, however, has been made in the right direction, by the presentation of a stained-glass window to be placed in the nave, which is being executed by Messrs. Clayton & Bell. And it is much to be hoped that not only the City companies and the Corporation of London, but also private individuals, will follow the good example; and that all who delight in the works of our great English architect will throw in their mite to bring to a happy conclusion that which Wren longed to see.

A RECTOR.

HEREFORD OLD TOWNHALL.

SIR,—Will you allow me to submit to your readers a few observations in reference to the censure which, by correspondents of the Builder and other newspapers, has been cast upon the town-council of this city because they are about to take down the old Townhall? Being a member of that body, I, and others holding a similar opinion, feel that we are not oblivious to the charge of Vandalism on account of our advocating the demolition of a decayed building, deformed by successive mutilations, unsuited to the civic requirements of the present day, and an obstructive nuisance, dangerous to the life and limb of wayfarers, and impedimental to the fast growing traffic of the ancient city.

Now, sir, we believe that our perceptions of the sublime and beautiful in art and nature are as deep and as genuine as are those of the fabricators of coarse iron or barbarism; but we believe, also, that where public buildings have not only outlived the offices for which they were erected in a gone-by age, but are likewise detrimental to the public weal, it becomes an imperative duty of those persons having the authority to remove them, and to provide successors more responsive to the exigencies of the present day. Let us then test our old Townhall by this standard.

The old Townhall was erected by John Abel about three centuries ago, and, doubtless, was a magnificent wooden edifice, forming a noble architectural object in the centre of the city. We learn its form and features from an engraving in Price's map of the city, a copy of which is in the possession of our respected town-clerk. At the time of its erection nearly all the houses in the city were timber-built and gable-ended; and this fine edifice must have stood out in the midst a grand building, harmonizing with the surrounding houses. It has been said that it was only repaired by John Abel, the king's carpenter, but tradition attributes the entire work to Abel, and I am not aware of any reliable adverse authority.

The old Townhall was a gable-ended timber edifice. It consisted of three floors. The ground-floor—an open-sided area, of 81 feet by 31 feet, within which are three rows of oak pillars, 18 inches in diameter, supporting the floor above. The first-floor is of the same extent as the ground, and would form a commodious hall of meeting, but along it run three rows of pillars, corresponding with those below; and these pillars render the room most inconvenient for assemblages of people, and inconvenient too for the storage of wool and hops, to which purpose it has of late years been applied. In this room all the public meetings of the city were formerly held. There was a second floor above; and this was divided into fourteen chambers, allotted to the fourteen trades, or rather guilds, or companies. In these rooms the respective guilds held their meetings; for in those days the *modus operandi* of every trade was under the rule and governance of its respective guild. Doubtless on this account the old Townhall was originally called the Guildhall.

The building was crowned with a handsome domed-shaped campanile, or bell-tower, the top of which must have been more than 100 feet, and unquestionably formed a striking object to the surrounding country.

A glance at the engraving in Price's map carries conviction that the old Townhall, two or three hundred years ago, was excellently well adapted for its uses in that day, and was a structure of which the city might well have been proud.

But while these centuries have been rolling away great changes have taken place in the habits of the people in the old Townhall and in the buildings around it, as well as in the manners and habits of the inhabitants themselves: the times have indeed changed, and we have changed with them.

The handsome and lofty campanile, the second-floor, or upper story, with all its guild chambers, and the beautiful single windows, have so long since departed that that very old and interesting personage, the oldest inhabitant, has no recollection of them; while the first floor is covered

with a low, mean-looking roof. This floor is nothing better than a lumber-room, and a very inconvenient lumber-room it is to the exterior, that has been so "mailed" and mutilated, and altogether presents such an architectural monstrosity, that could John Abel himself see it, he would not recognise the bastard edifice as the offspring of his own creation.

Well, but it is asked, why not restore the building to its pristine beauty? The negative answer comprises many reasons: a few of them, with your permission, I will briefly state.

Renovation, complete renovation—and anything short of it would not be justice to the architect or his times—would, I am assured, cost upwards of 2,000l.: besides, when done, the building would remain an obstructive nuisance, casting a still longer shadow and deeper gloom on the fronts of the houses on either side, and affording only a peculiar accommodation not required in the present day, and not meeting our growing civic exigencies, while it would continue to incommode the increasing traffic, rendering it still more dangerous through the High-square. This last fact may be estimated by the stranger to the city, when he is informed that the carriage-way on one side—the principal way through the city from the London and Brompton railway stations to the South Wales, Brecon, and Worcester railway stations—is but 15 feet from curb to curb; the chief entrance to the poultry and butter markets from the High-square opening right into this road, opposite the centre of the old Town-hall.

But if it were restored, as it is presented, the building would not harmonize, as it did in days of yore, with the houses around it. Three, nay, two hundred years ago, Hereford did not number 5,000 inhabitants; it now numbers 15,000. Prior to the year 1774, in which the *improvement Act* was passed, probably all or nearly all our houses were like the old Town-hall—timber-built and gable-ended. Their gables so projected from either side of the streets, we must should call most of them, that the inmates could in many places shake hands; and while the tradesmen sat below, shaded by the gables, discussing civic affairs, their good wives could, from the opposite windows above, discuss the no interesting because more personal, gossip of the city. There was but little if any foot pavement: some of the streets were pitched, both the road and footways, with pebbles obtained from the bed of the Wye; while the surface drains throughout the city were allowed to stagnate, and in summer they so fettered, that on a memorable occasion I doubt not they were one of the principal causes of the visitation in the shape of the plague. In those days the old Town-hall did not, as it does now, rattle and rebound from the busy passage of the "bus and the Hansom; the cart and the gig, the single and pair horse carriage."

Subsequently to 1774, and principally between that year and 1830, a great change was effected in the fronts of the houses of the inhabitants, both trading and otherwise. I believe there is a desire prevailing old enough to remember that a load of hay could not pass between the gable-ends of the houses at the top of Widemarch-street, or in the High-street, near the North-gate; but gables, harmonizing as they did with the old Town-hall, have nearly all disappeared; and mostly by an operation, which I regret to describe as a *sham*, and to stigmatize as detrimental to the architectural character of the city. The common practice has been to cut off the face, or gable end, and to run up a brick wall in front, thereby leaving the interior of the old house untouched, and handing the whole down to posterity, an *old friend with a new face*,—not a desirable possession in houses any more than in social life. With some exceptions the houses on either side of the old Town-hall are of this *sham* character; and although we have many very handsome shop fronts, we have likewise many small, low-roofed, ill-lighted, ill-ventilated, inconvenient houses.

A renovation, therefore, of the old Town-hall, on its present site, would, I venture to submit, be in every respect unwise; it would, indeed, be retrogression in progress; and it would be a course which, if Abel himself were alive, would be opposed by the king's carpenter.

For my part, sir, I consider that a great injustice is often committed on the character of great men of former times; Abel men, who were in advance of their age; who have left a deep mark of progression behind them, a mark which acts as an encouragement to those who come after them, and who, like them, must make up their minds to encounter obstacles in *deeds*, and obliquity in *words*, but who, nevertheless, press forward, and the end reward their highest reward—that of success. To appeal to such men of centuries ago as authorities for standing still, or remaining at the point where they left the world, is unjust to their memories: it belies the history of their lives, and is, indeed, contrary to the practice of the intellectual pioneers of all ages. If John Abel, and such as he, were citizens of Hereford in the present day, I believe we should find them breathing the spirit of progress at our council board; and Abel himself among the first to advocate the removal of the old Town-hall, and the erection of a worthy architectural successor—an edifice which should be consistent with the rising *status* of the city, with the daily increasing traffic in the High-square; in short, an edifice which would meet the wants and requirements of the present day, and in future ages would stand out in the midst of Hereford, as the old Town-hall did during the first two centuries after its erection—one of the principal architectural glories of the city.

I have said that I do not think I am insensible to the sublime and beautiful, in art or nature; nevertheless, am so far a utilitarian, that I would not preserve habitations merely because they are ancient picturesque objects. In Johnsonian interpretation, a knacker's horse is superlatively picturesque; so is a mud cottage with mud floor and fetid pools here and there; a thatched roof, with rotten straw in holes, and redolent of vermin; a small lattice window, through which the light and air of this beautiful world must struggle for admission; I plead guilty to a preference for neat stone or brick dwellings, with boarded floors, airy rooms, and comparatively large windows, for the abode of a poor man, and further, I indulge the opinion that such habitations operate beneficially on the physical, the moral, and the intellectual condition of the occupants of both sexes and all ages. Such improved cottages may be constructed with a judicious blending of the useful with the ornamental.

But the love of the picturesque, when manifested in an inordinate passion for old picturesque buildings, appears to me to be a phase of insanity. The other day, in a garden on our honoured me with a call for the purpose of remonstrating with me on the Vandalian, as he was pleased to term it, of demolishing the old Town-hall. I walked with him to the building, and I regret to say that he was to me as blind to its present hideousness, as I

was to him as to its present beauty. I accompanied him into the country, and showed him some mud cottages, such as I have just described, and which he warmly praised on account of their picturesque, but which I dispraised on account of their unfitness for the abode of a civilized man, his wife, and his children. I pointed out to him some stone cottages, which I have myself erected about two miles from the city, and which I thought were picturesque, and something more; but which he could not admire, as he did the mud cottages, and the fifty mud cottages. I thought, and still think, that such inordinate love for the productions of the past—and it is this extreme veneration that invests every old "inanimate thing with localities, associations, insanity, and that had such a passion been dominant in our city in past ages, the sixteenth century would never have witnessed the erection of Abel's glory—the old Town-hall; and had it been always dominant throughout the nation, I very much doubt whether our forefathers, the ancient Britons, would have progressed so far in art as to clothe themselves in the skins of the wild animals of their country.

There is, however, one suggestion as regards the old Town-hall, which might be carried out. The old Town-hall, being a timber building, might be taken to pieces, and be reconstructed on another site. The building will shortly be offered for sale by the Town Council: let the admirers of the splendid edifice, as erected by John Abel, seize the opportunity, to bid them forth with reasons and description, to purchase the building, to remove, and re-erect it on some site where it may be easily accessible to the stranger visitor, where it will not be a nuisance, but be an architectural ornament and a monument of the noble and edifice erected in England in the sixteenth century. For such a work I would willingly subscribe my mite; and it is a fair test of the sincerity of our censurers, who, by "doing likewise," will demonstrate their love of money.

*Hereford.* CHARLES ANTHONY, Alderman. P.S. Since the above has been written, and commended with as much regard as surprise, two letters from Mr. Clayton, one in the *Hereford Times*, the other in the *Builder*.

In the former Mr. Clayton states, "that the author of Design No. 50 (i.e., Mr. Charles H. Edwards), having given nothing but perspective views, and no geometrical drawings with dimensions, it was impossible to substitute competent architectural designs for those of Mr. Edwards's and Mr. Clayton's." You will, sir, scarcely believe that "no geometrical drawings, with dimensions" or specifications accompanied Mr. Clayton's design, or clock-tower, but three uses, positively had borne his design in order to prepare them. This, therefore, is a fling, as spiteful as unjust, against the successful competitor.

Mr. Clayton observes that his design for a clock-tower was carried by a majority of the votes of the subscribers; to which I again reply, that that majority was an "accident," the result of a "mismanagement," my belief being that a large majority of subscribers at that meeting were in favour of Design No. 50; and this belief is strengthened by the fact, that at the meeting of the Council, at which twenty out of twenty-four members were present, only two (the proposer and seconder) voted for Mr. Clayton's clock-tower. As to "the motives and good taste" of my observation, being myself conscious of the purity of my motives throughout the whole of this business, I am unwilling to impute improper motives to others; doubtless, Mr. Clayton is moved by no other motive than the honour and welfare of the city. As to the good taste,—"the good taste" does not come freely from Mr. Clayton, who has the taste to cast spiteful reflections on his brother architectural competitors.

In a postscript Mr. Clayton affects a sorrow, surely more just than in earnest: he writes as follows:—"The fine old timber Town-hall seems doomed to be removed." Will not you, sir, and Mr. Clayton's brother architects too, be so managed to hear that he has proposed, Mr. Clayton, *de motu proprio*, to have publicly proposed to demolish the old Town-hall, and furnished a drawing of a clock-tower, which he also proposed to erect on its site!—G. A.

#### THE TRADES' MOVEMENT.

At Bristol the strike of the operative masons is virtually at an end. The men have agreed to resume work at an advance of 6d. per day, with a 10 per cent. increase on March 1st, 1861, the two hours' labour less per week will be conceded. Several of the masters have agreed to this compromise; and it is expected the others will shortly follow their example.

At Walspool, the operative joiners are on strike, seeking an advance of 8s. per week, with a reduction of the hours of labour. Two employers have agreed, whilst the others, it is said, are determined not to give way. A guinea per week appears to be the present wages at Walspool, whilst in Chester they are getting 25s., and in Liverpool 28s. and 30s.

At Bradford (Yorksire) a numerous meeting of master builders has been held for the purpose of forming an association in the West Riding, as a means of protection against unjust and unreasonable demands on the part of workmen. The principal towns in the province are represented. Mr. William Beauland occupied the chair. Several resolutions were passed with a view to active organization. The object of the association is said to be purely defensive.

The miserable strike at Coventry is at an end, but numbers of the weavers are now awakening to the conviction that work is not to be had, on any terms, farless on their own—that they be paid by piece-work, and that they be allowed to work have been thankful to accept it on the masters' terms. It is proposed to introduce the cotton trade into the town to make up for all deficiencies in the ribbon trade. Miss Nightingale has again been drawing attention to those interested in the Coventry weavers in this direction, by using efforts to have some of the distressed and starving families transferred to Blackburn, in small detachments, at a time when the weavers are so miserably poor, and most charitable contributors to the wants of the poor; but this is far from being the case in many such instances as this; and the Blackburn operatives are not so miserably poor as they are represented to be, although they have made no objection to Irish immigration under similar circumstances. Is it that they are themselves so miserably poor, or is it that they have twenty-nine looms stood idle, owing to eighty Black-

burn weavers actually struck work because one Coventry weaver was introduced amongst them?

A most nefarious and abominable instance of "the tyranny of strikes" has occurred at Colne, in Lancashire, amongst the power-loom weavers, and has been very properly shown up in the *Times* and the *Manchester papers*. It appears that in this case money is exacted from those still in employment (girls as well as men) by threats and scandal of the vilest description, actually published in a printed form under the guise of "weekly reports of income and expenditure" of the strike, with the name of a fellow called "Abraham Pinder" attached as secretary. The whole affair reminds one of nothing, but the obscene and disgusting publications which once defiled the metropolitan press under the name of "The Statist," "The Town," &c. It is to be hoped Mr. Pinder has placed himself within the long range of the law, and that he will be well clawed before it is done with him.

#### Books Received.

*Lectures, chiefly on Subjects relating to Literary and Scientific and Mechanical Institutions.* By H. WHITEHEAD, M.A., Curate of Clapham; T. C. WHITEHEAD, M.A.; and W. DRIVER, Bosworth & Harrison, Regent-street, London, 1860.

This little volume may be described as a record of addresses to the working man by the thinking man. The Rev. Mr. H. Whitehead displays a special ability for the task he so frequently undertakes, of amusing and instructing those who listen to his lectures; and the Clapham Literary and Scientific Institution is fortunate in having so frequently the benefit of his *con amore* services. The rev. gentleman has hit upon the happy medium between the grave and the gay, and loses no fair opportunity of administering light doses of sagacious thought through an attractive and gossiping medium, which must render it pleasantly and easily digestible, even to tender mental organs of assimilation.

The subjects of the lectures in the present volume, besides an introductory one, are—Lending Libraries—George Stephenson—Literary and Scientific Institutions—Strikes and Documents—System, its use and abuse—Reading-rooms—Silence a Speech—Divide! Divide! The Talking Fish—Step by Step—Birds of a Feather—and Five Curs at St. Luke.

A lecture for a penny appears to be a very good form in which Mr. Whitehead's addresses are sometimes published at Clapham. Thus we observe one in this shape on "The Oldest Inhabitant." Another has been separately published, titled "Beating the Bounds," on the not merely locally interesting subject of Clapham Common.

In reference to the late strike of the London building trade, and to a lecture titled "An Outsider's Views of Strikes and Documents" which was delivered at the Clapham Institution, a correspondence took place between "the Clapham local committee for opposing the Document," and the Rev. Mr. H. Whitehead, in which the latter, who had been invited, but declined, to co-operate with this committee, says—

"We ought not to shrink from discussing such social phenomena, and from endeavouring to ascertain the laws which produce them. My own opinion is, that the particular phenomenon in question are but two of the many pernicious results of the fatal policy with which men now-a-days are compelled and content to think in masses. Commemorative views and commonplace outward measures inevitably ensue. Men who can think out a sound principle get no chance of a hearing. Hence short-sighted 'strikes' and short-sighted 'documents'! There rise to the surface, alike among men and masters, those who are incapable of calculating aught which will be the consequences of the measures they recommend. It is not my business to judge between them; but it is my business—and I trust it is my constant practice at all times and not merely when a dead-lock comes about—to encourage men to think for themselves and to be true to their own individuality and independence of thought and character. A much freer development of individuality of thought than is now prevalent is required to deliver us from 'strikes' and 'documents.'"

#### Miscellaneous.

NATIONAL GALLERY TRUSTEES.—A return recently made, on the notice of Mr. Coningham, shows that the trustees of the National Gallery have met ten times during the present year.

COST OF PUBLIC INSTITUTIONS.—In the evidence given before the South Kensington Museum Committee, it is stated that, taking the cost of various institutions and exhibitions for 1859, and dividing it by the number of persons who visited them, it is found that in the case of the British Museum the cost was 3s. 2d. for each visitor; at the South Kensington Museum, 1s. 3d.; at the Crystal Palace, 1s. 3d. The senior trustee of Sir John Soane's Museum in Lincoln's-inn-fields acknowledged that the expense of keeping it open is actually 10s. for each person who visits it.

**THE MERCAT CROSS OF EDINBURGH.**—A new stone has been laid at the Market-cross, High-street, to mark the site of the ancient cross of Edinburgh. While the street was being laid out, the excavations were carefully watched by gentlemen who have since given a certificate to the effect that nothing in the shape of coins or other deposits were found under the key-stone of the cross. The excavations were carried to the extent of 5 feet in depth, in order to ascertain whether any such deposits had been made. The cross itself was removed, about one hundred years ago, to a park on the Drum estate, and twelve years since a petition to the authorities to restore it was refused. The High-street is at present under repair.

**THE ENLARGEMENT AND DIMINUTION OF ENGRAVINGS AND LETTER-PRESS.**—We some weeks since gave an account of what was shown of the process for enlarging and diminishing engravings at "The Electro-printing Company's," in Burleigh-street, Strand. Our contemporary, *Once a Week*, in its number of Saturday, the 25th August, gives an interesting and illustrated account of this very useful invention, in which the following particulars are further stated as to a part of the various processes not exhibited on the occasion to which we allude. "If the picture has to be worked with type, the enlarged impression has, of course, to be made from block plates, the printing lines of which stand up like those of a wood-cut. This is accomplished by printing the picture with prepared ink upon a metal plate: the plate is then subjected to voltaic action, which eats away the metal, except those parts protected by the ink."

**RUGBY WATER SUPPLY AND SEWAGE.**—The artesian well which was begun in 1857, on Mr. Hawkesly's recommendation, is still in progress, but no water has been reached. A shaft, 50 feet deep, was first sunk, and then the boring commenced. The depth now reached is 1,023 feet. The bore has gone through 545 feet of red clay, and it is the engineer's opinion that water will be found so soon as the red clay is entirely penetrated, but the question when that may be, or how many more feet must first be gone through, seems to be a puzzle. The present cost of sinking the well and bore-holes is set down at 2,500*l.* As yet 200 feet of the bore have to be cased with iron piping. Meantime the work has been suspended, and intimation given that this has been done.—At a recent meeting of the Rugby Board of Health Mr. Edmunds read a report respecting the filtering of the sewage outlet, from which it appeared he had paid a visit, in company with the surveyor, to Ashby-de-la-Zouch, and that they there found the means employed more simple and much more effective than the process at Rugby. The surveyor had calculated that there would not be less than 100,000 gallons of sewage per day in excess after Mr. Walker had used all he could. The chairman said he approved of the way in which the sewage was filtered at Coventry. Mr. Edmunds said if lime was used in filtering, the ammonia would leave the sewage, and render it useless as a manure, and that Mr. Walker pumped, by means of steam, not less than 160,000 gallons daily. Mr. Edmunds said at Ashby-de-la-Zouch the deaths had decreased from 30 to 4 per cent. since the construction of the sewage works.

**FARM IN UPSALL, YORKSHIRE.**—At Upsall, near Thirsk, a farmstead is being erected by Captain Turton, from the designs of Messrs. Hatfield & Goldie. The north front will be seen from a projected mansion. The style of architecture is the Early Gothic. The stone for the most part is local, interspersed with some Whithy stone, brought from the private quarries of Captain Turton, in that district. A belfry ornaments the centre, with a tower to the east, which has a pyramidal capping, supported by columns of calcareous stone (the same as St. Mary's Abbey, York), which contrasts with the yellow iron-veined sandstone of the rest of the buildings. Muir's ventilators are introduced, as well as Richmond & Chandler's steaming apparatus. The site is charming, commanding views along the vale of Mowbray, from York Minster to the Richmond hills. Within a short distance are the remains of Upsall Castle, built by my Lord Scrope,—

"Go therefore hence,  
Poor, miserable wretches, to your death,  
The taste whereof God of his mercy give  
You patience to endure, and true repentance  
Of all your dear offences."

*Shakespeare, Henry V., act ii., s. 2.*

This Henry Lord Scrope was succeeded by his brother, Sir John le Scrope, who was summoned to Parliament as Lord Scrope of Upsall from January, 1426, to May, 1455.

**OPENING OF THE NEW IRON CHURCH AT KILBURN.**—An extensive new iron church has been opened in the Carlton-road, Kilburn, parish of Willesden. It has been erected by Messrs. Tupper & Co., of the City, under the immediate supervision of Mr. Brown, one of the firm.

**DARLINGTON MARKET COMPETITION.**—The Darlington Board of Health, at their meeting on Friday in last week, awarded the premiums for the designs sent in for the proposed covered market, as follows: "Utilitas" (no name accompanying the design), 50*l.*; Messrs. Pritchett & Son, Darlington, 30*l.*; Mr. R. B. Dixon, Darlington, 20*l.*

**THE IPSWICH SHOP-BLINDS.**—A report of shop-blinds under 7 feet, the height allowed by the Local Committee, was presented by the surveyor to the Paving and Lighting Committee, and it appeared that some were extremely low, one being but 5 feet 2 inches from the ground. The Clerk said it was quite understood that the Committee could not alter the law: the law said 8 feet, and any party who might feel aggrieved might summon the owner before the magistrates. The surveyor said that in the principal towns the law was carried out, and 8 feet was the limit. It was determined that all parties whose blinds were less than 7 feet should be proceeded against if they did not alter their blinds by the next meeting.

**AN ERUDITE CONTRACTOR.**—Amongst the replies to advertisements published by the Leek Improvement Commissioners for tenders for the execution of public sewerage works, the following epistle, dated August 20th, was received from a contractor, in the neighbourhood of Manchester. Here it is, *verbatim et literatim*:—"Tender for the Leek sewer per yard at 3 feet 3 inches as the advertisement state 2*l.* 15*s.* per yard or according to the kind of ground as it may be as I have not seen the Specification I am willing to make any agreement of price as will do the work and small sewers and others at a reduced price as one half or one third size just according to be reduced. With having seen the advertisement late I had not to send for a few lines of the specification send a few lines of the work by thursday." This accommodating document was addressed, "Mr. Hacker and Bloore law clerks public office, Leek."

**A NEW PESTILENCE.**—Reports have been received from the camp at Shorncliffe, during the last two or three months, which allude to the prevalence of a disease hitherto totally unknown to the climate of England. It is described in the *United Service Gazette* as "a disease which, although not, strictly speaking, genuine yellow fever, yet is so near akin to that fearful tropical malady as to inspire the medical authorities upon the spot with a due sense of the importance of instantly checking its incursions." The doctors, it is added, trust that, with the help of the continued cool weather and the airy position of the camp, they will soon be able to eradicate a disease for which they cannot account, and which terrifies the neighbourhood like the ancient plague. Another account says this is an exaggeration. Long ago we heard bad things of Shorncliffe.

**THE NEW STAMP DUTIES.**—The new Stamp Act (No. 2 of the late session) has been issued. The new duties are chargeable on the passing of the Act. From and after the 31st December the allowances now made on bill and receipt stamps are to cease, and a new allowance of 10*d.* in the pound is to be made. The duties on foreign promissory notes are to be denoted by adhesive stamps, or impressed stamps, and adhesive stamps or impressed stamps may be used for insurances. The duty on policies of insurance on lives for sums not exceeding 25*l.* is reduced to 3*d.* There is no duty on an insurance of workmen's tools for sums not exceeding 20*l.* The duty of 1*d.* on a delivery order is to be paid by the person requiring the order. Persons in the service of the Post-office may sell postage stamps. This provision states that "it shall be lawful for any person in the service or employment of the Post-office, without any licence or any authority other than this Act, to carry about for sale and to sell at any place or places within the United Kingdom postage stamps and printed forms of any kind, issued or used at the General Post-office, and any other matter and things relating to the business of the Post-office, and such person shall not be subject or liable to any penalty or forfeiture for so doing, anything in any Acts to the contrary notwithstanding." It is provided by the Act that if the Treasury direct that the district registrars be paid by salary, they may also direct the fees to be collected by stamps. The new duties are set forth in the schedule annexed to the Act, and it is expected that the duty on policies against accident will yield a large amount to the revenue.

**FALLING IN OF A CHAPEL AT SWANSEA.**—A portion of the front of the Primitive Methodist Chapel, now being erected in Pell-street, has fallen in, tearing away in its descent a considerable portion of the scaffolding placed at that end of the building. Fortunately the men had left work, and the wall fell inwards. The prevailing wet weather is thought to have caused the mass of brickwork to fall.

**FALL OF A HOUSE IN BOMBAY.**—The papers by the Overland Mail say that a fearful catastrophe happened on the 18th of July, by the falling of a house, burying no less than eighteen of the inmates in the ruins. It occurred at 11 o'clock at night. By the most active exertions of the officials, eighteen were taken out of the ruins in a comparatively short time. Five were dead, two all but dead, and eleven were so horribly mangled that very little hopes were entertained of their recovery.

**SURVEYORS SURVEYED.**—The Coventry Board of Health have just come to rather a novel resolution with respect to their surveyor, namely, to constitute him the successful tenderer for the reconstruction of a culvert, and to appoint "an independent surveyor" to see that the work is rightly done! One of the members of the Board (Alderman Browett) remonstrated with them on the absurdity of such a course; but it was of no use, and the Coventry Board of Health have determined to follow out their Japanese spy system, which they appear to regard as a capital idea. They only require, for their complete self-satisfaction, to appoint, as the "independent surveyor," that enterprising tailor who urged his capabilities for such an office on the ground that he was accustomed to use the tape line, and to take measurements. The precedent, in our opinion, is not only an absurd, but a dangerous one. If the Coventry Board of Health have not full confidence in their surveyor, why not dismiss him, and appoint another in his place? Their present course is precisely that of the Japanese, who appoint one "confidential" agent to act as a spy upon another agent equally "confidential." The following were the tenders sent in for the re-construction of the culvert:—

Mr. Abraham Salt.....	£267	0	0
Messrs. Hallam & Co. ....	240	0	0
Mr. Alfred Maull.....	225	0	0
Mr. James Wilson.....	198	15	0
The surveyor's estimate ..	118	4	0

**STREET TRAMWAYS.**—The horse-railway in Birkenhead, for which Mr. Train, of Boston, U.S., was the contractor, has now been opened. It extends from the Woodside Ferry, the landing-place at Birkenhead, just opposite the centre of Liverpool, by the shore-road, through Angle and Conway streets, and is so on to the entrance to Birkenhead Park. The whole distance is little more than a mile and a quarter. A junction in Conway-street enables the carriages to return from the park by Hamilton-street to the point from which they originally started. The tramway consists simply of two iron plates, each raised about an inch on the outer side. They are fixed upon longitudinal bearers, which rest upon transverse sleepers, and are so let into the street as to run completely on a level with its surface. To ply on these iron plates carriages for 50 to 60 passengers each have been built by Mr. Main, of Birkenhead. They are, of course, more than double the size of ordinary omnibuses, but are somewhat similar in shape, and are provided underneath with wheels like those of a railway carriage, but somewhat smaller in size. Each carriage is 24 feet long by 7 feet wide; 7 feet being also the height of the interior from floor to roof. It furnishes sitting room for 24 persons inside, and for as many more outside, for whose protection a handrail runs round the top. A space of two or three feet intervenes between the passengers on each side of the interior. A small platform at each end, raised about a foot and a half from the ground, and separated from the horses, which may be yoked to either end, affords the means of ingress and egress. The carriages are fitted up in rather a gaudy style. For ventilation, each has its sliding windows, with "louvers" to prevent a draught. An idea seems to be entertained that such a tramway and its adjuncts are unprecedented in Europe; but, for some years, the very same sort of conveyance (which, by the bye, we have for many years advocated, for London and other towns, in the *Builder*) has existed in Paris. There are also tramways (of granite) even in the streets of London, the last of which were laid along new Westminster Bridge; but large omnibuses specially adapted to run along such tramways—and, indeed, tramways specially adapted for such omnibuses, have not yet existed in London.

**STREAM-HAMMERS.**—Messrs. Hewitson & Walker, of Leeds, have patented some improvements in steam-hammers. They propose to apply a lever in such a manner that one end thereof is attached to or near the hammer, so that that end of the lever moves to and fro with the hammer; and by its other end the lever, through the intervention of tappets, levers, rods, or other suitable gearing, gives motion to the valve.

**THE OPEN SEWER IN BATTERSEA PARK.**—Whether in consequence of what was said in the *Builder* recently on this subject or not, we cannot say, but we are glad to observe that the Chief Commissioner of Works has written to the Metropolitan Board, requesting them to order the deodorization of the sewage running through the park, and further requesting that the sewer may be diverted.

**IMPROVEMENTS NEAR VICTORIA PARK.**—For some time past there has been a desire on the part of the inhabitants of the parish of Linchouse to be able to have access to Victoria Park. An intimation to that effect having been forwarded to the Metropolitan Board of Works, measures have been taken to carry out that object, and, in order to effect it, a number of houses on the line of road leading from Linchouse to the Park have been sold, and are to be removed in order to form a convenient communication between the Park and Linchouse.

**PROPOSED STREET FROM SOUTHWARK TO BLACKFRIARS ROAD.**—A large number of houses situate in Gravel-lane, Christchurch, and Blackfriars-road, have been sold, in compliance with directions from the Metropolitan Board of Works, and are to be taken down and cleared away for the purpose of the formation of the new street from Southwark to Blackfriars-bridge-road. The Board, it is said, have entered into arrangements with nearly all the owners and occupiers of property throughout the distance.

**TRAFFIC RETURNS.**—The traffic returns of railways in the United Kingdom for the week ending August 18th amounted to 584,585*l.*, and for the corresponding week of the last year to 546,285*l.*, showing an increase of 38,700*l.* The gross receipts of the eight railways having their termini in the metropolis amounted to 255,626*l.*, and for the corresponding period of last year to 240,861*l.*, showing an increase of 14,865*l.* The receipts on the other lines in the United Kingdom amounted to the sum of 329,359*l.*, and for the corresponding week of last year to 305,424*l.*, showing an increase of 23,935*l.*

**REST FOR THE WEARY.**—A seat for tired pedestrians has been conveniently placed within a railed space in front of St. George's Hospital, Knights-bridge, and is made good use of. A few years ago, when we first noted the desirability of providing such seats in towns and their suburbs, the idea was laughed at. Gradually, however, it is making progress. The drinking-fountain at St. George's Hospital, close to the seat in question, is greatly used. We pass it several times a day, and never do so without seeing a drinker or two indulging. The flow here appears to be properly arranged, so that there is no sloppy mess around it. Some of the drinking-fountains, through inattention in this particular, have become a nuisance.

**MONTMENTAL.**—The statue of Dr. Isaac Watts, at Southampton, his native town, has been commenced. It will be erected in the public park in July next, on the anniversary of his birth. The statue and basso-relievos will be of Sicilian marbles, and the pedestal polished Aberdeen grey granite. The total height will be nearly 20 feet. The sculptor is Mr. Lucas, of Chilworth, near Romsey.—A monument to Samuel Crompton, the inventor of the spinning mule, has been resolved upon at Bolton. The movement began with working men. A committee has been appointed, and Mr. R. Heywood has promised 50*l.* It is stated that a bronze statue would cost 1,500*l.*; but there is talk of an educational charity for factory workers.—A piece of sculpture has just been erected on the wall of the north aisle of Glasgow Cathedral, opposite the south entrance, to the memory of the officers and men of the 93rd Highlanders who fell in the Crimea. The memorial has been erected by the regiment, and was designed and executed by Mr. John Steel, R.S.A., Edinburgh, sculptor to her Majesty for Scotland. One of the 93rd Highlanders—the standard-bearer of the regiment—who has received a fatal stroke from the hand of the enemy, is represented as being supported by the goddess Fame. The material is fine white marble. Various designs by sculptors of London were received, but Mr. Steel's was adopted. The colours which the regiment had in the Crimea are to be placed on each side of the monument.

**SELF-MOVING VELOCIPEDES AND CABS.**—We have occasionally pointed attention to the possibility of applying some simple mechanical or other power to the movement of small carriages, such as velocipedes, bath chairs, cabs, &c. Our idea, it appears, is being carried out at Paris, according to the *Star*, which states that "a carriage, propelled by neither steam nor gas, but by the simplest screw imaginable, has recently been beheld for the first time in the streets of Paris, going with such amazing swiftness as to leave far behind the four-in-hand carriages of the Jockey Club, which endeavoured in vain to keep up with it. The inventor is said to be a poor man, who has constructed the vehicle entirely himself."

**THE TAPPING OF THE GANGES.**—"The long-hoped-for, long-wished-for, long-expected, and long-deferred event, of tapping the Ganges at Rajmehal," says the *Engineers' Journal* of Calcutta, "has at last been accomplished. The 4th of July, the anniversary of the declaration of American independence, will be for ever a memorable day in the annals of Indian railway enterprises. On that day the railway was completed from Calcutta to Rajmehal; the rich, fertile, and expansive alluvial plains of the Gangetic valley were placed in direct communication with the great seaport of Eastern India; and the commencement of a new and most brilliantly promising epoch in India's history was inaugurated as the last tremor was well driven home." One of the first runs on the line was that of a party of officials who went from Rajmehal to Calcutta in about four hours, or at the rate of twenty miles an hour, so that the line is in working order throughout. Mr. Turnbull, with Mr. Vigors and Mr. Denham (two district engineers), and other officers of the line, were present at the opening.

**LICHFIELD CATHEDRAL.**—The dean and chapter of Lichfield Cathedral have issued a second report on the restorations now in progress. The sum required for proposed additional works will not be less than 3,000*l.*, together with the ordinary fabric fund. The following estimated sums are still required to complete the choir:—Reredos, 1,600*l.*; to 1,800*l.*; sedilia and canopies, 300*l.*; screen opposite sedilia, 150*l.*; four screens and gates east of stalls, 560*l.*; steps to the communion-table, marble, and encaustic tiles, 60*l.* A proposal has been issued to raise the money for the pavement east of the stalls and below the steps, 270*l.*; pavement between stalls, 147*l.*; pulpit (a movable one), 100*l.*; faldstool, 75*l.*; oak benches for nave and transept (say forty in number, at about 6*l.* each), 240*l.*; remainder of gas fittings for lantern and nave, 200*l.*—by contributions from those numerous parishes the church, school, or parsonage of which has been in some way benefitted through the liberality of the late Mr. Herbert Minton.

**NEWS FROM HAYTI.**—The editor of the *Progress*, of Port-au-Prince, Hayti, says that the elements of great prosperity and high civilization abound in Hayti; that it possesses mines of different kinds, and of surprising qualities. The government of Hayti, continues he, has caused two coal mines to be examined: they are found to be of vast extent, and of a very superior quality. One of these is situated twenty-one miles from the town of Cayes. The coal might easily be transported from the mines to the town of Cayes by means of a railroad. It is the intention of the government of that island to invite foreign companies to work these mines. An iron mine has also been examined. This is found near the town of Anse-a-Year, close by the sea. The quality of the iron is identical with that from Sweden.

**PUBLIC EXHIBITIONS.**—The following table of the number of visitors at various public institutions and gardens shows the extent to which each proves attractive. The first time may be considered as in town, and the remainder as out of town; but in December last the Vernon gallery was removed from Marlborough House to South Kensington, and above 50,000 of the visitors to that gallery in 1859 went to it in that month, after its removal. The Great Exhibition year is given to show its unprecedented numbers:—

	1851.	1857.	1858.	1859.
British Museum ..	2,527,216	621,034	519,565	517,895
National Gallery ..	1,065,705	610,850	553,706	789,401

Science and Art Museum ..	—	284,943	456,288	475,263

**THE GODWIN SANDS: FLOATING SHIPWRECK ASYLUM.**—Rear-Admiral J. N. Taylor, C.B., has invented a floating apparatus for the rescue of the shipwrecked on the Godwin Sands. It consists of an open-framework of timbers, 160 feet long by 36 feet beam, moored by chains, piles, and anchors, and furnished with life-boats, and other requisite means for the preservation of life, together with a cabin for the life-preserving crew, saloons for the shipwrecked, and other requisites. It is proposed to be moored at the edge of the Sands. For forming harbours, a sufficient number of sections are to be placed in a continuous line, the intervals being filled up by a double line or chain-netting. Models are to be seen at the United Service Institution, Whitehall.

**TENDERS**

For the erection of a boundary and retaining wall on the Millbrooks Estate, borough of Plymouth:—

Foot .....	£340 0 0
Blight .....	319 0 0
Hammill & Stephens ..	215 0 0
Clarke .....	299 10 0

For a house at Sawbridge-worth for Wm. Barnard, Esq. Mr. G. Perry, architect. Quantities supplied:—

Markwell .....	£837 10 0
Ball .....	814 0 0
Glascock .....	770 0 0
Dickinson .....	759 15 0
Barton .....	278 0 0
Nicholls (accepted) ..	745 0 0

For building a villa at Wimbledon. Mr. W. A. Bulnois, architect:—

Smith .....	£3,577 0 0
Elliott .....	3,575 0 0
Lucas .....	3,465 0 0
Aviss & Co. .....	3,418 0 0
Holland .....	3,360 0 0
Myers .....	3,245 0 0
Longmire & Burge ..	3,198 5 0
Macey .....	3,141 0 0
Adams & Sons .....	2,911 0 0
Evans, Brothers .....	2,773 15 0

For 3,750 feet of 18-inch and 24-inch pipe sewer for the Commissioners of Pavement, Canterbury. Mr. Collard, surveyor:—

Capon .....	£2,002 15 0
Porter .....	1,678 15 0
Vincent .....	1,676 7 6
Gaskin & Golden ..	1,336 11 8
Garrett .....	1,299 0 0
Stratton (accepted) ..	1,153 5 10
Potter & Love .....	1,074 17 6

For Independent Schools, High-road Well, near Halifax. Messrs. J. E. & J. D. Gates, architects. Quantities supplied by the architect:—

The whole, exclusive of Smith's Work and Heating Apparatus.	
Ambler & Taylor .....	£579 0 0
Charnock & Booth .....	674 0 0
Webb .....	654 0 0
Walton & Dilworth ..	615 5 0
Wals & Sons .....	614 10 0
<i>Masonry.</i>	
Mausley & Turner ..	365 0 0
Greenwood & Wormald	320 0 0
Gledhill & Turner ..	319 6 6
Tully .....	312 10 0
Webb .....	319 0 0
Gates .....	297 0 0
Wals & Sons .....	291 10 0
<i>Wood Work.</i>

Handyside & Co ..	837 15 0					
Haywood .....	813 0 0					
Cliff .....	784 13 0					

\* The Committee recommend the Corporation to accept these tenders.

# The Builder.

VOL. XVIII.—No. 919.

*Strolls in London with a Purpose: The City Road: Needle-women.*

It would need a long life, completely devoted, to acquire more than a very superficial knowledge of the varied features of this vast metropolis. Look at the labyrinth of streets, roads, and lanes, filled with a dense population, getting their living somehow, going continuously from youth to manhood, and from manhood to the grave; and consider how little of all this is known to the generality of those who form part of the remarkable whole. Many of the districts have a character of their own, and all give matter for thought to reflective wanderers. The spot to which accident has led us in the City-road, a triangle bounded on one side by that great thoroughfare, by East-road, Murray-street, and Edward-street, leading up to

Wharf-road, including the Eagle Tavern, is but a small patch, but it is covered with buildings, densely inhabited, and shows a peculiar style of dwelling, which, in consequence of decay and the awakened spirit of improvement, is fast disappearing. The City-road, although lined with buildings that are irregular and without heauty, is picturesque and striking. Trees are struggling in the front gardens of public houses, while in what were the fore-courts of other residences are shed-like shops, occupied by photographers, pigeon-dealers, bird-cage makers, and the pursuers of their unsettled occupations. In one garden are huge iron boilers, while others have become stone-yards and carriage depôts. Shoe-blacks (shining result of modern philanthropy), blind musicians and readers, and other wanderers, throng the pathway, attracting attention in their various ways. Here is an unfortunate mechanic, who has lost a limb by machinery; his case is painted on a large canvas, which is unrolled to view. It shows the accident, the conveyance of the sufferer to the hospital, a medical operation, the sick ward, and other scenes. There are others who also employ art for the purpose of exciting the charity of the passengers: shipwrecks, fires, and coal-pit explosions are shown in a peculiar style. Heavily-laden omnibuses, cabs, and other carriages, roll thickly along, ploughing up the macadamized roadway, and making such furrows as to suggest the desirability of tramways forthwith.

Walking along Mount-row—a short cut, which in the morning and evening is thronged with well-dressed wayfarers, proceeding to and from business—we come to Winckworth-buildings, on which is the date 1766, at about which time many of the dwellings here were built. Long streets of small two-story houses run in various directions, some in irregular lines; others, of a more modern build, are on a regular plan, the streets running at right angles; and it is worthy of remark, and very fortunate, that the chief thoroughfares are wide and of great length. There are, however, some narrow passages, in which the corresponding amount of sickness is to be met with.

It is understood that the neighbourhood is generally well drained and tolerably healthy. This may partly be attributed to the gravelly soil. Moneyer-street, Union-street, Cross-street, and some other parts must, however, be excepted, and steps should be taken to get rid of the cesspools which are

there to be met with. There are in Hoxton persons who think that the District Board are not sufficiently active in this and some other matters connected with the public health. Most of the rooms in the houses are very small, and many of them overcrowded with families. Here the usual complaint is made of the want of cleanliness and sanitary knowledge. One visitor, who is much engaged amongst the poor, complains of the difficulty there is in getting them to attend to matters which are actually for the benefit of their families, and may save life and health. Some think themselves insulted if suggestions be made to them. As an instance of the need there is for diffusing knowledge of the means by which life may be preserved, it may be mentioned that a decent-looking woman lately hurried to a surgeon in this neighbourhood and stated that her child was in convulsions. He gave her some medicine, and told her to put the child into a hot bath. Some hours afterwards she came back to say that the child was still in fits. On this the surgeon, surprised to hear that the child had been so long in such a state, went at once to see what was the matter, and found her standing in a pail, naked, in the draught of two doors, with her feet in about three inches of water! Such an occurrence and a hundred others that might be mentioned show, as we have often urged, the great need which exists for making the general laws of health a part of education in our national and other schools. It is difficult to deal with the adults of the present generation, but we may work usefully on those who are rising. The Ragged Schools and Reformatories are proving their usefulness. These are checking juvenile crime, which, in a large majority of cases, is the result of the want of right employment, or the chance of doing well. Reared in poverty and under miserable conditions, accustomed from the earliest years to neglect and the worst kinds of vice, thousands have been made into dangerous and expensive criminals with little will of their own. In a marked way Ragged Schools are improving the children in some of the worst parts of the metropolis. Boys and girls, who were formerly in the most deplorable state, may now be seen cleanly dressed, practising orderly habits, and looking hopefully to the future. Some are put into the way of going to sea, and others recommended to situations, where, instead of being in misery and disgrace, they are made comfortable themselves and useful to others. These schools, in which earnest men and women devotedly labour, are hidden in back slums from the view of the more prosperous classes of the community. It is most important, however, that they should be visited, and that all should in their various ways assist in supporting them and extending their usefulness.

In connection with many of the Ragged Schools there is a voluntary Reformatory and School of Industry, where, according to the extent of the means available, boys are sheltered, fed, and provided not only with book knowledge, but are taught by the labour of their hands to earn an independent livelihood. Many of the boys who have (to them) the great privilege of occupying these homes, were found in a state of destitution; others either had committed, or were on the brink of crime; some, the children of respectable parents, had become so spoiled by associates, that it was necessary, to prevent further contamination to the family, to remove them to where they could be kept under proper control: for the support of such children the parents contribute according to their means. During the stroll of which we have been speaking, we heard of one case worth mentioning. It was of a widow left with six children, whom she managed with difficulty to support by her labour. The oldest boy, twelve years of age, had fallen amongst had companions, and had been persuaded to commit a trifling act of theft. Whenever he went into the street, the older boys persuaded him to do worse; causing him to commit acts which they, being well known by the police, were unable to execute. This boy was on the highway to ruin, when a person who had influence with a Ragged School obtained admittance to it for him.

Since then the lad has been educated, fitted for and apprenticed to the sea; and it was but the other day that he, on returning from a voyage, was able to assist and comfort his mother. But for the Ragged School and Reformatory, this boy would not only have been lost to good himself, but would probably have led his brothers into the same road.

The cost of crime in Great Britain, and its evil results, are enormous. The statistics which prove that since the introduction of those schools and reformatories, the convictions for illegal offences amongst the young have declined at the rate of from 25 to 30 per cent., ought to obtain for them increased aid. It has been shown that the teaching of these institutions is more useful than that of the prison, the hulks, or the langman.

Opposite Winckworth-buildings there is a tall and singular-looking building, of considerable size, of massive brickwork. Many of the windows are very small, and present the appearance of the port-holes of a man-of-war. This is now let in tenements; but was originally erected for a workhouse. In some parts around, the houses have a squalid appearance: none more so than Mount-pleasant, Northward, beyond Murray-street, houses of a better and larger description have sprung up, which gain by the contrast. The vast assemblage of streets and squares of houses of a good class which stretch quite to Kingsland, and almost to Dalston and Newington, have grown up like mushrooms. Little more than twenty years ago Murray-street abutted upon the fields. Since then London has stretched upwards of two miles in that direction. The increase of the population of Hoxton and the adjoining districts has been immense.

In the group of houses under notice it should be mentioned that although the streets are wide, and health better than in Agartown and some other places which might be pointed to, there seems to be plenty of employment for undertakers, some of whom display paintings of cemeteries and stately processions. One exhibits a large picture of his horses and stables. Great rivalry seems to exist in this solemn business, and advertisements are made so agreeable that one might be induced to look upon a funeral as a somewhat pleasant occurrence.

The sweeping of the streets here is for the most part badly attended to. Those whose duty it is to supervise this neighbourhood should not be content with looking at the front of premises. Near the Eagle Tavern there are some shops of a better description. Some of them are occupied by those who deal largely amongst the poor on the tally system. Not far off is a curious mart for dogs. Here, in kennels fashioned somewhat in the style of Jaques the First's reign, are dogs of many descriptions, and in front of the house is a large sign, on which are shown all the varieties of the species. Sheds for drying skins and some other matters near the back of the Eagle Tavern, with its accompanying theatre, the Grecian Saloon, are objectionable, and cannot add to the healthfulness of that place of resort. On the evening in question hundreds were flocking into it to witness "The Pirate's Love, or Ocean Birds of Prey," and other highly-spiced entertainments.

Already the hand of improvement is busy with the houses round about, and before long buildings of a better class will probably be raised in their place.

In a shop not far from Nile-street, which was literally filled with stalls and "Buy, buy, huyers," a number of poor women were waiting, probably to be paid. It is said that there are in the metropolis more than 30,000 women who earn a miserable income by the various departments of needlework. Their condition remains a sad one. Competition in trade, the large number who seek this kind of work, and other causes, make the value of it so small, that it will be a mercy when it is superseded, and this large body of women, instead of trusting to such an insufficient dependency as this is, are led to look in other directions for employment.

The large users of needlework, the makers of soldiers' and other rough clothing, in many instances carry out a system which is con-

stantly pressing upon the very poorest. They give out their work to a certain limited number of persons who are able to find security for the materials. These persons are every now and then underworking each other. Having undertaken a certain amount of work, to be completed in a given time, and at the lowest cost, these sub-contractors look around for assistance, and perhaps each distributes the materials to seven, eight, or more persons, who are in a less prosperous condition than themselves, but who are "good" for the value entrusted to them. These again often divide the work. Each process must, of course, be attended with profit, and so does this system work that the sum which comes to the actual sewer, the poorest of the whole, is not sufficient to procure the commonest necessaries of life.

In Whitechapel and other eastern districts women may be met with who have been well brought up and in comfortable circumstances, and who, by the incessant labour of from sixteen to seventeen hours a-day, can with difficulty earn in the week 3s. 6d. Even this miserable remuneration is declining, and there is a difficulty in getting regular work. This, in some measure, may be attributed to the use of the sewing machine, not only in the houses of the rich and middle classes, but also of the large manufacturing clothiers, and amongst the sub-contractors to whom we have referred. Sewing machines have been so much brought into use, that either the work of the poorer persons at home is reduced in value, or is altogether dispensed with.

We have from time to time noted the terrible sufferings, the temptations and troubles, which beset those who have no reliance but on this kind of work. Such is their hopeless condition, that we cannot help whispering a belief that, though the immediate distress would be much, it would be an advantage if the needle and thread were altogether superseded, and placed in the Brompton Museum with the flint-and-steel tinder-box, the old-fashioned spinning-wheel, and other curiosities.

During the past few years, most praiseworthy efforts have been made to better the condition of needlewomen; and we believe that, in large and important millinery establishments in the fashionable quarters, improved arrangements prevail. Homes to which we have directed attention have been opened for the use of young women engaged at those places; and lately an institution has been established in Lamb's Conduit-street, for the same class. One of its chief objects seems to be an endeavour to provide work without the loss of profits consequent on the middle people to whom we have alluded. It is mentioned that, in connection with most establishments, unless a woman can deposit sums of from 10s. to 1l. and upwards, they cannot be provided with work. It is proposed, in order to prevent the institution from being entirely of a charitable nature, that those who wish to avail themselves of the advantages of the institution in providing work without the loss of the grinding profits mentioned, should pay towards the support of the establishment a small percentage on the sums earned. It is a matter of both surprise and sorrow to notice how slowly such means as these are appreciated by the classes it is wished to serve. The proper development of women is one of the most urgent and important social problems of the time. The question needs to be looked at, not from a prejudiced or an old-world point of view, but with thoughts of the changed conditions of society, and the marvellous discoveries and improvements which have been made. The electric telegraph is weekly extending employment to educated and respectable females. The increase of the national schools, not only in this country, but in the colonies, opens out a source of income to those who are fitted to instruct. When we have met in dismal dens women of superior ability in great poverty, we have thought of the great need there is for intelligent nurses for the sick, and that they might thus usefully employ themselves. In houses of the middle classes it is particularly desirable that "Mrs. Gamp" should be superseded by women of a different stamp; and much good would be done if arrangements

could be made on an extensive scale, so that females might undergo an examination as to their fitness for nursing, not only the sick, but young children. Females with diplomas of ability in this respect and certificates of character would be much sought after and well paid. Removing the pressure from other kinds of employment would improve the condition of those remaining.

Poor woman! poor woman! And yet, as our greatest female poet says—

\* Be satisfied.  
Something thou hast to bear through womanhood—  
Fecund suffering answering to the sin,  
Some pang laid down for each new human life;  
Some weariness in guarding such a life,  
Some coldness from the guarded. But thy love  
Shall chant its own healings  
After its own life working. A child's kiss  
Set on thy sighing lips shall make thee glad;  
A poor man served by thee shall make thee rich;  
A sick man helped by thee shall make thee strong.\*

Our triangle of houses has more than three sides, and offers many points of view, but we may not now look farther.

#### HISTORY AND CONSTRUCTION OF THE PIANOFORTE.\*

At length the time had arrived, when, by a discovery of inestimable value, the dominant defect of the harpsichord and its precursors was to be removed, and a new era opened in the annals, not only of all musical instruments of that most prolific class, but of music itself, as connected in its development with one of the most mighty vehicles ever devised for its expression—the pianoforte.

The simultaneous advancement of art in general with mechanical science is so evident that we need scarcely insist upon it; but in the case of music the rule seems more than usually perceptible, and we see at once that though the genius of Beethoven, or Mozart, or Weher, or Mendelssohn, would have burst through the trammels of the most primitive specimen of the offspring of the key-board, yet many of the masterpieces they have bequeathed to us would never have been written, but for the means afforded us to execute them by the magnificent triumph of mechanism presented to us in the pianoforte.

The discovery of the great principle that distinguished the pianoforte from all instruments of the same class that had preceded it, was made almost simultaneously by three foreigners—Marius, a Frenchman; Schröter, a German; and Bartolommeo Cristofali, an Italian. The claims of a Frenchman would naturally be the first recognised by a Frenchman, in accordance with time-honoured custom, and accordingly, M. Féris, by the way, a Belgian, in his "Sketch of the History of the Pianoforte and of Pianists," before alluded to, gives the priority of claim to the Frenchman, and states that he submitted his invention to the *Académie des Sciences*, in 1716, whilst Schröter did not complete his till 1717, and Cristofali not till 1718. Again, in his treatise entitled "La Musique mise à la Porte de tout le Monde," he says:—"As early as 1816, a manufacturer at Paris, by the name of Marius, had presented to the Academy of Sciences, for their examination, two harpsichords, in which he had substituted little hammers for the strips of wood used to strike the strings. Two years afterwards Cristoforo, a Florentine, improved upon this invention, and made the first piano, which has served as a model for those which have since been made."

Dr. Burney, in "Rees's Cyclopedia," says, "There is a minute account of the invention, and a description of the pianoforte in the 'Giornale d'Italia,' printed at Florence, 1711. This instrument was invented at Florence, by Bartolommeo Cristofali, harpsichord maker, a native of Padua, in the service of the Grand Duke of Tuscany." To the same effect are statements in the "Oxford Encyclopædia," "Wilkes's Cyclopedia," and the "Encyclopædia Britannica," &c.

The claims of Cristofali might, nevertheless, have been superseded, and his very name forgotten, but for a curious account of his invention in the *Giornale de Letterati d'Italia*, Venice, 1811, written by the celebrated Scipione Maffei, under the significant title of "New Invention of a Harpsichord, with the piano and the forte; also some Remarks upon Musical Instruments." This interesting article, which is printed by Dr. Rimbault, in the original Italian, entire, accompanied with an English translation, gives so clear and detailed an account of the substitution of hammers for jacks, with the mechanism of working

them, and all the other novelties of this improved instrument, that the claims of Cristofali to priority of invention can scarcely again be called in question.

It is singular that the same idea should have struck both Marius and Schröter, a few years later, and without the slightest suspicion of collusion with Cristofali, or with each other; but so it was. Engraved plans and descriptions of Marius's "Clavecins à Mallets," were published in the *Recueil des Instrumens et Machines approuvées par l'Académie Royale des Sciences*, 1716. These inventions of Marius displayed great ability. They consisted of four instruments, one in the form of the common harpsichord; another with a mechanical contrivance above the strings; the third, vertical; and the fourth wherein both jacks and hammers were used. The first differed from the obichord only in this, that each tone of the instrument was furnished with three strings, and that the hammers, the weight of which restored the key to its position after the key had been struck, were faced with leather for the purpose of softening the tone. As for the rest, the hammer, which stood perpendicularly upon the key, was carried directly to the string by the key itself, without any intermediary aid, and without an escape movement. In the second instrument, he approached still nearer to the desired result, by arranging the hammers in such a manner that they swung in a kind of stirrup. By this means they were independent of the keys, which, meeting them in their course, impelled them against the string; and the hammer fell after striking the string, even though the performer kept his finger upon the key. By different combinations, Marius had rendered his mechanism fit to be placed either above or below the strings. His third *Clavecin à mallets* was a verticle one, in which the key impelled a rod, furnished with the hammer, directly upon the string. His last invention, as we have stated, united the two principles of the jack and the hammer.

The remaining claimant to the invention is Christopher Gottlieb Schröter, born at Hohenstein, in 1699. In a letter, dated 1738, printed in Mizler's "Musikalische Bibliothek," Leipsic, 1752, he thus alludes to his invention:—"Indeed, some of these artists, who for several years have understood one of my inventions, have given it out as their own. In 1717, I constructed at Dresden, after much consideration, the model of a new clavier with hammers, partly with, partly without springs, upon which one at pleasure might play loudly or softly."

In explanation of this invention Dr. Rimbault observes:—"According to Professor Fischoff, the mechanism was simple. The hammer consisted of a lever about 3½ inches in length, moving on a pivot with a leather head; the lever rested near the pivot on a pin with a leather head, screwed into the further end of the finger key; and the pin was of such a length that, when the key was slowly pressed down, the face of the hammer came within about a quarter of an inch of the string; but when the key was smartly struck, the hammer by the rapid motion communicated was thrown up to give the string a blow, and, instantly recoiling, fell on the leather head of the pin, and left the string free to vibrate."

Thus were these three ingenious men, in different parts of the world, engaged simultaneously in elaborating an idea individually conceived and independently worked out, as far as we know to the contrary.

Be that as it may, the object of centuries was accomplished, the grand discovery made, and a legacy of inestimable value bequeathed to the world in the instrument distinguished by the indelicate name of the Pianoforte.

Before adverting further to the historical and constructive details contained in the work of Dr. Rimbault, we may briefly glance at the influence this world-renowned instrument has exercised upon the musical art generally. When we include in the long list of writers for and performers upon the pianoforte, the names of those great composers who united in themselves the qualifications of the greatest pianists of their period with the highest genius for musical invention that the world has ever produced, such as Handel, Haydn, Mozart, Beethoven, Weber, and Mendelssohn;—men, who not only left behind them works for that instrument which will serve as models for all ages to their successors, but works of far higher aspiration in the masterpieces which have stamped them for ever as the giants of the orchestra and the chorus; we feel how illustrious are the names that have graced its annals.

These stars of the first magnitude, however, like the lesser lights of the musical system, owed in

\* See p. 560, ante.

great degree the growth and development of their talents to the improved condition of the instrument of their predilection, and their names form time-marks in its history that will not readily obliterate. The student in musical history looks back with self-gratulation at the period, when, sustained sounds not being capable of execution on the early variety of instruments of the class, it was found necessary to supply their place by simple and double trills, and numerous similar devices, with which the works of Diruta, Squarcialupi, Gabrieli, Schmidt, Merulo, and Frescobaldi abound. Their works, like those of their many imitators of the fifteenth century, consisted mostly of *ripiamenti* of the themes of madrigals or motets, variations to French or Italian songs, and dances, more or less ornamented,—music analogous to the means of playing it. With the increased perfection of the instrument the art of playing progressed, and Frescobaldi, born in 1591, may illustrate a fresh epoch in it. This great artist was the first who wrote exclusively for the harpsichord, and, as Fétis says, may be considered as the founder of the harpsichord school; for, before his time there was no difference between the music for the clavicord, spinet, and harpsichord, and that composed for the organ. His many pupils spread his method, and the residence at Paris of one of the most distinguished of them, Froberger, much influenced the progress of the harpsichord among the French about the middle of the seventeenth century. The style of Froberger was adopted by Chambonnières, whose harpsichord pieces attest his ability. These, like all of the period, consist of allmandes, sarahands, gígues, and other dances, well laden with shakes, heats, and the like. Of the school of the latter were the elder and younger Couperin, the latter of whom, called the great, also effected much among his countrymen. Still more was effected in Italy by Scarlatti, who totally eclipsed his predecessors, and whose "Harpsichord Lessons" are a study for pianists to this day. In Germany, J. S. Bach carried the art still farther, and by his preludes, fugues, and fantasias, enlarged the domain of the instrument. Later, Mûthel and Wagenseil introduced the *sonata*, a form of piece consisting of a regulated number of movements, which gradually supplanted the *loccata*, a piece in one movement only. In France, Rameau composed the first *concerto* for the harpsichord heard in Paris, and at the same period Bach did the same in Germany, and Handel in England.

Such were a few, very few, of the celebrities who prepared the way for that race of pianists whose name is legion. Of them, in an inverse ratio to their superior claims and numbers, we must name still fewer. Nor can we stop to mention even these with regard to date, but rather in respect of school. These schools may be divided into the classical, the romantic, and the bravura, and (we smile as we write it) the school of the future! In the classical school of pianoforte writers, besides the immortal names of Mozart, Beethoven, Weber, and Mendelssohn, we may include such writers as Clementi, Cramer, Dussek, Steibelt, Woelfl, Hummel, Kalkbrenner, Schubert, and Moscheles. The name of Clementi marks a period of peculiar interest, and many of the greatest of his successors (including Beethoven himself) have acknowledged with gratitude that they owed to the works of "the father of pianoforte music" what they missed from his instruction. The romantic school is best represented by Chopin, whose original genius has provoked endless imitators, but found no rivals. The bravura school includes such names as Herz, Czerny, Thalberg, Liszt, Döhler, De Meyer, Heller, Henselt, and a host of others, who consider the surmounting of enormous difficulties a legitimate object where talent is so plentiful, but genius so scarce. The "music of the future" of Schumann, Wagner, Liszt, David, Berlioz, &c., does not come strictly within the range of our subject; but we may draw a moral from its failure, and apply it to the pianoforte as a lesson to avoid. To name the writers for the pianoforte of the present century would be difficult, to name the players impossible. Like the fruits of the dragon's tooth sown by Cadmus, they seem to spring from the ground ready armed for the contest, and like those ready-made warriors, spare no efforts to annihilate their rivals. The result, however, is, that the short space of fifty years has produced a race of players of matchless skill, simultaneously with the rapid improvement of the instrument that forms the vehicle for its display.

To return from this digression: the progress of the pianoforte on the Continent was at first but slow. Of Cristofali and Marius we hear no more, but Schröter was better appreciated by his fellow-

countrymen, and Silbermann, of Freyberg, or of Strassburg, improving upon his discoveries, is generally considered as the inventor throughout Germany; it was upon one of his pianos that J. S. Bach performed before Frederick the Great. Stein, of Augsburg, a pupil of Silbermann, settled in Paris in 1758, and became celebrated as a maker, and his pianos are the subject of repeated mention by Mozart. Streicher, son-in-law to Stein, settled in Vienna, where he formed an extensive manufactory for pianos. He died so late as 1833. Dr. Burzey, in his tour in Germany, gives many anecdotes illustrative of the progress of the instrument in that country.

In France, the discovery of Marius brought him no success, though others profited by his labours; but down to 1779, France had remained dependant on Germany and England, until the brothers Erard removed the reproach. The history of Sebastian Erard, horn at Strassburg, 1752, affords another instance of the triumph of real genius over drawbacks of birth and fortune. In the house of the Duchesse de Villeroy, at Paris, he found a home and patronage, and there he constructed his first piano. Quitting the Hôtel Rue de Bourbon, Faubourg St. Germain; which the efforts of the two brothers finally rendered one of the finest in Europe. The Revolution drove Erard to London, and there, as in London, he filled his manufactory with instruments of his own invention. In 1796 he returned to Paris, and introduced his first "horizontal grands" of the harpsichord shape. About 1808, Erard returned to London, and crowned his reputation by the invention of the double-movement harp. Finally, he succeeded in inventing a grand piano, uniting every excellence of which the instrument is susceptible. He died, near Passy, in 1831, and his funeral was attended by some of the most distinguished artists of Paris.

We can only allude to one more foreign manufacturer of importance, Ignace Pleyel, born near Vienna, in 1757. As a composer, he ranked high in times long past, but as a competitor with Haydn, he stood no chance; therefore, whilst the one is ever welcome, the other is obsolete. Nevertheless, he occupies a respectable niche in the temple of fame, and illustrates a period in the art. In 1795, he turned music publisher and manufacturer of pianofortes, at Paris. Having realised a competency, he retired to the country to enjoy it, but the revolution of July produced a fatal effect upon him, and he died in 1831.

We have evidence that the pianoforte was known in England about 1767, as it was introduced that year on the stage of Covent-garden Theatre, as "a new instrument." An old play-bill, in the possession of Messrs. Broadwood, bearing date the 16th of May, 1767, setting forth the performance of "The Beggar's Opera," contains the following notification:—"End of Act 1. Miss Brickler will sing a favourite song from Judith, accompanied by Mr. Dibdin, on a new instrument, called Pianoforte."

Backers, a German, is supposed to have been the first who manufactured the pianoforte to any considerable extent in England, and the name-board of a piano, inscribed "Americus Backers, Factor et Inventor, Jermyn-street, London, 1776," is still in existence. The manufacture was early taken up by Tschudi, Stodart, Kirkman, Zumpf, and others, and such was the rapidity of its progress, that within the short space of ten or fifteen years, the harpsichord ceased entirely to be made. A suitable style of music and school of players were not long wanting. Muzio Clementi founded both.

We now arrive at the period of the foundation of the two firms of Broadwood and Stodart, and will simply condense Dr. Rimbault's narrative of their origin.

John Broadwood, born in Scotland in 1731, when about twenty years of age, reached London in search of employment; and, entering the firm of Tschudi, the eminent harpsichord makers, became his son-in-law, partner, and successor. The earliest notice of the square form on his books is dated 1771; the earliest of the grand, 1781. This ingenious artist died in 1812, aged 81, and was succeeded by his son, James Tschudi Broadwood.

Robert Stodart, fellow-workman of John Broadwood, succeeded Americus Backers, and founded the firm of Stodart. The Patent Office books, under the date Nov. 21, 1777, contain the entry of a grant to him, "for his new invented sort of instrument, or of grand forte piano, with an octave swell, and to produce various fine tones, together or separate, at the option of the performer."

Jacob Kirkman, founder of the firm of Joseph Kirkman & Son, was succeeded by his nephew

Abraham, who was among the early improvers of the pianoforte. Harpsichords, nevertheless, were made by this house as late as 1800.

The names of other makers, and their improvements, are to be found in Dr. Rimbault's work, but we must content ourselves with one more in addition to those already cited; but it is an illustrious one.

Muzio Clementi was born at Rome in 1752, and at twelve years of age had attained such proficiency in music that a gentleman of fortune, Mr. Beckford, brought him to England to complete his studies at his expense. His great talents, however, soon made him independent of patronage, and at an early age he was considered on a par with the greatest contemporaries. Visiting the Continent, he competed with Mozart at the court of Vienna, with equal credit to both. In 1784, Cramer, then about fourteen, became his pupil. After this he again visited Paris, but returned the following year, and continued in London till 1802, enjoying the highest reputation as composer, pianist, and instructor. On the failure of Longman & Broderip, by which he lost considerably, he was induced to engage in the music-publishing and pianoforte-making business. A new firm was formed, at the head of which was his name, and from that time he ceased teaching, and devoted himself to the improvement of the instrument he himself had rendered popular. He was associated in the manufacture with Mr. F. W. Collard. Thus arose the great firm of Collard & Collard.

The pianoforte appears generally in three forms—grand, square, and upright; in the two former the strings being horizontal; in the latter vertical. The form of the grand—that of the harpsichord—is naturally suggested by the graduated length of the strings. It has three strings to each note, admits of the best kind of mechanism for the "action," and is the most advantageous in many points of view. To save expense and economise space, many modifications have been adopted: thus the *bi-chord* and *semi-grand* have but two strings, and the *boudoir* or *collage-grands* have shorter strings, and take up still less room. The oblong rectangle, commonly called the square, being the form of the German clavicord, was probably the first shape the piano assumed. It remained, however, an inferior class of instrument till the adaptation to it of the improved action of the grand, which has now distinguished it by the name of *grand-square*; and, as thus improved, it is perhaps the best substitute for the grand. The form, however, is objectionable on mechanical grounds: it is difficult to strengthen in the framing, and the oblique position of the action, with respect both to strings and keyboard, is unfavorable on many accounts to its perfection.

The upright form, so desirable for small rooms, and so superior as regards symmetry, has had several mutations in its history. The upright grand was its first phase; being no less than a grand set on end, and raised on legs 2 or 3 feet above the ground, the strings being struck at the lower end.

The cabinet soon supplanted this unwieldy instrument: a compact form, wherein the frame was brought down to the ground, the blow being given in front and at the upper end of the strings, through the medium of levers and long vertical rods from the key to the hammer. It was introduced at the early part of this century, and its elegance occasioned it a great demand. Its principal objection, however, was its height, about 6 feet, and length of action, which much deteriorated its delicacy and touch. As a remedy to these defects, a shorter and still more elegant variety was invented, introduced, about 1812, as the *harmonic*, but now called the *collage*, varying from 4 to 5 feet in height; and, in 1827, the *piccolo*, standing only 3 feet 6 inches from the ground, which has served as a model for many others of the same size under different names.

In uprights the strings are struck against their rests, which is generally considered the most favourable direction for the blow, and much simplifies the framing. Attempts have been made to apply this method to grands and squares, but it is not yet generally used.

The compass of these instruments was originally but five octaves, from F below the lowest note of the violoncello to the fifth F above it; and when, in time, the compass was extended upwards to C, making five and a half octaves, these extra notes were known as "the additional keys." Another half octave upwards to F, was next added, and subsequently half an octave downwards to C. Another note was then added in the treble, and the compass thus arrived at, from CCC (called on the organ 16-foot C) to G, six and a half

octaves above, remained the extent for some period. Six and three-quarter octaves were next obtained; then six and seven-eighths, and finally, the best grands and uprights of the present day present the magnificent compass of seven octaves, from A to A, or from G to G, an extent sufficient for any amount of display that the most insatiable excitement can require.

For the technical details of construction of the instrument we cannot say more than refer our readers to Dr. Rimban's book. The operations requisite in the four great divisions of parts that form the structure of the instrument, be its description what it may, viz., the framing,—a portion of the utmost importance, as upon its strength depends its power of resistance to the strain, which, in a grand, will amount, perhaps, to eleven or twelve tons; the *stringing*, the material and thickness of the wire, and method of securing it; the *action*, by which is meant the machinery through which the impulse of the finger is given to the string; and the *case*, which belong to the cabinet-maker's or decorative art, are there given at some length. The manufacture of pianofortes in London is a most important branch of trade, and, if the estimates contained in Mr. Pole's "Review of the Musical Instruments in the Great Industrial Exhibition of 1851" (a clever little work to which we are indebted) be correct, the produce of the London manufacture alone amounts to near a million sterling; the number of workmen employed in it are between 3,000 and 4,000; and the extent of this trade in England is three times that of France. The principle of division of labour is adopted in it to a considerable extent, and, as an illustration, we may state that a grand pianoforte passes through the hands of upwards of forty different workmen, each, with his assistants, occupied with a special branch of the manufacture.

Some observations by Mr. Pole, upon the acoustical defects of the instrument, are of value. "Notwithstanding the great intelligence and care that are brought to bear on the manufacture of pianofortes, we doubt whether the aid of science has been called in to the extent that we should wish to guide their construction. Arrangements are often seen which appear unwarranted by the principles of mechanics; and, generally speaking, the engineering of the construction is not so well studied as it ought to be. But, in the application of acoustical science, pianoforte-making is yet more behind hand. The theory of the production of tone, at least as regards its quality, is at present wrapped in mystery. Few persons seem to have any definite idea what are the essential conditions under which 'a good tone' in general, or, still less, any particular quality of tone, can be insured. A series of tentative experiments leads to certain methods of construction which are considered good; and all possible care is then taken to avoid defects in the manufacture; but the result is, after all, frequently due to some fortuitous combination of circumstances which cannot be foreseen. Hence arises the variety in the qualities of tone, not only of instruments by different makers of equally good repute, but also in those turned out from the same house, and made apparently in precisely the same manner. Nay, even in the same pianoforte it frequently happens that the practised ear can detect considerable variations; sometimes a certain portion of the scale may be far superior to the rest; sometimes a few notes, here and there, may be deficient in resonance; sometimes one note only in the same instrument may be faulty; but the reason for these anomalies it is impossible to explain."

One more observation we may make before quitting the subject. Men of intellect are beginning to turn their attention to "cheap" pianos; new and more simple actions are being invented; and we are quite willing to believe with Dr. Rimban that "the dawn of that day is visible when the 'box of stretched strings,' giving forth sweet sounds, shall be in every man's house, his comfort, his solace, his companion, ay, his friend! Let us, then, look forward to that day. Shall we not be a happier, if not a better, people?"

#### ROBERT STICKELLES, ARCHITECT.

In Milizia's "Lives of Celebrated Architects," vol. ii., p. 159, of Mrs. Cresy's translation, mention is made of one "Stickles" who "was also an excellent architect of this time" (the Elizabethan period); "and, in 1596, he constructed a galley which would take to pieces." Walpole ("Anecdotes," Wornum's edit., 1819, i. p. 185), states that "Stowe mentions one Master Stickles, an excellent architect of that time, who, in 1596, built for a trial a pinnacle that might be taken to pieces;" *Chron.* p. 769." I have not been able

hitherto to find any other authority for this laudatory notice of this member of the profession: it was, therefore, with some satisfaction, whilst lately turning over a volume of the Lansdowne MSS. in the British Museum, when making an abstract of another paper for a friend, that I observed the signature "Robert Stickelles" to two papers. The first document is in a very plain hand; the second more cramped, with a few words almost unintelligible. I send a copy of both of them, thinking they may prove acceptable to some of your readers, as illustrative of thoughts upon art during that renowned period. We must regret that he did not add the answers to his own questions.

WYATT PAPWORTH.

#### BRUGES.

All tourists who have visited Bruges have remarked, in that ancient Flemish city of precious memory, a magnificent chimney-piece of wood, marble, and alabaster, of the Renaissance, in one of the halls of the court-house, or *palais de justice*. To admire this work, the Parisians need not stir beyond the precincts of the Louvre, where there exists an exact reproduction, made by the French Government in 1838.

This hall at Bruges is called *La Salle de Franc*, the name of a canton near the town, formerly governed by a magistrate of great influence, and which became, after a lapse of time, the fourth member of the Flemish States. As long as the jurisdiction of the "Frane de Bruges" lasted, viz., until the French Revolution, this piece of sculpture remained almost unknown; and was subsequently saved from pillage by being taken to pieces, and hid in a garret of the palace of Philip the Good. Calm being established, the Government determined to restore the monument to its original condition, and they moreover succeeded in discovering the names of the statues.

Tradition, according to local guides, gives those of *Enagier Holtzman* and his daughter; but it is possible that it may be *Haltmas*, the device of Maximilian of Austria. According to the researches of M. de Hondt, it was a trophy erected to the honour of Charles Quint, in memory of his victory of Padua, and the treaties of Madrid and Cambrai. In absence of the information as to the occasion of the monument being erected, owing to a painting lately found of Jacques Van Oost le Vieux, the authorities have been able to contemplate the representation of a solemn court assembly of the Frane magistrates, wherein are depicted the decorative *ensemble* of the hall. This painting has served as a guide to the artists who were, in 1814, appointed to restore the sculptured woods and marbles of the chimney-piece. One of the decorations of this saloon consisted in a tapestry which hung all round from the councillors' benches to the cornice where the paintings commenced. It was thought at first that these hangings were of gilt leather; but, according to the archives of Bruges, they were tapestry, "*de haute lisse*." So this necessary complement to the decoration of the Frane of Bruges has at last been determined; and, only a few days ago, the new tapestry has been placed. The ancient piece—whose designs have been skilfully put together from fragments found here and there, in cellars as well as in garrets—was made at Audenarde, celebrated at that time for this work. That which is to be seen at present comes from Ingelmünster, near Courtrai. To the Comte de Montblanc, haron of Ingelmünster, is due the happy idea of reviving this branch of art, so much cultivated formerly in Flanders, and of which the secret is now lost, in Audenarde. In carrying out this idea the noble Comte also comes out with a great and good work; for, instead of making it a speculative transaction, he acts only with a view to employ the inhabitants of a commune, where work is hard to be obtained for the suffering working classes. From the hands of poor children who have been thus

collected together, initiated into the elements of an art of which they were totally ignorant, and taught the art of design, &c., spring forth the above work of tapestry—the work of the *Flemish Gobelins*. No particular subject is represented: it contains only a pattern of flowers interspersed by different animals: a charming border, of wonderful effect, completes the piece, and represents rows of Cupids astride on dolphins.

Thus the assembly-room is now restored to the same decorative style as when the Franc council sat therein in the sixteenth century.

#### THE TWO BOYHOODS,\* GIORGIONE AND TURNER.

BOY—half-way between the mountains and the sea—that young George of Castelfranco—of the Brave Castle—Stout George they called him, George of Georges, so goodly a boy he was—Giorgione.

Have you ever thought what a world his eyes opened on—fair, searching eyes of youth? What a world of mighty life, from those mountain roots to the shore;—of loveliest life, when he went down, yet so young, to the marble city—and became himself as a fiery heart to it?

A city of marble, did I say?—nay, rather a golden city, paved with emerald. For truly, every pinnacle and turret gleamed or glowed, overlaid with gold, or bossed with jasper. Beneath, the unsullied sea drew in deep breathing, to and fro, its eddies of green wave. Deep-hearted, majestic, terrible as the sea,—the men of Venice moved in sway of power and war; pure as her pillars of alabaster, stood her mothers and matrons; from foot to brow, all noble, walked her knights; the low bronzed gleaming of sea-rusted armour shot angrily under their blood-red mantle-folds. Fearless, faithful, patient, impenetrable, implacable—every word a fate—sate her senate. In hope and honour, lulled by flowing of wave around their isles of sacred sand, each with his name written and the cross graven at his side, lay her dead. A wonderful piece of world. Rather, itself a world. It lay along the face of the waters, no larger, as its captains saw it from their masts at evening, than a bar of sunset that could not pass away; but for its power, it must have seemed to them as if they were sailing in the expanse of heaven, and this a great planet, whose orient edge widened through ether. A world from which all ignoble care and petty thoughts were banished, with all the common and poor elements of life. No foulness, nor tumult, in those tremulous streets, that filled, or fell, beneath the moon; but rippled music of majestic change, or thrilling silence. No weak walls could rise above them; no low-roofed cottage, nor straw-huilt shed. Only the strength of rock, and the finished setting of stones most precious. And around them, far as the eye could reach, still the soft moving of stainless waters, proudly pure; as not the flower, so neither the thorn nor the thistle, could grow in the glancing fields. Ethereal strength of Alps, dream-like, vanishing in high procession beyond the Torcellan shore; blue islands of Paduan hills, poised in the golden west. Above, free winds and fiery clouds ranging at their will;—brightness out of the north, and balm from the south, and the stars of the evening and morning clear in the limitless light of arched heaven and circling sea.

Such was Giorgione's school—such Titian's home.

Near the south-west corner of Covent Garden, a square brick pit or well is formed by a close set of lock of houses, to the back windows of which it admits a few rays of light. Access to the bottom of it is obtained out of Maiden-lane, through a low archway and an iron gate; and if you stand long enough under the archway to accustom your eyes to the darkness, you may see on the left hand a narrow door, which formerly gave quiet access to a respectable barber's shop, of which the front window, looking into Maiden-lane, is still extant, filled, in this year (1860), with a row of bottles, connected, in some definite manner, with a brewer's business. A more fashionable neighbourhood, it is said, eighty years ago than now—never, certainly, a cheerful one—wherein a boy being born on St. George's day, 1775, began soon after to take interest in the world of Covent Garden, and put to service such spectacles of life as it afforded.

No knights to be seen there, nor, I imagine, many beautiful ladies; their costume at least disadvantageous, depending much on inconspicuity of hat and feather, and short waists; the majesty

of men founded similarly on shoebuckles and wigs;—impressive enough when Reynolds will do his best for it; but not suggestive of much ideal delight to a boy.

"Bello ovile dov'io dormii agnello," of things beautiful, besides men and women, dusty sunbeams up or down the street on summer mornings; deep-furrowed eahage-leaves at the greengrocer's; magnificence of oranges in wheelbarrows round the corner; and Thames's shore within three minutes' race.

None of these things very glorious; the best, however, that England, it seems, was then able to provide for a boy of gift; who, such as they are, loves them—never, indeed, forgets them. The short waists modify to the last his visions of Greek ideal. His foregrounds had always a succulent cluster or two of greengrocery at the corners. Enchanted oranges gleam in Covent Gardens of the Hesperides; and great ships go to pieces in order to scatter chests of them on the waves. That mist of early sunbeams in the London dawn crosses, many and many a time, the clearness of Italian air; and by Thames's shore, with its stranded barges and glidings of red sail, dearer to us than Lucerne lake or Venetian lagoon,—by Thames's shore we will die.

With such circumstance round him in youth, let us note what necessary effects followed upon the boy. I assume him to have Giorgione's sensibility (and more than Giorgione's, if that be possible) to colour and form. I tell you farther, and this fact you may receive trustfully, that his sensibility to human affection and distress was no less keen than even his sense for natural beauty—heart-sight deep as eye-sight.

Consequently, he attaches himself with the faithful child-love to everything that bears an image of the place he was born in. No matter how ugly it is,—has it anything about it like Maiden-lane, or like Thames's shore? If so, it shall be painted for their sake. Hence, to the very close of life, Turner could endure ugliness which no one else, of the same sensibility, would have borne with for an instant. Dead brick walls, blank square windows, old clothes, market-womanly types of humanity—anything fishy and waddy like Billingsgate or Hungerford Market, had great attraction for him; black barges, patched sails, and every possible condition of fog.

You will find these tolerations and affections guiding or sustaining him to the last hour of his life; the notabest of all such endurances being that of dirt. No Venetian ever draws anything foul; but Turner devoted picture after picture to the illustration of effects of dinginess, smoke, soot, dust, and dusty texture; old sides of boots, weedy roadside vegetation, dung-bills, straw-yards, and all the soilings and stains of every common labour.

And more than this, he not only could endure, but enjoyed and looked for *litter*, like Covent Garden wreck after the market. His pictures are often full of it, from side to side: their foregrounds differ from all others in the natural way that things bave of lying about in them. Even his richest vegetation, in ideal work, is confused; and he delights in shingle, *debris*, and heaps of fallen stones. The last words he ever spoke to me about a picture were in gentle exultation about his St. Gothard: "that *litter* of stones which I endeavoured to represent."

The second great result of this Covent Garden training was, understanding of and regard for the poor, whom the Venetians, we saw, despised; whom, contrarily, Turner loved, and more than loved—understood. He got no romantic sight of them, but an infallible one, as he prowled about the end of his lane, watching night effects in the wintry streets; nor sight of the poor alone, but of the poor in direct relations with the rich. He knew, in good and evil, what both classes thought of, and how they dealt with, each other.

Reynolds and Gainsborough, bred in country villages, learned there the country hoy's reverential theory of "the squire," and kept it. They painted the squire and the squire's lady as centres of the movements of the universe, to the end of their lives. But Turner perceived the younger squire in other aspects about his lane, occurring prominently in its night scenery, as a dark figure, or one of two, against the moonlight. He saw also the working of city commerce, from endless warehouse, towering over Thames, to the back shop in the lane, with its stale herrings—highly interesting these last; one of his father's best friends, whom he often afterwards visited affectionately at Bristol, being a fishmonger and giubbonier; which gives us a friendly turn of mind towards herring-fishing, wbling, Calais poissardes, and many other of our choicest subjects in after

life; all this being connected with that mysterious forest below London Bridge on one side—and, on the other, with these masses of human power and national wealth which weigh upon us, at Covent Garden here, with strange compression, and crush us into narrow Hand-court.

"That mysterious forest below London Bridge"—better for the boy than wood of pine or grove of myrtle. How he must have lamented the watermen, beseeching them to let him crouch anywhere in the bows, quiet as a log, so only that he might get floated down there among the ships, and round and round the ships, and with the ships, and under the ships, staring, and clamouring;—these the only quite beautiful things he can see in all the world, except the sky; but these, when the sun is on their sails, filling or falling, endlessly disordered by sway of tide and stress of anchorage, beautiful unspcakably; which ships also are inhabited by glorious creatures—red-faced sailors, with pipes, appearing over the gunwales, true knights, over their castle parapets—the most angelic beings in the whole compass of London world. And Trafalgar happening long before we can draw ships, we, nevertheless, coax all current stories out of the wounded sailors, do our best at present to show Nelson's funeral streaming up the Thames, and vow that Trafalgar shall have its tribute of memory some day. Which, accordingly, is accomplished—once, with all our might, for its death; twice, with all our might, for its victory; thrice, in pensive farewell to the old Temeraire, and, with it, to that order of things.

Now, this fond companying with sailors must have divided his time, it appears to me, pretty equally between Covent Garden and Wapping (allowing for incidental excursions to Chelsea on one side, and Greenwich on the other), which time he would spend pleasantly, but not magnificently, being limited in pocket-money, and leading a kind of "Poor Jack" life on the river.

In some respects, no life could be better for a lad. But it was not calculated to make his ear fine to the niceties of language, nor form his moralities on an entirely regular standard. Picking up his first scraps of vigorous English chiefly at Deified and in the markets, and his first ideas of female tenderness and beauty among nymphs of the barge and the barrow, another boy might, perhaps, have become what people usually term "vulgar." But the original make and frame of Turner's mind being not vulgar, but as nearly as possible a combination of the minds of Keats and Dante, joining capricious waywardness, and intense openness to every fine pleasure of sense, and hot defiance of formal precedent, with a quite infinite tenderness, generosity, and desire of justice and truth—this kind of mind did not become vulgar, but very tolerant of vulgarity, even fond of it in some forms; and, on the outside, visibly infected by it, deeply enough; the curious result, in its combination of elements, being to most people wholly incomprehensible. It was as if a cable had been woven of blood-crimson silk, and then tarred on the outside. People handled it, and the tar came off on their hands; red gleams were seen through the black, underneath, at the places where it had been strained. Was it ochre?—said the world—or red lead?

Schooled thus in manners, literature, and general moral principles at Chelsea and Wapping, we have finally to inquire concerning the most important point of all. We have seen the principal differences between this boy and Giorgione, as respects sight of the beautiful, understanding of poverty, of commerce, and of order of battle; then follows another cause of difference in our training—not slight,—the aspect of religion, namely, in the neighbourhood of Covent Garden. I say the aspect; for that was all the lad could judge by. Disposed, for the most part, to learn chiefly by his eyes, in this special matter he finds there is really no other way of learning. His father taught him "to lay one penny upon another." Of mother's teaching, we hear of none; of parish pastoral teaching, the reader may guess how much.

I chose Giorgione rather than Veronese to help me in carrying out this parallel; because I do not find in Giorgione's work any of the early Venetian monachist element. He seems to me to have belonged more to an abstract contemplative school. I may be wrong in this; it is no matter;—suppose it were so, and that he came down to Venice somewhat resurgent, or insentient, concerning the usual priestly doctrines of his day,—how would the Venetian religion, from an outer intellectual standing-point, have looked to him? He would have seen it to be a religion indisput-

\* From Mr. Ruskin's 5th volume of "Modern Painters."

ably powerful in human affairs; often very harmfully so; sometimes devouring widows' houses, and consuming the strongest and fairest from among the young; freezing into merciless bigotry the policy of the old; also, on the other hand, animating national courage, and raising souls, otherwise sordid, into heroism: on the whole, always a real and great power; served with daily sacrifice of gold, time, and thought; putting forth its claims, if hypocritically, at least in bold hypocrisy, not waiving any atom of them in doubt or fear; and, assuredly, in large measure, sincere, believing in itself, and believed: a godly system, moreover, in aspect; gorgeous, harmonious, mysterious—a thing which had either to be obeyed or combated, but could not be scorned. A religion towering over all the city—many-butressed—luminous in marble stateliness, as the dome of our Lady of Safety shines over the sea; many-voiced also, giving, over all the eastern seas, to the sentinel his watchword, to the soldier his war-cry; and, on the lips of all who died for Venice, shaping the whisper of death.

I suppose the boy Turner to have regarded the religion of his city also from an external intellectual standing-point.

What did he see in Maiden-lane?

Let not the reader be offended with me; I am willing to let him describe, at his own pleasure, what Turner saw there; but to me, it seems to have been this. A religion maintained occasionally, even the whole length of the lane, at point of constable's staff; but, at other times, placed under the custody of the bundle, within certain black and unstately iron railings of St. Paul's, Covent Garden. Among the wheelbarrows and over the vegetables, no perceptible dominance of religion; in the narrow, disquieted streets, none; in the tongues, deeds, daily ways of Maiden-lane, little. Some honesty, indeed, and English industry, and kindness of heart, and general idea of justice; but faith, of any national kind, shut up from one Sunday to the next, not artistically beautiful, even in those Sabbatical exhibitions; its paraphernalia being chiefly of high pews, heavy elocution, and cold grimness of behaviour.

What chiaroscuro belongs to it—(dependent mostly on candle-light).—we will, however, draw, considerably; no goodness of escutcheon, nor other respectability being omitted, and the best of their results confessed, a meek old woman and a child being let into a pew, for whom the reading by candlelight will be beneficial.\*

For the rest, this religion seems to him discreditably—discredited—not believing in itself; putting forth its authority in a cowardly way, watching how far it might be tolerated, continually shrinking, disclaiming, fencing, fencing; divided against itself, not by stormy rents, but by thin fissures, and splittings of plaster from the walls. Not to be either obeyed, or combated, by an ignorant, yet clear-sighted youth; only to be scorned. And scorned not one whit the less, though also the dome dedicated to St. Louis high over distant winding of the Thames; as St. Mark's campanile rose, for goodly landmark, over mirage of lagoon. For St. Mark ruled over life; the saints of London over death; St. Mark over St. Mark's Place, but St. Paul over St. Paul's Churchyard.

Under these influences pass away the first reflective hours of life, with such conclusion as they can reach. In consequence of a fit of illness, he was taken—I cannot ascertain in what year—to live with an aunt at Brentford; and here, I believe, received some schooling, which he seems to have snatched vigorously; getting knowledge, at least by translation, of the more picturesque classical authors, which he turned presently to use, as we shall see. Hence also, walks about Putney and Twickenham in the summer time acquainted him with the look of English meadow-ground in its restricted states of paddock and park; and with some round-headed appearances of trees, and stately entrances to houses of mark: the avenue at Bushy, and the iron gates and carved pillars of Hampton, impressing him apparently with great awe and admiration; so that in after life his little country house is—of all places in the world—at Twickenham! Of swans and reedy shores he now learns the soft motion and the green mystery, in a way not to be forgotten.

And at last fortune wills that the lad's true life shall begin; and one summer's evening, after various wonderful stage-coach experiences on the north road, which gave him a love of stage-coaches ever after, he finds himself sitting alone among

\* Liber Studiorum. "Interior of a church." It is worthy of remark that Giorgione and Titian are always delighted to have an opportunity of drawing priests. The English Church may, perhaps, accept it as matter of congratulation that this is the only instance in which Turner drew a clergyman.

the Yorkshire hills.\* For the first time, the silence of Nature round him, her freedom sealed to him, her glory opened to him. Peace at last; no roll of cart-wheel, nor mutter of sullen voices in the back shop; but earlew-cry in space of heaven, and welling of bell-toned streamlet by its shadowy rock. Freedom at last. Dead wall, dark railing, fenced field, gated garden, all passed away like the dream of a prisoner; and behold, far as foot or eye can race or range, the moor, and cloud. Loveliness at last. It is here then, among these deserted vales! Not among men. Those pale, poverty-struck, or cruel faces;—that multitudinous, marred humanity—are not the only things that God has made. Here is something He has made which no one has marred. Pride of purple rocks, and river pools of blue, and tender wilderness of glittering trees, and misty lights of evening on immeasurable hills.

Beauty, and freedom, and peace; and yet another teacher graver than these. Sound preaching at last here, in Kirkstall crypt, concerning fate and life. Here, where the dark pool reflects the chancel pillars, and the cattle lie in unhardened rest, the soft sunshine on their dappled bodies, instead of priests' vestments; their white furry hair ruffled a little, fitfully, by the evening wind, deep-scented from the meadow thyme.

Consider deeply the import to him of this, his first sight of ruin, and compare it with the effect of the architecture that was around Giorgione. There were indeed aged buildings, at Venice, in his time, but none in decay. All ruin was removed, and its place filled as quickly as in our London; but filled always by architecture loftier and more wonderful than that whose place it took, the boy himself happy to work upon the walls of it; so that the idea of the passing away of the strength of men and beauty of their works never could occur to him sternly. Brighter and brighter the cities of Italy had been rising and broadening on hill and plain, for three hundred years. He saw only strength and immortality, could not but paint both; conceived the form of man as deathless, calm with power, and fiery with life.

Turner saw the exact reverse of this. In the present work of men, meanness, aimlessness, unrightfulness; thin-walled, lath-divided, narrow-garretted houses of clay; booths of a darksome Vanity Fair, busily base.

But on Whitby Hill, and by Boltou Brook, remained traces of other handiwork. Men who could build had been there; and who also had wrought, not merely for their own days. But to what purpose? Strong faith, and steady hands, and patient souls—can this, then, be all you have left! This the sum of your doing on the earth!—a nest whence the night-owl may whimper to the brook, and a ribbed skeleton of consumed arches, looming above the bleak banks of mist, from its cliff to the sea?

As the strength of men to Giorgione, to Turner their weakness and vileness, were alone visible. They themselves, unworthy or ephemeral; their work, despicable, or decayed. In the Venetian's eyes, all beauty depended on man's presence and pride; in Turner's, on the solitude he had left, and the humiliation he had suffered.

And thus the fate and issue of all his work were determined at once. He must be a painter of the strength of nature, there was no beauty elsewhere than in that; he must paint also the labour and sorrow and passing away of men; this was the great human truth visible to him.

Their labour, their sorrow, and their death. Mark the three. Labour; by sea and land, in field and city, at forge and furnace, helm and plough. No pastoral indolence nor classic pride shall stand between him and the troubling of the world; still less between him and the toil of his country,—blind, tormented, unwearied, marvellous England.

Also their Sorrow; Ruin of all their glorious work, passing away of their thoughts and their honour, mirage of pleasure, FALLACY OF HOPE; gathering of weed on temple step; gaining of wave on deserted strand; weeping of the mother for the children, desolate by her breathless first-born in the streets of the city,† desolate by her last sons slain, among the beasts of the field.‡

And their Death. That old Greek question again;—yet unanswered. The unmeasurable spectre still flitting among the forest trees at twilight; rising ribbed out of the sea-sand;—white, a strange Aphrodite,—out of the sea-foam;

\* I do not mean that this is his first acquaintance with the country, but the first impressive and touching one, after his mind was formed. The earliest sketches I found in the National Collection are at Clifton and Bristol; the next, at Oxford.

† The Tenth Plague of Egypt.

‡ Rizpah, the Daughter of Aiah.

stretching its grey, cloven wings among the clouds; turning the light of their sunsets into blood. This has to be looked upon, and in a more terrible shape than ever Salvator or Durero saw it. The wreck of one guilty country does not infer the ruin of all countries, and need not cause general terror respecting the laws of the universe. Neither did the orderly and narrow succession of domestic joy and sorrow in a small German community bring the question in its breadth, or in any unresolvable shape, before the mind of Durero. But the English death—the European death of the nineteenth century—was of another range and power; more terrible a thousand-fold in its merely physical grasp and grief; more terrible, incalculably, in its mystery and shame. What were the robber's casual pang, or the rage of the flying skirmish, compared to the work of the axe, and the sword, and the famine, which was done during this man's youth on all the hills and plains of the Christian earth, from Moscow to Gibraltar. He was eighteen years old when Napoleon came down on Areola. Look on the map of Europe, and count the blood-stains on it, between Areola and Waterloo.

Not alone those blood-stains on the Alpine snow, and the blue of the Lombard plain. The English death was before his eyes also. No decent, calculable, consoled dying; no passing to rest like that of the aged burghers of Nuremberg town. No gentle processions to churchyards among the fields, the bronze crests bosed deep on the memorial tablets, and the skylark singing above them from among the corn. But the life trampled out in the slime of the street, crushed to dust amidst the roaring of the wheel, tossed countless away into bowling winter wind along five hundred leagues of rock-fanged shore. Or, worst of all, rotted down to forgotten graves through years of ignorant patience, and vain seeking for help from man, for hope in God—infirm, imperfect yearning, as of motherless infants starving at the dawn; oppressed royalties of captive thought, vague age-fits of bleak, unavailed despair.

A goodly landscape this, for the lad to paint, and under a goodly light. Wide enough the light was, and clear; no more Salvator's lurid chasm on jagged horizon, nor Durero's spotted rest of sunny gleam on hedgerow and field; but light over all the world. Full shone now its awful glohe, one pallid barnel-house,—a ball strewn bright with human ashes, glaring in poised sway beneath the sun, all lilending-white with death from pole to pole,—death, not of myriads of poor bodies only, but of will, and mercy, and conscience; death, not once inflicted on the flesh, but daily fastening on the spirit; death, not silent or patient, waiting his appointed hour, but voiceful, venomous; death with the taunting word, and burning grasp, and indeed sting.

"Put ye in the sickle, for the harvest is ripe." The word is spoken in our ears continually to other reapers than the angels, to the busy skeletons that never tire for stooping. When the measure of iniquity is full, and it seems that another day might bring repentance and redemption,—*"Put ye in the sickle."* When the young life has been wasted all away, and the eyes are just opening upon the tracks of ruin, and faint resolution rising in the heart for nobler things,—*"Put ye in the sickle."* When the roughest blows of fortune have been borne long and bravely, and the hand is just stretched to grasp its goal,—*"Put ye in the sickle."* And when there are but a few in the midst of a nation, to save it, or to teach, or to eberish; and all its life is bound up in those few golden ears,—*"Put ye in the sickle, pale reapers, and pour hemlock for your feast of harvest home."*

This was the sight which opened on the young eyes, this the watchword sounding within the heart of Turner in his youth.

So taught, and prepared for his life's labour, sate the boy at last alone among his fair English hills; and began to paint, with cautious toil, the rocks, and fields, and trickling brooks, and soft white clouds of heaven.

NEW DISCOVERY IN DYING.—For a long time past the dying trade has been endeavouring to imitate the green dye used in China, and the French, according to the *Journal des Débats*, appear to have succeeded in obtaining it from one of their own indigenous vegetable substances, a chemist of Lyons having been put on the right track by an instructive note which the Chevalier de Montigny had sent from China, along with samples of the primary substance, to the Department of Commerce.

### THE PRINCE OF WALES AND CANADIAN WORKS.

THE New York journals, and the able correspondent of the *Times*, give graphic details of the progress of the Prince of Wales in Canada. The Prince landed at Montreal on Saturday morning, the 25th ult., and was received with the most enthusiastic demonstrations of welcome by about 60,000 people. The occasion was probably the most striking ever witnessed in Canada. The streets were decorated, and the procession which accompanied his Royal Highness from the wharf after the presentation of an address from the mayor, embodied all the civic societies, the clergy, the fire-brigade, the regular military, and the volunteers, not only of the city but of distant places. The procession proceeded immediately to the Crystal Palace, which was formally opened by the Prince.

The building which has been erected for this purpose stands in a commanding situation on the northern side of the city, just where the slopes of Mont Royal, from which the town takes its name, begin a slow rise. The building itself, in outer form and general internal arrangement, is described as very like one of the end transepts of our Crystal Palace, only, of course, on a much smaller scale, and built with brick walls, roofed in with an arched wooden ceiling. For the rest, the columns, girders, and tie-rods of the interior are much the same in principle as in the English building. The outside, however, is handsomely adorned with light ornamental woodwork and painting, which give it a clean and pleasing effect. The whole of the articles to be exhibited had not then arrived.

The Prince afterwards sped away to the Victoria Bridge, 2½ mls. being the fare demanded and obtained by carriage-drivers for taking a fare from the Exhibition to the bridge, a distance of some 2½ miles.

We have before now given particulars of the bridge, one of the most remarkable works in the world. The Prince laid the last stone and drove the last rivet, a silver one. "The ceremony was nothing to describe, though it would have made a fine picture. The two workmen wielding their tremendous hammers with a din that was awful, the rich uniforms of the Prince and suite, half hidden in the gloom, and softened down by the wreaths of thick wood-smoke which curled from the funnel of the engine in the background—the little glimpses through the opening into the bright sunlight, the St. Lawrence far beneath—the flaunting decorations and shining roofs of Montreal beyond the river—all made a striking subject for a picture."

A bronze medal, with appropriate devices and inscriptions, had been prepared by the workmen on the Grand Trunk Railway, for the Queen, and was given to the Prince for that purpose. In response to the address of the workmen, his Royal Highness said:—"Gentlemen,—I accept with peculiar pleasure an address of artisans and working men, who have, by the sweat of their brow and skilled labour of many a hard day's toil, contributed to erect this monument to the greatness of their country—a structure scarcely less honourable to the hands which constructed it, than to the minds which conceived it. I mourn with you the loss of Robert Stephenson. In your regrets you bring to mind that it was from your class that his eminent father sprang: let me further remind you that England opens to all her sons the same prospect of success to genius combined with honest industry. All cannot attain the prize, but all may strive for it; and in this race victory is not to the wealthy or the powerful, but to him whom God has given intellect, and has implanted in the heart the moral qualities which are required to constitute true greatness. I congratulate you upon the completion of your work, and earnestly hope it may prosper; and to you who have raised it to its present grandeur, and to your families, I heartily wish every happiness."

The Prince Consort said, at the Trinity House banquet, some time ago, "It will be a curious coincidence that, nearly at the same time, a few weeks hence, though almost at the opposite poles, the Prince of Wales will inaugurate, in the Queen's name, that stupendous work, the great bridge over the St. Lawrence, in Canada, while Prince Alfred will lay the foundation-stone of the breakwater for the harbour of Cape Town. What vast considerations as regards our country are brought to our minds in this simple fact! What present greatness! What past history! What future hopes; and how important and beneficent is the part given to the Royal family of England to act in the development of those distant and rising countries, who recognize in the British Crown, and their allegi-

ance to it, their supreme bond of union with the mother-country and with each other!"

The Prince of Wales, in this visit to the Colonies and to the United States, is doing a great work, and is doing it wonderfully well. Without reference to their position, he has reason to be grateful to his Mother and his Father.

### ARCHITECTURAL EXAMINATIONS. NORTHERN ARCHITECTURAL ASSOCIATION.

At a special meeting held at the Old Castle, Newcastle-upon-Tyne, on Tuesday last, the 11th instant, for the purpose of considering a communication from the Royal Institute of British Architects respecting the proposed architectural examinations and diploma, Mr. John Dobson, F.R.S.A., President, in the chair, it was unanimously resolved,—

"That it is the opinion of this Association that the establishment of an architectural examination, whether voluntary or compulsory, and a diploma, would be of great advantage to the profession.

That it is the opinion of this Association that, in carrying out the scheme for establishing an architectural diploma, the Royal Institute of British Architects should make provision for admitting architects of established practice as members of the Institute without undergoing examination, and for granting to such architects a diploma based upon the merits of their works.

That this Association suggests that all action in this matter by the Institute should be taken with a view to the ultimate adoption of a compulsory examination. And

That this Association leaves with confidence the details of this scheme in the hands of the Royal Institute of British Architects."

### STOCKPORT MARKET.

THE Town Council have accepted the designs and estimate of Mr. James Haywood, jun., Phoenix Foundry, Derby, for covering in their present open Market-place. The design consists of wrought-iron framed principals, about 25 feet span each, supported on cast-iron columns and gutter girders. The outer pillars are ornamented and panelled. The design shows a mode of enclosing the sides and ends of the Market at any future time if required. These plans have been selected from among those of nine competitors.

### PARK OBSERVATORY COMPETITION, STOCKDALE.

THE designs submitted for the intended observatory in Vernon Park have been exhibited to the public. Last week a limited number of the designs were chosen out by the committee, and from these the ultimate selection was made. The first premium (20*l.*) has been awarded to Mr. J. Stevens, of Manchester, and the second to Mr. Wilson, of Bath. It is not expected that the selected design can be carried out for the stipulated sum,—1,000*l.* 3*s.* 6*d.* of drawings were sent in.

### HOW BALTIMORE OBTAINED ITS PARK.

GREAT desire is manifested in the United States of America to provide public parks. At Baltimore a project with this end in view has been on foot for a year or two, which is somewhat peculiar. Mr. Howard Daniels enables us to give a brief account of it.

In an ordinance for giving a system of city railways, the company was required to provide more and better accommodations for the public at five cents, than the omnibuses had for six cents; and to pay also to the city one cent for each passenger carried, for the purpose of creating a fund for a public park. It is estimated that this "park-cent" (as it is called) will average, during the fifteen years of the grant, no less than 100,000 dollars per annum, making the city passenger railways just that much more valuable to the city of Baltimore than the similar grants of New York, Philadelphia, and Boston.

Thus the introduction of the city passenger railway system, which was considered an adjunct to a park, has not only served to enlarge the views of the Baltimoreans on that subject, but has furnished the means for its purchase and adornment, without resorting to direct taxation. For the purpose of carrying this project into effect, a commission, composed of five gentlemen, who were selected for their integrity and taste in rural affairs, was created, and clothed with power by the city authorities, to select and purchase a

suitable site, or sites, and lay out the same as a public park.

The result was the selection of Druid Hill, the property of Mr. Lloyd N. Rogers, embracing about 517 acres, at a cost of 497,300 dollars, and located within five minutes' walk of two of the city railway lines. The site is diversified by gentle hills of varied forms, connected by flattened ridges into groups, or irregular ranges, forming grand foregrounds, and broken and intricate middle-grounds and distances; one large eminence near the centre of the park, and at the rear of the mansion, being 366 feet above tide.

The valleys being broad and gentle in their undulations, furnish admirable sites for parade-grounds, play-grounds, &c., producing great breadth of effect in the landscape. As a whole, the grounds are characterized by greatness, distinctness, and strongly-marked divisions, conspiring to give grandeur, rather than easy transitions and delicate flowing lines.

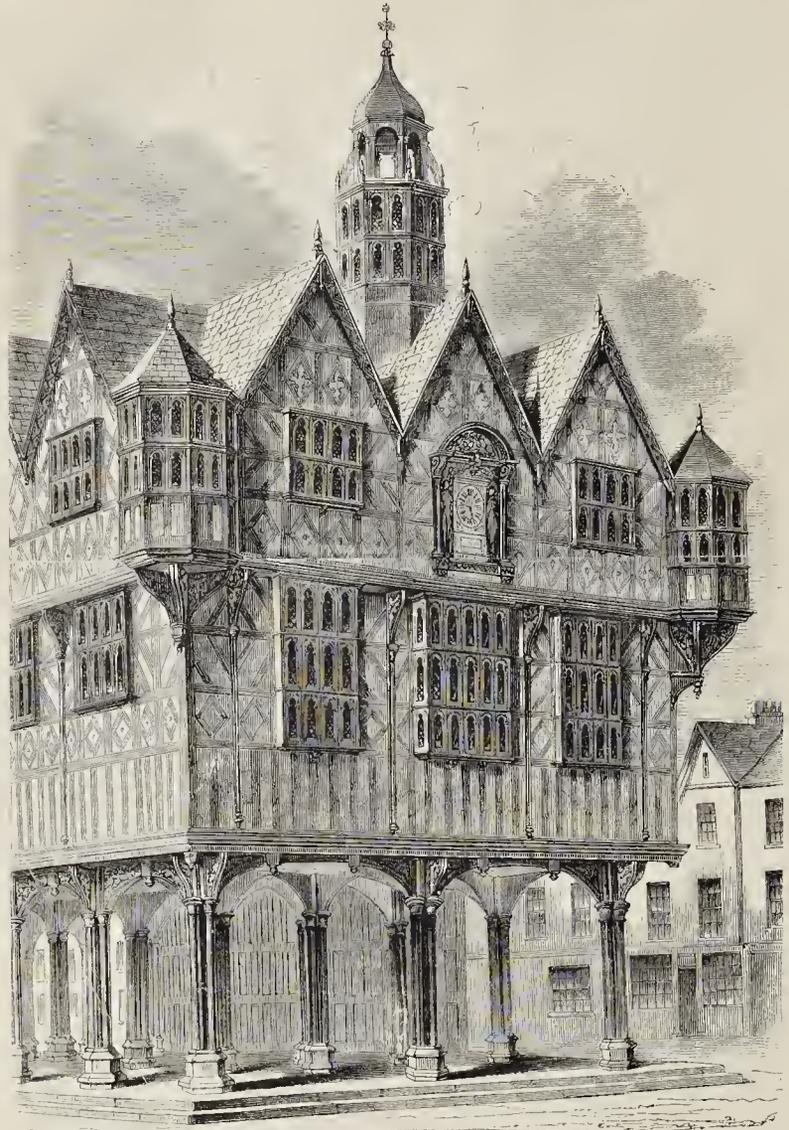

To the arboriculturist, these grounds are particularly interesting for the great number and variety of large, healthy, and park-like trees, among which are to be found scores of magnificent old oaks from 12 to 15 feet in circumference, that would do credit to Windsor Great Park or Fontainebleau; sometimes standing singly, at others having marshalled around them generations of descendants, forming groves of families; numbers of bickories from 8 to 11 feet in circumference, and from 60 to 90 feet in height; also gigantic tulip trees, of which no European park can boast, that loom up here and there 20 to 30 feet above their neighbours, giving variety to the sky-lines and spirit to the groups. These giants of the forest, when allowed room to spread and develop themselves, make admirable park trees, having a robust, masculine character peculiar to themselves.

There is reason to believe that if this project, so well commenced, is completed with improvements adapted to the wants and enjoyments of the public, conceived and executed in the spirit and genius of the place, the result will be a grand park, worthy of the Monumental City.

### THE LATE MR. JESSE HARTLEY, ENGINEER, OF LIVERPOOL.

READERS have doubtless learnt the death of Mr. Jesse Hartley, the engineer of the Liverpool Docks, which took place on the 24th of August, at his residence, Bootle Marsh. Mr. Hartley, who was upwards of eighty years of age, was a native of the North Riding of Yorkshire, in which district of that county his father held the position of bridge-master, and his son, the subject of the present remarks, after receiving an ordinary education, served his apprenticeship as a stonemason, and worked at the building of Borough-bridge. Subsequently, he succeeded his father as bridge-master in the district named, until his removal to Liverpool, on receiving the appointment of engineer to the Dock Committee. As a dock engineer, Mr. Jesse Hartley is admitted to have occupied a very high position; we have had occasion at different times to refer to his works. Possessing great natural sagacity and imbued with an innate perception of the leading features of constructive design, he speedily acquired a profound knowledge of the requirements of that branch of science to which he devoted himself, and in the design and construction of the numerous docks of Liverpool he has left monuments of his skill as an engineer. During the long period in which he held the responsible office of dock engineer in Liverpool, Mr. Hartley altered, or entirely constructed every dock belonging to the town. Besides this, he was employed as engineer for the Bolton and Manchester Railway and Canal, and he was also consulting engineer for the Dee Bridge at Chester, the centering for which was considered a triumph.

He was buried at Bootle Church. From the general esteem in which he was held, the funeral was attended by a large number of gentlemen, including inhabitants of the locality, many persons from Liverpool, a considerable number of the *employés* of the Dock Board and the Corporation, as well as many of the contractors who had executed work under Mr. Hartley. The following officiated as pall-bearers:—Mr. Wm. Brown, Mr. Thomas Cook, Mr. Charles Turner (chairman of the Dock Board), Mr. J. Bramley-Moore, Mr. James Bibby, and Mr. James Walker. There were also present Mr. Wm. Rathbone, Mr. Alderman Robinson, Mr. North (solicitor to the Dock Board), Mr. Weightman (corporation surveyor), Mr. Millar (surveyor of the docks), Mr. Newlands (borough engineer), Mr. John Bibby, Mr. Henry

HEREFORD TOWN-HALL, RESTORED.

Forsbaw, Mr. R. Newby, Mr. T. Haekott, Mr. D. Mason, Mr. Smith, and others.

#### THE OLD TOWN-HALL, HEREFORD.

To enable our readers to form a judgment on the statements which have been made in our pages as to the town-hall of Hereford, now threatened with destruction, we give a view of the end of it restored to its original condition.\* It stands in High Town or High Square, which is the centre and principal business part of the city. It is 84 feet long, and 34 broad, and consists of one large room supported upon three rows of oak pillars. The upper floor contained many rooms used by the different city companies. This has been removed, and the present aspect of all that remains above the bottom story is very miserable.

\* It is an old block and somewhat damaged, but it will serve the purpose.

#### FALL OF A HOUSE IN CLERKENWELL.

A FEW nights ago, considerable alarm was created in Clerkenwell by the falling in of a house, the Hat and Feathers Tavern, at the corner of Wilderness-row and Goswell-street. The house was in process of being rebuilt, and fortunately there was no one residing on the premises. The inhabitants of the house next door, eight in number, were, however, placed in some danger, owing to the falling of part of their party wall.

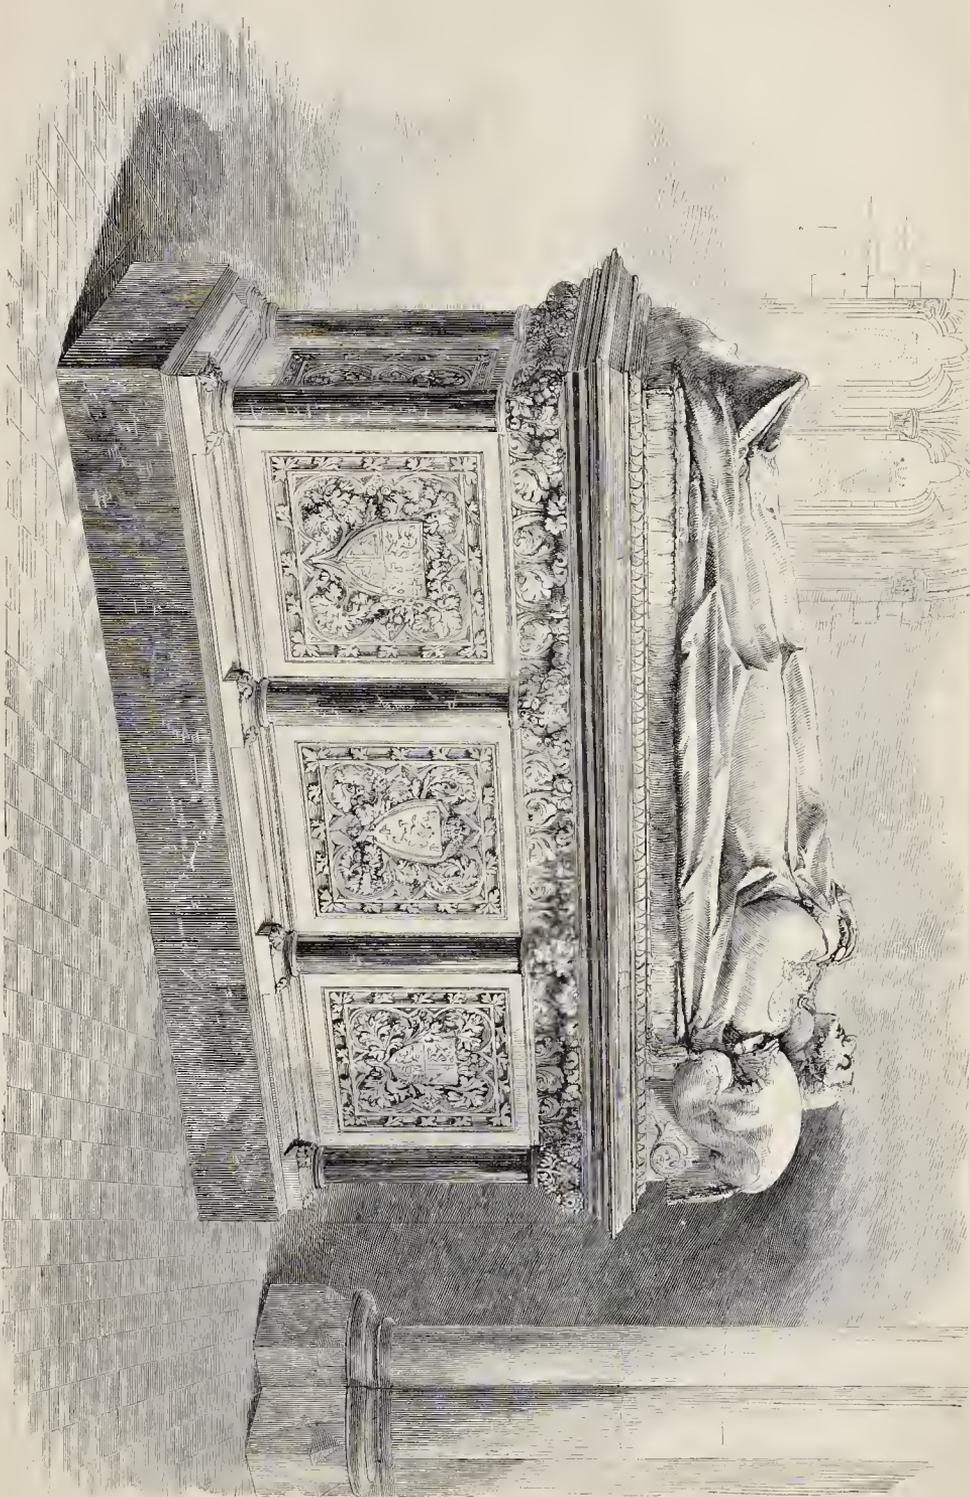

The work was under the direction of an architect, and the cause of the disaster is unknown. The walls are said to have been of ample thickness, the timbering good. The whole collapsed and fell internally, carrying with it the upper part of the party-wall, in which there was a corbelled chimney on the third story.

It has been suggested that the continued wet of the last two months had flooded the basement story, injured and weakened the foundations, and caused the walls to settle;—whence the failure.

#### MONUMENT TO THE LATE EARL OF ELLESMERE.

THIS elaborate and costly monument has been recently placed in Worsley Church, near Manchester, by direction of the present Earl of Ellesmere. The body of the tomb is of Caen stone, enriched with panels, foliated, and bordered and filled in with foliage, exceedingly well executed. Columns divide each side into three: these columns are of Devonshire marble, the capitals being of Caen stone. The plinth of the tomb is also of Devonshire marble. The slab upon the top is of the same material. An effigy of the deceased nobleman reposes on this. It is of statuary marble, and is a dignified personation of the late earl, in the robes of the order of the Garter. It is from the studio of Mr. Noble. The design of the monument is by Mr. G. G. Scott, and the carving on it was executed by Mr. Philip, of Vauxhall-bridge-road.

THE EARL OF ELLENBERG'S MONUMENT, IN WORSLEY CHURCH, NEAR MANCHESTER.

## RAMBLING: BOLEBROOK, SUSSEX.

ABOUT a mile and a half from the picturesque village of Hartfield, in Sussex, stands Bolebrook, an old brick mansion, said by Horsfield, in his "History of Sussex," to have been built about the middle of the fifteenth century. It is very striking in appearance, being of grand and lofty dimensions; and having a very interesting gateway still existing, besides great portion of the old manor-house. The gateway is formed by two large towers, with a connecting building between them, and contains three tiers of apartments. The towers are from 40 feet to 50 feet high, including the peculiar ogee-shaped cupola roofs (similar to one still remaining on Brambletye ruins), with which they are surmounted, and have been pierced all round in numerous places with narrow apertures for defence.

The entrance, which does not appear to have been at any time a gateway, but merely a doorway, has still the large hole in the wall, into which the huge oaken beam that barred the door used to slide. The ground-floor apartment of the centre building was evidently the porter's room: it has in each side-wall two large recesses for seats, with smaller niches to the left at a convenient height to hold the drinking-horns which contained the Medieval substitute for porter, with which the gossipers of those days refreshed themselves while waiting their masters' pleasure, or their own. To the left on entering, is the seat of honour—the "hall chair,"—furnished with elbows formed in the wall; and in one of the opposite recesses, an oaken seat is still firmly fixed in its place. All the apartments are provided with open fireplaces and chimneys.

A decaying winding-stair round a stout oak newel, in the left-hand tower, gives access to the upper rooms, the floor-boards of which are blackened as with fire, and the original doors are missing. This tower is seen from the outside to be slightly out of the upright, and a number of the bricks are loosened in their beds of mortar: a large crack, too, runs down the brickwork of the connecting building close to it; which, added to the fact, that the stairs are formed of two boards,—one for the footway, and one for the riser,—and are not cut out of a solid cube of wood as are those of the manor-house, strengthens the supposition that the tower has been subjected to a conflagration in which the original stairs perished.

The farther entrance to the porter's room, as seen from what is called the court-yard, is a spacious opening formed by a large Tudor arch; and at each angle of the outer wall, running up the entire height of the building, is a small turret, apparently only for ornament, or perhaps strength.

Back and front, the coping is built up in the centre into a sort of canopy, which overhangs a flat niche, in which is inserted a small stone tablet, but not even the assistance of a glass could detect any traces of an inscription; and Mr. Whitehead, the present tenant, who most obligingly left his own occupations to show the visitors over his house and grounds, said he had not discovered a date in any part of the building. It is to be hoped Mr. Whitehead will not deem this mention of his name too great a liberty, nor that an unworthy return is thus made for his kindness and urbanity. So good a specimen of a true English farmer it is seldom one's good fortune to meet: frank, open-spoken, intelligent, and kind in the extreme, it seems but just to name him when speaking of Bolebrook.

The house, even what remains of it, is exceedingly extensive; and the old cooking departments must have been designed to supply an enormous number of retainers. The ovens, especially, are very large and numerous. Of one of these the story is told, that a farmer's wife having heated it and raked out the ashes preparatory to putting in her hatch of bread to bake, was amazed—as well she might be—to perceive within the entrance the figure of a woman. To whom the unhappy spirit once belonged that haunted this very warm abode, the legend does not say; nor whether the oven has since been heated, to try if the apparition would reappear.

The apartment above this bakery is panelled with oak, still mostly very perfect and smooth, and capable of easy restoration. But over the fireplace the panelling has been stripped from the walls, it is supposed by Lord De la Warr, while building his new residence at Buckhurst. It probably was handsomely carved up to the ceiling, as is seen in many old houses of the same date. This room and the bakery below have a large recess, which forms here a fine lay window; and the appearance altogether of the apartment recalls

vividly to mind the stately library in which poor Lady Jane Grey is often represented sitting at her studies, with her tutor, the good Roger Ascham; while through the open lattice gay ladies and cavaliers are seen, with their hooded hawks on their wrists, entering away to enjoy the pleasures of the chase.

In a capitolium-stocked, refreshingly cool dairy, stands a curious old meat-safe, the panels of which are formed of large squares of tin, stamped into open-cut patterns with some sharp die; an ingenious and ornamental precursor of our modern perforated zinc.

The broad stairway—whose steps are made, as we have said, of solid cubes of oak,—protected by its strong heavy hand-rail and enormous newels, leads to the uppermost rooms or garrets. In one of them stands a lumbering old cheese-press, fast hastening to decay; and the white-washed lean-to ceilings of all are scrawled over by the blackened fingers of lazy serving-men or women, for whose "idle hands" Satan found some "mischief" to do, while after the lapse of nearly a century is rather interesting to look upon. There is one date "1788," but a certain "John Paris" in "1794," seems to have been the principal scribe. With more reason than rhyme, he has misquoted a well-known epitaph, and it stands thus:—

"The world is vanity,  
All things show it;  
I thought so once,  
And now I know it."

One very spacious apartment, with magnificently lofty stone-mullioned windows in it, was shown, but there was barely time to more than glance round, for preparations for the dinner of the kind *cicerone* were on the table, and his visitors were of course anxious to depart, notwithstanding his hearty assurance that they were not inconveniencing him in the least. A hasty examination was made of an old (no doubt Sussex) iron fire-back in the ample chimney-corner, very much defaced with time and use, but on which could just be distinguished the word "Honi" on the royal rafter encircling the central arms, and the board-headed "supporter" on one side.

An ancient and picturesque oak, which must have braved the summer sun and winter snow ever since the day that William the Norman first set foot on English soil—and that soil Sussex soil, by the way—stands near to the bay-windowed end of the old house: oh! if it could but speak, like Tennyson's "Talking Oak" of Summer Chase! Its pride of spreading branch has long since departed, but in girth it measures 32 feet 6 inches at 1 foot from the ground, and 16 feet 9 inches 5 feet higher up the trunk.

"The manor of Bolebrook," says Horsfield, "was the property of the family of Lynde, and carried, on the marriage of Joane de la Lynde to John Dalyngruge, of Bodiam, to that family, who continued owners till temp. Richard II., when Margaret, the heiress of that family, carried it, on her marriage to Sir Thomas Sackville, whose family has ever since held it." And again,— "Bolebrook was one of the earliest brick edifices in this country. . . . At what time it was first suffered to go to decay we are not informed, but it was probably on the transfer of the property to the Tufton family in the reign of James I. A park and demesne were formerly attached to the venerable mansion. This was originally the property of the Dalyngruges of Bodiam, and passed to the Sackvilles by marriage of Margaret, the daughter and heiress of Sir Edward Dalyngruge. By the Tuftons, Earls of Thanet, who succeeded to the possession by marriage, the estate was bequeathed to charitable purposes. In 1770 it was sold under a decree of the Court of Chancery, and purchased by Lord George Germain, who, when afterwards created a peer, took from this place his second title of Baron Bolebrook. At length it was again united to the large possessions of the house of Dorset, in 1790, when it was bought by John Frederic, fourth Duke of Dorset, of Viscount Sackville."

In a "Guide to Knole," by Bridgman, published in 1827, we find that Richard Sackville, third Earl of Dorset, born March 28, 1589, married Anne Clifford, daughter and heir of the Earl of Cumberland, and died on Easter Sunday, March 28, 1621. He had three sons, who died infants, and two daughters, one of whom, Margaret, born July 2, 1624, married ——— Tufton, ancestor to the present Lord Thanet.\* In a "Catalogue," quoted by the above-mentioned "Guide," of the "household and family of the Right Honourable Richard Earl of Dorset, in the year of our Lord 1613; and

so continued until the year 1624," mention is made of "Bolebrook House, Sussex," showing that it was not then dismantled.

Mr. Mark Anthony Lower, in his paper on "Bodiam and its Lords," given in the ninth volume of the "Sussex Archaeological Collections," says, speaking of the family of Dalyngruge, "their true origin is from the extinct manor of Dallingridge, on the confines of the parishes of East Grinstead and West Hoathly, where they appear to have been located as early as temp. Edward II. John Dalyngruge, the first recorded progenitor of the family, was married in that reign to Joane, a daughter and co-heiress of Sir Walter de la Lynde, lord of Bolebrook, in the parish of Hartfield, co. Sussex."

Returning to Hartfield, a beautiful view of the village, crowed by the church, is obtained, at a bend of the road about a mile from Bolebrook. On a nearer approach, the church is not so worthy of remark. The tower is thin and shapeless, and very tall in comparison with the crowning spire, and the larger portion of the church appears to have been rebuilt at some debased period of architecture, for the south aisle is much more elegant than the nave. The chancel is very long, being quite half the entire length of the church. On the north wall there is the old opening—now closed up,—to the roof-loft, and the mark of the stairway leading to it. The frightful fashion of high pews instead of seats, still maintains in Hartfield Church, and on the doors of some two or three of these small brass plate bears the name of Bolebrook. Horsfield tells us "the benefice is a rectory and vicarage united, in the archdeaconry of Lewes and deanery of Pevensey, and is valued in the king's books conjointly at 177. s. and in Pope Nicholas's taxation the church was rated at thirty-five marks, and the vicarage at twelve marks. The vicarage is in the patronage of the rector of Hartfield; the rectory is a sinecure, and the Earl de la Warr is patron."

Having several times mentioned the name of Dalyngruge, we may say that there is a very handsome—though shamefully damaged—brass in Fletching Church, in memory of a member of it, together with his wife; the date is about 1395, according to Mr. Bontell. Mr. Lower assigns "this monument to Sir Roger Dalyngruge, who had free warren in Sheffield (in the parish of Fletching), 48 Edward III.," which would be in 1375. It may be so, yet Bontell be correct, for Sir Roger may have lived eighteen or twenty years after the date of the aforesaid grant.

Fletching Church is also the last resting-place of Gibbon, the historian. He had returned to England from Lausanne, in June, 1783, on account of the Continental troubles, and had gone to visit his friend, Lord Sheffield, at Sheffield-place, Fletching. There he died on the 17th of February, 1794, and he was interred in the Sheffield Mausoleum in the north transept of Fletching Church.

It was during a visit to Lord Sheffield, in 1788, that the concluding volumes of Gibbon's great work, "The Decline and Fall of the Roman Empire," were presented to the public. Speaking of it himself, he says, "It was at Rome, on the 15th of October, 1764, as I sat amidst the ruins of the Capitol, while the barefooted friars were saying Vespers in the Temple of Jupiter, that the idea of writing the decline and fall of the city first started to my mind." He commenced his work in 1770, after the death of his father, from whom he inherited a large fortune, and completed it in 1787 at Lausanne. How little promise his boyhood and youth gave of his manhood's renown, may be gathered from his own words.—"To the University of Oxford I owe no obligation; and she will as cheerfully renounce me for a son, as I am willing to disclaim her for a mother." How far was his prophecy from fulfilment! And how bright a fact is it in the annals of John Lord Sheffield, that he could call the great historian, "friend!"

## CHURCH-BUILDING NEWS.

**Grantham.**—A steeple climber has been engaged in putting a new copper lightning conductor on the spire of Grantham church, in room of the old one of iron. He found the upper part of the spire out of repair, and sadly in want of pointing. The spire, according to the *Lincolnshire Chronicle*, literally shook. The subject has been considered whether it should be repaired. But to do the repairs a scaffolding would be required both inside and out; and the persons putting up the conductor suggested a scaffolding from the highest openings or windows in the spire to be erected by the climber with poles drawn up for the purpose, and passed through the windows.

\* The title is now extinct.

**Great Warley.**—The new cemetery in this recently-formed ecclesiastical parish has been consecrated by the Bishop of Rochester. Mr. T. E. Knightly, of Cannon-street, was the architect; and Mr. J. Hammond, of Warley, the contractor. The cemetery is situate on the western side of the road leading from the Brentwood station, and adjoins the grounds of the County Lunatic Asylum. There are but few dissenters in the parish, so that but one chapel has been built, the plan of which comprises nave, chancel, and vestry, the style being the Early Decorated. The chancel has a three-light window, with a trefoiled circle in the head: over the entrance is a low-pointed arch, surrounding a circle filled with trefoils and quatrefoils. The roofs are open, the floors paved with black and red tiles, and the benches are placed stall-wise. A bell gable surmounts the chancel arch. The entrance to the ground, which is flanked by a lodge for the cemetery-keeper, consists of a low screen, surmounted by ornamental iron-work, and has gate-piers, with tall pyramidal terminations: the gates are of oak, the upper panels being filled in with ornamental iron-work. The buildings and walls at the entrance are constructed of Kentish rag stone, with dressings of Ancaster stone.

**Bicknor.**—The very old church of this parish is now under restoration. The funds have been raised by subscription, but are still far from sufficient. The edifice was found to be in a much worse condition than was expected, and the long continuance of bad weather, and the unusual cost of all labour and materials, have largely increased the expense. The work is being carried out with preservation of the ancient features of the building.

**Bodelwyddan.**—The church recently erected here has been consecrated by the Bishop of St. Asaph. The foundation-stone was laid on the 24th July, 1856, and the church has been erected at the exclusive cost of the Lowager Lady Willoughby de Broke. The site selected is an eminence by the north gate of the avenue leading to the mansion of Bodelwyddan, the seat of Sir Hugh Williams, Bart., and commands a view of the picturesque vale of Clwyd. The whole cost of the erection is 22,000*l.*

**St. Fagans (near Cardiff).**—The parish church of St. Fagans has been reopened by the Bishop of Llandaff. The church which has now been restored is dedicated to St. Mary. The work of renovation commenced in 1859. The architect employed was Mr. G. E. Street, and the works were contracted for by Mr. Thomas Williams, of Canton, builder. So far had decay advanced, that little short of 2,000*l.* and a period of twelve months have been required to repair the damage which time had wrought on the fabric. The principal works have been an entire new roof, the picking off the plaster from the interior of the walls, and the repointing them both within and without, repewing the whole, and flooring the chancel and all the aisles with encaustic tiles, and restoring the ancient Decorated windows in the chancel and other parts. An entire new north aisle, the full length of the nave, and a vestry on the north side of the chancel, have been added; the former containing five windows in the Decorated style, and the latter, above the entrance from the churchyard, an ornamental trefoil window. A heating apparatus, by Rimington & Son, of Halifax, has been supplied. The bells have also been restored to the tower; the four old ones which had been broken having been recast at the expense of the Baroness Windsor. New gates have been placed in the porch, and a new screen at the base of the tower to divide it from the nave. The churchyard walls have been repaired, and in many parts rebuilt. The stained-glass window above the altar is a memorial one, erected at a cost of 150*l.* The window is emblematical of the atonement and the two sacraments, and illustrates the Crucifixion, Christ blessing little Children, and the Last Supper. At the bottom of the window is the inscription, in memory of the Honourable Robert Windsor Clive, M.P. The window in the south side of the nave is also a memorial. It is placed immediately above the seats set apart for the Clive family, and is to the memory of the Hon. Wm. Windsor Clive. This window is in the Perpendicular style, and is divided into three lights, each of which illustrates the subject of Christ's raising the widow's son.

**Shirley.**—The foundation-stone of a new tower to the parish church has been laid. The new tower is intended to replace the old one, which had fallen into a ruinous condition. The architect is Mr. H. I. Stevens, of Derby; and the builder, Mr. J. W. Thompson, also of Derby.

## STAINED GLASS.

**West Wickham.**—The parish church here has been recently embellished by the addition of two stained windows. The principal one, at the east end, represents in its three compartments the Transfiguration of our Lord between Moses and Elias; beneath are the sleeping Apostles, Peter, James, and John. The second window is on the south side of the chancel. This window is of two compartments: in the first is the figure of our Lord, and in the second the kneeling figure of St. Peter.

**Sidmouth.**—It is the intention of the Queen, it is said, to give a new west window to the church of Sidmouth, in memory of her Majesty's father, who died there.

**Liverpool.**—St. John the Baptist's Church, Toxteth-park, which has but little decoration in its interior, has recently been improved by the introduction of two stained-glass windows. One is a memorial to the late Andrew Browne, Esq., and is the gift of his grandson, the Rev. J. W. Hardman. It is in Early English work of a Geometric character, enclosing three groups, the subjects severally being—“Hannah bringing Sannael to the Temple,” “Jacob blessing Ephraim and Manasseh,” and “St. John the Baptist Preaching in the Wilderness.” In the east window the groups occupy the entire breadth of the window, and the figures are life-size. The first is filled with “St. John the Baptist Preaching in the Wilderness.” The centre compartment is filled with the “Baptism of our Lord in the River Jordan.” The third is occupied with “St. John pointing out to the Two Disciples Jesus as the Lamb of God.” The donor was Mrs. Elizabeth Wheeler. The whole has been executed by J. A. Forrest & Co., of Liverpool.

**Hulme.**—A fifth stained-glass window for St. Philip's Church, Hulme, has been completed by Messrs. Edmundson & Sons, of Manchester. The window is for the west end of the church: the four sections of which it is composed cover an area of 18 feet high by 10 feet wide. The subject is, “Christ Blessing little Children.” The picture contains 17 life-sized figures. The subject is surmounted by a canopy of foliated ornaments. More than a thousand pieces of glass have been combined to produce the window. Above the canopy the tracery completes the picture. The descending dove forms the central object, and on each side angels are introduced holding scrolls bearing inscriptions. St. Philip's Church will shortly be opened for public worship.

## SPONTANEOUS FIRES.

NUMEROUS and extensive fires continue to rage in the metropolis. Night after night the dome of St. Paul's and other important buildings have been lighted up by conflagrations which have caused loss to the extent of many thousands of pounds. Few persons remember such a continued succession of large fires which seem to have happened without the cause being clear. It has been said that certain conditions of the atmosphere, even when the heat is not great, contribute to spontaneous combustion. If this be so, great care should be taken of lucifer matches, which are liable to cause much mischief. We have heard persons remark lately that they have seen these matches explode without friction or other obvious cause. Many of the fires in dwellings and manufactories are caused by lucifer matches. They ought to be kept in close tin or iron boxes.

## TASTE AND DRINKING-FOUNTAINS.

GOOD taste is rare. Look where you may, unmistakable proofs are found that while money is lavished on works both public and private, in some points of view there is still great need of the artistic schoolmaster. This is remarkable in the street fountain movement: many of the designs, as we have already said, will be looked at with wonder by generations yet to come.

Without now again remarking on the design of these works, which should have afforded such a good opportunity for displaying art, we would observe that in nearly every instance, even where the general form of the fountains is not objectionable, the shape of the drinking-cups is unpleasant.

Attached to the fountains at the chief entrance to the British Museum there are cups of plated silver, of an elegant form which corresponds well with the architecture of the fountains. In most other instances no care has been taken in this respect. It is said to be necessary to use the commonest articles in order to prevent mischievous persons carrying away the cups; but it does not

follow that because an inexpensive material be used for this purpose the form must be ugly. Without being costly, these vessels might be made agreeable to the sight, and in correspondence with the general design.

**SIR.**—Should a design be required for a drinking-fountain, permit me to draw your attention to one of Stothard's chaste conceptions which you will find as a vignette in Rogers's “Poems” (London: T. Cadell, 1834), p. 128.

Nearly all the designs which I have hitherto seen seem to me so unnatural and often so disgusting that I am at a loss to conceive how easily they are accepted by the public. What, for instance, can be fouler or more filthy than to drink the vomit whether of a monster or a man? And yet this is the common design of our modern drinking-fountains! As well, nay, more naturally, might one adopt as a model the well-known mannikin of Brussels.

I know of no place where a fountain is more needed than Primrose-hill; yet, in that portion of the park, which is so much frequented, especially by children, there is an utter absence not only of this, but also of every other convenience.

M. A.

## THE PROFESSION OF CIVIL ENGINEER.

OF all the trades, callings, or professions by which men of the present day earn wealth and fame, there is not one requiring more education, experience, and natural talent than that of the civil engineer. To be properly fitted for discharging his various duties creditably he must understand the theory and practice of land-surveying, levelling, mapping, architecture, bridge-building, road-making, railway engineering, construction of harbours, canals, &c., &c., in addition to the mathematical and mechanical training required for the foundation of this superstructure of knowledge, to all which is to be superadded hydraulics, hydrostatics, pneumatics, geology, chemistry, mineralogy, and other sciences.

Stimulated by the success of Telford, Stephenson, Brunel, and a host of others whom we could name, who have acquired wealth and fame for themselves, and have conferred honour and dignity on their country as well as upon the profession of a civil engineer, pater-familias are induced to place their sons in the offices of civil engineers, and pay with them premiums proportionate to the status of the recipient, varying from one to five hundred pounds, or even more. By this means a considerable addition is made to income, as two or three pupils may be taken every year where the operations of the principal are extensive, as well as cheap labour obtained, out of which a considerable profit is also derived.

The usual course adopted with these aspirants is to place them under an assistant, who gives them drawings to copy and other work suited to their capacity as they advance in the knowledge of their profession. If the apprentice be an idle fellow, fonder of billiards and theatres than study and hard work, he may frequent his master's office, coming late, yawning, and listless, and idly whilst there, leaving at the earliest moment, during the three years of his apprenticeship, without making any great advance in the knowledge and practice of what he intends to be his future profession. One object of great importance he generally secures, however, by the payment of his fee, viz., the patronage of his master, who generally feels bound in honour to retain his apprentices for some years after their time is expired, if not otherwise provided for. If you apply to an eminent civil engineer for employment, he will in all probability tell you that several young men who served their time to him are down on his list for employment so soon as a vacancy occurs in his staff; and men well qualified, but who have not yet attained eminence, are obliged to walk about idle because they never had a patron or be no longer patronized. Of course clever men cut out work for themselves: that is to say, men who are clever in the ways of the world, or more probably their friends, originate railways and other engineering works, on which they obtain employment. It is not talent alone, in a professional point of view, which insures success: a combination of circumstances is needed to that end in all professions, but more so in that of the civil engineer than in any other. Doubtless, opportunity must be given, and previous training endured, to enable its improvement to be turned to account. But for the ambition of Buonaparte the military talent of Wellington might never have been fully known and appreciated.

Numbers who have been brought up to the

profession of a civil engineer find it often exceedingly difficult to obtain employment. In all probability they have passed the age in which they might have competed for an Indian appointment: and if they offer for a local surveyorship to some borough town, they will find the salary small, and local influence too great for them, and they may either remain idle, or accept some of the munificent offers which now and then appear in the public prints, such as the following:—"To Draughtsmen.—Wanted, a good draughtsman and colourist, for an engineer and architect's office, to reside in the country. Office hours, from ten till five o'clock. Salary, 17. per week." In the same paper in which this appears (the *Dublin Advertiser*) we are informed that a journeyman tailor's wages have been settled at 27s. per week; and we know masons, bricklayers, and carpenters are getting 33s. a-week in London. Surely this is a poor prospect for a young man to look forward to, after serving a time, for we conclude nothing short of that would qualify him to take the situation of a draughtsman and colourist in an engineer and architect's office. The profession of a civil engineer should never be entered on by any one unless he be in a pecuniary condition to bide his time, and labour for practice, and the information acquired thereby, without being obliged to think much about the remuneration, which we know to be frequently but of trifling amount to junior assistants, when employment can be obtained, which often happens not to be possible. Trades societies have endeavoured to regulate such matters by trying to impose laws on masters as to the number of apprentices they should employ; but it is better in all such cases to leave individuals un fettered in action, although some evils may thereby result, but they will be found of less magnitude, than would be created by a different mode of procedure. Fathers will not be desirous of apprenticing their sons to a profession in which numbers are already unable to find employment, and time will remedy the evil of which we now complain.

AN ENGINEER.

## THE PLANNING OF CITIES.

A READING article in a recent number of your publication induces us to trouble you with a few remarks. It is very rarely indeed, in this country, that we have to lay out an entire town *de novo*, although in the United States and other new lands, it is done almost every day. The subject, however, is of very great importance, involving the convenience, economy, and beauty of buildings, and sanitary considerations of the thousands living in the town. As far as we know, there are but three systems at present in use. First, the rectangular or gridiron system, where every street is in a straight line, and crossed at right angles by others; second, where there is no regular plan at all observed, but the streets run about in glorious uncertainty as chance may have led them; and, third, a mixture of the two previous systems, a part being laid out with regularity, and part confused;—this being the case with old towns that have been extended by new buildings.

Much has been said in recommendation of the rectangular plan, and it has no doubt many advantages; but, as respects convenience of traffic, we doubt if it is a great improvement on the pell-mell system. A passenger wishing to go from one part of a rectangular city diagonally to another part, must perforce pass along two sides of the square, or by the base and perpendicular, as there is no hypotenuse; or, which is equally prolonged, he must work a zigzag alternately to the right and left. Thus a man at Chelsea would have to go to Walworth, or tantamount thereto, in order to reach Hackney. Now, in the mighty maze of London, which we are so apt to censure, we can generally find a street which will lead tolerably direct from any one spot to another. Thus at Piccadilly we can travel with reasonable rectitude either to Kilburn, Islington, or White-chapel. What we may fairly complain of is the want of regularity of system, and of continuity in the thoroughfares, with their occasional contraction into painful defiles.

A mixture of the rectangular with the *Diagonal* system appears to us to combine the advantages of both plans, without any serious drawbacks. We suggest that straight streets should be laid out, radiating on all sides from the centre of the town, and crossed by other straight streets, inscribed polygonally within circles struck from the same centre. The streets crossing the radiating streets might indeed be perfect circles; but that, as in the case of crescents, &c., would be inconvenient

in the planning of the houses. In other words, an octagon, or other polygonal figure, would be formed with streets drawn from each corner to the centre, and with other polygonal streets inscribed within the outer, and parallel to it: of course, in practice, the centre must be an open square, market-place, or cathedral yard.

Some time after striking out this plan, we happened to observe a spider's web, and it proved in a moment that the identical plan we advocate has existed on a small scale in nature for ages. Any one who can find a distinct and complete web unbroken will see how beautifully regular it is, and how perfectly adapted for the quickest passage from any one point to another. The concentric rings are not circles, but polygons, the radiating lines exquisitely regular and straight.

Of course it may be objected that in an old country like this it is impracticable to alter our towns to such a form; but even here new towns occasionally spring up, and large additions are made to ancient ones; so that an approved plan, whether of this or of any other form, may yet prove of important use.

H. &amp; R. P.

## CONDENSATION OF MOISTURE ON GLASS.

SIR,—Could you allow me, through the medium of your widely-circulated journal, to inquire if any of your readers can suggest a good method, applicable to dining or drawing-room windows, of preventing the condensation of moisture from frost on the inside, which in many instances accumulates to such a degree as to be a source of great perplexity to domestics, as well as serious mischief to the painting and furniture? In best rooms it would be very desirable to avoid this, and if the matter has come under the notice of any of your numerous readers, I should feel obliged for any suggestions.

G. W.

\* \* \* Good ventilation would seem to be the best preventive.

## THE SMOKE NUISANCE.

Go where I will, I see houses being built in all directions in the neighbourhood of London; but I do not see any provision being made to abate or extinguish the smoke nuisance. Can nothing be done? Are Dr. Arnott's smoke-consuming stoves introduced? Might not a batch of houses be so built that the smoke should be conducted into a smoke chamber, and there precipitated by water? Landlords should consider that the easier they make living for their tenants, the more likely they are to obtain their rents. The consumption of smoke would save coal, diminish the expense of washing, and help to keep the doctor from the door. If something be not soon attempted, I fear the central part of London will be perpetually smoky. I wish you would be kind enough to call attention to this subject in the *Builder*, as it might lead some ingenious constructor to provide a remedy which would be applicable to both old and new houses.

A LOVER OF FRESH AIR.

\* \* \* All sorts of plans have been proposed in our pages. The opinion strongly expressed by us as to the advantage of a certain amount of carbon in the atmosphere has, perhaps, aided by the difficulty of the subject, tended to prevent changes in other respects most desirable.

## PROFESSED RESTORATION OF ST. PATRICK'S CATHEDRAL, DUBLIN.

I SHOULD feel much obliged by your calling public attention to the present doings in St. Patrick's. Public opinion on a subject of this kind is, I am afraid, at a very low ebb. Indeed, the worthy inhabitants of Dublin appear more concerned about such little matters as replacing the ball on the spire, than about the careful restoration of the cathedral to its pristine beauty; so that unless some pressure be brought to bear on those having the execution of the works, I fear we shall have to regret the loss of our noblest monument of church architecture.

The matter from beginning to end has been done in a corner. Mr. Guinness first privately announced his intention to restore the nave, no doubt a very laudable undertaking; but, as a *vis quæ non*, he required the greatest secrecy on the part of a few of those in office; so much so, that although, at the time, the work of restoration was actually in progress, those who had charge of the building, I believe, were not informed of it for a considerable time. I think we may well call in question the conduct of the Dean and Chapter in the matter. In fact they, and not Mr. Guinness, are the parties answerable for what has been done;

and, in my opinion, they have been guilty of a gross breach of trust.

The letter written by Mr. Guinness containing the terms of his agreement, to restore the nave at his own expense, is a curiosity in its way, and will afford to future ages a remarkable instance of the neglect of all that is ancient and beautiful at this side of the chancel, in the latter half of the nineteenth century. I am informed on good authority that Mr. Guinness merely says that he will restore the south wall of the nave, and give it up complete as it originally existed, but stipulates that his promise to do so shall become null and void, should the Dean and Chapter in the slightest degree interfere with him.

How has Mr. Guinness responded to this act of overweening confidence on the part of the Dean and Chapter? First he refuses to have anything to say to those who have been engaged for many years in the restoration of the cathedral. Next he shuts up the place, and will allow no one to enter to see the works. He even makes a boast that he can and will shut out the Dean and Chapter themselves from inspecting them. He entrusts them to a builder, very respectable indeed, but wholly inexperienced in such works. He may know something about Gothic architecture, but how much we may guess from his proposing to erect flying buttresses to an Early English wall, after the pattern of some debased works at the east end of the choir.

Drawings for the restoration of the church were made by the late Mr. Carpenter some years ago, which, on the whole, were excellent, although, in some points, especially the exterior, they were not in accordance with Irish traditions. Even these he has informed certain parties, he does not intend to carry out, as they do not agree with his preconceived theories. The south wall of the nave has been already taken down in such haste that no drawings whatever could have been prepared of it, or no measurements taken to guide its re-erection. This wall was peculiar in many respects, and of these peculiarities no proper notice could have been taken in time. Besides, it was in such a state that it would be only by the most careful examination and collection of fragments that a satisfactory restoration could be made. This, I fear, is now out of the question.

Mr. Guinness would he thought much more of in future ages if he left for a monument St. Patrick's restored,—not a building erected in pseudo-Gothic according to his own ideas, which, however talented he may be as an amateur, are not likely to produce an edifice to be proud of.

I have drawn this letter out to some length, but the matter is of imperial, and not merely of local, interest, and should not be allowed to proceed further without some attention being directed to it.

MEDLEVALIST.

## THE STRIKE IN BRISTOL.

SIR,—In the *Builder* of the 8th inst., under the head of "Trades' Movement" it is stated, "at Bristol the strike of the operative masons is virtually at an end. The men have agreed to resume work at an advance of 6s. per day, with a promise that, on March 18, 1861, the two hours' labour less per week will be conceded. Several of the masters have agreed to this compromise, and it is expected the others will shortly follow their example."

As this paragraph might tend to mislead the operatives, and induce them to prolong the strike, you will oblige by allowing me to state that there is not the slightest prospect of the masters acceding to the present demands of the operatives, nor am I aware that more than three or four "master builders" have resumed work on the terms stated.

ROBERT COMPTON,

Secretary Master Builders' Association.  
\* \* \* The statement came to us from a master builder of Bristol.

BRISTOL MASTER BUILDERS' ASSOCIATION.—THIS STRIKE.—On Monday last, the annual general meeting of the members of the Bristol Master Builders' Association was held at the offices of the Association, No. 50, Quay. A general invitation was held out to all master builders to attend, and there were about fifty present. Mr. Baker occupied the chair. The committee, in their report, pointed out the importance of the Association, stating that it had been forced upon the master builders in consequence of the operatives having combined, from time to time, to enforce demands that have been considered unjust and tyrannical, and to which the masters on many occasions, not being united, were obliged to submit. The association had been called into existence "to resist any unjustifiable demand on the part of the operatives, and to promote the general interests of the building trade;" and on this principle, the committee stated, they had acted. They had entered into correspondence with similar associations, and they had reason to believe that the present movement of the operative masons in Bristol, as well as in many towns in the north, would be the means of inducing the masters to see the absolute necessity of fol-

lowing the example of the builders of Bristol, by immediately forming similar associations. The committee then detailed the circumstances connected with the strike in Bristol, and regretted that they could not conclude the report with the gratifying intelligence that perfect harmony existed between the masters and the operatives. It is thought that the demands of the operatives were such as the masters could not accede to, and expressed regret that the operatives had refused to leave the masters in dispute to the arbitration of an equal number of masters and operatives, with a chairman independent of each. The chairman, in moving the adoption of the report, referred to the misrepresentations by which the operatives had, to some extent, gained the sympathy of the public. But what, he asked, was to dictate the rate of wages? Surely they should not elevate the wages in one individual town into a prominence largely above the surrounding towns. Within a radius of fifty miles of Bristol there was not to be found a single instance in which wages were so high as they were in Bristol. The general average was a guinea a week; but if the demands of the Bristol men were acceded to they would receive 29s. per week. Having pointed out the evils that would result from this high rate of wages in overslocking the labour-market in Bristol, the chairman said the association was purely one for defence—its rules forbade any aggressive policy. They must confine for such purpose only until men obtained more experience and more education, and he was quite sure that it was only by the strong arm of defence of that kind they would be able to hold their relative positions. Mr. Baker then alluded to the tyrannical measures adopted by the operatives' society to prevent men going to work, after which he continued by saying that the masters had considered the question relative to a re-arrangement of wages, or a re-adjustment of the system of paying men to set aside any question relative to lessening the hours of labour. It had been suggested that the men should be paid by the hour; that an increase of wages should be given under the new system, and half a day's holiday on Saturdays. That suggestion, however, did not meet the approval of the men, though it was hoped that the masters would yet be able to carry out such an arrangement. The carpenters, he believed, would be ready to fall in with such a scheme, and the masters hoped next year to remodel the whole system of paying wages.

Mr. Yalland seconded the motion, observing that the struggle which they had entered into was a painful one, but it was their duty to continue their resistance. He had experienced for the last year or two the inconvenience, trouble, and anxiety, caused by strikes; but he was now getting a little used to them. He thought the demands of the men were unjust and tyrannical, and that the masters would do right to adhere to their first resolution. The report having been adopted, a vote of thanks was tendered to the committee for their services during the past year.

Mr. Foster then proposed, "That this meeting highly approves the course adopted by the master masons in resisting the exorbitant demands put forward by the operative masons, and would urge them still to continue the same." He said they did not wish to take any advantage of the men. If the state of things in the country and the neighbourhood would justify any advance of wages for the men, the masters of Bristol, he thought, would be prepared to give it, and would have no disposition to resist it; but they had resisted the present demand because they did not think such an advance was called for. If the present demands were conceded, the masters would be masters no longer, and they might almost as well give up business altogether, and leave the public without any one to manage the business for them, so that they must go to the workmen themselves.

Mr. George seconded the motion, after which Mr. Bowden alluded to the report the men had published to the effect that thirty master masons had already given the advanced wages. He had looked in the "Bristol Directory," and could only find ten out of the thirty names there, and of these ten, he had told him that it was not true that they had given the advanced wages, while of the other five some were speculative builders, and only one or two general masons. Mr. Bowden never said the master builders were unanimous, and he believed there was not the slightest desire on the part of any one master to give way to the men.

A vote of thanks was then passed to the chairman, and the proceedings terminated.

We may add that owing to the strike, there is no public work in hand in Bristol at present.

### Miscellaneous.

**EVIDENCE AS TO THE ARCHITECTURAL MUSEUM.** We have in type some part of the evidence given to the parliamentary committee on the South Kensington Museum bearing on the Architectural Museum, but we are compelled to postpone it.

**LAMP-BLACK AND OIL AS A CAUSE OF FIRES.**—Some correspondents of the *Star* testify to the liability of lamp-black to take fire under certain circumstances. One of them, Mr. W. Estwick, of Southgate-road, says,—"A few years ago one of my workmen placed a ladle which had been recently used for the purpose of measuring linseed oil upon the top of a cask of lamp-black, and a few drops of the oil fell into the cask. One evening, just before closing the works, I discovered a very disagreeable smell; I therefore searched the factory to ascertain the cause, and to my great surprise found the whole of the black in the cask resemble a large ball of fire, and I have no doubt that before morning it would have burst into a flame, and caused not only the destruction of the stock, but the entire premises. My plan since the occurrence has been not to keep more black in stock than required for present use." Wood or canvas, painted with lamp-black and oil, ought to be carefully looked to; at least till well seasoned, if entirely safe even then.

**TREASURE TROVE.**—The finding of gold, silver, and copper coins, ornaments, and other relics, having led to considerable confusion and dissatisfaction among the persons finding and those claiming a right to them, the Government has issued, through the Home Secretary, instructions authorizing the payment to finders of relics of antiquity in England and Wales, of the actual value of the articles, on the same being delivered up for behoof of the Crown. Where persons refuse or neglect to deliver them up, measures may be taken for their recovery, and information forwarded to him.

**HIGH-ROAD RAILWAYS.**—The subject of a line of rails to be laid down on the present high road between Paisley and Glasgow, so as to admit of omnibuses, drawn by horses, for the cheap, safe, and speedy conveyance of passengers, has been mooted. It was on this line of road, we recollect, that Mr. Scott Russell started steam carriages many years ago; and they ran well till the road trustees, as stupidly as maliciously, laid on a very thick stratum of loose "metal," which compelled such high pressure on the engine that an explosion ensued, which "blew up" the whole scheme. Now, it is to be hoped, road trustees have more sense; for the broad wheels of such carriages would benefit a road rather than injure it; but a line of rail or tramway would obviate, of course, even this supposed difficulty.

**THE FIRST RAILWAY IN SOUTH AMERICA.**—The great event of the past month, says a June number of a *Natal* paper, has been the official opening of our little railway, which has now become a matter of history. True, it is only a single line, and no more than two miles in length, namely from the "Point" landing jetty, near the custom-house, on the margin of the bay, to the centre of the town of Durban, near St. Paul's Church. That event took place on Tuesday, the 26th of June, exactly eighteen years to-day after the relief of Captain Smith and his brave little band of Britons by the arrival of the Southampton, when Port Natal was wrested from the Dutch Boers and declared a British colony.

**DRINKING-FOUNTAIN MOVEMENT.**—The Bath City Act Committee, at the suggestion of their engineer, propose to erect drinking-fountains near urinals, so that the surplus water from the former may run in and purify the latter. The association of ideas is by no means a pleasant one, and the practice appears to be objectionable, and likely to bring the Bath drinking-fountains into bad odour. A design for one of the proposed fountains, to be erected inside the railings near the rinal at the Old Bridge, has been submitted to the Board and generally approved. It is of simple character, consisting of an iron pillar surmounted by a vase, from which the water will flow into a reservoir at the top of the pillar.

**THE LATE "RAINY SEASON."**—Sir John Herschell, while repudiating certain rumours that he had "predicted the weather," or become "a weather prophet,"—a reputation which he does not seem to covet,—nevertheless says,—"I do plead guilty to having formed an opinion, from some remarkable phenomena exhibited by the sun last year, and others which it has since continued, and still continues in a somewhat diminished degree, to exhibit, that this summer would prove, as it has done, a rainy one. . . . Scientifically speaking, and connecting these phenomena (which are *publii juris*) with the laws of solar periodicity, regard the meteorology of the last twelve months as more pregnant with instruction than may take some opportunity of time on record; and I that matter in a more definite and public form." An "eminent astronomer and meteorologist in Belgium" is said to have published a theory on the subject, according to which the continued monsoon winds from the south-west brought a settled continuance of rainclouds from the southern regions, where "a volcanic eruption in the latitudes has occasioned the melting of immense quantities of ice, and produced an enormous amount of vapours and clouds" deluging Australia, and resisting other causes tending to change, of course, till they had all passed over the north of Europe. With south-west winds such as we have had, however, passing north-eastwardly over the *Pacific* and *Atlantic*, there seems little occasion to look to "volcanic eruptions" as a continued source of moisture. And, after all, has not the singular diminution of the rainfall for a series of years (leading to fears of its permanent decrease, as we noted, it may be remembered, at the time), something to do with the recent excess as a restoration to the average quantity? As to what part the sun may have played in *both* cases, it is for Sir John Herschell to enlighten us.

**LOOK TO YOUR RAILWAY ARCHES.**—A government inspector is sent to examine a new line of railway: he "goes over" it, dines with the directors: the people flock up and down for a few years: a dreadful accident occurs, and an inspector is again sent down to find out how it happened. I think now it would be better for these gentlemen to inspect the lines every two or three years, so as to point out how accidents may be avoided; and I beg to suggest that they commence with the North London Railway, looking first of all to the arches which cross the King's-road and York-road (late Maiden-lane), for these two alone will show to what condition railway works can soon get if not attended to.—G. T.

**MONUMENTS AND MEMORIALS.**—The London correspondent of a Manchester contemporary says:—"The sub-committee for the erection of a monument to Mr. Hallam have induced three of our younger sculptors to enter into a competition for a full-length statue to be erected in St. Paul's. The authorities of Westminster Abbey would have given the space for a tablet or bust, but declined to entertain the project of a statue. The sculptors are Messrs. Theed, Noble, and Mauro."—A memorial tablet has just been placed in the north aisle of Exeter Cathedral, by the officers and privates of the 9th Lancers, in remembrance of officers and privates killed during the late campaign in India. The tablet is of white marble, with the figure of a lancer, fully accoutred and mounted, on each side, and the medals, stars, and crosses awarded for services in India, pending from a scroll.—A monument is in preparation, to be erected at St. Paul's Church, Penzance, to the memory of "old Dolly Pentraeth," who is said to be "the last person who spoke the Cornish language." This will bear a suitable inscription, and is being prepared, conjointly, by the vicar and Prince Lucien Bonaparte.—September 12th was definitively fixed as the day of the inauguration on the heights of the *Pay de Dôme* of a colossal statue of "the Virgin," cast from the cannon taken at Sebastopol. The bishop of the diocese, Mgr. Morlhon, in a pastoral letter, says—"This colossal statue will remind future centuries that on September 5th the Emperor promised to Mary the canons of Sebastopol, and that on September 8th Mary opened the gates of Sebastopol to the Emperor's soldiers. May this happy alliance between heaven and earth, between religion and authority, be drawn closer every day." The transaction, as thus stated, does not look altogether admirable!

**ELECTRO-TELEGRAPHIC PROGRESS.**—The Electric and International Telegraph Company having offered the French Government to establish a line between Dieppe and Newhaven, and to transmit messages from the coast of France to all parts of Great Britain and Ireland at a reduced tariff, the directors of the Submarine Company have, under the terms of their concession, given notice to the Government, that they will exercise their right of preference. The directors state that they have ever been advocates of low charges, and they believe that a reduction in the tariff may be met by an increased traffic.—The failure of the attempts hitherto made to connect America with Europe by a submarine telegraphic system has not discouraged the hope of the eventual realization of the project. In addition to the Shaffner and other schemes of deep sea telegraph cables, Mr. Perry Collins, formerly United States commercial agent at the Amoor River, is pushing his scheme for uniting St. Petersburg, Moscow, &c. direct with San Francisco. The Russian Government is also interested in it; and the Canadian parliament has freely granted permission so far as the line will pass through their territory. The Russian-American Telegraph Company is the title adopted. There are one thousand miles of telegraph line already constructed directly eastward from Moscow to Perim, while another part is being constructed further east across the Ural Mountains to Ekatarinburg, with the design of extending it to the Amoor river. The Russian Government has granted to Mr. Collins the initiatory surveys from the Amoor river eastwardly, so far as the Russian possessions are concerned. It is proposed to extend the line from the Amoor either by the western coast of the Sea of Okhotsk to Kamtschatka, and thence by Bebring's Straits into Russian America, stretching down along the coast of San Francisco, or else by and down the island of Saghalien across the Strait of La Perouse into the Japanese islands, with a branch line to Hongkong, and up north by the Kurile and Aleutian islands to Russian America. The distance from San Francisco to the Amoor river will be about 6,000 miles—half way to Moscow; and the total cost of the line needing to be done, independent of Russian, will be about 2,000,000 of dollars.

**NEW CHURCH AT HORNSEY.**—It is in contemplation to erect a new church at Crouch-end, Hornsey. The population is rapidly increasing, and the small chapel in which service is performed is no longer adequate to the wants of the locality. A site is promised by Mr. Charles Scrase Dickens, of Cooleshurst, Hornsey, and the church is to cost about 3,000*l.*, of which rather more than half is subscribed. Mr. E. H. Chapman and lady give 150 guineas, Mr. G. Warner and Mr. Hitchcock 100 guineas each, Mr. W. Block 100*l.*, Mr. Clay, 100*l.*, Mr. R. Hanbury, 50*l.*, Lord Shclrhurc and Mr. R. Hanbury, M.P., 20*l.* each.—*Guardian.*

**THE BUILDING TRADES MOVEMENT.**—At Bath a conference of the masters and masons has been held, at which the masters, it is stated, we know not with what truth, have offered to increase the rate of wages 6*d.* per day, and to allow the men to leave at four o'clock on Saturdays after 1st of March next. The proposal has been favourably received by the representatives of the operatives.—A petition of the working builders of Kettering is in course of circulation, praying for the masters to allow them to strike work on Saturdays at four o'clock; their weekly wages to be paid at that hour.

**Gas.**—The Warminster Gas and Coke Company have resolved, says the *Wills Mirror*, to reduce the price of their gas one-fourth, viz., from 6*s.* 8*d.* per 1,000 cubic feet to 5*s.*: this reduction, it adds, will no doubt lead to a much larger consumption.—At the annual meeting of the Truro Gas Company it was resolved to reduce further the price of their gas: the net charge will be 5*s.* to 5*s.* 4*d.* per 1,000 feet. "The company," says the *Cornish Telegraph*, "have in the past twelve months expended upwards of 2,000*l.* in rendering the works capable of supplying the increased requirements of the town; and this almost simultaneous reduction in the price of gas will no doubt be fully appreciated by the consumers, and lead to its being more extensively used, especially in private houses."—The Wolverhampton Gas Company have just announced their usual dividend of 5 per cent. for the half-year, and the addition of a remainder to their reserve fund. The chairman, in moving the adoption of the report, justified the expenditure incurred in laying larger mains, by the necessity for giving a larger supply of gas, and said the reduction recently effected in price would, it was presumed, increase the consumption.

**STEAM BAKERIES.**—Steam-baking companies have been formed in many of the large cities of the Union for the purpose of supplying pure bread at a moderate price. The freight on a barrel of flour from New York to London is 3*s.* 3*d.* per barrel; other charges, 9*d.*, making flour costing 2*s.* 9*d.* in New York worth 33*s.* in London. Now, if the bakers there sell an 18-ounce loaf at 3*c.*, being 6 ounces for a half-penny, the bakers in London should sell, allowing for the charges of transportation, a 4-lb. loaf at 6*d.*, instead of which many bakers are charging 7*d.* and 7*d.* for these loaves. Estimating the average price of the best bread at 7*d.* per loaf, it is 1*d.* more than we should expect to find it, judging from the American prices of flour and bread. There is this difference between steam bread-making and baking in America, and manual bread-making and fire-baking in England. Everything is in favour of a cheaper production of bread in this country than in America, when flour is sold at the same price, excepting that there the bakers have availed themselves in their business of steam and machinery, which cost less than the cheap hand-labour of this country. A penny a loaf may seem to some a small matter. It makes little difference to the wealthy, or even the middle class; but there are thousands in London to whom the extra penny a loaf is almost a matter of life and death. The population of London is estimated at 3,000,000. Allowing these inhabitants to consume on an average 5 ounces of bread a day, the annual loss to the consumers in this city, occasioned by the inferior manner in which the baking business is conducted, is fully 5,000,000*l.* sterling. Besides the pecuniary loss arising from the hand-and-foot process of making bread (for it is asserted, on good authority, that many bakers of London make use of the latter in preparing the dough for the ovens), the foul, unwholesome air of the underground bakeries of London kills hundreds, and perhaps thousands yearly, before they have lived half man's allotted years. The advantages afforded by the steam bakeries are cheapness of production, a superior quality of bread—not only more palatable, but more wholesome,—and the amelioration of the condition of the journey-men bakers. The certain deficiency of the wheat harvest of Europe invests this subject with peculiar interest.—*The London American.*

**TELEGRAPHY.**—The Queen's Speech, which contained 872 words, was sent by the Magnetic Telegraph Company, from their new Central London Station in Threadneedle-street to Manchester in 20 minutes, Liverpool 21 minutes, Glasgow 25 minutes; and other places, including Leeds, Hull, &c., in the same proportion; the whole transmission averaging about 40 words per minute. The quickest transmission was 43 words per minute.

**MACHINES FOR CUTTING STONES IN QUARRIES.** Mr. Le Blanc, Welbeck-street, has provisionally specified an invention which is intended to facilitate the cutting of stones in open quarries. The *Mining Journal* says,—The machine moves on iron rails, and cuts the stone by means of twelve pickaxes, about 30 inches in length: they are bolted to a cast-iron plate of 60 inches in diameter: these plates are five in number. The boiler is tubular, and is furnished with cylinders, the connecting rods of which act on the same shaft with a double crank. Two pulleys on the same communicate the movement to two other pulleys, the shaft of which is held by two supports on windlasses placed in front of the machine. The same shaft carries two pulleys, communicating movement to two others, each armed with twelve pickaxes, as above shown. The machine when placed on the rails runs from one extremity of the quarry to the other, cutting the stone in a straight line: on arriving at the end it is made to go back, the rails being placed obliquely, so that on arriving at the side it began at, it is in position to commence a second cutting. On the windlasses above mentioned two cords are rolled, and which pass on a pulley fixed at the opposite end of the quarry to that the machine starts from: the shaft, held by two supports on the windlasses, hears also two eccentrics, whose rods govern two iron half-boops furnished with a groove, by means of which the amplitude of their oscillations is increased according as the rods are placed more or less near the centres of oscillation. The half-boops have each at their lower part a catch which governs a ratchet-wheel, fixed on a shaft bearing two endless screws, one having the worm to the right, the other to the left: each of these screws gear with a wheel with helicoidal teeth fixed on the shaft of the wooden drums, forming the windlasses, forces each to turn, and the two ends of the cord winding up, the machine is obliged to advance, drawing as it does on a cord fixed at the other end of the quarry. On the machine having completed a run, cutting the stone a determined depth, the scythes or pickaxes are raised by means of a screw, and the machine is backed to where it was started from.

**WATCHMAKING.**—We gather a few notes from the *Clerkenwell News* respecting the progress of horology in America, which ought to teach the workers in Clerkenwell the absolute need that there exists of advancing with the improved intelligence of the times. On the southern banks of the river Charles, Waltham, Mass., so the report states, Mr. A. L. Dennison has erected a brick building, two stories in height, and enclosing a large quadrangular court. Surrounding this large building there are 100 acres of land, on which, here and there, are placed the cottages which form the rural homes of the watchmakers. Some years since, Mr. Dennison having paid a visit to the Springfield armory, and having been brought up to the watchmaking business, the thought occurred to him that it was possible to manufacture watches also by the aid of machinery. In this attempt he seems to have succeeded; and now, in a large building so constructed that the greatest amount of light is admitted, there is accommodation for something like 250 hands, more than half of whom are females. Driven by a steam shaft, the bands traverse the whole building, and move the various machines which are used in this manufacture. By means of machinery the first cutting of the stamps and dies is effected; also hardening and forming the barrels and gears, coiling and fastening the mainsprings, clamping, coiling, and fastening teeth, sharpening of pinions and axles, cutting escape-wheels, tripping and marking the porcelain dials, drilling and shaping the jewels, and adjusting and fitting together the various parts. The following figures will serve to give some idea of the extent of this trade:—In 1858 there were imported into Great Britain 846,894 watches. In the same year the number of watches half-marked were,—In London, 39,614 silver, and 26,870 gold cases. In Chester, 18,643 silver, and 8,200 gold cases. In Coventry, 16,000 silver cases. In all, 148,923. In 1857, 14,141 watches of British manufacture were exported to America.

**"WORK" HOUSES FOR PARIS.**—It appears that the Emperor Napoleon is determined to do away with mendicancy in his capital. A large building is now ready for the reception of beggars of both sexes, who, after an examination by a commissary of police, to ascertain that they are really unable to obtain work, or too infirm to perform it, are provided with food and clothing. Those who are capable of labour have work to do, according to his or her profession, and the surplus of earnings, after deducting expenditure, which is on a low scale, forms an accumulating fund for individual benefit. The daily food of each consists of a pound and a half of bread, soup and vegetables, and on Sundays there is the addition of meat with little indulgences, according to the state of health of the inmates. Napoleon thus appears to be not only inclined to introduce our workhouse system into France, but to improve upon its modern degeneracy, or rather to go back to the fountain-head, by adopting Queen Bess's original design.

**ANOTHER "NEW MOTIVE POWER," TO SUPERSEDE STEAM.**—The Paris correspondent of the *Star* thus announces the invention or discovery of another of the thousand and one forms of power that are ever threatening to "supercede steam":—"The whole of the scientific world is in a state of revolution at the bare prospect of the success obtainable by M. Lenoir's new motive power, for which we have been prepared for many months past. The trial has been made at last, and the result has excited the greatest interest throughout Paris. As usual in all great discoveries, that made by M. Lenoir is founded upon the simplest fact in science, being merely the application upon a large scale of one of the elementary experiments in chemistry,—that of the synthesis of water in the radiometer. He has simply utilised the principle of the expansion of air, when at a lofty temperature, by means of combustion through the spark of induction of hydrogen. The economy produced is calculated at not less than 40 per cent. by the suppression of the boiler, the chimney, and the other accessories hitherto used in the construction of steam engines, and the machine itself offers a saving of 30 per cent. Several engines, varying from five to ten horse power, constructed by Marinoni, have been despatched to England and Belgium."

**"UNITED HOMES."**—At Lord Dartmouth's house, at Sandwell, near Birmingham, there has been in operation for some time an establishment where unmarried ladies and widows with their children can live as ladies should live, "each lady being expected to select some branch of occupation connected with the objects of the institution, and to assist therein." The rules are rather sternly worded, but as no one is obliged to accept them, or to abide by them longer than she wishes, there may be no harm in that. It is not our present object to advocate the establishment of such institutions, for the difficulty of management must be overpowering; nor do we intend to speak of the sisterhoods now forming in so many places. They have our hearty sympathy; we venture to foresee great results from them; and it is well that we are beginning at last to unlearn the prejudices which not long ago were as marks of orthodoxy to us all, and to learn that so long as a thing may be made good, it matters but little whether sometimes it has been distorted from its proper nature, and been made bad. The nature of the establishments which we wish to submit to the consideration of our readers (calling them, for lack of a better name, "united homes") may be described as compounded of the nature of a boarding-house and of a club; for we would have some members to reside on the premises, but others to have homes, or half-homes, of their own. If we were asked how we would have such an institution set on foot and managed, we should say that it must be done by an individual, not a committee; not by the aid of subscriptions, but, to speak practically, as a commercial speculation. It should be in a town, or, at all events, near one: a large furnished house is required, or, which is better, two houses adjacent in a street, so that a door can serve for communication. The director should be a married man without young children; upon him personally the success of the design would depend; for indeed, in all institutions, and especially when people have to live together, the working of the whole depends upon the head, more than upon any written rules. He should reserve his own apartments in the building; and of course calculate the number of resident members by the accommodation that remains. As public rooms, there should be set apart a drawing-room, a dining-room, and a gentleman's library and a ladies' library; likewise, upstairs, a music-room; if more rooms can be spared, all the better.—*Friend of the People.*

ART IN NEW YORK.—A new Art Gallery, 200 feet by 35 feet, is being erected on Broadway, near St. Thomas's Church, New York. A collection of paintings from Dusseldorf and elsewhere will be placed in it.

RIFLE BUTTS.—According to a drawing and description forwarded to us by the architect, the rifle butt erected for the Leicester Rifle Corps is built of hard Leicester bricks, with close joints of Barrow lime mortar; and afterwards faced with Staffordshire vitrified blue bricks, laid in cement. This facing, though not impervious by rifle balls, is so hard that it will sustain a very heavy fire; and, as the onlay upon it is very small compared with iron facing, it may be refaced annually at about the sum of the 5 per cent. interest on the value of an iron facing. The curve of the plan renders a battering-face to resist the action of wind unnecessary. The cost of the erection was 150*l*. We are not disposed to recommend such a mode of construction. The height, 20 feet at the ends and 25 feet in the middle, seems hardly sufficient.

ANOTHER DEVIANCE TO ST. SWITHIN.—We have often wondered whether it were not possible to desiccate the hay and corn crops, by means similar or analogous to those used for desiccating timber, or to that for rapidly drying clothes at the wash-houses. It is satisfactory to observe that engineers appear to see little difficulty in doing so. Mr. Wakley, in a letter to the *Times*, refers to two machines manufactured by Mr. Lloyd, engineer, No. 70, Guildford-street, Southwark, and Mr. Davison, No. 8, London-street, Fenchurch-street, by which ripe corn, wet from the field, may speedily be dried. Mangel-wurzel and turnips, and possibly potatoes, might be saved by the same means in wet weather. We know not how these machines are constructed, but the mode in which certain desiccations are made is by rapid centrifugal motion; perhaps some modification of the farmers used in winnowing may have been adopted.

A PUBLIC PARK WHICH MUST NOT BE WALKED ON!—The regulations for the government of the West End Park, Glasgow, lately agreed to by the Town Council, have been confirmed by the sheriff, Sir A. Alison. One of these regulations, imposing a fine of 5*l*. on any one walking on the sward, created a good deal of excitement, through the opposition of a locally well-known "people's man," Councillor Moir. That gentleman appeared, by his agent, as an objector, urging that the proposed rule was inconsistent with the object for which the park was acquired, and without precedent in any similar case. The sheriff said that what he had to do was merely to see that the regulations were "not inconsistent with the law of Scotland," and, as such an objection could not be applied, he gave his confirmation.

BRISTOL TIMBER TRADE.—Messrs. Barnes & Co., in their monthly circular of the 1st instant, say the trade is in a more prosperous state than has been known for several years, and that prices are steadily advancing. The arrivals for the past month have been 24 vessels, 13,184 tons register (against 33 vessels, 15,606 tons, for the corresponding month last year), and consist of 5 from Quebec, 4,035 tons; 3 from New Brunswick, 1,787 tons; 1 from Memel, 424 tons; 3 from St. Petersburg, 2,347 tons; 4 from Norway and Sweden, 1,131 tons; 6 from Archangel and Omega, 1,921 tons; 2 from the United States, 1,439 tons; showing a decrease of 9 vessels, 2,422 tons register, compared with the corresponding month last year. For the season commencing February 1st, 1860, to the present time, there have been 71 vessels, 35,071 tons register arrived, against 96 vessels, 45,543 tons register, for the same period last year, showing a decrease of 25 vessels.

ACCIDENTS TO PERSON AND PROPERTY.—At Kildermister, a bricklayer, named Benjamin Bourne, has died from injuries received from falling off a wall at the back of a public-house in Blackwell-street on the previous night. Verdict, "Accidental death."—At Manchester, an excavator, named Emmanuel Cheney, in the employ of Messrs. W. & J. Worthington, contractors, was engaged in making the bottom of a main sewer, near the Queen's road, Cheetham-hill, when a quantity of clay fell upon the back of his neck. The sewer measured 3 feet by 3 feet, and 6 feet 6 inches in height: neither centres nor stays were used. Deceased was taken to the infirmary, where he died on Sunday. A verdict of accidental death has been returned.—A temporary building, in the course of erection at Toulon, for the purpose of a grand ball to be given to the Emperor, recently fell, killing three and wounding fifteen of the workmen, most of whom, fortunately, however, were absent at their dinners.

NEW IRON CHURCH AT KILBURN.—Sir: Oblige us by saying, as to your notice of the above church, that Mr. Browne is not a member of our firm: he superintends that portion of our business relating to the erection of iron churches, schools, and houses.—TUPPER & CO.

THE FIRE AT BLACKWALL: STEAM RAM WARRIOR.—The fire which occurred last week in the premises of the Thames Iron Works and Ship-building Company, at Blackwall, destroyed property of the value of about 10,000*l*. The enormous steam ram called the *Warrior* will be much delayed by this fire. The tonnage of this vessel is estimated at between 6,000 and 7,000, and her aggregate cost at about 380,000*l*. Her machinery will be about 1,250 horse-power, and will propel her at the rate of 13 or 14 knots an hour. She is, first of all, built wholly and strongly of iron, and upon this groundwork she is being covered over with oak 18 inches thick, and over this again encased from stem to stern in wrought-iron 5½ inches thick. All the woodwork for this gigantic specimen of naval architecture, including the sawing, planing, tenoning, mortising, and moulding, with all the machinery, has been burnt. The vessel has been on the stocks about twelve months, and was expected to be launched about Christmas.

THE AMERICAN SHIP BALLOON.—The preparations, it is said, are nearly completed in New York for the departure for Europe of Professor Lowe and his associates in their aerial ship. A trial trip has already been made with a successful result. Should this European voyage be successfully accomplished in the short space of 48 hours, as the professor anticipates, it will make a complete revolution in the manner of conveying intelligence between the two continents, as advantage can be taken of the eastward current in the return voyage, by passing round the world. The name of this novel ship is the *Great Western*. Its extreme length or height is 300 feet; its largest diameter, 135 feet: the basket in which the mail and passengers are to be conveyed is 30 feet in diameter, and constructed to carry twelve persons. Under this basket is an iron life-buoy, 40 feet long, which contains a calorific engine, designed to give direction to the ship by moving a fan, rather than to propel the ship itself.

TENDERS

For board-room, surveyor's residence, &c., at Ebury-bridge Wharf, Finsbury, for the parish of St. George, Hanover-square, Mr. R. W. Jencks, architect. Quantities supplied by Messrs. Pearson & Doughney, and Mr. Green:—

Williams, Brothers.....	£6,987 0 0
J. Harding.....	2,478 0 0
J. & C. Todd.....	6,958 0 0
G. Myers.....	6,990 0 6
Rowe.....	6,830 0 0
T. Jackson.....	5,756 0 0
Batterbury.....	6,559 0 0
Jackson & Shaw.....	6,475 0 0
Fish.....	6,250 0 0
Atkinson & Son.....	5,993 0 0
Watson.....	5,750 0 0
Evans, Brothers.....	5,672 0 0
Todd, Junr.....	5,509 0 0
John Grant.....	5,575 0 0
Ruddin.....	5,544 0 0
Woodruff.....	5,497 0 0

Received by Board of Works for the Hackney district, for granite. Mr. James Lovetogov, surveyor:—

Pennington (Guernsey granite).....	16s. 11d. per cubic yard.
Newton (Blue Elvia granite).....	12s. 4d. "
Ross (Bombay granite).....	12s. 2d. "
Ross (Port Phillip granite).....	9s. 2d. "

Note of the tenders were accepted. "

For sewer works at Stoke Newington:—

Wood & Sons.....	412 0 0
Bilton & Clarke.....	413 7 11½
Hartland & Bloomfield.....	350 17 0
Tottle.....	340 6 2
Abbot & Hopwood (accepted).....	320 0 0

For a public-house at Victoria-park-road, for Messrs. Holt. Mr. Charles Dunch, architect:—

Ennor.....	£1,760 0 0
Wood.....	1,735 0 0
Perry.....	1,753 0 0
Brown.....	1,740 0 0
Hedges.....	1,694 0 0
Chapman.....	1,664 0 0
Hack & Son.....	1,455 0 0
G. J. Watts.....	1,450 0 0
G. Blackburn.....	1,432 0 0

For building Jireh Chapel, in East-road, City-road, for Mr. J. A. Jones and Committee; and for pulling down the old chapel in Brick-lane, Old-street, Mr. Richard Howard, architect. Quantities not supplied:—

Sargeant.....	£749 0 0
Bugg.....	649 19 0
Raby.....	623 0 0
Riley.....	590 0 0

For setting out, forming paths, planing, and completing the pleasure-gardens in connection with the Link Hotel, for the Great Malvern Hotel Company. Mr. E. W. Elmist, architect:—

Bowker (accepted).....	£774 0 0
------------------------	----------

For new mill, Blackfriars, for Mr. Neville. Messrs. John Young & Son, architects:—

Henshaw.....	£595 0 0
Larke & Son.....	589 0 0
Hollam.....	564 0 0
Chessum.....	470 0 0

For works to be done in pulling down and rebuilding warehouse, No. 52, Bow-lane, for Mr. William Vivian. Messrs. Tiltot & Chamberlain, architects:—

Lawrence & Son.....	£1,757 0 0
Brown & Robinson.....	1,767 0 0
Rider.....	1,754 0 0
Ashby & Sons.....	1,695 0 0
Fish.....	1,650 0 0
Piper & Son.....	1,667 0 0
Wills.....	1,663 0 0
Thamer & Son (accepted).....	1,650 0 0
.....	1,591 0 0

For residence for Mr. L. S. Watson, Wisbech. Mr. W. Adams, architect:—

Bateman.....	£3,920 10 0
Andrews.....	2,990 0 0
Stimpson (accepted).....	2,970 0 0

For a brewery at High Wycombe for Messrs. Lucas. Messrs. Pontifex, engineers. Quantities supplied by Mr. Arthur W. Q. Nicoll:—

Williams (accepted).....	£1,990 0 0
--------------------------	------------

For new residence for Mr. C. J. Gibb, M.D., Westgate-street, Newcastle-on-Tyne. Mr. T. E. Watson, architect:—

Masonry.

Reed.....	£1,735 0 0
Spoof.....	1,522 10 0
Scott & Reid.....	1,500 13 9
Dunlop.....	1,477 0 0
Ferguson.....	1,457 0 0
Gibson (accepted).....	1,448 0 0

Carpentry.

Spoof.....	£1,210 0 0
.....	1,120 0 0
W. & C. Burnop.....	1,117 0 0
J. & W. Lowrey.....	1,128 0 0
Waite & Howard.....	1,009 4 0
Curry.....	986 4 2
Dunlop (accepted).....	950 0 0
Gowland.....	945 0 0
Belderby.....	835 0 0

Slating.

Sanderson.....	£131 0 0
Beck (accepted).....	139 0 0

Plumbing.

Simpson.....	£262 2 2
Watson.....	219 10 0
Balby.....	219 8 0
Stewart & Young.....	200 0 0
Graham (accepted).....	198 0 0

Plastering.

Wilkinson.....	£246 5 0
Aitken (accepted).....	223 14 0

Painting, &c.

Hodgson.....	£157 4 0
Richardson.....	155 10 0
Gibson.....	148 0 0
Leighton.....	140 10 0
Gibson (accepted).....	138 14 0
Dunn.....	133 0 0

For addition to Curzon-street Schools, Mayfair. Mr. R. Heseth, architect:—

Welshman & Gale.....	£1,300 0 0
Watts.....	1,010 18 6
Hayward.....	990 0 0
Cook.....	983 0 0
Macey.....	975 0 0
Fish (accepted).....	973 0 0

For the construction of 4,971 feet of brick sewers, and 4,555 feet of pipe sewers, in the borough of Derby. Mr. T. C. Thornbury, C.E., borough surveyor:—

Thompson & Tycer.....	£2,283 10 0
Royas & Whittle.....	2,100 0 0
Hyslop (accepted).....	1,458 8 4
Surveyor's estimate.....	4,153 7 9

For the erection of a homestead at the Manor Farm, Barking, for Sir Edward Hulse, Bart. Quantities supplied by Mr. Robert Leabon Curtis:—

Hughbridge.....	£1,530 13 0
Wood & Sons.....	1,386 0 0
Hosworth.....	1,250 0 0
Ashmole.....	1,245 0 0
Martin.....	1,215 0 0
Hamaond (accepted).....	1,147 0 0

For works to be done at No. 12, King-street, Chapside, for Mr. Surr. Messrs. Tiltot & Chamberlain, architects:—

Canon.....	£630 0 0
Wills.....	583 0 0
.....	538 0 0
Sewell.....	526 0 0
Jennings.....	522 0 0
Papps (accepted).....	434 0 0

For works at the Armoury House, Finsbury, for the Hon. Artillery Company, under the superintendence of Mr. Henry W. Luss, architect. Quantities supplied by Mr. S. H. F. Cox:—

NAME.	Magazine.	Basement.	Drainage.	Clothing.	Armoury, &c.	Total.

# The Builder.

VOL. XVIII.—No. 920.

Cottage Garden Shows.

HE body and the spirits are alike improved by the cultivation of the garden. It offers an enjoyment for which no one is too high or too low. More grows in the cottager's plot than flowers: the cultivation of pansies may tend to his heart's ease: the bed of thyme may speed a dull hour; and kind thoughts spring up

while watering the clump of forget-me-nots. Every where the heart of man blesses flowers: the child seeks them in the hedges; the old man finds, in their culture and study, soothing recreation and delight: Pagan and Christian have used them in their rites: flowers deck the bride, and are strewn on the grave. In every country they smile around us; to every grade they offer enjoyment: they give additional beauty to the new palace; they lovingly shroud the decaying ruin. Babylon had its hanging gardens; Greece its roses and lilies,—

“*Lilia mista Rosis,*”

and Rome its box-trees cut into the figures of animals, ships, and letters; to say nothing of its violets and crocuses. Our first parents, indeed, came into the world in a garden, and Milton makes Eve say, as amongst her griffs,—

“O Flowers,

My early vilitation and my last  
At even, which I had bred up with tender hand,  
From the first opening bud, and gave ye names,  
Who now shall rear ye to the sun, or rank  
Your tribes, and water from the ambrosial fount?”

The ancients had a different idea of horticultural beauty from ours, if we may judge from a passage in Plutarch, quoted by Dr. William Smith, where he speaks of the practice of setting off the beauties of roses and violets by planting them side by side with leeks and onions, a passage which has been thought to give a proof, that flowers were cultivated more to be used for garlands than to beautify the garden.

Be this as it may, onions and leeks concern us just now as much as roses and violets,—greatly as we prefer the latter on all occasions,—for our purpose is to speak of a Cottage Garden association, the inauguration of which on Wednesday in last week, has led us to make the preceding observations. It was the East Grinstead and Lingfield Cottage Garden society, and the meeting was held to distribute prizes in Felbridge Park, the seat of Mr. Gatty, a short distance from the town. The place was well adapted to the purpose, an expansive sward, with water and noble trees. Here, too, is a monumental column, bearing an altar (very ugly, by the way, in outline), erected from the design of the late Sir John Soane, when young, in memory of the last of the Evelyns, a name well known to the arboriculturist, and inscribed, *inter alia*, with the motto, “Manners maketh man.” A large tent, with “Reward Lightens Labour,” in flowers, and (elsewhere) “Nothing without Labour,” also petalically set forth, contained the various specimens. The society owes its origin, we should say, to Mr. J. Henry Rogers, and it is not the first good work for East Grinstead and its neighbourhood in

which Mr. Rogers has mainly assisted. Similar societies have of late years been established in great numbers in Sussex, and, indeed, in most parts of England, and have been productive of much good. He had no experience of them himself, but thinking it rather a disgrace that a town of so much (relative) importance as East Grinstead should be without one, set to work in the early part of this year to collect information on the subject, and then proposed the promotion of a society for the district. Mr. Lennox, of the same place, cooperated with him as joint honorary secretary, and the result was most satisfactory. The premiums offered included:—For the gardens or allotments which up to the month of September shall have been kept the best stocked, in the neatest order, and the freest from weeds; first prize, 1*l.* 10*s.*; second prize, 1*l.*; third prize, 15*s.*; fourth prize, 10*s.*; fifth prize, 7*s.* 6*d.*; and it was set forth that, in awarding these prizes, the judges, who from time to time inspected the gardens, would take into consideration, not merely the crops, but the size and general state of the premises, including fences, walks, edgings, flower borders, seeds, tools, dung, and piggery. Other prizes were offered for potatoes (some capital specimens were shown), onions, carrots, turnips, apples, pears, and so on. In respect of flowers, no fine words were used; there was no demand for polio-postemonopetala, or the izactepotzaucochiticohuayo! The prizes offered were, “for the best rosegay, 5*s.*; for the second-best, 3*s.* 6*d.*; for the best plant grown in a pot, 4*s.*; for the second-best, 3*s.* 6*d.*,” and so forth. Many societies combine with a cottage show a general show, and award prizes to amateurs and professional gardeners; but this seems a mistake, diverting the attention, and, worse than all, the funds, from those who are especially intended to be benefited, and it was not pursued on this occasion. All the flowering plants shown at Felbridge Park were contributed by the gardeners of gentlemen in the neighbourhood, by far the greater portion being from the gardens of a wealthy Chinese, long resident there, and who preserves that love of flowers for which the Celestials are said to be distinguished.—Mr. Hochee. The gardens of the cottagers in this part of the country, although often admirable, are by no means equal to what they are in many other rural districts of England, though still immeasurably superior to those in most foreign countries or our own Highlands. All must be struck on returning home from a foreign trip with the neatness and freshness of our cottage gardens. After the prizes had been delivered, the specimens, still the property of the exhibitors, were sold by Dutch auction for their advantage.

Cottage garden societies might be made the means of spreading a knowledge of the best modes of cultivation to all parts of the land. This has not been sufficiently attended to yet. At East Grinstead they have endeavoured to make a beginning by presenting to each competitor a copy of Sir Joseph Paxton's capital little work on cottage gardening, and by inducing some of the gentlemen's gardeners to go round from time to time and give their poor neighbours a little practical instruction. Much good might be done if this were generally imitated. Some plan might be devised for supplying, at moderate price, seeds and plants of the most approved kinds. It requires no more labour to grow the best than the worst sorts; but, as a general rule, cottagers, and often those far above them in the social scale, go on perpetuating the kinds of apples, pears, gooseberries, or currants which their fathers cultivated before them, instead of the improved, and equally hardy, and often far more productive varieties which have since been introduced.

An endeavour was made to direct cottagers to the advantages to be derived from keeping bees, and a number of prizes were offered; but not one person competed,—a proof of the unfavourable season. There has been, we fancy, no honey-making this year in the south of England. In the whole, fifty-five persons sent objects for competition, varying in number from one to twenty-three kinds each, forming a total

of 316 lots. It is rather a curious illustration of the effect of trying for too much, that the man who sent twenty-three different articles did not get a single prize, and we have seen this occur elsewhere. The number of contributions by those who did obtain prizes was much less numerous.

Rather more than half the exhibitors obtained premiums, and a number of additional prizes were subsequently awarded.\* Mr. Rogers, writing on the subject, says,—“I am not a cricketer, and therefore, perhaps, somewhat prejudiced; but I have always found that the advocates for that amusement dwell a great deal on its alleged beneficial influence in bringing the high and the low together; but certainly much more might be said on that head in favour of cottage-garden societies, since the earth yields its produce without favour to the high or the low, the rich or the poor. Cricket may develop the muscles, but the spade is surely capable of producing this effect as well as the bat; and, whatever skill a man may have attained as a cricketer, he is incapable of applying it to any useful purpose. At best it is a manly amusement, and but too often the cricket-field not only takes men from their work, but leads to public-house visitings, which do not cease after the cricket season is over. I have often been struck with the dull, vacant gaze of the spectators at cricket matches, loitering about with pipes in their mouths, or seated in the booths drinking beer. The appearance of visitors at a cottage-garden show is very different.”

It is interesting to notice the extent to which gardening has grown. In 1403 the chief products of our gardens were cabbages, onions, and garlic. Apple, pear, cherry, and quince trees seem to have been the only fruit-trees in England at that time. The plum-tree was first introduced into this country in 1580, being brought from Asia. The cockspear hawthorn was first cultivated here in 1692. The maple-leaved hawthorn was introduced into England from America in the year 1738. A beautiful variety of the alder was first cultivated in England in the year 1780, being brought from Switzerland, Siberia, and other cold countries. The cedar was first cultivated here in 1664, and the common white larch, which now covers with such excellent effect so many wild parts of the kingdom, but is becoming diseased, was accidentally taken to Scotland in 1737. Mr. Menzies, of Culladro, having procured four of these plants from Siberia, gave two to the Duke of Atholl, which are still in full vigour at Dunkeld, and may be called the parents of all the larch trees in the kingdom.

The mulberry-tree was introduced in the reign of James I. The lime is said to have been brought into England by the Romans, but it does not appear to have been planted in Scotland before the reign of Charles II. The general cultivation of carrots, it is said, originated with certain Flemings who fled hither in the reign of Queen Elizabeth, and settled at Sandwich, in Kent. Peas were a rarity in that same reign. They were brought from Holland. Fuller speaks of them as “fit dainties for ladies: they came so far and cost so dear.” The opinions which prevail in respect of some flowers are curious. The snap-dragon, for example, is thought by the less advanced people in some countries to exercise super-natural influence—to have the power of destroying charms and baffling malignities. Bachelors' buttons were viewed as having a magical effect on the fortunes of lovers. How oddly, too, have some plants reached us. Saffron, which was at one time cultivated to such an extent in Essex as to give its name to a town, came to us from abroad at the risk of a life. Hakluyt was told at Saffron Walden that a pilgrim brought from the Levant to England, in the reign of Edward III., the first root of saffron, which he had found means to

\* For the gardens and allotments which up to the month of September shall have been kept the best stocked, in the neatest order, and freest from weeds—1*st.* 1*l.* 10*s.*, James Sargeant, Lingfield; 2*nd.* 1*l.*, Richard Blicke, Lingfield; 3*rd.* 15*s.*, George Brooker, East Grinstead; 4*th.* 10*s.*, William Penfold, Lingfield; 5*th.* 7*s.* 6*d.*, John Steer, East Grinstead; 6*th.* 7*s.* 6*d.*, James Borer, Lingfield; 7*th.* James Huggett, East Grinstead 8*th.*, Felix Borer, Lingfield.

conceal in his staff, made hollow for that purpose. "If he had been taken, by the law of the country from whence it came, he had died for the fact." Saffron-hill, Holborn, part of Ely Gardens, had its name from the crops it bore.

Fashion alone produces constant changes in our floriculture. The holly-hock was nearly banished by the dahlia, and is found, even now, more of the pity, often in the cottager's garden than in the dressed ground of the squire. It is to be hoped the cottar will not give it up, and that the squire will take it back; indeed there is evidence that he is doing so. What can be finer than a varied group of them, pillars of brilliant colours, against an old stone wall, or clump of dark shrubs? The most gorgeous bit of colour we can remember to have seen was a front garden thus fitted up, near Wilton, in Wiltshire. There are some capital single specimens round about the spot of which we have been speaking. The dahlia, we may mention, which comes from Mexico and is named after Dahl, a Swede, was brought into fashion by Lady Holland, at Holland House, Kensington, in 1804. The English are peculiarly favoured in being able to cultivate, thanks to climate and science, nearly every description of plant. The wonderful orchid from Mexico, the moss from Iceland, the creeper from Indian jungle, can alike be made to flourish in this country. However, what we have chiefly in view just now are the flowers—

"That dwell beside our paths and homes,"

the pleasures they afford, and the means of extending these enjoyments. In the vicinity of populous towns, advantages would arise from proprietors letting small portions of land to their less fortunate neighbours for garden purposes, in which the wives and children might assist. We can speak positively as to the benefits of such a system, and of how many kindly feelings it is the producer. We would have the enjoyments of the garden made as general as possible. We do not ask for an Isola Bella, where a barren rock, manured with gold, is made to bloom with bays and orange trees, or *Louis Quatorzime* expenses with fountains and statues, and delusive perspectives, the glories of Beulheim and Stowe, or even gardens after the "grand manner" of Batty Langley (much abused of men). We plead but for the simplest enclosure, and the homeliest flowers. How much is the family strengthened by the daisy necklace strung in infancy, and the after-life brightened with the recollection of chaplets of wild flowers woven for saucy faces in early life. It has been said too, and wisely, that "if you are poor, yet modestly aspiring, keep a vase of flowers on your table, and they will help to maintain your dignity and secure for you consideration and delicacy of behaviour." For the same reason, it is not surprising to learn what they who have been in the habit of awarding prizes in various parishes say, and it is this,—that in almost every instance where they have found a good garden, they have observed that the woman, the children, and the house, are also neat, orderly, and well kept. We need not seek a better piece of evidence with which to close our notice of the East Grinstead Cottage Garden Society, or a better reason for advocating the establishment of a similar association in every village where there is not one already.

#### EVIDENCE TOUCHING THE ARCHITECTURAL MUSEUM.

A COMMITTEE of the House of Commons, it will be remembered, were appointed during the last session to inquire and report concerning the "South Kensington Museum." The following is that part of the evidence given by Mr. Henry Cole, C.B., which refers to the Architectural Museum:—

**Chairman.**—Will you state the circumstances connected with the collection of architectural casts?—The collection of architectural casts was originated by the School of Design; the South Kensington Museum have added but very little to them for want of room, chiefly, and partly for want of funds; but a large collection of architectural casts is deposited in the South Kensington Museum which is the property of the Architectural Museum, and which was formerly deposited in hay-lofts in Cannon-row.

Will you state under what agreement they were depo-

sited at South Kensington?—They requested that space should be assigned them in the South Kensington Museum, and permission was given to them to have them there for three years, which will expire next year; and, owing to the state of the building and owing to the want of room, notice has been given to the committee that the space can no longer be available for them.

What was the state of the building which caused that notice to be given?—The space allotted to the Architectural Museum Committee was in the galleries of the iron building, and an engineer found that the floors began to swing, and we thought that the building was in some jeopardy, so that we were obliged to take all the heavy articles out of the gallery and put them down stairs.

That was one reason, was there any other?—Another reason for giving them notice was, that the casts which the country had purchased as examples for the Houses of Parliament had been handed over to the Department; they were in fact, originals of a great many of the casts of the Architectural Museum; so that it was hardly justifiable to find space at the public cost for the originals and for duplicates.

Are these casts taken for the Houses of Parliament valuable?—I believe that they cost about 7,000l. You are not able to find room for them at present?—At present we cannot receive them.

Can you state any advantage that has resulted from this architectural collection?—Partly owing to this architectural collection, and partly owing to the disposition of the country to build churches at the present time, and partly owing to our School of Design, Gothic architecture is very much better than it was thirty years ago.

**Mr. Hankey.**—What is the Architectural Museum?—It is a voluntary association of gentlemen and workmen, who subscribe from 1s. to 100s. a year, who elect a committee, the president of which is Mr. Alexander Bercsford Hope, and the treasurer Mr. Gilbert Scott. It is a sort of architectural society for the express purpose particularly of improving carvers in stone.

Is it not an institution intended as a private speculation?—No.

**Mr. Adairley.**—Is that Museum much attended by visitors?—As a popular collection, I think that it is the least popular part of the South Kensington Museum; as to its use to workmen, it is used by them and by the students.

**Mr. Hankey.**—Is this Museum in a completely separate building from the other buildings?—No; it is the same building, with a large portion of the ornamental art collection.

You spoke of it as being in a critical state?—I referred to the galleries.

Mr. G. G. Scott, A.R.A., gave the following evidence:—

**Chairman.**—When was the Architectural Museum established?—It was originated at the close of 1851, and it was actually established in March, 1852.

What were its objects?—It had two objects: the main object was to facilitate the studies of art-workmen in all the arts subsidiary to and connected with architecture; the other object was to supply a deficiency which up to that time existed in all our public collections, that they did not attend to Medieval art except in a trifling degree.

What were the circumstances which led to its formation?—It was mainly owing to the want which had been very long felt for our art-workmen: the arts subsidiary to architecture had much sunk of late years, and art-workmen, being usually men of rather the humble orders, had no means whatever of following up their studies. Supposing the objects they should study from to have existed in England, they had not the means of travelling to ancient buildings in England; and those objects were abroad still less had they the means of studying them: it was only therefore by bringing the subjects of study within their reach that we could in any degree hope to improve their taste; but the exact circumstances originating the Museum were these: Mr. Bruce Allen wrote several letters on that subject to the *Builder* in 1851, which had been suggested to him by the Great Exhibition; "Just about the same time, I happened to write a letter to the *Builder* on a different subject, which was this. The only great collection of Medieval art which had been made up to that time in England, consisted of architecture, was the late Mr. Cottingham's, and it was the very offer of the Government for sale. I wrote to the *Builder* suggesting the importance of the subject being pressed upon the Government. The Government, however, refused to entertain it. That brought me in contact with Mr. Bruce Allen, and we invited a number of architects to meet together with the view of doing for ourselves what the Government had partially refused and partially neglected to do for us, and from that originated the formation of the Museum. Those architects formed themselves into a committee and founded the Museum.

Is it limited to one style of architectural art?—No; one of our leading objects being Medieval, that naturally takes the precedence; but, our object being educational also, we have intended it to become a general museum, and it contains a very great number of specimens in the Classic and Renaissance styles.

**Sir John Shelley.**—You stated that "the Government partially refused, and partially neglected," will you explain that?—It was refused, and the Government proposition had been placed before them in a specific form, and it had been deliberately refused. They had not done that; it was rather that the subject had not been attended to as regards Cottingham's collection; however, they had declined what had been proposed to them.

**Chairman.**—What means have you taken to render your museum instructive to art-workmen?—Many different means; we have instituted lectures in connection with the museum: there is a series of lectures every year, perhaps half a dozen lectures, intended more or less to help the studies of workmen. In addition to that, we offer every year prizes for the best works of architectural art of different kinds; but the great thing of all is, that, as architects are really the employers of those men, each Museum, and we take pains to instruct them in it.

What were the circumstances which brought the Architectural Museum into contact with the Department of Science and Art?—There were two or three: a deputa-

\* For years before this we had urged continuously the desirability of establishing an Architectural Museum. The conductor of the *Builder*, in 1846, in conjunction with the British Museum, of Northampton, as one of the trustees of the British Museum, the body at that time looked to for assistance in it, had schemed out such a museum as has since been striven for and remains still to be formed.

tion from our committee called at an early period of our existence (I cannot remember the year: I think in 1844), Mr. Cole, Mr. Hankey, and I were kindly received by them, and they came and attended at a meeting of our committee, and gave us useful advice, and altogether we entered on friendly relations with them. In 1855 they opened a museum to us, and we took them to us, and it should be annual, for that year, in consideration of our Museum; the lectures, the use of our Museum, and other advantages.

How came you to occupy a portion of the space of the South Kensington Museum?—I should have mentioned that at that time our Museum was in a very rough place in Cannon-row; we had extensive premises in a sort of loft, in which was an extraordinary collection of casts, &c., procured either by gift, or loan, or purchase. We had raised funds by applying in all quarters, and in the course of a year or two we had formed a wonderful collection of casts and other objects, and had completely outgrown the room we had. When we applied to Mr. Cole and Mr. Redgrave after the close of that year for which they subscribed 500l., to ask whether they would continue that as an annual subscription, we received a reply to this effect,—that the circumstances under which they were placed were about to alter; that they were about to remove their museum and schools of art from Marlborough House to the South Kensington Museum, and therefore their students would be more removed from the neighbourhood of our museum, and would be less able to make their building good; to ask whether they would thought they should not continue that subscription; but they suggested to us, that, instead of applying for a subscription, we would shape our application in another way:—that we should apply to the Government for a museum, though they could not answer for the reply we might receive, probably it might be favourably entertained. We therefore thoroughly considered the subject at a meeting of our committee, and after some rather somewhat lengthy negotiations, ended in their agreeing to admit us as tenants of a certain portion of their galleries, we retaining our power over the collection as before.

How was it admitted, accordingly to a portion of the iron building?—Yes.

Has your occupation been of advantage to you?—In most respects it has: the situation is not quite so convenient as was in the workmen; but that is an inconvenience which things must necessarily occur, you cannot get space for these things in London; but in every respect it has very much served the object we had in view.

In what way?—It has reduced our expenses: we were very poor; and it has relieved us, perhaps, to the extent of 150l. a year; also we have the collection placed in a much better building than we had then; the specimens are seen better, and it is generally an object to have such collections in a public building.

Has your museum been successful in effecting your objects?—Most entirely successful in effecting our objects. In the first place, we have collected together an extraordinary number of specimens: I do not say that they are all good, because we have purchased, and had the means of procuring, what we have had good and bad together; but, putting aside the indifferent ones, and viewing it only in reference to the thoroughly good specimens, it is a most wonderful collection, such as has never been made in this or any other country before, nor anything approaching to it.

Have the arts connected with architecture been benefited by it?—In a most important degree: the taste of carvers has improved wonderfully; I have letters from several master carvers which state in the strongest terms that the skill of the workmen has improved in the most remarkable degree, and I have found myself, in all my own works, there is no comparison between the work executed before and after the formation of this museum.

You think that you can trace that distinctly to this museum?—Distinctly; because the men who have executed them have all been in the Museum, and they have seen them, and they have improved their taste by it.

It is an attractive collection to the public?—Only partially so; our object has never been to make an attractive collection to the public: our intention was to satisfy a want which we were every day feeling, the want of proper education of the workmen who have to carry out the ornaments of our work; and therefore it was not practical that the public at large, after going through the picture galleries, and the other more attractive objects of art, when they came to our Museum feel particularly gratified; but that part of the public who have given any attention to architecture, or who feel any interest in it, are delighted with it.

Have you and the Department got into any difficulties as to co-operation?—We have not, until lately, got into any difficulty of a serious kind: we have gone on in the main very smoothly till the last few months.

What has happened now?—The iron building has been found to be giving way. We found that we had unwittingly become tenants of a building incapable of bearing the weight which we had brought into it, and at the beginning of this year we received a letter from the Department of Science and Art, saying that Captain Fowke had examined the floors of the building, and had found them to be very insufficient for their weight, and requesting us to allow all the heavy part of our collection to be removed into the lower part of the building. We, of course, objected to that within certain limits: at the same time we objected to its being carried to such an extent as to ruin the arrangement of our museum altogether, and mix up objects of different styles; but within such limits as that we thoroughly acceded to their request. We followed up that consent by a suggestion, which was the result of a careful examination of the building by a large number of our committee consisting of architects: the suggestion was, that it might very easily be temporarily strengthened and supported, so as to be quite capable of bearing the weight which part of our museum might wish to be put upon it; that a permanent measure for security should be taken, or some new building should be erected; and we begged that such measures should be taken rather than that our collection should be disturbed.

What happened then?—They declined to take any temporary measures whatever, and gave us notice to quit.

**Sir John Shelley.**—Would those alterations have entailed any considerable expense?—Perhaps several hundred pounds.

**Chairman.**—Do you complain of the non-observance of any of the conditions on which you occupy your space?—No; we were a little interfered with at one time, a

doubtless of eight lights, with appropriate decorations. A richly-moulded arch would lead to the chancel, the details of which can be supplied only by probable analogy. This, at least, there can be no reason to doubt, that it was both externally and internally a structure of very considerable elegance, and one which would excite the admiration, as well as the interest, of all who looked on it as a legacy from the deceased Crusader to those who had not been privileged to see its prototype in the Holy City.

It did not, however, satisfy more than two or three generations in the state in which Simon de St. Liz left it; and probably it was then, as it was often again, and is now, perhaps for the last time, want of space for those who would worship in it that led to essential changes in the fabric. It was probably about 1180, during the time of the gradual introduction of the Pointed arch, but while the old Norman details were generally retained (thus forming a transition era), that the northern wall of the chancel was cut through, to form an arcade, for the addition of a northern aisle. The work does not seem to have been judiciously or even carefully conducted, for the changes about this time originated a series of failures in the fabric, which led first to the necessary erection of certain unsightly buttresses, and ultimately, perhaps, to the failure of the round, and the sacrifice of the old triforium and clerestory. The twelfth century, however, probably closed upon a church scarcely differing from that which St. Liz had finished before 1155, except that a northern aisle had been added to the chancel.

Thus so far as at present appears, the church remained for upwards of a century, for it is not till early in the fourteenth century that there are any indications of a south chancel aisle. And it was before the close of the same century that the present tower and spire were erected. This was not without a purpose; for the round had probably suffered so much by former changes as to require great repairs. The aisle vaults and the triforium were probably sacrificed at this time, and the clerestory rebuilt on a much more meagre scale, though certainly not so wretchedly as at present. A tower and spire were therefore required to give character to the church. I need hardly tell you that this last feature is of great beauty; and long may it remain an ornament, not to this church only, but to the town of Northampton.

Whatever has happened to St. Sepulchre's since the erection of the spire has been by way of destruction and deterioration. The only comfort we can derive from an inspection of it is this, that the very fact that matters have been getting worse and worse for two hundred years necessitates so entire a reconstruction, that we destroy, without compunction and regret, what the exigencies of restoration and enlargement require to be swept away; and that we are certain, under the direction of our very able architect, to hand over the remodelled edifice to the parish, and to the people generally, as greatly increased in beauty as in usefulness, and not diminished in interest.

Sir Henry Dryden, bart., in proposing "That the historical interest of St. Sepulchre's Church recommends its preservation," said nothing was truer than a remark made by Mr. James, that restoration not unfrequently meant destruction. More mischief had been done in the last twenty-five years than in any previous half-century, and the time would come when loud and grievous would be the lamentations. They could not do more mischief than to set about knocking down right and left, and then to commence the work of restoration according to their own fancy. Take, for instance, the Elgin marbles. Suppose a committee was formed for the purpose of putting noses and ears, and heads and tails, on those celebrated fragments, what would be the comparative value of them? It would be little more than that of old lime. Those old churches were left them as memorials of the past, and they could not commit a greater architectural sin than by spoiling them as models. The resolution said the historical interest of the church recommended its preservation, but nothing was more abused than the word restoration. Restoration meant to put back to its original state, and the interest of St. Sepulchre's Church would not consist in what Mr. Scott would give them at the east end, but in what other people had left them.

The Mayor was afraid, from the remarks of Sir Henry Dryden, that some persons might go away with a wrong impression. That the work of restoration would be conducted in a proper manner, there was a sufficient guarantee in the name of the architect to whom it was entrusted. It must not be forgotten, however, that, while it

was intended that the round part of the church should be preserved in all its integrity, the spiritual wants of the parish must be provided for; and how could they be provided for unless the church was enlarged? He trusted they would all go away determined that that noble structure should not only be preserved as a memorial of the past, but as a place affording adequate provision for the future.

Mr. Scott, in afterwards proposing a resolution of thanks to the mayor, said it gave him peculiar pleasure to see so well-qualified a member of his own profession preside at that meeting as chief magistrate; but it gave him far greater pleasure to hear one of his own profession not only speak in such hearty terms of the dignity of their craft, but, in union with that, advocating in such a heart-stirring manner the claims of their holy religion. In the abstract he agreed with several of the remarks made by Sir Henry Dryden, as all engaged in the study of ancient architecture must do. It was better that ancient monuments should be preserved, where that was possible, than altered. In the case of the Elgin marbles, that was absolutely the case, and the desirability of it would be greater or less with all objects of art, just in proportion as the uses of them were obsolete, or were required to be adapted to the wants of the present day. When first called on he felt very unwilling, and expressed a hope that the present size would suffice, but as such was not the case, was it to be restored as a mere piece of antiquity, or was it to be restored in such a manner that antiquity and utilitarianism should be united? The claims of the present day required that that should be done: at the same time he agreed that as far as was practicable that which was ancient should be preserved, and exposed to view. There were other portions, however, the age of which was doubtful, and it would be ridiculous to preserve a semi-barbarous part on the principle that nothing was to be meddled with. He was glad to say those views were advocated by Professor Willis, for few people had said more against restorations than he had done; and yet, with reference to the restoration of the upper part of Becket's Chapel, at Canterbury, on which he (Mr. Scott) was engaged, Professor Willis not only did not oppose, but urged the destruction of the barbarous additions that had been made to the original building. That was the opinion of the man who stood in the van of the anti-restoration party. He (Mr. Scott) admitted the principle advocated by Sir Henry Dryden, but it must be applied according to the dictates of common sense.

At the evening meeting, Lord Alwyne Compton in the chair, a paper was read by the Rev. T. James, on "Round Churches," to which we shall return.

#### ARRANGEMENT OF KITCHENS.

WHILE I agree with your correspondent, "J. D. A.," that the "kitchen often has not sufficient of the architect's care in its details,"—that it is apt to be "ill ventilated" and "inefficient," and with some of his views of what a complete apparatus should be, I differ with others. I do not, however, propose to discuss these, but rather to speak of the plan and arrangement of the kitchen itself, to which, if architects would devote more thoughtful attention, great advantage would result to their clients and increased reputation to themselves.

A chief and very frequent annoyance in connection with this department is that of the smell of cooking, which is so readily diffused throughout a house. That this evil is the result of defective ventilation, and ought to be avoided in all new erections, and may be remedied in old buildings, is unquestionable. The main difficulty is that of convincing either employer or architect, and too frequently both, of the necessity for very special arrangements for the purpose.

To provide, as "J. D. A." recommends, spring doors to close, which servants invariably take special trouble to "wedge" open, and a slything opening above the cook's head for the development of rheumatism, are but sorry ventilating arrangements; and, I would say, should only be submitted to when proved to be unavoidable.

A good kitchen should, of course, be roomy and lofty. It should be lighted by windows in the side walls, of full size, reaching within a foot of the ceiling, and from 3 to 5 feet from the ground, according to the height and size of the kitchen. These windows should open readily, both at top and bottom, for summer ventilation, and should be situated relatively to the cooling apparatus, so that the air admitted through them should tend to direct the heated air of the kitchen towards

the smoke and ventilating flues, and away from the doors communicating with the main building.

The cooking apparatus, in recesses, should occupy one entire side of the kitchen. These recesses should have "hoods," or canopies, commencing 6 feet from the floor-line, and reaching to the ceiling, enclosing the whole space above the stoves, hot-plates, &c. Each recess should be provided with a smoke-flue, and also with a ventilating flue within the "hood," and near the ceiling, to carry off the heat and smell of cooking. Above the roasting range, in the centre of the chimney-breast, and near the ceiling, a ventilating flue should be constructed, of full size, to obtain ample ventilation in cold weather, when the windows cannot be kept open. The ventilating flues, if constructed under Boyd's patent, with cast-iron plates dividing them from the smoke flues, derive so much heat from the latter as to maintain in all weathers a powerful upward current, without risk of return smoke, dirt, or annoyance of any kind.

Provision must be made for the free supply of fresh air to the kitchen in cold weather, or the ventilating arrangements will manifestly fail. The position of the windows having been indicated with the view of favourably influencing ventilation, it follows that the best position for the admission of fresh air in cold weather will be in their vicinity, and probably through gratings on the wall face, immediately beneath them. The air thus supplied should first be made to circulate in a chamber closely adjoining the heated apparatus, whereby it would be sufficiently raised in temperature to avoid risk of giving cold.

The door between the kitchen and scullery should be conveniently near the stove or hot-plate where the chief hoiding operations are carried on, so as to avoid unnecessary traffic in the kitchen. The ventilation of the scullery should be duly cared for, upon the same principles as indicated for the kitchen.

Much may be effected by a good plan towards the complete isolation of the kitchen department. Too frequently the kitchen-door affords a ready channel of escape for heated air from the kitchen to the main building. Instead of this a passage, well ventilated at both ends, should intervene, to which the doors of communication with the kitchen and house respectively should lead at distant points.

Should you deem these observations of sufficient interest to claim a space in your widely-circulated journal, I shall be glad on a future occasion to trouble you with a few remarks, in the hope of inducing the satisfactory ventilation of dwellings in general. The vital importance of ventilation you have yourself ably insisted upon on many occasions, and the conviction of its necessity is extending; but it is deeply to be regretted that the builders of houses systematically disregard its obligation.

D. O. BOYD.

THE article by "J. D. A." in the *Builder*, p. 574, on the subject of kitchen arrangements, is one which deserves to be followed up. His instructions on a large scale, if acted on, would go far to bring about some ameliorations in that greatly-neglected department of the English mansion. To one whose travels have brought him in the way of becoming acquainted with the economy of foreign culinary arrangements, the kitchen of the British islands can hardly fail to appear as if planned for some totally other object than that of cooking. The room is generally commodious enough, and the display of chairs and fireside conveniences more than sufficient. As a contrivance for the accommodation of the servants, the place is a decided success; but, as a culinary workshop, it is as complete a failure.

A large sum may very probably have been paid to some ironmonger,—whose ideas of dining hardly go beyond the inevitable potatoes, and who cannot believe in the possibility of breakfast without tea or coffee,—for an imposing mass of metal called a *range*. It might be supposed that a convenient and prominent place would be found for this wonderful piece of hardware. Nothing of the sort. The builder of the premises, looking upon the kitchen merely as a room, and never having seen the grate or stove of a room placed anywhere but in a recess or chimney, has instinctively constructed a wide hollow in the wall for the accommodation of the range, over which, of course, runs the legitimate mantel-shelf, which every orthodox chimney must have, and for which we have the model already to our hand in the first room we choose to go into. Of course, there is a proper height for a chimney: everybody knows that: 4 feet is just about the thing. It is true that within these last twenty years mantel-shelves

have been gradually diminishing in height; but this change not having reached the cellars, there can be little doubt as to the height of the fireplace. A mantel-shelf, therefore, must run in front of our range at a height of 4 feet from the ground, quite irrespective of the relative position the shelf and the cook's head are to occupy, when the latter is at work. Place your cook in front of the range, and let him or her have a dish or two which require careful watching going on. The under-edge of the mantel-shelf comes, we will say, on a level with the cook's chin; so that, in standing up straight, she cannot see her pans even in the distance: she must stoop, and, passing her head underneath the shelf, poke it into an ill-lighted recess, and retain it in this constrained position so long as the article cooking requires close attention. Apparently with no other very obvious object in view than that of rendering more meritorious the art of cooking under difficulties, it is not unusual to place in front of the range a broad fender with a flat top, designed evidently for a row of pans, which most admirably answers the purpose of placing at a disadvantage the centre of gravity of the operator, who is supposed to be stooping over her work, her shins rubbing on the edge of this fender, the back of her head making acquaintance with the under-surface of the mantel-shelf, her face exposed to the heat and smoke of a grate full of live coal, and her dress demanding a portion of her attention to prevent it catching fire! And we wonder why cooking as an art has ceased to be. Foreigners, who see no lack of eggs in this country, and plenty of butter, wonder how it is they can rarely or ever get an omelet worthy of the name, while travelled Englishmen, without knowing the reason why, find themselves obliged to bid good-bye to many a savoury dish as soon as they set foot on the English packet in the Channel.

Now, not only in France and other European countries, but among Turks, Arabs, and other Asiatics, common sense has suggested and brought about the raising of the front of the chimney to such a height as will allow the head of the cook easily to pass under it, and this has led to the greater projection of the chimney, and the bringing forward of the range out of the recess in the wall, so that the cook can scrutinize any of her pans at her ease, standing under a sort of wide canopy, which collects the whole steam and fumes, and directs them into the chimney. It is in the British Islands alone that the kitchen-chimney is modelled after the fireplace of an ordinary chamber, and yet this is the so-called *chamber, par excellence*, of practical good sense and comfort, where there are professional builders, who can count the houses they have erected by thousands. What would be the fate of any manufacturer, chemist, or tradesman, who should conduct his business after such a fashion, who should persevere in constructing his furnaces in such a way as to give his workmen the greatest possible amount of inconvenience; and rather than alter his arrangements would forego the advantages to be derived from the proper carrying on of all the more delicate processes of his business? Yet this is what is being actually done in almost every kitchen in this country, whether in Belgravia or Islington, and with very few exceptions, in the mansions of the upper ten thousand as in the houses of the more humble millions. A little more attention to such obvious common-sense and inexpensive suggestions would do more to reform the British kitchen than the complicated arrangements so much in vogue, which seem chiefly contrived to benefit the pockets of patentees and ironmongers.

J. B. M.

#### NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.

The fourth annual meeting of this Association will be held at Glasgow, on Monday, 24th of September, and the five following days. The order of proceedings will include:—

**Monday.**—Special service and sermon to members and associates in the cathedral. Sermon to be preached by the Rev. John Robertson, D.D., minister of the High Church. General meeting in the City Hall. The opening address will be delivered by the Right Hon. Lord Brougham.

**Tuesday.**—The Lord-Advocate of Scotland, the president of the First Department, will deliver an address in the Common Hall of the University. Immediately thereafter the business of the several Departments will commence in the class-rooms of the University appropriated to their use, when papers will be read, and discussions taken on the subjects embraced under each. In the evening

there will be a *conversazione*, on the invitation of the Lord Provost and members of the Corporation, in the Corporation Galleries, Sauchiehall-street.

**Wednesday.**—Sir James Kay Shuttleworth, President of the Second Department, will deliver an address. The business of the departments will then proceed. In the evening a working men's meeting will be held in the City Hall, when Lord Brougham and other leading members of the Association will be present. The Corporation Galleries will be open, also, for promenade to members and associates.

**Thursday.**—The Hon. Arthur Kincaid, M.P., President of the Third Department, will deliver an address. The business of the departments after. *Conversazione* in the evening, in the Queen's Rooms, Kelvin-grove Park.

**Friday.**—Sir James Emerson Tennent, President of the Fifth Department, will deliver an address. Immediately thereafter the business of the departments will proceed as before. Members and associates will afterwards dine together in the City Hall, Lord Brougham in the chair.

On **Saturday** the concluding meeting of members and associates will be held in the Trades' Hall.

#### METROPOLITAN UNDERGROUND RAILWAY.

THE works for this line are now making progress. Reports have reached us of costly errors in re-forming the sewers on wrong level, but we have no certain information on the subject. The railway, it is expected, will absorb a million and a half of money at the least before it is opened for traffic. It will commence at the Paddington station of the Great Western Railway, into which it will run on a low level, and then descend till it begins to burrow under the ground. Passing under, and in a line with, the New-road, it will pick up the traffic of the London and North-Western Railway at Euston-square, which will be carried to it by an underground branch. At King's-cross it will pick up the passengers from the Midland Railway and the north of England, and proceed to Farringdon-street. Here it will throw out a branch into, or rather under, Smithfield, and wait until the London, Chatham, and Dover shall meet it from the other side of the Thames.

The contracts for the works have been taken by two firms: Mr. Jay has the section from Farringdon-street to Euston-square, and beyond that to Paddington has been taken by Messrs. Smith & Knight.

The heaviest part of the line is at King's-cross. Straightforward tunnelling, or even going round a corner at a sharp curve, with nothing, to all outward appearance, to guide you as to the spot at which you may come out, is simple and easy to those who understand the business; but such a complication as that at King's-cross seems thoroughly bewildering.

At King's-cross there are two branch lines running up to the station, one on the east, the other on the west side. The two lines run in on a curve, the one from the west running in an easterly, the other from the east in a westerly direction, and they therefore cross each other something in the form of a letter X. At the point of intersection the arch of the tunnel has in consequence to be groined. As the main tunnel is 23 feet 6 inches in width, and the branch lines about 14 feet, the necessity presents itself to combine in one arch at the point of junction two arches of a different radius.

The *Engineer*, in a recent account of the works, says,—"The tunnelling has to be carried out in forms which may be represented by a monogram formed of the letter X and two Y's placed thus:  each leg of the letter X forming the upper limbs of the Y's, and all the arching and building up has to be made to fit accurately together. An ant's nest, a rabbit warren, a colony of heavers, or mole's burrow, would not be more intricate. We fancy that we have explored the whole region, and traversed the whole maze, when we come upon the flicker of candles through an interminable tangle of timber, and are informed that the work there is the pointsman's house, with retiring rooms. The immense hauls of timber supports become more and more numerous, and we feel something of nervousness when we are told that this was and is the most critical part of the business. The walls and arches of the small and large tunnels of the great hell-mouth press with such immense force on this pointsman's dwelling, which is at the centre of the complicated junction, that it has been necessary to use the greatest possible precautions to prevent the whole from coming to

one grand collapse. There are timbers upright, horizontal, diagonal, straight, curved, interlaced, and crossing and recrossing each other, till it becomes a marvel how it was possible to have got such masses under the earth and into any useful position. The ground plan has now grown more complicated: the monogram of the two Y's and the X has received the addition of one large and two small O's, and these letters are placed in the forks of the two horizontally placed Y's. The 'round house,' which is a sort of key of the position, is completely covered in by a circular dome, and here will be stationed the switchmen and signalmen, who will attend to the points necessary for running the branch traffic on to the main line: for the through trains—that is, from Paddington to the City—there will be no points to attend to at the junction, as the switches will, of course, be open."

The brickwork of the tunnel is 2 feet 3 inches in thickness, and some idea of the extent of the work may be judged from the fact that 10,000 bricks are swallowed up for each yard formed as the tunnel advances.

#### MUSEUM FOR BUILDING MATERIALS, MELBOURNE.

UNDER this title the Department of Public Works at Melbourne, Victoria, has recently created an experimental edifice of a novel kind. In the external portions are introduced every procurable variety of stone, brick, cement, lime, timber, slate, &c., both colonial and imported, for the purpose of practically testing the qualities of the various materials, and also for exhibiting samples of workmanship to be regarded as standards of reference in future contracts. The interior of the building, which contains a hall 66 feet by 33 feet, is to be devoted to the exhibition of such specimens of art and mechanism as are applicable to the requirements of decoration or construction.

The Museum has been carried out at the suggestion and under the honorary direction of Messrs. Knight & Kerr, the architects to the Victoria Houses of Parliament; and an advertisement in our present number invites contributions from England of a similar kind to those displayed at the Architectural Exhibition, such contributions to be accompanied with full particulars and prices, for the guidance of intending purchasers.

#### THE FIRST SUBWAY FOR WATER AND GAS-PIPES IN LONDON.

OUR readers are aware that the Metropolitan Board of Works, with a view to obviating the expense and inconvenience attending the breaking up of the pavement for the repair of mains and pipes, sewers, and other underground works, determined, in making the new Covent-garden approach, to form a subway under the street for the reception of gas and water mains, electric telegraph conductors, and other matters. The construction of this subway in the street commencing at the corner of Long-acre, opposite the end of Cranbourn-street, and 318 feet in length, is proceeding rapidly. The arch of the subway is 12 feet in span and 1½ brick thick: the headway in centre is 6 feet 6 inches. There are side passages to admit of connection with houses. The sewer 3 feet 9 inches by 2 feet 6 inches is below the road level of the subway. On either side of the subway at a short distance from it the vaults for intended houses are being formed. We must applaud the Board and their architect, Mr. Murrill, for the improvement thus inaugurated. Mr. E. Thirst is the contractor employed. Mr. W. Fisk is the clerk of the works.

#### THE BURIAL OF THE POOR.

THE other day a poor care-worn looking woman applied to one of the police magistrates for advice respecting the interment of a child who had died. It appears that the dead child was in the same room with the living family, and was remaining there after having perished through small-pox. The parents being without the means of defraying the cost of the funeral, the mother had made application to the parish authorities, who refused assistance, saying that they must wait until the man got his wages on the following Saturday. It was pointed out that this was dangerous to the family and those living in the adjoining tenements, and that supposing the wages to be sufficient for the purpose of defraying the expense of the funeral, the family must starve during the ensuing week. The funerals of the struggling classes in large towns are a difficulty: the parish authorities say

that, if strict rules are not observed, the expense thrown upon the ratepayers in poor parishes would be very great. It should, however, be borne in mind that the danger is imminent in keeping the dead in rooms surrounded by other rooms thickly crowded with people; and measures should be taken to prevent the keeping of dead bodies in such situations for a week, fortnight, or (as we have known it), three weeks. The position of persons situated as the woman above referred to should be very carefully and kindly considered. Those who are really unable to pay for the burying of their dead should be assisted; but, in case of imposition, punishment should be resorted to.

It is remarkable that, amongst the poor Irish, some preparation is generally made for their burial. They often, in secret, manage to hoard some valuable for this purpose, or else their neighbours raise a subscription. Even in those localities which are inhabited by thieves and other notorious persons, by the disposal of some article of small value by raffle amongst a number of subscribers, for a sum which each can conveniently spare, the necessity of applications to the parish is obviated. There are also the trade and other societies. Numbers, however, who fall into the "Town Swamps," being unaccustomed to the ways of those used to such circumstances, are comparatively helpless.

#### THE CRAIGENTINNY MAUSOLEUM.

The mausoleum erected to the late Mr. Miller, of Craigentenny, on a portion of his estate near Edinburgh, on the Portobello-road, was, on Thursday, the 13th, consecrated by Bishop Heriot, according to the forms of the Episcopal Church. The mausoleum, which is from a design of Mr. Rhind, is a massive structure, something after the fashion of the ancient Roman tombs, and nearly 50 feet high. It is oblong in form, and is capped by an enriched circular roof, in the gables of which are sculptured figures in full relief, modelled by Mr. Thomas, of London. There is also a rich frieze, with carved festoons of flowers and fruit. But a still more important decorative feature remains to be added, namely, four immense bas-reliefs for the panels, which are now being sculptured in marble by Mr. Gattley at Rome. The subjects are classical. The mausoleum, within which the remains of the deceased are interred, will, we believe, cost about 8,000*l.* when completed.

#### FALL OF A HOUSE IN CLERKENWELL.

SOME of our readers are calling out for further information as to the cause of the fall of the public-house in Goswell-street,—“The Hat and Feathers,” mentioned last week. Some investigation has, doubtless, been made to settle on whom the loss is to fall, but no clear opinion appears to have been arrived at. Some have attributed the disaster to the fall of a heavy stone core, prepared for the cornice, which, striking on the scaffolding, might have caused one of the uprigths to kick in a pier, and thus, as there was little external brickwork, the house having a circular corner, open, and being carried mainly on narrow piers or columns and girders, have led to the disaster. An old party-wall on one side, not in a very good state, had been made use of and was raised to some extent: the mischief has been imputed to this by some. On this point the district surveyor, Mr. Sibley, writes to us as follows:—

“Sir,—Having seen some statements to the effect that the disaster may be ascribed to the raising on the old party wall, I beg to say that I conceive them to be perfectly erroneous.

The wall in question was a 14-inch wall, plumbed and found to be fair and level by the surveyor of the adjoining owner, who also declined any interference. I need scarcely inform you that this wall could not be deemed to be in any way ruinous.

The wall itself stood unroofed without a fracture, with the exception of a small part, about a third of the upper story only having been drawn in by the building collapsing; in itself a conclusive reply to this statement.

The building was well timbered, and the brickwork also of good character. It is a matter of great gratification that the disaster was unaccompanied with loss of life or injury to persons.”

The proprietor is Mr. Leake. Messrs. Finch Hill & Parnie are the architects. Mr. Dent acts for the lessee of the adjoining house, and Mr. Hardwick for the Charterhouse, to whose estate the land belongs. Mr. Hill is the builder.

THE “NINEVEH” REMAINS.—It is stated that a French *savant* and traveller of reputation denies altogether that the remains discovered by Mr. Layard, and now in the British Museum, have anything to do with Nineveh. His proofs will be looked for.

#### THE ANNUAL DINNER OF THE BUILDERS' BENEVOLENT INSTITUTION.

THURSDAY, the 25th of October next, at the London Tavern, should be noted down by all interested, as the time and place of the thirteenth annual dinner of the Builders' Benevolent Society. The time is long gone by, when much urging or canvassing were requisite to get up a respectable show of diners at the annual convivial, and yet charitable, meeting of this now prosperous and well-established Institution. What we have at present to do, by way of aiding in this good cause, is merely to jog the memories—not the wills—of the troops of friends who can ensure its continued and increasing prosperity. Let all and sundry remember Thursday, the 25th of October, then; and, in good time, cause all other arrangements to steer clear of that settled pre-engagement.

#### PLAN PROPOSED FOR THE HOSPITAL OF A REGIMENT.\*

“*Le bien le plus précieux est le sang du soldat.*”

I SUPPOSE that it is not possible for any one, at the particular point which the demonstration has now reached, to tell us any new principles of hospital construction. The rules required for bringing modes of structure and arrangement into accordance with the absolute laws of health have been laid down, and there is no appeal from them, and there is no conceivable ground on which they can be called in question.† Besides, there are two or three existing structures which, owing to certain happy circumstances, it has been possible to erect in the manner prescribed by these laws, and where these structures fall short, as they do fall short in some points, one can hardly regret the defects, considering that a valuable lesson is thereby more impressively conveyed.

This sketch seeks to address itself, among other points, to a practical difficulty, not of principle, but of detail. In most large buildings, notably in all government buildings, perfection is very apt to be missed owing to the limitation imposed by

“—that eternal woe of pence  
Which vexes public men.”

I propose to endeavour to see how far it is possible to bring the absolute laws of healthy construction into harmony with a state of public affairs which is indicated by the existence of a temporary income-tax. When such is the idea from which one starts, it may seem likely that there must be a good deal of giving and taking on both sides, but I humbly conceive it to be practicable to obey all the most important and imperative laws of health, and, at the same time, to build a cheap hospital. Hitherto, military hospitals have been costly as well as bad, because money has been spent in carrying out the worst principles. It is worth while to try if we can project one in which sound principles can be given effect to without great expense.

The grand principles which it is necessary to bear in mind are three—absolute cleanliness, absolute purity of atmosphere, and the largest practicable allowance of sunlight. In so far as these three points are reached or fallen short of, so far is the building a success or a failure. What one has to attempt is to make the fulfilment of these principles as much as possible consistent with individual comfort, and to make it as much as possible subservient to the most effective discipline, and the simplest and easiest administration. Happily it is found in practice to be the case that structural arrangements which provide the greatest cleanliness and the purest air are also those which most conduce to personal comfort, and effective discipline, and render administration easy. Further, the points on which money has hitherto been lavished, are those which are rather opposed to than promotive of health. The stately buildings and great masses of brick and stone have been found, ere this, to promote anything but the health of their inmates. Health has been known, ere this, to visit the victims of famine and impurity, rather than in such places as these, in tattered hovels, and even under the hedges on the public road. The objects in view, then, being economy and efficiency, I propose to plan a hospital for a regiment. That is the only sort of army hospital which the present generation is ever likely to see built. There are but three general

\* By Dr. Combe, Royal Artillery.

† The latest, and, as far as I know, the best and most complete detail of these principles is to be found in the various papers by Mr. Robertson of Manchester, which have appeared in the *Builder*, especially three in August and September of 1856, and in the papers by Miss Nightingale which were read to the Social Science Association at Liverpool.

of the Royal Victoria Hospital for the British army. One is small and of little note. One was not built as a hospital, and has been long condemned. The third, at Netley, was condemned (by the *Builder*) before a stone had been laid down. It is hardly possible that such an opportunity for building a perfect general hospital can ever occur again as was afforded when it was determined to build one for 1000 beds, in 1855. The lessons to be found

“Among the myriad-room'd  
And many-corridor'd complexities”

of the Royal Victoria Hospital will not, whatever they may be, be lessons in sound hospital construction. Strangely enough, we have been lately told by an authority which all men respect, that, for reasons which those who know the subject best must be permitted to think very visionary, we ought to huddle together the sick of several regiments—that, on considerations other than sanitary, we ought to *congregate* sick. I give my vote, with Sir John Pringle and Sir William Blizard, for segregation.

For many reasons, the best form that could be adopted would be a straight line, with the offices in the centre, the wards extending on either side of the offices, and the ward conveniences at the furthest ends of the wards; but, to accommodate ninety-two beds in this way, on one floor, would require a line so extended as to become inconvenient. On the whole, I venture to submit that the form shown in the plan is the best for the requirements in view, that a smaller number of objections can be raised to it than to any other. Every brick and every pane of glass would have its own share of the sunlight, and each part of the whole would have as much chance of being blown upon by the direct current of the wind as is possible where any form but that of the straight line is adopted. The choice seems to be between this form and that of the Melville Hospital at Chatham, where three parallel blocks are simply connected by an open colonnade, and in which the different offices are distributed among the blocks, and placed at that end which touches the colonnade. Now in all pavilionated buildings where the pavilions are placed side by side but little of the direct current of the wind, from whatever quarter it may blow, can ever reach any part of the whole building, excepting on one side of one pavilion, or through the windows at the free ends of the pavilions. This is a consideration which does not seem to have been much thought of. It is one, however, which must very forcibly present itself to the mind of any one who may have had occasion to treat sick in a hospital where there is marked “stagnancy” of air from elevation of the neighbouring ground, or from the neighbourhood of dead walls.

Again, in parallel pavilions there seems always to be a difficulty about the place for the small wards, which must be provided somewhere. At Lariboisière, they are at the furthest end of the long wards, so that you must pass through the latter to reach them. Still further, what sort of a view is there out of the windows? At Lariboisière, if one may hint a fault and hesitate dislike about what seems to be almost a perfect plan, an extended view can only become attainable by placing yourself between the filthy latrines, which are so much condemned, and the foul-lined store. At the new Marine Hospital at Woolwich a patient who looks out of any ward window proper will see nothing but another sick marine in the opposite pavilion, like himself vainly trying to obtain a distant view. If our sick marine in search of the picturesque perseveres, he will be rewarded by a very glorious landscape, but to enjoy that he must go to the end window, and perch himself on the washbasin-basins, with the water-closets on one side and a sink on the other, surroundings which can be by no means exhilarating. If the form of the Vincennes Hospital is adopted (not the details, which seem to be objectionable on two grounds—the separation of offices and the intercommunication of wards without intervening passages), and if the transverse block is used for offices and attached directly to the two perpendicular ones, then you have simply an enclosed square with one side wanting. The form of the letter H, and the form adopted at Dundee, which is the letter J, with one-half of the perpendicular sides struck off, are open to the objection that there are closed angles. On all these considerations, setting one thing against another, I submit that this form, for accommodating ninety-two beds on one flat,\* is the most advisable. It provides a glazed square in the

\* The regulations require accommodation to be provided in the ratio of one bed for every ten effective men, and the average strength of a battalion may be taken at something between 900 and 1,000.

centre, cut off from the offices by glass, and if deemed necessary, the three other limbs of the cross could be easily isolated in the same way.

The building must be sufficiently raised from the ground on a solid, impervious foundation, and the walls need not, as far as health considerations go, be much more than a screen of brick, sufficiently strong to support themselves and a light, high-pitched roof. Great thickness of walls is no sanitary advantage, but the reverse, while it must add materially to cost. Does any one object that a building so constructed would not be sufficiently permanent? Surely we need not provide military establishments for a remote posterity. A gradually progressive increase of armaments all over Europe is what Mr. Carlyle would call a "self-cancelling business," and it seems evident that before the least enduring structure, now erected, can become dilapidated, a climax in the world's affairs must occur to render it, one way or another, useless.\*

"Large wards" and "small wards" are comparative terms. In Paris, what we call a large ward is looked on as a small one, and what we call a small one they would hardly consider to be a ward at all. With this question is closely connected that of discipline, and that demands a word or two of explanation. The non-military reader must not suppose that military discipline and military hospital discipline mean the same thing. In this application method, management, or arrangement would, perhaps, be more correct terms than discipline. Between the sort of discipline required in a civil hospital and that required in a regimental one there is a very broad distinction. It arises from this. In the former your arrangements must be made on the supposition that the great majority of your patients will need much extraneous assistance, and that all will need a certain amount of it. In the latter it is safe to suppose that but rarely, only now and then, will cases occur which are quite unable to help themselves, and that the great majority will be almost as capable of hospital work as the hospital servants. From this it results that a great part of the ward work can be done by the patients themselves; and if some theories lately broached by Mr. Neison have any truth in them, the more work they have to do the better. As to the minute details which go to make up the meaning of the word discipline in a military hospital, that officer is the best who can discover the exact point at which interference should cease, and spontaneity of individual action be allowed full scope. Perhaps the best plan is to put out of reach the means of interfering with sanitary arrangements. In naval general hospitals, and in most civil hospitals, it appears that one attendant is provided for every seven patients. If that is a good rule, I think we may say that for a regimental hospital one trained sick orderly to every fourteen would not have too much to do. The number in each ward should therefore be a multiple of seven; and thoroughly convinced as I am of the total impossibility of maintaining proper discipline in a small ward, and believing that it is better not to go much beyond thirty, I propose to place twenty-eight beds in each ward.

The wards are 100 feet long and 22 feet broad. A height of 15 feet will give 1,175 cubic feet per bed.† This "cubic space" is an arbitrary, and apt to be a misleading guide; very useful when we lay down laws for buildings of small space, which is liable to be encroached on, but of little use on such an occasion as the present. The consideration that ought to be attended to is not the number of inches of space, more or less, but the facility for the renewal of air. Proceeding on an estimate of the rate and quantity of excretion of carbon from the lungs, it has been laid down that 2,000 cubic feet per person are required when windows are opened once a day for the restoration of the air. Of course, a very much larger space would be required if the windows were opened less frequently, or if walls did not happily allow of a constant transference of air.‡ A less space is required when the means of changing the air are ample, and constantly in operation. The high-pitch of the roof, which I propose to leave open interiorly, would add very much to the air-space. Besides that, I propose to have ridge windows, or proper dormer windows, leaving it possible to

open them at discretion. In addition to all this, there would be a window and a door at the end, by opening which a flood of air could be, at any time, poured through the entire building. There are seven windows on each side. Where so many are provided, the fashion of the windows is a matter of indifference. I confess to a prejudice in favour of the old-fashioned sashes. Perhaps, the best form would be two sashes of the ordinary sort, and above them, and so far independent of them, a large single pane opening by means of a pivot, as is done with all the parts of the tripartite windows at the Middlesex Hospital. The windows should be low enough to permit the great luxury of looking out of them; high enough to be decidedly above the level of the patients' head in bed; and they should reach to within 1 ft. or 2 ft. of the top of the wall. They are 4 ft. broad.\*

Is there in this arrangement the promise of a sufficiently frequent renewal of air? The whole art and mystery of ventilation is this,—to provide a constant renewal of clean air with the least degree of discomfort from "drafts." It is customary to say that the best ventilation is by windows and fireplaces. That is partly true and partly not true. In the first place, the fireplace and chimney are not, *in intention*, any part of the system, and we are bound to give our assent to a principle laid down by the Commissioners on Warming and Ventilation (Messrs. Fairbairn, Glaisher, and Wheatstone), that the firegrate should "not be studied as a contrivance for the ventilation of rooms; that so long as it is studied with a view to a twofold application (warming and ventilating), it will not succeed well in the performance of either." In the second place, windows can only be useful for ventilation when they are open, and in making our plan we must allow for the prejudices of foolish people who think it dangerous to admit "night air" through an open window, and prefer to breathe over and over again air tainted with the excretions of their own skin and lungs. Accordingly, I think that something more is required than the fourteen lateral windows, the end window, and the roof-windows. That I propose to give by placing a Moore's ventilating pane in the upper part of each window, the means of regulating which would be under lock and key, the latter in the hands of the surgeon; and also, by introducing one or two of Mr. Jennings's very beautiful ventilating bricks towards the top of the wall, between each window-space.†

If two indispensable requirements—purity of air and ample window space—are fulfilled, how far does this plan meet the other—the greatest possible cleanliness? In plans and in recent buildings one most often sees all the domestic offices placed together, but it would be difficult to say why such should be the case. Any one who knows how stupid soldier orders sometimes are will see a very good reason why there should be no chance of their mistaking one of these places for another, and that it may be of some consequence that they should have to enter a separate door to reach each of them. The proposed distribution seems to provide for convenience, distinct ventilation, and efficient drainage. In the ward given in outline only there is suggested a different position from that shown in the other two. No instance can be shown in which a ward or room is tainted by the sewer air of a neighbouring projecting water-closet, *through the window*. The impurity is always due to the want or imperfect ventilation of the necessary connecting lobby. Passage through the external air always dissipates the effluvia. This of course does not apply to such a case as where the arrangement is a series of open tanks, so close to the window as to obstruct the light, an arrangement which is to be seen in a very recently erected barrack. It must be confessed that the offensiveness of these places in military hospitals is most frequently caused by the patients putting improper things into them. This is a matter which must be regulated by individual discretion. My own humble opinion is, that the things so misused are such as need but seldom or never be found in any hospital; that tow, poultices, sawdust, quacklime, and chloride of lime are much better away; and that

\* In the Report of the Commission on Warming and Ventilation, there is related a number of experiments which reduce to demonstration the fact of the importance of the panes being large sheets of plate-glass, and of making the sashes double, with an interval of from 6 inches to 12 inches between each.  
† It may be doubted whether or even all this will be enough. I can state, from long continued and frequent observation of some six-bed wards with one window opposite the door and a large opening over the door, that when the window is open at the top to the extent of two inches, it is impossible to discover, at any time, an appreciable current in the middle of the room.

the best disinfectants and "deodorizing agents," are pure air and pure water, and plenty of both. In the watercloset chamber there should be a trapped, air-tight basin, with flushing power for emptying and rinsing out close-stools and bed-pans. The water-closets, scullery, and kitchen, should be lined throughout with white glazed tiles. The sink in the scullery should be of enamelled metal. People say that the Yorkshire stone troughs are the best, and that they do not stink, but, in point of fact, they do stink. The ward-wall plaster should be Keene's, or the Parian cement or some other smooth, non-absorbent substance.

At convenient spots in the centre of the floor there would be two fire-grates, with a downward chimney-flue, and removable in summer. One of them would have two fire-faces. The fire space should be made entirely of fire-brick, so as to prevent unpleasant contamination of the air. Perhaps none are better than those made by Mr. Pierce, of Jermyn-street. The fireplace, standing in the middle of the ward, could be fitted with a means of keeping poiltices hot, as is done in French hospitals. At present the "hot poiltice" is apt to be just so much cold dirt, and a late distinguished surgeon, when he found one in his wards, used to do with it as Dr. Slop did when he had his celebrated controversy with the maid Susannah over the cataplasm for little Tristram's wound.

For the sake of cheapness of material, I shall be content with a flooring of fir. Most people say that frequent washing of wood floors is a cause of erysipelas, but it would not be easy to demonstrate a connection between the two except on the *post hoc ergo propter hoc* principle. When you find erysipelas in a hospital you are likely to find present much more probable causes than soap and water and the wholesome practice of scrubbing on the hands and knees. It is quite true that in old hospitals where there has been a long course of dry scrubbing of soft wooden flooring, and especially where sawdust is allowed to lie about, you will find between the joists a quantity of woody *detritus*, and that when water reaches this, there is just the condition which may give rise to noxious effluvia; but I suspect that when erysipelas or pyæmia occur, the cause must be sought in something much more palpable and potent. Remember, too, that soldiers are, more than other men, but children of a larger growth; that the two principles which ought always to be set before them are, first, obedience, and then cleanliness, and you will admit that, just as children in a nursery should be surrounded with objects of beauty and symmetry for their education, so should these full-grown children be taught the great lesson which is conveyed by a plentiful and frequent use of soap and water.

There are two small wards of four beds each. If you have an eye-case with much intolerance of light, you must either place it in a small ward in which the light can be regulated for the exclusive use of one, or you must allow the patient to wear a shade, which leaves the inflamed eye hot and unventilated. Anything is better than putting up screens in a large ward. Other cases may also occur which the surgeon may wish, for special reasons, to seclude. If these two wards were to be looked on as a permanent part of the accommodation, they would be the greatest blots in the plan, but they should only be required under occasional and exceptional circumstances.

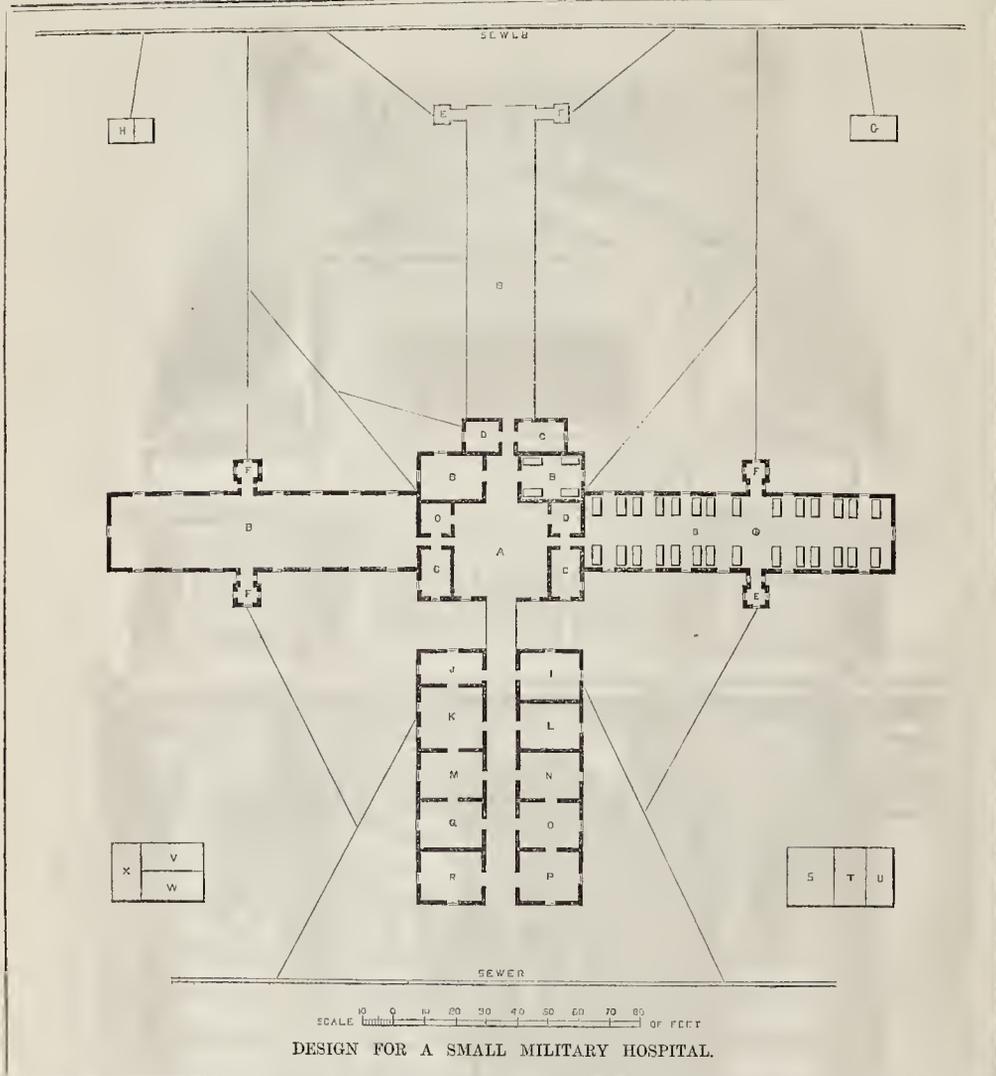

There is one particular convenience wanting, because even in the best regulated establishments it is always a cause of offence. All that is required in place of it, is the arrangement which was mentioned in a late *Builder* as having been put in force at a recently built club-house, after trial and failure of the more common plan. This arrangement has now been in use at that club-house for some months and answers well. There is no "itch ward," as none is required. There is no "foul linen store," because foul linen should be sent away at once and, in contradiction to Napoleon's maxim, should not be washed at home. A small quantity requiring temporary storage may be provided for by a cupboard in the purveyor's store-room. Of course there is no "ward for contagious diseases." Should the surgeon wish to isolate a case, he has only to leave one or more beds on either side of his patient empty. If that does not satisfy him, all he has to do is to open the end doors and windows which would enable him to pour in such a flood of air as must surely blow away every particle of contagium!

The offices are cut off from the rest of the building by a passage, 15 feet long and 10 feet broad. It should be altogether of glass. Two or three of the offices might be dispensed with, and

\* "It is often bad economy to build in too temporary a manner, but the converse is also true. The best materials should be provided where they are required, but it is quite proper to use inferior materials when they will answer the purpose as well."—*War Office Circular*, April, 1860.

† The latest War-office regulations prescribe 1,200 cubic feet.

‡ Some very interesting experiments on this subject are reported by the Commission on Warming and Ventilation.

some of them might be curtailed without great disadvantage.

The central hall would be lighted and ventilated by a glass roof, and also by two large side windows. It would be available for use as a chapel, and also, if desired, as a dining-room for convalescents. It may seem desirable to make this central glass hall somewhat larger, and also to place a short interval of glass between the two small wards and the large ward which is beyond them.

One skilled sick orderly being sufficient for the service of fourteen patients in a regimental hospital, each orderlies' room need not accommodate more than two. The unskilled orderlies, the hewers of wood and drawers of water, would live in barracks, and march to and from their hospital duty just as they would to or from any other duty. At the same time it is very desirable to have eight or nine skilled orderlies in a regimental hospital of such a construction as this, because a pressure of cases may, at times, require that two of them should be night-watchers, and two out of eight would give three "nights in bed" for all. At ordinary times, one night-watcher would be sufficient, which would give five nights in bed to a total number of six, and seven to a total number of eight.

It may be thought advisable that the hospital serjeant should live under the hospital roof; but there is no reason why his wife and large family should be there—and hospital serjeants always

have a large family. Accordingly his quarters are external, and I think that that and the other arrangements of the external buildings will be generally approved.

It may be objected that the position of the respective ward conveniences, with their necessary ventilated lobby, is such as would spoil the general look of the building, and that these places are made too prominent. But in planning for the accommodation of soldiers, it is a good rule to put well in front those places which require most constant attention and supervision. Miss Nightingale very pertinently remarks,—“As an invariable hospital rule, rather more in military hospitals than elsewhere, publicity may be considered as the best police and the best protection.”

A competent person has been so good as to make a rough calculation of the probable cost of such a building as this, and he estimates that it should be possible to build it for something decidedly less than 100*l.* per bed, exclusive of cost of site. It appears, by the army estimates for the current year, that the projected hospital for Woolwich, which will be a series of regimental hospitals conglomerated on the principle of *congregating* sick—a plan which should have the advantage of comparative cheapness, if none other—is to cost 120,000*l.* for 650 beds, or 181*l.* per bed, inclusive of cost of site. As the ground purchased for the site is a piece of waste land, with a wet clay soil, on which no one would ever dream of

building a private dwelling-house, though it is in “a desirable villa neighbourhood,” it may be assumed that the sum paid for it has made no great inroad on the 120,000*l.*

In deprecation of criticism of minor details, let me remind the professional reader that this is a project by an amateur. As to all other points, what it asks for is criticism, and the more searching and trenchant the criticism is, the better will the author be pleased, and the more fully will his purpose have been realized.

THE "FONTAINE SAINT MICHEL," PARIS.—M. DAVIoud, ARCHITECT.

## THE FOUNTAIN OF ST. MICHAEL, PARIS.

MIGHTY changes are taking place in Paris: miles of streets have been cleared away; other streets formed: fountains are erected, palaces finished, and statues everywhere set up. Money is not thought of: it is applied with stintless hand. The result is a beautiful city and a dear one. The proceeding has its admirable side—most admirable: but it has also its fear-exciting side, as the owners of house property, who, as we stated many months ago, are rising rents inordinately, may one day find out to their cost.

The Fountain of St. Michael, of which we give an engraving in our present number, is placed at the fork of the new Boulevard Sebastopol, facing the bridge of St. Michael. Its height is not less than 26 metres, and its width 15 metres. It was commenced in the month of June, 1858, and was inaugurated on the 15th of August last. It is raised upon vaulted cellars, constructed of rubble work and Portland cement. The basement, 6m. 40c. high to the base of the columns, is formed of Saint Yllie stone (Jura): the rest of the monument is of the *de Méry* stone. The four stages for the water-fall and the basin are executed in Saint Yllie stone: the border of the lower basin is raised only 30 centimetres above the level of the footpaths. At each extremity of the lowest stage are two pedestals, supporting apocalyptic animals vanquished by angels. In the basement, two pedestals on each side serve to support columns. The panel between each pair is ornamented with a tablet of grey Breccia marble, cut in facets. In the niche, and above the topmost stage, is a group of St. Michael subduing Satan. This group is 5m. 50c. high: it is supported by a rock of stone from Soignies (Belgium). This rock, from which the water flows, covers a cast-iron reservoir, that serves for support to the group, and supplies the fountain at the rate of 23 litres a second. The spandrils of the niche are ornamented with chimæra: the arms of the town of Paris, with the legend, "*Fluctuat nec mergitur*," are sculptured upon the key-stone. On each side of the niche are two columns, of the red marble of Languedoc, having their bases and capitals of white veined marble. The entire height of the columns is 6m. 20c. In the intervening panel is a sort of buckler in bronze, bearing upon a field of bees an N, surmounted by an imperial crown, and surrounded with sceptres and branches of oak and laurel. The cartouche below is ornamented with the head of an angel and a plaque of lapis lazuli.

The frieze of the entablature is decorated with small angels, bearing garlands of flowers: an escutcheon, with a lion's head upon it, is placed above each column. Over the columns, and in the following order, commencing on the left-hand side, are placed four statues, representing the cardinal virtues, Prudence, Strength, Justice, and Temperance: their height is three metres, including the plinth.

The centre of the attic is ornamented with designs in different coloured marbles: the two lateral portions bear a cartouche, enclosing the cypher of Saint Michael, surrounded by the collar of the order of that name created by Louis XI. in 1469. The square frame outside the cartouche is of coloured marble.

The pediment is decorated with a tablet of sea-green marble, bearing the following inscription:—

"Fountain of Saint Michael. Under the reign of Napoleon the Third, Emperor of the French, this monument has been raised by the City of Paris, in the year 1858."

On each side of this tablet is placed a pilaster, bearing the medallion of Saint Michael and the cordon recalling the military order instituted by Louis XI.

Two large volutes, ornamented with horns of plenty, terminate the sides of the attic, and do not demand our admiration. The whole is surrounded by an escutcheon, bearing the arms of the empire, supported by two allegorical figures—Power and Moderation. The covering is of slate: the cresting, the ridges, and the eagles, which are at the angles, are formed in hammered lead. The situation of the fountain is unique: it can be seen at a distance of 400 metres, the eye traversing the entire breadth of the city. Unfortunately its north-east aspect will scarcely ever admit of its details being lighted up by the sun's rays. This situation explains the necessity under which the architect felt himself of making use of various coloured materials in the construction of the monument so as to supply, as it were, artificial light and shade.

The works of St. Michael's fountain have been executed by the Municipal Service of Promenades and Plantations of the city of Paris in charge of

the Bois de Boulogne, and of the squares and the decoration of public places, under the direction of M. Alphand, engineer-in-chief. To the same service we owe the restoration and removal of the fountains of the Châtelet and of the Innocents.

The monument with which we are now more particularly occupied has been executed from the designs of M. Davioud, architect-in-chief to this service, who has already contributed to the embellishment of the capital. Messrs. Flamant & Simonet, inspectors of works, have seconded M. Davioud.

The group of St. Michael subduing Satan is due to the talent of M. Duret, member of the Institute. This figure was cast in bronze by M. Victor Thiébaud, in the space of three months, and with complete success. The bronze, contrary to the usual custom, is of a light colour, to harmonize with the surrounding stone. A darker colour is given to the demon. M. Auguste Debay executed the figures of the pediment.

The statues of Prudence, Strength, Justice, and Temperance, proceed from Messrs. Barre, Guillaume, Elias Robert, and Gumery. They were cast in bronze by Messrs. Eck & Durand, in whose studios the groups for the lower basin, by M. Jacquemart, are in course of execution. The sculptured ornaments have been executed by Messrs. Biés & Liénard. The general execution of the works was entrusted to Messrs. Montjoie & Ducros; and M. Séguin superintended the marble works. The interior mechanism of the fountain was executed by M. Lalo, inspector of waters, under the direction of M. Bellegrand, engineer-in-chief.

The Paris journal, *L'Illustration*, has some just observations on the fountain and its accessories, which may be usefully condensed; and with these we will close our account.—

The St. Yllie stone (Jura), whose yellowish grey colour contributes variety to this grand façade, is seen in conjunction with the white stone of which the rest of it is composed. The red colour of the Languedoc marble shafts of the columns forms at present a somewhat harsh contrast with this stone; but time will, doubtless, harmonize that effect. Perhaps, also, when the back part has blackened a little, it will restore to the white marble of the capitals of the columns their due pre-eminence, which at present they do not possess. The bronze of the statues is of an harmonious tone.

The talent displayed by the architect of the fountain of St. Michael, and by the artists who have aided him in its execution, will receive well-deserved praise; nevertheless there are some details to which criticism may justly take exception: it is upon the general effect, and upon the conditions themselves of the programme, that we think it useful to make some observations; because in our opinion there is therein a grave error arising out of the vexatious necessity, imposed upon the artist, of elevating his monumental façade against a simple domestic abode. Again, if this house had been rectangular, there would have been a point from which the façade of the fountain alone could have been seen without the return lines of the house thrusting themselves into view. But, unfortunately, this is not the case. The house to which the fountain is attached is built with an oblique front; so that it is impossible to escape from the odious perspective of shop-windows and the casements of the various stories, which stretch themselves out behind this richly inlaid face, with the most impertinent agreement in height, that establishes, in spite of every effort at disguise, a melancholy solidarity between the work of the artist and the construction of the builder. Notwithstanding the talent which the elevation exhibits, one feels that the architect was not free to choose his proportions according to his own inclination. The elegance of style and the richness of ornamentation do not prevent the spectator from seeing the evident effort made to give the design sufficient elevation, in order to mask some portion of the roof of the house. It is in vain that the ornamental cresting and the leaden eagles placed at the angles form a magnificent crown to the façade: this lacework ends on each side where the roof begins; and, behind it, the eye encounters the vulgar details of dormer-windows and chimneys. The system of placing fountains against private houses, of which there are numerous examples in Paris, is admissible for monuments of small proportions; but it seems to us essentially wrong, in every respect, when the monument to be erected is of large development and grand style.

We must also insist upon another point, too much neglected in the greater number of monuments of our day. We speak of unity and

fitness. It seems to us these are qualities of which the age is too little careful. The fault, it must be admitted, is not always due to the artists, who are compelled to carry out their instructions. We are ignorant if such were the case in the present instance with regard to the choice of subject; but, standing before the fountain of St. Michael, one naturally asks oneself by what peculiar train of thought any relation could have been found between a group of the Archangel, the figures of Prudence, Strength, Justice, and Temperance, vanquished chimæra, the enwrathed Cupids of the frieze, the crowning eagles, escutcheons bearing the saint's cypher, bucklers with the imperial cypher, the arms of France in the pediment, and those of Paris on the key of the lower arch? What idea can we gather from this biblical, mythologic, allegoric, symbolic, municipal mixture? The answer is difficult and dubious. Some persons may see therein a distinct allusion to contemporary politics; but it appears there is nothing of the sort intended; and, according to the description which has been issued, the idea sought to be expressed is the Christian one of 'The triumph of good over evil.' So be it!

Although we may be running the risk of exposing ourselves to ridicule, by avowing a remnant of tender affection for the superannated fabulous deities which our sceptical era has banished by force of contempt, we still think that for ornamentation of a monumental fountain (when no one of course dreams of consecrating it to the image of any one of the great men who have rendered France illustrious), naiads, tritons, dolphins, nay even the old classic urns, are still the most graceful, as well as the most natural subjects, notwithstanding their insignificance. These poetic creations adjust themselves the most readily to the necessities of the case; and, if they have the fault of being mythological, they possess at least the great advantage of logically belonging to a subject wherein, after all, it is the water alone which is the pretext for the arrangement.

## CHURCH-BUILDING NEWS.

**Hanworth.**—The parish church was re-opened on the 31st ult., after having undergone a restoration of the interior. The seats are all open and uniform, and are plainly finished in English oak. The contractor was Mr. William Chapman, of Hanworth. Wood-carver, Mr. Daynes, of Norwich. The entire cost of the alterations has been about 300l.

**Thurston.**—The foundation stone of the new church of Thurston has been laid. The new structure will exactly follow the dimensions of the old one which recently fell, except that the tower will be 2 feet wider each way. It will consist, as before, of a nave and two aisles with five arches, measuring inside 50 feet by 42 (exclusive of the chancel, which remains); height of nave, 34 feet; of the aisles, 24 feet; tower, 12 feet square, height, 70 feet. A bed of concrete, 6 feet deep, is laid under the whole area of the tower, and 5 feet under the walls of the church. The tower has two square buttresses at each angle, instead of the former angle buttress: above the plinth will be a course of quatrefoils, and the whole of the openings and decorations of the tower, which in the old structure were very inferior, will be in keeping with the body of the new church. The windows of the porch will show four recesses of compartments within but only two without, in agreement with the original form. The materials of the walls will be flint and rubble, with Ancaster and Barnack stone dressings, such of the old Barnack stone as remains sound being used again, including the three pillars of the north aisle, which are left standing for the present, but will be rebuilt on proper foundations, all the church being rejected. The woodwork fittings, including doors, pulpit, seats, &c., will be of oak. There will be a row of free benches on each side, as well as at the west end of the church. All the sittings will be open benches, those in the nave having poppy-head ends. The work has been carried above the height of the plinth nearly all round, by Mr. Farrow, under Mr. Bonner's supervision.

**Ditton.**—The parish church has been under restoration. The work has chiefly been confined to the interior of the edifice, but it is hoped that before long the repair of the exterior may also be accomplished. On the north side a vestry has been added, and two new windows on the south side. A new chancel arch has also been erected, and the church entirely re-seated, the old pews being substituted by open benches, and the accommodation proportionally increased. All the walls have been re-plastered, and the timbers of the roof, which had been hidden with plaster and

whitewash, have been laid bare. New pulpit and reading-desk have likewise been provided, and other alterations and improvements made. Mr. Scott was the architect, and the work has been executed by Mr. Ephraim Wallis, of Maidstone, and Mr. Church, of Larkfield. During the progress of the work the remains of an old mural painting, consisting of a portion of the figure of a man, was discovered, and has been left exposed.

**Maidstone.**—It having been found that the Baptist chapel in King-street was in an unsafe condition, and in many respects inconvenient, it was determined to erect a more commodious building on the same site. The foundation stone of the intended new church has been laid. The church will be a large structure. The architects are Messrs. Peck & Stephens, and the builders, Messrs. Sutton, Walter, & Goodwin.

**Heathfield (Sussex).**—On the 8th inst., the spire of the parish church was brought to the upright position, which it is supposed, by some architects and others, never to have occupied since it was erected, some 500 years ago. This critical operation was an important step to the restoration of the church, which is now in progress. Ten years ago the north aisle was entirely rebuilt, and the roof of the nave repaired, the piers and arches renovated, and the north side of the church re-seated, at an expense of about 800*l*. Four years afterwards the chancel was restored, at a cost of about 600*l*. The tower and spire, and the entire south side of the church, still remained to be repaired, the spire and the chapel, especially, being in a dangerous condition. These repairs were estimated to cost about 900*l*. Funds were collected by private subscription to half the amount required, and the two most important portions of the work were undertaken, viz., the rebuilding of the chapel and the repair of the spire and tower, and these are now progressing, while the committee are endeavouring to raise the remainder of the funds required to complete the entire restoration. The bringing of the spire to the perpendicular, effected under the superintendence of Mr. John Billing, of Westminster, the architect, was an operation which excited a lively interest in the parish, mingled with some anxiety as to the possible danger of a downfall. The divergence from the perpendicular of the apex of the spire (which is about 50 feet in height) was 2 feet 3 inches. To rectify this it was found necessary to raise the eaves of the south side 5 inches, and to depress those of the north side to the same extent. The spire was supported on four powerful screw-jacks, and the masonry was then carefully removed from beneath the five resting points on the north side of the timbering when they should be lowered. The two jacks on the south side were screwed upwards, and the two on the north side were lowered simultaneously, the spire turning upon the axis of a single horizontal beam. No sound of creaking was heard among the network of timber. The moment the timbers came to their new leanings, and the spire was upright, two flags were run out from the top story of the framework, and a volley of musketry was fired from the tower walls. The tower and spire rise 120 feet from the ground, and show for many miles.

**Burbage (near Buxton).**—The foundation stone of a new church has been laid at Burbage, which is about one mile from Buxton. The Duke of Devonshire gave a site, on the Macclesfield-road, and 350*l*. Other subscriptions now amount to upwards of 2,600*l*. The estimated cost of the new church is 2,600*l*, including a peal of bells; but the contractor's estimate is 2,080*l*. The church is expected to be finished in June next. Its style of architecture will be Norman, and it will have a tower 52 feet high. It will have a nave, two aisles, and a chancel, and will be erected of freestone dressing, from a stone quarry at Reve-edge, in the neighbourhood. There will be 400 sittings, the seats being open stalls. The roof will be open, in grained oak.

**Congleton.**—The new church of St. Stephen, erected on a plot of ground in Moore-lane, Congleton, has been consecrated. The building stands about midway between Congleton and Baglinton, occupying, with the burial-ground surrounding it, 1a. 15p., an area of half an acre being reserved as a site for a parsonage-house. The church consists of an apsidal chancel, with nave and north and south aisles, having the vestry open to the church, with the heating chamber under on the north side of the chancel, and a chapel or organ-chamber on the south side of same. There is a southern porch and a western entrance. The total length of the church exceeds 100 feet: it is about 49 feet wide, and bolds 600

persons. A tower is contemplated at a future time; but at present the single bell is carried in a turret over the chancel arch. The style is Early Third Pointed, of the latter part of thirteenth century. The expenditure on the edifice has been about 3,000*l*. The chancel is decorated with painted glass, the floor laid with tiles. The seats and fittings are of oak. The chancel is parted off with wrought-iron screens. The whole of the seats in the nave are open, of pitch pine. The passages beyond the chancel are laid with plain tiles, made by Messrs. Garrett, of Burslem, who have also supplied the roof tiles and patent ventilating tiles for the ridges. The roofs are paneled, with the main timbers exposed, and a series of ornamentation is carried throughout the church by the introduction of floral and geometric drawing. All the woodwork, other than oak, is stained and varnished, and the oak is bees'-wax polished. A Caen stone font stands at the entrance. All the windows on the south side and in the clerestory are filled in with patterns in different shades of Hartley's patent glass. The interior ashlar work of the church is in Bath stone, with Alton and Forst red sandstone introduced alternately into the arches of the nave. Derbyshire marbles are used in the piers of the chancel arch. The walling stone is from the locality, and the exterior ashlar of Staffordshire stone. The church is heated by hot water. The works have been carried out from the plans, and under the direction, of Mr. Joseph Clarke, of London, by Mr. Samuel Faram, of Odd Road, builder. The chancel has three windows filled with stained glass by Messrs. Edmundson & Son, of Manchester. The subjects are designed with reference to the memorial, those in the centre window being taken from the New Testament, and those in the side windows from the Old. In the middle window are:—The aged Simeon with the infant Jesus in his arms, and the stoning of St. Stephen. In the north window are Jacob blessing the children of Joseph, and Joshua before his death addressing the tribes. In the south window are Job and Daniel.

**Stockport.**—St. Thomas's Church is being painted and decorated by artists from the establishment of Mr. Crace. The work is now approaching towards completion. Mr. Winship is the superintendent of the work. The ceiling is coloured an aerial blue, with maroon line; the margin two tints of vellum colour, with maroon and drab lines. The pendants on the ceiling are in imitation of bronze and gold, and the cornice in vellum colour, relieved with deep maroon, blue, bronze, and gilding. The gallery ceiling is coloured two tints of buff, with drab and maroon lines; and the walls are a subdued green, ornamented with maroon lines and corners, the columns being of stone colour, and the caps a soft white. The gallery fronts are of vellum tint, relieved with drab and maroon lines and ornaments, and a portion is gilt. The pilasters supporting the galleries are ornamented and embellished to correspond. The pews are a cinnamon colour, painted and varnished. At the communion end the finished portion is embellished with blue, green, and maroon lines.

#### SCHOOL-BUILDING NEWS.

**Chatham.**—Another new National School has been opened in the Military-road, making the fourth new school for the children of the poorer classes built and opened at Chatham within a comparatively short period. The building in question has been erected at a cost of 1,647*l*, of which sum 250*l* were given by the Lords of the Admiralty, and 740*l* by the Committee of Council on Education, and other Government departments, the remaining 657*l* having been obtained by private subscriptions, raised chiefly through the exertions of the Rev. St. Arnott, vicar of the adjoining church of St. Mary. The school has been erected by Mr. Wilkins, and is of Kentish rag with brick and freestone dressings: it will accommodate infants as well as boys and girls of more advanced age.

**Husbands Bosworth.**—In February, 1858, a new parochial school was opened in this village. At the end farthest from the master's residence, another building, some 30 feet by 20 feet, has just been erected, in the same style as the first, which it crosses at right angles. The rooms communicate with each other by means of large double sliding partition-doors, which have been lined with felt. The school is warmed by the Hyde stove. The cost of school and master's house was about 800*l*, and the newly-erected infant-school about 350*l*. Both were erected from the designs and under the superintendence of Mr. E. F. Law, of Northampton, architect. The buildings are of red brick,

with white brick quoins, and black and white brick arches, black brick pilinths and chimney-caps, and black brick dispersed work between the windows and in the gables. The walls on the inside are finished and coloured on the bricks. The roofs are open, with Gothic ribs resting on corbels, and the whole stained and varnished. The building is situated on the village green.

**Salisbury.**—St. Edmund's new schools, erected on the east side of St. Edmund's churchyard, for the education of the children of the poor in this large parish, have been formally opened by the bishop of the diocese. The buildings, which are in the Decorated style of architecture, were designed by Mr. H. Goodyer, and the works have been carried out by Mr. Entebor, of Fisherton, builder. The total cost of the erection is about 4,500*l*. The accommodation afforded is for 500 children, namely, 150 girls, 150 boys, and 200 infants, besides a residence for the master. The central portion of the edifice is occupied by the girls and infants' schools, the boys' department being on the left, and the master's house on the right. The infants' room, which is on the ground-floor and underneath the girls', is 50 feet long by 20 feet wide, with a gallery, 18 feet by 14 feet, capable of holding 100 children. The dimensions of the girls' department are 50 feet by 20 feet, with two class-rooms, one 14 feet by 20 feet, and the other 18 feet by 14 feet. The boys' room is in the shape of the letter L, the portion at the end being 20 feet long, having a class-room 14 feet by 18 feet, whilst the room itself is 50 feet by 18 feet. The roof of this apartment formerly belonged to an old edifice that stood on the site of the new Salisbury Market-house, and is supposed to be of the fourteenth century. It was presented to the building committee by the directors of the Market-house, and has been restored at the expense of Mr. Charles Radcliffe. Each room is lighted with numerous windows.

**Birmingham.**—Tenders are invited from a limited number of contractors for the building of St. Jude's National Schools, class-rooms, teacher's residence, &c. The schools will accommodate upwards of 200 children. The Council on Education have granted 554*l* towards the erection of these buildings, so long wanted in this densely-inhabited locality. The architect is Mr. J. L. Pedley, of Southampton.

#### MODERN ILLUMINATION.

The art of illumination is being revived, and is more practised and appreciated than might be expected. It is urged that "it is at once disciplinary and delightful, and tends, even as an accomplishment, to strengthen those qualities of patience, thoughtfulness, and delicacy, which shed so salutary an influence upon our daily life."

We have before us the outlines of the Beatitudes, for illuminating, for which prizes were awarded by a society termed itself the Illuminating Art-Union of London,\*—a great mistake, this title, by the way, as it looks like pilfering the good name of another. The outlines are designed by Madame Citerio, Mr. Edward Ofor, and the Hon. Louisa Tension, and may be had partially coloured, so that they may be finished after the pattern by the learner, a very good arrangement. The prizes were awarded by Messrs. Owen Jones and Noel Humphreys. The arrangement of the colours, probably, in No. 1, overcame the objection that might be taken to the style of the outline.

A second edition has been issued of the "Manual of Illumination on Paper and Vellum," by J. W. Bradley, B.A., and T. Goodwin, B.A.,† which conveys a considerable amount of information, evidently the result of some experience. It contains, too, twelve lithographic illustrations.

#### MORTAR IN MARYLEBONE.

The monthly report on the health and climate of St. Marylebone during August, 1860, by Dr. R. D. Thomson, F.R.S., the medical officer of health for the parish, shows a very satisfactory state of matters as regards health and sickness, but in a certain measure attributable to the moderation of the heat of summer during the late rainy season. The mortality for the month of August was 258, or sixteen under the mean of four years. There were 4,462 cases of sickness compared with 5,091 and 6,306 cases in the two previous years respectively. These statistics, however, only show the more clearly how much life and health depend on the absence

\* Gambart, Rowney & Co.; D. Laurent de Lara, Torrington-square.

† Wansor & Newton, Rathbone-place, 1860.

of those noxious effluvia which the heats of summer so generally raise up into a state of injurious activity, wherever the source of them exists. In course of his report the medical officer says—"My attention has frequently been called to, I trust, an almost obsolete practice indulged in by some builders, of mixing up putrid slop from the streets with their mortar, instead of using sand, which has a chemical relation to the lime. A case of this kind having been reported to me by the inspectors at Hamilton-terrace, I found the slop used, to consist of putrid organic matter, 873; water, 366; and inorganic matter, 5468. Being of opinion that the use of such a mixture in plastering the interior of a house is not likely to be promotive of health, while it undoubtedly produces an inferior binding material, I requested the builder and the architect to discontinue its use; but not in time to prevent the fall of an arch, and the injury of three men engaged in the construction of the building. The inspectors, who were present soon after the occurrence, are of opinion that the accident was partly due to the mortar, while the district surveyor reports to me that 'the falling of the arch was from improperly striking the centre, and not from the use of bad material.'"

SOCIAL SCIENCE AND THE STEAM ENGINE.

It may not appear at first sight that there is any very intimate relation existing between social and mechanical sciences, for the former is treated at the present time in a manner very similar to that of education some thirty years since, and considered to be entirely a question of the brain. It was then thought that the only requisite to bring youth to the most perfect state of maturity was a head full of wisdom and theoretical knowledge; the great fact being overlooked, that the efficiency of the functions of the brain is the basis of vigour and power, and that that efficiency is dependent on physical development and physical health. Experience demonstrated, in course of time, that the first stone of mental and moral culture is laid in physical culture, and that whatever superstructure of wisdom, experience, or knowledge, is erected on any other but this its natural basis, it is liable at any moment to tumble into a premature grave, with a decrepit and half-developed physical organization. What physical health is to the body, industry is to the social existence. It is the foundation stone of social peace and progress, national security, and international friendship; and no country has ever yet enjoyed constitutional freedom, or manifested any of the evidences and accompaniments of social health except by its aid. As industry, therefore, is greatly developed by the agency of the steam-engine, it follows that mechanical science is a great contributor to social progress, and has an important bearing on social science. One of your correspondents, in a recent number, called attention to the desirability of a more general diffusion of knowledge on this subject, and a closer investigation of those laws which govern the health of communities. This is very true; but it is equally true that, if any good result is to flow from discussion and investigation, it must be open to perfect freedom of speech. Social science is treated, at the present time, both by the public and the press generally, as a wealthy sensualist treats his doctor. The twinges and pains of his frame warn him of decaying health: he knows the reason and the remedy if he likes, but he dares not look it in the face; so he consults the doctor, and woe be to the doctor that stabs the truth. He is willing to be physicked, or to be subjected to any discipline that does not attack the real cause of his malady; he expects, by some *presto-change!* system, to be able to keep in active operation all the agents of disease, and to enjoy all the fruits of health and ease. In investigating this subject, it should be borne in mind that nothing which is natural and legitimate fears to be looked at, and that any man who is imprudent enough to attack that which is sound and healthy, only brings injury on himself; therefore, if any good is to flow from discussion, the whole subject may be safely laid open; for that which will not bear the test of light is an element of disease, and that which will is one of health. It will be found, in this question, as in every other, that the natural operation of the element of social life leads to health, and that disease is but the evidence of some impediment to that operation; and that the remedy must be effected by removing the impediments, rather than by efforts to counteract their effects. Society is not honest in this matter. It wishes to maintain existing social conditions intact, and to dis-

cover some specific by which social health may be wrought on from the elements of social disease. Social life is subject to two phases of development; and to one, and to one only, of these is every member and every class of the community contributing. The most insignificant event of the every-day life of every individual yields something either to the consolidation or to the decay of the social fabric: the result is only perceptible when viewed in the aggregate, when matured, for (as in the individual) every inspiration of the breath affects the health of the body. That effect is not perceptible except in like general results, and I am induced to thus trespass on your consideration solely from the conviction that this is a question of the utmost importance at the present time to the commercial interests of the country, and to all whose interests are identified with legitimate and constitutional progress; for the law of social development is absolute, and will accomplish its ends either with the concurrence of society by a yielding to its conditions, or else in defiance of society, by bringing into action the elements of disorder and rebellion. The following forcible warnings are not to be despised—*an increasing population, increasing taxation, decreasing trade* (both home and export), and a gradual rising in price of the staples of life and of industry; and these have been the precedents to every previous period of industrial, commercial, social, and political disorder.

Society in its development is neither theoretical nor experimental, but is absolutely subject to simple and definite law; and the characteristics of health and of disease are in all ages and in all cases the same. The former are constitutional or responsible power, commercial freedom, and industrial independence, and prosperity; the latter are fictitious or irresponsible power, commercial dependence, and industrial poverty. No political disorder ever arises in any country where industry has a free and legitimate field for employment; and no tendency to foreign aggression or war is ever manifested when capital enterprise has a legitimate field for action and expansion in the pursuit of commerce. When, however, the industry of a country is fettered, its energy becomes the parent of rebellion; and when the sphere for the legitimate employment of capital is choked up, it finds an artificial outlet in foreign aggression.

I will now just call your attention to the two most prominent events in the social history of the country,—the Reform Bill, and the birth of Free Trade; and to the direct connection which exists between them and the two mechanical eras which were marked by the steam-engine becoming an agent of "manufacture" and "transportation." The passage of the Reform Bill was the consummation of social and political changes that had long since been effected in the condition of the community. Previous to the manufacturing era, the soil, its minerals, and its agricultural produce were the great elements of national wealth; and, as a natural consequence, political power was entirely in the hands of its possessors: when, however, steam came as an agent of manufacture, a rival element of national wealth was produced, and from it grew up a wealthy and powerful commercial interest; and, in spite of all the efforts of its opponents, by legislation, by war, and by national extravagance, nothing could check the growth of this interest, fed by the expansive power of the steam-engine. It grew, attained independence, and set the seal to that independence in the Reform Bill. At that time finality was accepted by both aggressors and defendants: time, however, which matures all things, brought forth another period of maturity for commercial and mechanical science (represented by the locomotive). This gave another stimulus to commerce: markets became more accessible, more numerous, and more absorbing: the advantages which resulted from cheap and efficient locomotion suggested to the commercial mind the desirability of Free Trade; and, as soon as the policy of protection was felt to press sorely on the interests of trade, the whole commercial community united these cases (and in every other), on the one side, was found irresponsible power lacking up commercial restriction; on the other, constitutional effort, the fruit of unity of commercial interest, struggling to give birth to its first-born—Free Trade. The steam-engine then, first, gave birth to a commercial community; secondly, gave it wealth and power; and thirdly, gave it a political recognition. In the second era of its progress it gave cheap and efficient locomotion, showed the advantages of freedom in commerce, and gave both unity and power for its accomplishment. As both

these great events in the progress of our country towards its present state of maturity were preceded by a mechanical agent, so will be the next. I will on some future occasion draw your attention to the third (and coming) era in commercial progress, the evidences of its approach, its character, and prospective results. JOHN GILES.

LETTERS ON MARBLE: PAINT ON LEAD.

ONE of your correspondents asked lately for a good mode of colouring letters in mural marble tables: allow me to say I have tried black and red sealing-wax, dissolved in spirits of wine, with much success.

Can any of your readers inform me whether it is impracticable to paint lead? A country painter—I apprehend on the principle "sweets to the sweet"—tells me white lead to white lead ruins the lead, and that painting lead ruins it in three years. Is such the case? EBORACUM.

DRYING WET CROPS.

SIR,—Allow me a few lines with reference to the paragraph, that the different wet crops can be well housed in defiance of wet weather.

My object is to say that the idea is not new, as I can fully prove. I was managing a large brewery at Burton-on-Trent. There I had an occasion to superintend some haymaking. It was very wet weather, and the idea then occurred to me. Accordingly, I went with a man into the field, and procured half a truss of green wet grass direct from the swathe: we then placed it in a vessel which contained air, heated by steam, and I can assure you, sir, that that wet grass was rendered into hay in one hour, with an excellent colour and beautiful flavour. I could have done ten trusses at a time in the vessel, but I thought the half truss was sufficient to convey the idea. I have a specimen of the experiment now by me, which is four years old, and it is exceedingly good.

I think I may say, that I am the first person who made hay by drying grass artificially. W. W. WYNNIE.

THE STAGE.

*The Adelphi Theatre.*—It is a long time since a more legitimate success was achieved than that which has attended "The Colleen Bawn, or the Brides of Garryowen," a piece founded on Gerald Griffin's Irish novel, "The Collegians," by Mr. Dion Boucicault, and in which he plays very cleverly an Irish ne'er-do-weel Myles-na-Coppaleen. Miss Agnes Robertson as *Ely O'Connor* (the Colleen Bawn), and Miss Woolgar, as *Ann Chute* (the Colleen Road), are both excellent; and Mrs. Billington, Mr. Edmund Falconer, and Mr. C. H. Stephenson, demand special mention. Indeed, the piece is altogether well played, and if we are not mistaken will serve to fill the Adelphi for many weeks to come. The scenery by Mr. Pitt and Mr. Thompson, although not yet even quite equal to the capabilities of the new stage, is very good and effective, especially the first scene, "The Lake of Killarney by Moonlight."

The management of the scene, "The Water Cave," wherein *Danny Nyan* attempts to drown the Colleen Bawn, and *Myler* rescues her, is remarkably good, and produces all the effect of reality.

*The Olympic.*—The "New Farce" here, as it is called, entitled, "Savage as a Bear," is a literal translation of the French vaudeville, "Un Tierce de Bengale," with omissions. Not a single incident, not a stray idea, is there in it which is not in the French original, if we except an absurd alteration at the end, which destroys the point of the French piece for the sake of strict propriety. So long as the public will permit managers to do this sort of thing,—so long as English writers have the hardihood to put their names to pieces which they have had nothing to do,—which they have no more right to call their than Mary Smith has to call herself the author of "Telemachus," when she has done a few pages of it into halting English,—so long will our modern drama, in a literary point of view, remain the scoff of Europe. Unlike most pieces at the Olympic, the farce is very badly played, too, at least by the gentlemen. Those who saw the original acted by the Zouaves at the Princess's Theatre (half-amateur as they were) could scarcely sit to listen to the unnatural ravings of Mr. F. Robinson in the part of the jealous peevish husband. This gentleman, useful in Shakespearean plays at Sadler's Wells, is entirely out of his element in the parts he is now acting at the Olympic.

## CUPS FOR PUBLIC DRINKING-FOUNTAINS.

As one of your constant readers, I beg to offer my individual thanks for your remarks from time to time upon drinking-fountains, in which I feel great interest. I am sensible of the prudence and justice of your observations in regard to the miserable taste generally displayed, and very often the only embellishment, "so to speak," is the donor's name, or some Scriptural quotation, both of which would be far more honoured in the breach than in the observance. Those at the entrance to the British Museum are admirable as regards fountain and cups; but it should be remembered that they are carefully guarded by day, and inaccessible at night, which other public drinking-fountains are not.\* The same silvered cups in an exposed situation would be mutilated or stolen within twenty-four hours, and are, therefore, not applicable to such service generally.

I am sure you feel a deep interest for the public benefit on such matters; and, having taken minute pains to find the best kind of drinking-cup, I hope you will kindly receive the result of my experience, and as kindly publish it. Common tin cups soon inherit a rusty look and a greasy feeling; tinmed iron soon become rusty, and are withal heavy; enamelled iron chip become rusty, and in wear soon assume a dirty appearance, from people's thumbs and fingers, which is not easily removed. Cups of that description should be renewed once a week, or at furthest, once a fortnight, which is the extreme extent of their decent durability and wholesome appearance. Such cups, with chains, were tried at Kensington-gore very fairly for above two months last year, and the result was a very large amount of trouble, no perfect satisfaction, and considerable expense to replace what were stolen or damaged. The average expense for the whole period named rather exceeded 2s. 2d. a week. These various evils led to the adoption of earthenware cups, marked "Kensington Drinking-Fountain," for identity, which have been in use ever since: not one has been stolen. They always look clean and wholesome, create no trouble, and the breakage does not amount to 6d. a week. I take leave to send you one, that you may be able more confidently to refer the public to the consideration of the question if you approve, because I believe them to be the best possible for the service in all its bearings. Through the kindness of Sir Richard Mayne, the police take charge of a small store; and, when one is broken, another is substituted without difficulty. They are perfectly plain, because any rims, handles, or projection, would tend to breakage. They have no pretension, but utility, cleanliness, and economy, and the cost is 4s. per dozen. I feel sure you would confer a public benefit by making these facts known. You kindly inserted a letter of mine in your journal of the 17th September, 1859, when these cups were first put into use, and the subsequent experience respecting them may be interesting and useful. KENSINGTONIAN.

## ILLUMINATING AND ELECTRIC CLOCKS

SIR,—A plan for illuminating clock hands without the entire dial being lit up was arranged in detail in 1857, with a view to its being applied to one or more of the Westminster clock dials; and it is one amongst several improvements to introduce which I have endeavoured to obtain the necessary control over the clock for some time past.

The experiments which I made with the plan in October, 1857, showed that an ordinary gas-light, at a moderate elevation, could be seen from a greater distance than the angular space on the dial permitted the time to be read off by the hands, and that an ordinary-sized gas-light on each hand would be sufficient for dials as large as the Westminster.

Your correspondent in the *Builder* of the 8th instant suggests the use of the electric light; but, as the experiments of 1857 showed that the distance at which the time could be read was limited by the amount of space on the dial, and not by the want of a more powerful light than gas, there would probably be no advantage in employing the electric light, sufficient to compensate for its uncertainty and extra cost.

As I may give a detailed account of the plan and experiments in a future number of the *Builder*, I need only add that three gas-lights were used,—one near the point of each hand, and

\* The marble rim should have been made to slope inwardly in order to prevent drops from the cup, inwards from wetting the person, while obliged to stand close to it. Nor can we approve of the lion's head as a spout.—Ed.

one in the centre of the dial; and that different coloured glasses were placed before them, in order to distinguish the hands and centre from each other. E. T. LOSEBY.

SIR,—My plan for illuminating clocks, introduced to the public years ago through the *Builder*, is again taken up; and the old, old story is exemplified, that the public mind requires a great deal of hammering before any impression can be made upon it. The chief idea of my plan is, that no hands are required. When a person looks at a clock or watch, he simply examines the position of the ends of the hands. Instead of the enormous leverage required to turn long hands, such as are required in public clocks, which are also interfered with by the wind, my plan embraced two thin copper disks, with a circular hole in one portion of them. These disks are placed in front of a red band of glass for the hours, and a white band for the minutes, and the time would be shown by the relative position of the red and white circle, as seen at any part of the disks. The light being directed on the two disks instead of the whole face, as at present, the contour of the clock is shown by a band of white light, with projections for the quarters.

For watches, merely feeling the position of the two holes at night would answer the purposes of a repeater. W. H. BETTERFIELD.

\* \* I explained my plan to one of the first clock-makers in London, who candidly stated that three patents which he now holds would be rendered valueless if my plan were adopted. I am not a clock-maker, but I know enough of mechanics to be certain that much less power would be required to turn the disks than the lightest hands that could be made.

The suggestion of Mr. C. Deut, relative to the illumination of clock-dials, contained in the *Builder* of the 8th inst., may be seen carried out in a very beautiful and ingenious manner in the clock of the Musée de la town of Havre. There the great body of the dial remains dark, the hours and the hands only being illuminated. I have often wondered why the method so successfully carried out in Havre was not followed in other places. I regret that I am not able distinctly to describe the arrangements of this remarkable specimen of illuminated dial, but I believe every facility would be given by the guardians of the Museum, for examining it in detail. I hope that this hint may not be lost sight of by those interested in this branch of horology. NIGHT.

\* \* This clock was also referred to in our pages some years ago.

*Time by Electricity.*—The telegraph has already worked strange innovations; but electricity is as yet an infant, and has to be applied to purposes that science has not yet taken up. For instance, our public clocks—those silent purrers,—cannot we do without them? They are ever misleading the Queen's lieges,—to-day slow, to-morrow fast, the next day stationary. What is there to prevent our having a central electrical, or rather galvanic, time-keeper, that should beat the pulses of the hours, and send the true arterial time along the railway lines through the city and over the country, with dials and honest fingers (but no clocks!), moving almost simultaneously from Land's End to John O'Grat's, "from Lynn to Melford Bay?"—GO-A-HEAD.

\* \* The electric clock is now an old invention, but has not come into use.

## DRINKING FOUNTAINS.

SIR,—On the 11th inst., at twelve o'clock noon, we had presented to this parish (Spitalfields) a granite drinking-fountain, the gift of T. F. B., a gentleman well known for his liberality, &c. It has been erected by the Association formed for that purpose. Of course, as you are the well-known supporter of the cause, a much more detailed account will be sent you. What I wish to call attention to is the shocking mess that the paving is in through the water being spilt after the fountain had been opened only twenty-four hours. There is a little grate, about 2½ inches by 2½ inches, let into the base, to carry off the water that is (at present) continually running over, for the outlets are stopped up in the basin. What can the parties know of such matters to finish it in such a way? It looks very much to be leaning towards Shoreditch—not quite upright. It seems a very great pity that good money should be spent on such bad work.

The fountain in Fleet-street, the *Duke's* one, is very bad from the same defect, causing a sloop and

puddle over the paving, in spite of all the staring description that is given of the liberal donor. What I would suggest is, that a proper grate be let into the stone paving, strong enough to bear rough usage. If the water should continue running through the winter, serious accidents must happen. This is not written to disparage the movement, but only the way in which the fountains are fixed. If the mode of construction is not altered, few will run the risk of wet feet for a cold draught of water.

A PARISHIONER.

A drinking-fountain of cast iron, comprising a female figure pouring water from a vase, with a white marble slab behind the figure, has been erected at Gravesend. It was executed by Mr. Hood, of Thames-street. The figure standing in the basin into which the water falls, an impression of feet-washing is conveyed, which can scarcely be intended.

## ARCHITECTURAL EXAMINATIONS.

SIR,—The question of a voluntary or compulsory architectural examination is a subject which should be duly considered in all its applications; for, whilst the want of an examination has been felt generally, the means proposed for its introduction are calculated to offend practising architects generally, and sever their practical connection with the Institute. The report of the Northern Architectural Association expresses not only their own opinions, but the opinions also of a large section of the members of the Royal Institute. Our profession is simply in a similar position to that of the medical and legal professions, before examinations in these professions were compulsory, and their precedent must be followed by us. If any in the architectural profession is to be maintained by granting diplomas to all establishments, a compulsory examination for the profession generally in place of opposition to the Institute, and a compulsory examination for all future architects; by these means support will be given by the profession generally in place of opposition to the Institute, and a compulsory diploma will be given to the architect of established practice. I would not consent to pass an examination, nor would I belong to the Institute, if it contained diploma non-diploma men. Such a general severance would not only injure the welfare and position of the Institute, if not form the nucleus for a rival and more liberal society. A MEMBER OF THE INSTITUTE.

## ARBITRATION LABOUR COUNCILS.

SIR,—It is by no means consistent with the vaunted supremacy of civilization in England, that the relations between the employers and the employed are in their present unsatisfactory condition, and that, between these two all-important interests, a state of petty civil war is from time to time raging. The Rev. Mr. Widdington, who has endeavoured most benevolently to mediate between the weavers and their employers, at Coventry, proposes to create a board of arbitration,\* composed of the employers and the employed. There would seem to be no better way of meeting the question than this, excepting that it would be incomparably better that the members of such a board, while holding the relative position of masters and servants, should be drawn from other trades or occupations, than that in which is the dispute as to the price of labour, the duration of work hours, &c. An equal number to be chosen as arbitrators to represent either class; the number to be a dozen on each side. Personal attendance to be urged upon them as very desirable; but, as their avocations will often render this inconvenient, in such cases voting by proxy might be allowed, but no question should be decided, unless a certain number [say half] were present of each class of representatives. To give a prestige to the character of the proposed councils or boards, and invest their decisions with an air of respectability, they should receive, in the commercial world, the representatives of either class should enjoy a minimum amount of income. Those on the employers' side to have say [as a rough approximation] at least 400l. per annum, while those representing the employed should be receiving [either in the form of wages or otherwise], a sum of at least 100l. per annum. By thus fixing the incomes of the arbitrators, and selecting men to a considerable extent removed from the possibility of collusion and bribery, who under less fortunate circumstances it is not improbable might be tempted to declare in favour of one or the other side, and yield to a pressure and without due influence. The proposed boards being so novel a feature in our social organization, it will be necessary that their formation should be maturely considered, and the suggestions now offered may be regarded as an instalment towards their foundation.

The great point of difference between the masters and men in the recent Coventry strike was, that the masters proposed that the wages should be fixed at a certain price, but that every master should be at liberty to make the best terms he can with his workers. The men protest against this, and have suffered much privation rather than submit. They do not object so much to a reduction of wages, but wish to know the extent of it, and where it is to end. The only equitable and just principle in trade, and the prevention of that ruinous over-competition which now exists, is that the price of every commodity or article [inclusive of labour as one of them] should be fixed from time to time by the consent of each trade as represented by their boards or councils of arbitration. Labourers should be designated according to their skill and proficiency as first, second, third class, &c., and a minimum rate of wages affixed to each one, with penalties or fines recoverable for any infraction of so wholesome a law. Till these things be done, injustice, misery, degradation, and discontent must continue to prey at that important branch of our social economy—the relations of the employer and the employed. VERITAS PRÆVALEBIT.

FALL OF A ROOF.—The roof of a foundry, belonging to Messrs. Hamilton & Co., at Liverpool, fell recently, causing the death of one man, and seriously injuring several others.

Books Received.

*Sussex Archaeological Collections, relating to the History and Antiquities of the County.* Published by the Sussex Archaeological Society. Russell Smith, Soho-square, London. 1860.

This is a goodly volume of archaeologically interesting and well-printed matter, illustrated, as usual, with engravings. There are papers on Uckfield, the Leper Hospital at Seaford, Hastings, and various other places in Sussex, and on its religious houses, its churches and chapels, monumental inscriptions, &c.

In the paper on Uckfield, by the Rev. Edward Turner, an account is given of the rocks at Buxted, in which there are curious chambers, with fire-places, apparently of considerable age. Some additional specimens of Medieval pottery, from Hastings, are figured in the volume, which is altogether a good one.

Miscellaneous.

**THE EXPLORATIONS AT MEMPHIS.**—A communication from M. Maretti, at Cairo, says:—"I write a few lines just to say that the explorations made at Memphis have come on the establishment of a founder in metals. The labourers have found the tools of the artisan, about forty pounds weight of silver in the rough, gold earrings, a score of silver coins hitherto unknown, and other objects, all destined for the crucible."

**IMPROVEMENTS AT CLAPHAM.**—On Friday, 14th inst., a large side of houses was completed at Clapham, by Messrs. Pallen & Son (by order of the trustees under the will of the late Rev. J. Jeffreys), on whose estate they were. There were as many as forty houses disposed of, nearly all of a superior character, and which are to be taken down to clear the site for the intended new road from Clapham-rise to Larkhall-lane, through the Stockwell estate.

**DESTRUCTIVE FIRE AT THE SAVOY CHAPEL ROYAL.**—On Sunday morning last, between six and seven o'clock, a disastrous fire happened in the Savoy Chapel Royal, in Savoy-street, between the houses in the Strand, near Waterloo-bridge. Smoke was first seen issuing from the roof, and also through the windows, which had been left open. The fires had been lighted in the stove for warming the chapel, and overheating is said to have been the cause of the conflagration. The plate and wine having been removed to a place of safety, the fire continued to spread, and at length the organ, bellows, pipes, and appointments became involved in flame. From that valuable gift of George IV. the flames extended to the roof—one of very elaborate character, only recently restored. The damage done, before the fire was extinguished, by fire and water, was very considerable; and, judging from the external and internal appearance of the roof, there must be something like 20 square feet of the ceiling totally destroyed; to say nothing of the damage done by heat and smoke to the other parts, not only of the ceiling, but also the pews. The font is also much scorched and blistered, and one or two of the ancient carved wooden monuments have been completely burned off the wall at the eastern side of the organ.

**AN ODD CARPENTER'S BILL.**—The following "little bill" was lately delivered, which completely put the arithmetic of the debtor at fault:—

	To Mr. Jones	Dr.	
	To Mr. Oldoak	s. d.	
2	Rosewood Boxes at 5s.	10	0
1	Wood do	5	0
1	Wooden do	5	0
		5	0

According to this there appeared to be charged four boxes, each differently described, the total of which was less than the price of one. As only one box had been received, the bill, of course was disputed. The learned creditor, however, explained, by the rule of thumb, as follows:—

Two rosewood boxes, sent for approval,	s. d.
at 5s. each	10 0
One was accepted (or, in the language of the bill, would do.)	
One was returned (or, wouldn't do),	
the price of which deducted	5 0
Left a balance due of	5 0

SET SQUARE.

\* Our correspondent is wrong in saying lately delivered." The bill is one of some standing; but it may, nevertheless, serve to give a laugh some of the rising generation.

**BISHOPSGATE INFANT SCHOOLS.**—On Friday the foundation stone of a building for infant and Sunday schools at the back of the church in Bishopsgate-street, in the neighbourhood of the churchyard, was laid. Mr. Hoppock, the treasurer of the funds collected for the erection of the schools, laid the foundation stone with the usual ceremonies. The length of the building, it is stated, will be 55 feet, and its width 25 feet, and it is calculated to cost about 900l.

**UTILIZATION OF SEWAGE.**—Mr. Richard Dover, of Baker-street, of whose system we have before now spoken, is again calling the attention of the parochial authorities of the metropolis to the expediency of utilizing and decorating all the sewage and waste water of the various districts throughout London. He proposes to establish in each of the parishes large filtering tanks, or reservoirs, in which the sewage will be received, and then and therein to treat it with an infusion of morriatic acid and sundry chemical salts, which have the effect, in little more than five minutes, of disengaging the solid sewage from the liquid, which latter comes out "in a purified and transparent stream, useful for flushing sewers, watering roads, and other purposes; while the residuum or solid matter precipitated furnishes, according to the attestation of eminent chemists, a guano or manure full of the most fertilizing ammoniacal matters, and valued at from 2l. to 2l. 12s. per ton." Mr. Dover estimates that the sewage of the entire metropolis may be decolorized and utilized in this way for a 3d. rate, instead of a 6d. rate as now proposed by the main drainage system, besides entirely preventing the pollution of the Thames. The vestry of St. Martin-in-the-fields have, we understand, examined Mr. Dover's system, and "consider it to be of such great national sanitary importance, that the public welfare demands its immediate and more ample test."

**ROAD AS WELL AS STREET TRAMWAYS.**—Since our paragraph on highroad railways appeared on the 15th instant, a correspondent of the *Morning Post* has addressed that paper on the subject; recalling attention to the absurd manner in which Portland-places was covered with a thick coating of macadamised stones, and the folly and cruelty to animals having to drag a carriage through it; reurging, at the same time, the cheapest, easiest, safest remedy in laying down the long granite kerb-stones of the streets in a double line for the wheels of all carriages to run on, so long and successfully done in Friday-street, Cheapside; the Commercial-road; in Regiate-hill, &c.; not raised above the common level, or laid down through the metropolis alone, but from one end of the kingdom to the other, by which dust, dirt, noise, and almost draft, would be all abolished together. This work any unskilled labourer, disbanded militia-men, or discharged prisoner, could perform, while it afforded him bread and employment without end. Again, much of the lost traffic and pleasure of the public roads would return. Half the number of horses would suffice, and the produce of the land they consume (according to the late Sir J. Macadam "four acres per horse per annum,—enough for eight men") would be available for human food, and its enormous price would be diminished.

**THE MULTIPLICATION OF PHOTOGRAPHS BY MACHINERY.**—A highly interesting and singular paper was read before the American Photographic Society on 13th August, 1860, and is reported in the *Architects' Journal* of New York. By this paper it appears that twelve thousand photographs or stereographs an hour can now be produced from a single negative by means of condensed or focalized light and simple machinery worked by a crank! A sheet of ordinary paper, sensitized, was exhibited, containing 300 of these photographs. Mr. Charles Fontayne, of Cincinnati, Ohio, is the inventor of the process. The prepared or sensitized paper is simply passed, in a continuous sheet, before a negative, in a box, where condensed light is made to penetrate through the negative and impress its image upon the paper, which it does in '03 of a second for each impression. The condensing lens is 7 inches in diameter. Thus, as it is said, "the illustrations for a book, having all the exquisite beauty and perfection of the photograph, may be turned out by the use of this machine with a rapidity wholly undreamed of either in plate-printing or in lithography." The cost of engraving, also, will of course be dispensed with. All sorts of drawings, too, may be thus multiplied, as well as actual objects photographed or stereographed, in cheap and endless profusion. The *Architects' Journal* publishes a print thus produced from a rough sketch by the ordinary ammonio-nitrate process.

**COMPETITION FOR A NEW CHURCH, TORQUAY.**—In a select competition for the above, nine designs were submitted to the committee, out of which that by Mr. A. W. Blomfield was unanimously selected.

**BALLOON OR BIRD'S-EYE VIEW PHOTOGRAPHY.**—At Providence, United States, a photographic sketch has been taken from a balloon. A Mr. Black ascended to the height of 1,200 feet, his balloon being held by a rope, while several negatives were taken. Mr. Black regards it as fully demonstrated that bird's-eye views may be taken in this way.

**TRAMWAYS IN LONDON.**—It is stated that the first street railway in the metropolis, of a similar kind to that successfully completed at Birkenhead, will be laid down in the course of a week or ten days, by way of experiment, along Victoria-street, Westminster, extending from the Broad Sanctuary, near the new Westminster Hotel, to the Vauxhall Bridge-road.

**NETLEY ABBEY.**—Local papers say the restoration of Netley Abbey, on the banks of Southampton Water, is progressing. During the past week the workmen engaged in restoring the abbey discovered the grave and tombstone of one of the monks. According to the inscription on the stone the name was John Wade, and he died in 1431. An inscription has also been discovered at the base of one of the columns in the chapel, from which it appears that the abbey was built in the reign of Henry III. What is really about to be done, and what aspect the place will take, we do not know; but at present we are told appearances are not very promising. The trees are being cut down, and the place is being trimmed with a vengeance.

**DEATH OF MR. JOSEPH LOCKE, M.P.**—We regret to hear of the death of Mr. Joseph Locke, the member for Honiton, which took place on Tuesday last at Moffat, Dumfriesshire. The deceased was born at Atercliffe, near Sheffield, in 1805, and was educated at Barstley Grammar School, Yorkshire. Mr. Locke had represented the borough of Honiton in Parliament since 1847, and in politics was a Liberal, having voted in favour of the Ballot in 1853, against Church-reforms in 1855, and in favour of Lord Derby's Reform Bill in 1859. His profession was that of a civil engineer, and he was extensively connected with railways, being a director of the Glasgow, Paisley, and Greenock Railway. He was a Fellow of the Royal Society, and President of the Institution of Civil Engineers. In 1815 he received the ribbon of the Legion of Honour from the late king, Louis Philippe. The deceased gentleman was in his 55th year. The death of one who was so well worthy to tread in the footsteps of Brunel and Stephenson, occurring as it has so soon after their own, is suggestive of painful reflection on the frail tenure on which the greatest genius holds its well-earned honours, though it is rarely we have to record the decease of three such men within the brief period of twelve months.

**THE CHARGE AGAINST ARCHITECTS OF ADDING TO TENDERS.**—In the case of Pooley, the bankrupt contractor, who stated that 100l. had been added to a contract at the instance of the architects, some further explanation has taken place on an adjourned certificate meeting, before Mr. Commissioner Perry, at Liverpool. Mr. Evans, for the bankrupt, apologized for having so expressed himself as to leave it to be understood that he alluded to the customs and habits of architects generally. "God forbid that he should say so," Mr. Martin, on the part of the assignees, said, from investigations which he had made it appeared that there was a dispute between the trustees of the church and the architects with regard to some former plans, but the latter gentlemen had been advised very properly by Mr. Dodge, that, although they might have a claim upon their constituents in respect to plans, it was not what they ought to have done to add to the estimate for the purpose of getting payment for their claims. Therefore, under the circumstances, they had paid over to the estate the 100l. which was received from the bankrupt, and also paid to their constituents the 100l. added to the contract. The judge, in allusion to the same transaction, said,—"the bankrupt," through his brother, had given in a contract for the building of a Presbyterian church at Birkenhead, the amount of which was 2,260l. The architects are said to have wished to be remunerated for previous plans made, and therefore requested that 100l. should be added to the estimate, which was accordingly done, and the tender was accepted. This arrangement was communicated to the bankrupt, who paid back part of the 100l. himself to the architects, and directed the other part to be paid.

**THE LATE MR. HARTLEY'S SALARY.**—The amount of the salary of the late Mr. Jesse Hartley, surveyor of the Liverpool Docks, was 3,500*l.* a year.

**ST. PAUL'S CATHEDRAL.**—A handsome stained glass window, according to the daily papers, has been presented to the Dean and Chapter of St. Paul's, who have resolved upon placing it in the nave of the Cathedral. It is to be hoped the authorities will admit nothing but what is excellent. Very little of the painted glass that is just now being manufactured is worth anything.

**THE MEDITERRANEAN ELECTRIC CABLES.**—A new line between Corfu and Otranto, in the heel of the Italian Peninsula, is about to be laid down. The landing-place in the heel of Italy will be as near Otranto as possible. The submarine cable will be of the same size and description as that existing between Malta and Sicily, which it is said continues to work satisfactorily. The new cable is now being manufactured by Messrs. Glass, Elliot, & Co., the contractors for laying it down. The screw steamer *Bernick*, with the cable on board, may be expected in the Mediterranean early in October. Mr. Andrews, the company's engineer and superintendent, has made a proposal to the directors to construct a land line, for the purpose of connecting their two cables—that is to say, the Malta and Sicily cable and the Corfu and Otranto one—through the island of Sicily and Southern Italy, and to complete the communication by laying a short submarine cable across the Straits of Messina. This would render the telegraphic communication between Malta and Corfu instantaneous, and would greatly facilitate the transmission of intelligence between both islands and the United Kingdom. In conjunction with these lines, the French Government are making preparations for laying a new submarine cable between Toulon, Corsica, and Gaeta. Another plan proposed by Mr. Andrews, and approved by the directors, is to connect Corfu with Turkey, Greece, and the Levant, by means of a new submarine line between Corfu and Albania. If time and weather admit, attempts will be made this season to repair both the Cagliari and Corfu lines, which have been so long interrupted; and, in the event of these operations failing, as much cable as possible will be recovered.

**THE GAOL OF NEWGATE.**—Newgate was rebuilt after the Great Fire by Wren; and, when burnt in the Gordon Riots, by George Dance, R.A., who designed the building in 1720, his plan being objected to by Howard. While the work was progressing it was arrested by the rioters, who, breaking into the completed portion, liberated 300 prisoners, and left it in flames, so that the prison was not finished until 1782. The external architecture was thought suitable, from its gloomy grandeur and severity, to the proposed object; but the interior was so insufficient for classification or moral discipline, that within the last few years the whole plan has been changed, nothing of Dance's work remaining but the walls, which are remarkable for their thickness and solidity. Old Surgeons' Hall was close to Newgate, and convicts sentenced to be anatomized had this part of their doom performed there. While executions took place at Tyburn, corpses of murderers or traitors were placed under the operator's knife, as we see in Hogarth's ghastly picture of "The Idle Apprentice's Fate," and as really occurred in the case of Earl Ferrers, and a thousand other criminals. Our old chancellors, and especially Maitland, speak with horror of the prison discipline. The unfortunate wretches in confinement were placed in dark dungeons, where the foul air engendered "the gaol distemper," which often led to a fearful mortality, for a dozen or more deaths not unfrequently happened in one day. In 1750, while the assize was going on, the pestilential effluvia infected the whole court—judges, barristers, witnesses, and spectators—and not less than sixty persons died in consequence. This led to the erection of a ventilating shaft, and ever after the court was strewn with sweet herbs, and bouquets were laid before the presiding judges, though at present an abundant supply of fresh air is a far better preventive. Lord George Gordon died here of gaol distemper, while in confinement for a libel on the Queen of France. After the riots, if not before, his reason became impaired. He affected to be a convert to Judaism, and was remarkable for his monstrous hard, which would have gained no notice in our modern streets, for heads are again fashionable, and our hirsute ancestors are more than rivalled. Formerly, debtors and criminals were huddled together in Newgate. Even while contagious fever raged, 800 human beings were packed in spaces which made healthy respiration impossible.—*City Press.*

**MR. SCOTT RUSSELL AND THE "GREAT EASTERN."**—The disputes between Mr. Scott Russell and the Great Ship Company, relating to the *Great Eastern*, have at length been decided by the arbitrators, Messrs. Hawshaw, McLean, & Fowler, awarding him the sum of 16,000*l.*

**PECKHAM CHURCH STRUCK BY LIGHTNING.**—During a recent storm the tower of East Peckham church was struck by lightning. The vane on the top of the low spire was first struck. The lightning descended the south-west side of the spire, tearing off the shingle and wooden framework, with the quartering. It then crossed, internally, over all the bells, to the south-east corner of the tower, where it displaced some of the stonework and entered the wall itself, down which it passed in an irregular direction till it reached the level of the nave roof, a distance of about 15 feet, making in its passage several fissures in the internal face of the wall. At the point just above the junction of the ridge of the nave roof and the tower wall, a stone, measuring 14 inches square and 4½ thick, was forced out of the wall externally; and through this opening the lightning escaped. The stone must have been carried over the roof, as not a single slate was broken. It appears to have fallen first upon the iron shoot on the north side of the nave, which was shattered to pieces, and thence it descended to the ground.

**SMOKE FROM GAS LIGHTS.**—It is pretty generally imagined that the smoking of ceilings is occasioned by impurity in the gas, whereas, in this case, there is no connection between the deposition of soot and the quality of the gas. The evil arises either from the flame being raised so high that some of its forked points give out smoke, or more frequently from a careless mode of lighting. If, when lighting the lamps, the stop-cock be opened suddenly, and a burst of gas be permitted to escape before the match be applied to light it, then a strong puff follows the lighting of each burner, and a cloud of black smoke rises to the ceiling. This, in many houses and shops, is repeated daily, and the inevitable consequence is a blackened ceiling. In some well-regulated houses, the glasses are taken off and wiped every day, and before they are put on again the match is applied to the lip of the burner, and the stop-cock cautiously opened, so that no more gas escapes than is sufficient to make a ring of blue flame; the glasses being then put on quite straight, the stop-cocks are gently turned, until the flames stand at 3 inches high. When this is done, few chimney-glasses will be broken, and the ceilings will not be blackened for years.—*Sir John Robinson.*

**STATUES AND MONUMENTS.**—It is intended to erect a statue of St. Thomas Aelend. The model is now completed. Mr. Stephens is the sculptor. —A movement is set on foot to repair the stone of the Wallace Monument at Wallacestone, says the *Falkirk Herald*, and make such improvements as shall make it worthy of the hero to whose memory it was erected some fifty years ago. Upon the elevated spot where the stone already stands, it is supposed that the brave patriot took up his position and surveyed the two armies entrenched, previous to the first battle of Falkirk. The words "Hic stetit, 22nd July, 1295" are inscribed on the tablet. —The Swedish monument in honour of Charles XII., at the spot where he fell, close to Fredrikshald, in Norway, is now completed, in the shape of a Gothic tower, with four gables, surmounted by an eight-cornered spire ending in a cross. The whole rests on three steps of stone, and is 34 feet high. This monument was uncovered by the King of Sweden and Norway on August 29.

**RAILWAY PROGRESS IN SOUTH AUSTRALIA.**—The Gawler and Kapunda Railway was nearly completed in June last. It is laid with the patent sleepers of an inverted iron-peg form, much used by Mr. Stephenson where the ballast is light, and chiefly in India and Egypt. The cost is above the average, but the sleeper is considered to be well adapted to light ballast, and durable. There are two intermediate stations between Gawler and Kapunda, namely, Roseworthy, 5½ miles; and Freeling, 12 miles from Gawler. The two more important bridges on the new line are, one over the Gawler, which is already completed at a cost of about 7,000*l.*; and the other over the Light, which is yet in course of construction, and the estimated expense of which is about 6,000*l.* The entire cost of the Kapunda extension will be about 9,000*l.* per mile, including bridges and stations, but not including rolling stock. The Bill for the completion of the last 2½ miles was passed on the 1st of September, 1859, and the entire line, including the bridge over the Light, would, in all probability, be opened within twelve months of that date.

**SHORT SEA PASSAGE BETWEEN ENGLAND AND IRELAND.**—The directors of the Luttre and Carrickfergus Railway made an excursion on the 11th inst. in the *Giraffe* steamer, which the owners, the Messrs. Buras, of Glasgow, placed at their disposal free of expense, for the purpose of testing the merits of the two modes of crossing the channel, viz., *via* Donaghadee to Portpatrick and Larne Lough, to Lough Ryan. In the published account of the trip it is stated that the time occupied by the *Giraffe* in crossing from Donaghadee to Portpatrick was 1 hour 34 minutes; and from Lough Ryan to Larne Lough, 2 hours 1 minute, to which some minutes should be added, making the difference of time in favour of the route by Donaghadee and Portpatrick about half-an-hour; but, to counterbalance this, the harbours at these places offer neither the same security, depth of water, nor facility of access and departure at all times, which are to be found at the natural harbours of Larne and Lough Ryan (though this is denied by the Government engineer), notwithstanding the immense sums which have been spent by Government in the attempt to form artificial harbours at Donaghadee and Portpatrick. It is proposed to connect Antrim and the junction of the Banbridge and Ulster railways, by a railway through Crumlin along the banks of Lough Neagh, shortening the distance from Dublin to Antrim eighteen miles, and affording railway communication to a fertile and densely populated district. Mr. Bower is the Engineer.

## TENDERS

For first portion of works, Cambridge Townhall. Messrs. Peck, Stieghens, Madstone, architects. Quantities supplied:—

Myers .....	£7,750 0 0
Bullock .....	7,343 0 0
Thornley & Clayton .....	6,970 0 0
Young .....	6,300 0 0
Bell & Sons .....	6,157 0 0
Ayres .....	5,990 0 0
Architects' Estimate, £6,000	

For farm buildings at Woddingham, in Surrey, for Mr. Joseph Kitchen. Mr. W. Hey, architect:—

Ward .....	£1,693
------------	--------

For alterations at the King John's Head Tavern, Abbe

maire-street. Mr. W. E. Williams, architect:—

Grass & Co. ....	£270 0 0
Green .....	377 0 0
Scott .....	305 10 0
Tolley .....	290 0 0

For alterations to Coach and Horses, Blackheath-hill, Mr. William Nunn, architect:—

Wills .....	£222 0 0
Miller .....	220 0 0
Dry (accepted) .....	215 0 0

For building warehouse at Birmingham, for Messrs. Copestake, Moore, Crampton, & Co. Mr. J. G. Bland, architect:—

Harris .....	£2,368 10 0
Hardwick & Son .....	2,273 0 0
Jones .....	2,260 0 0
Matthews .....	2,188 0 0
Bugs .....	2,180 0 0
Parsons & Sons .....	2,150 0 0
Robinson .....	2,113 0 0
Anley .....	1,994 0 0

For re-building the Two Brewers public-house, Brick-lane, Spitalfields. Mr. William Reddall, architect:—

Croder .....	£2,939 0 0
Blackburn .....	967 0 0
Asby & Sons .....	945 0 0
Scott .....	930 0 0
Cass .....	907 0 0

For the Kingsfield Congregational Church, Southampton. Quantities supplied by Messrs. Hlavcs & Bellborough, architects:—

Richardson .....	£2,360 0 0
Gaulson .....	2,122 10 0
Nickols .....	2,100 0 0
Stevens .....	2,060 0 0
Balley .....	1,967 0 0
Hardiman .....	1,790 0 0
Watts (accepted) .....	1,740 0 0

For the foundation of Tower or Observatory, Vernon Park, Stockport. Mr. J. Stephens, architect, Manchester.

Quantities supplied by the architect:—

Goehard & Ormerod .....	£247 5 0
Forrest .....	370 0 0
Thackrah & Peirce (accepted) .....	349 0 0

For the villa residences at Forest-gate, West Ham, Essex.

Messrs. Francis, architects:—	
Myers .....	£2,677 0 0
Calls & Co. ....	2,475 0 0
Mansfield .....	2,307 0 0
Holland .....	2,355 0 0
Keys & Head .....	2,119 0 0
Rivet (accepted) .....	2,042 0 0

For kirking and paving Morgan-road, Charlton, for Plumstead Board of Works:—

Duvers .....	£200 0 0
Hobbs .....	206 10 0
Gleavers .....	194 10 0
Harnes (accepted) .....	176 10 0

# The Builder.

VOL. XVIII.—No. 921.

The Social Science Association  
in Glasgow.

HE meeting of the National Association in Glasgow, which was opened on Monday last, and will close on the 29th, has been in many respects very successful. The number of tickets sold, 2,600, if not more, is larger than on any previous occasion: there has been a good supply of papers, and some of the discussions, especially on mercantile and international questions, will probably produce fruit. The receipt of a letter from Professor Katchenowsky, of Charkow, in the heart of Russia, suggesting a wide extension of the operations of the Society, so as to give its proceedings an additional interest in the eyes of all countries, was a subject for much congratulation, as showing how far the Association had already spread its

feelers. At the meeting of the Council on Monday, with which the business of the week commenced, a liberal and wise offer was made anonymously, by one who, himself "a poor boy fifty years ago," was anxious that other poor boys, on leaving reformatories and similar institutions, should receive a handbook of advice and information for assistance through life. To obtain this handbook he thought a wide appeal should be made; and he proposed, therefore, to offer, through the Association, if they would undertake the management of the competition, 2000, 1000, and 500, for the first, second, and third best composition for the purpose. Further, he would print, at his own expense, 10,000 copies for distribution. The offer will doubtless be accepted. After the meeting of the Council, the Cathedral, now in a good sound state of repair, opened its venerable doors to receive the members and associates, and the Rev. Dr. Robertson delivered an excellent discourse, lucid, sensible, and appropriate, showing the connection between his text, "Thy Kingdom come," and the objects of the Association. He said:—

"Touching some of these objects, any minister who has had charge of either a town or a country parish could easily say a great deal. It has fallen to my lot to have some short experience of both positions; and, in both, one soon sees enough to make him pray heartily for social amelioration. It is not long till one who attains to the somewhat intimate knowledge of rural life a country minister can hardly fail to acquire, discovers with pain that, though there is much in the character of our peasantry he cannot but admire and love, he must modify, to a great extent, the poetical ideas of his youth about the cottage in its nook among the trees, and with its blue smoke curling up to heaven, being quite so sacred, as he had once imagined, to innocence and peace. And in the towns—I will not speak of the lower orders in terms of disparagement: there is among you very much good feeling, very much one cannot but respect greatly; yet, how often are there sights that come before him at which one's heart bleeds? I could tell of such a thing, in this very parish, as 48 families—that is to say, probably about 240 human beings—living in one single tenement. How

can there be health or religion there? I could tell that, to my certain knowledge, you might have seen there, within the last ten days, children literally without a rag or clothing of any kind, and the mother with so little as scarcely to be fit, for decency's sake, to appear in the presence of my valued assistant, by whom she was visited. These things are saddening; and yet there is something almost more saddening still than such abject misery—in the perfect self-satisfaction with which hundreds flout in gaudy dresses who can hardly read their Bibles, and cannot at all sign their own names; and with which many parents, who are making tolerable wages, consider themselves good, worthy people, who are doing their duty to society, and are quite entitled to all sorts of trusts, politically and otherwise, while they are yet neglecting altogether, or discharging in the most perfidious way, one of the first and most sacred trusts of nature, by either permitting their children to grow up without education, or by withdrawing them from school whenever their poor young hands are able to contribute in the least degree to the earnings of the family. But why do I speak of these things? Fortunately the public mind is become thoroughly awakened to them, and we are begun to be determined that, God keeping us, they shall not continue. Preachers, poets, novelists, statisticians; the pulpit, the platform, and the press, have all been occupied about them, and not without result. It has not all been talk or sentiment. Witness the ragged and industrial schools, the reformatories, the model lodging-houses, which are the growth of the last few years: witness the extension of the ordinary means of education: witness our city missions, and, what seem to me the best of all kinds of missions, the territorial missions of churches: witness many other agencies that might be named. May I not be permitted to add, witness the present meetings of we of this city so unfeignedly rejoice to see convened among us."

In the evening, Lord Brougham, as president, delivered his address in the City Hall, reading for two hours. The address was too long, and at times his voice was so low that they who sat at the farther end of the hall could hear nothing. Nevertheless they remained, giving testimony of respect and admiration; and at the close hearty shouts showed the general appreciation of a remarkable effort by a man of 82. On commencing, he said,—

It is impossible to open the congress without expressing the satisfaction felt by all, that this, our fourth meeting, should be held in the great capital of the west of Scotland, the centre of her manufactures, and the emporium of her trade. But we also are highly gratified at finding ourselves in a place not more renowned in the history of commerce than in that of philosophy, and of those branches of philosophy which have exercised the most important influence in the promotion of Social Science. It was here that Black made those discoveries which have changed the face of natural science more than any since the days of Newton; that Watt gave the great invention to the world which has made such an alteration in its aspect, and such a revolution in its fortunes; that Stewart learnt and Simson taught the ancient geometry which he restored; that Reid placed the philosophy of mind upon its firm foundations, and freed it from sceptical evils; that Millar traced the history of the constitution on principle,—freed it from vulgar errors of empirics as well as of absolutists; that Smith established those sound doctrines, now happily become the faith of practical statesmen, as they had long been of the learned, connecting the commercial gains of all nations with the improvement of each, and making their mutual intercourse a mutual and equal benefit, and the bond of peace. Nor let it be forgotten that here the first step was made by Birkbeck (on which, five-and-thirty years ago, I congratulated you) of throwing open to all classes the temple of science, and showing that the highest intellectual cultivation is perfectly compatible with the daily cares and toils of working men. These are proud recollections for Glasgow; and this pride is shared, not envied, by her sister, Edinburgh, whose own glories are far too bright to dread being outshone.

Of the various topics treated of in his address we must confine ourselves to what he said of one, namely,—

## Co-operative Societies.

Nothing can be more gratifying, in this and in every other view, than the success of the great measure which the working classes themselves have lately adopted to provide for their comfort, to husband their resources, and to protect them from imposition, by the formation of Co-operative Societies; and happily these have greatly multiplied, especially in the manufacturing districts of Lancashire and Yorkshire. Such societies are of two kinds. The one has for its immediate object to expend the income of each member to the best advantage for himself; the other to enable him to obtain the largest return for his capital and industry. Sixteen years ago, forty Rochdale artisans, desiring to establish a society of the first kind, amassed, by a weekly subscription of 3d. from each member, the sum of 28s., hired a room for a store, laid in a stock of necessaries, and began to trade; selling not only to members, but to all who would buy. The enterprise provoked laughter. A neighbouring shopkeeper boasted that he could carry away the whole stock in a wheelbarrow. Now, however, the single room is multiplied into many distinct shops, spread over the town, and the weekly vend of the society exceeds 2,700l. per week. Every member must be the owner of five shares of twenty shillings each, the permitted maximum being a hundred such shares. The capital is paid in by small weekly or quarterly instalments. All the transactions of the society, whether purchases or sales, are for ready money, the entire absence of credit being the corner-stone of the institution. The customer, whether member or stranger, is charged at the same price as at the ordinary shop of the town; but at the end of each quarter a division of net profits is made, and he receives his quota according to the amount of his purchases. To arrive at the net profit, the following deductions are made from the gross returns—the cost price of the goods, the current expenses of the stores, including the wages of the manager and his assistants, rent, repairs, a proper allowance to a depreciation fund, and 5 per cent. for interest upon capital. The residue is the net profit, for which, however, before it is divided among the customers, 20 per cent. is deducted for the maintenance of a library and a news-room. The society is governed by a committee elected from the members, which meets weekly, when it gives patient attention to all complaints. If real cause of dissatisfaction exists it is removed. If the complainant is in error he is reasoned with; and so successful has been the course taken by the committee that, although arbitrators have been appointed from the first, pursuant to the Acts under which the association is registered, yet it has never been necessary, even in a single instance, to engage their services! The benefits derived by the individual in the expenditure of his income upon this plan are manifold. It is enough to enumerate a few. First, antagonism of interest between buyer and seller is annihilated. All motive, therefore, to adulteration, or in any way to lower quality for the sake of diminishing price, is absent. No extra price is put on the goods to pay the rent of shops in expensive situations, nor for the plate-glass or other costly fittings, nor for the loss occasioned by the expense of articles in the windows to attract customers, nor for advertisements. Indeed, show is altogether discarded; and, while no cost is spared to insure high quality in the articles themselves, no money is wasted on the means of attraction. The exact price of the article, too, is not very material. If the price is high, the customer's returning profit is also high, and vice versa. But not only economy is consulted: the improvement of the character and habits is incalculably promoted. The workman is stimulated to the exercise of self-control, beyond his reach in ordinary circumstances. He must refrain from anticipating his income by running in debt in order that he may be able to pay ready money, and also to acquire capital; and to the self-denial essential to compassing these objects he is urged when he has their advantages clearly and forcibly set forth by his brother members, and more than all, by the example of the body of which he forms one. Finding, then, strict economy a necessary condition to his maintaining the rank to which he has aspired, he casts about that he may so exercise his thrift, and abridge his expenditure, only in what is not essential to health and comfort; and soon discovers that abstinence from drink and tobacco not only subtracts nothing from his well-being, but greatly adds to it. But a working man out of debt, acquiring capital, however slowly, and abstaining from stimulants, is on the road to happiness, and with a prospect of attaining

it as bright as is vouchsafed to any citizen of the State, even the highest in the land.

The second class of these institutions, namely, those which have for their object to enable each member to augment his income, are at present but few in number, and their experience has been short. At Rochdale, a society was founded four or five years ago for spinning cotton-yarn and weaving it into calico. The principal distinction as regards financial arrangements between the two classes is, that the net profits are divided among the artisans instead of the customers, each in proportion to his or her wages, the wages being fixed according to the rate of payment in the mills of the district. The disastrous years of 1857 and 1858 sorely tried this infant establishment, but it weathered the storm successfully; and although during a period of fifteen weeks no sales were effected, or sales only to a trifling amount, yet the hands were never put upon short hours, although the other mills of the town yielded in this respect to the pressure of the times. It is, however, far too early to predict success for co-operative societies of this class with any degree of confidence, or to speak of them otherwise than as hopeful. It appears manifest, and the observation is important, that co-operation is not only distinct from communism or socialism, but repugnant to it, far more so than to the ordinary course of trade, with which, indeed, it agrees in giving to every man the benefit of his own industry, skill, and economy. Co-operation leaves its votary in freedom, whereas communism, which makes him receive according to his wants, instead of according to his merits, extinguishes the ordinary motives to exertion; and failing, as it always has failed, to induce men to work from higher motives, must, if it continue in action, fall back upon coercion. Communism is in truth slavery in disguise; but, as the slaves are also their own masters, they quickly emancipate themselves; and that being done, the communities of socialists come to an end. Such is the appointed lot and fate of the kindred associations arising from strikes, even where these are carried on without breach of the law—that is, without in any manner exercising compulsion, directly or indirectly, to obtain the increase of members. This most interesting subject will certainly occupy both our general and judicial departments.

Sir John Pakington, Lord Ardmillan, Sir Archibald Alison, and Sir John Lawrence, afterwards spoke. On the following morning the Lord Advocate delivered his address as president of the jurisprudence department, and then the various departments went to work in earnest, reading papers and discussing them—some fully, but many otherwise.

In the fourth department, "Public Health," Mr. Edwin Chadwick presided, in the absence, through illness, of Lord Ebrington.

Dr. James Wallace read a long and elaborate paper "On some of the Causes of the high Rate of Mortality in Greenock, with an Account of their Origin, as well as the Measures which have been taken, and are still required, for their Abatement and Removal." After a consideration of the nature of the soil, the position and extent of the town, its mode of construction, particularly its over-crowded condition, the causewaying of the streets, the nature of the houses, the mode and nature of the water supply, the drainage, as well as enumerating certain nuisances of a very deleterious character, such as the West Burn and the contiguous mill dam, he went on to show that from a very early period continued fevers had exercised a most malignant influence, and almost always in the crowded and filthy parts of the town. The Infirmary report and other documents were quoted to show that since the commencement of that institution, half a century ago, no fewer than 12,360 cases of fever had been treated, the average cost of each of which had been exactly 2*l.* 2*s.* 6*d.*; thus showing that, for the treatment of those afflicted with this disease alone, the subscribers to the infirmary had paid in fifty years no less a sum than 30,000*l.* And if to this were added the expense entailed on the community by the three epidemical visitations of cholera in 1832, 1849, and 1854, in which years there were affected 897, 964, and 141 respectively, the annual interest of which, if properly and regularly invested, would, long ere this,—not to speak of the desolation of many happy homes,—have

saved the ratepayers much of the difficulty which they would soon have to encounter. But this sum, large as it appeared, must be far below the reality, as there was excluded from the calculation the number of fever patients who did not come under the eye of the hospital authorities, as well as the widows and orphans whose maintenance from this cause lay from time to time upon the parochial authorities. To show how this condition of the town had been brought about, he gave a short history of its rise and formation, according to which the overcrowding was shown to be the result more of the cupidity of the feuars than of the proprietors of the land; although, at the same time, he urged that the latter were not altogether blameless, because they had failed, in certain parts of the town, to lay out their land according to a plan in conformity with the ideas of modern sanitary legislation. The errors on the part of the constituted authorities were then taken up, when it was shown that nothing in the way of provision against the evils complained of was attempted till within the last fifteen years.

#### Condition of Glasgow.

Dr. McGill read a paper on the "Sanitary Condition of the Lower Districts of the City of Glasgow, chiefly as regards Overcrowding, with some of the Causes leading thereto, and several proposed Remedies for the Removal or Mitigation of existing Evils." In the course of it, Dr. McGill said,—

"As illustrative and typical of a state of things common in the centre of the city, I will take a square or area covered with buildings and occupied as dwelling-houses. The square or area contains, after allowing for two large public works situated in one of its angles, nearly two acres and a half, every foot of which is built on, with only a few narrow spaces for passages, and having a population of the lower labouring class of about 2,800. This gives about 1,100 human beings to every acre, or 1 to four square yards.

One house or building in this area, 28 by 14 yards, having a common stair, contains a population of 120; and, as every foot of ground is built on, it gives only 3*1*/<sub>2</sub> square yards to each inmate.

Again, as respects the interior of the apartments, assuming as correct that every adult requires about 700 cubic feet for respiratory purposes, the greater number of the apartments in the square are so small and ill-ventilated, that in scarcely any is there anything approaching an adequate supply of vital air. In some instances, so small is the space, that, even were the apartment well ventilated, which it seldom is, there is not a sufficient supply of air for one, while there may be four or more, living and sleeping in the apartment. One or two examples will suffice:—

One apartment, containing 450 cubic feet, with very imperfect ventilation, and having four inmates.

One apartment on the ground flat, with a damp earthen floor, little bed accommodation, little furniture, and both in a filthy, unhealthy, and unwholesome condition, contains only 800 cubic feet, and little ventilation, for nine individuals.

These are merely typical of a large class of houses which, in addition to the smallness of the apartment, and deficiency or absence of ventilation, have what furniture there is, in the shape of chests, &c., piled up in the apartment, so as still more to contract its size, with large quantities of dry and wet clothing hanging through the apartment, in the beds, and in front of the beds large fires and filthy personal clothing.

Innumerable instances of these apartments, although they may have windows, yet these cannot be opened, in consequence of opening into filthy dungheaps, the smell from which is intolerable, and occasionally the fluid filth passes through the walls, and causes a damp, unwholesome apartment.

There are many lodging-houses in this district, licensed and otherwise, and while the former have generally three or four beds in an ordinary sized apartment, with narrow passages between them, and breathing space to the extent of about 150 feet for each inmate, the latter, being under no control, are frequently much worse. Assuming the boundaries of Glasgow proper as four miles in length, by three in breadth, thereby giving an area of twelve square miles, with a population of 400,000, we have about 92 square yards to each inhabitant.

While this gives a very large average space as compared with what exists in the districts to which I have referred, yet it is small as compared

with Leeds, which is stated to have an area of forty square miles, with a population of 220,000, or 563 square yards to each individual. If this is correct as regards Leeds, it illustrates what I have already alluded to, of the different class of houses in the two places, and shows that Glasgow ought not to be judged by the same standard as respects its sanitary condition.

The construction of the houses in the square or block which I have taken for illustration, and which prevails in other parts of the city, is of a faulty description, viz., the buildings fronting the street are frequently of the height of four or five stories, while those in the centre of the square or area, being much lower, not above two or three stories in height, are deprived of that ventilation so necessary for the due preservation of the health of the inmates. The air in the centre compartment would almost be in a stagnant state were it not for the passages, some of which are occasionally yet rarely thorough, thereby permitting a somewhat imperfect degree of ventilation. Again, in consequence of the great height to which the buildings have been carried, and the fact that every foot of ground has been built on, there is not only the congregating of a large mass of human beings, but also the absence of an open space behind the buildings, for the purpose of ventilation, so that of necessity the air in these places is of a very impure and unwholesome description.

Apart altogether from the buildings, there is an insufficient supply of dungheaps, or ashpits, and other conveniences for the wants of such a great number of inhabitants as are collected in the houses on either side of these long narrow passages.

There is also, frequently, an insufficient supply of water.

The closes and stairs leading to the houses, the houses themselves, and the external walls of the buildings, present, in numerous instances, either from the inability or cupidity of the owners or occupiers, such a ruinous, smoky, and filthy appearance, that they are unfit for human occupation.

Want of personal cleanliness, want of necessary clothing and furniture, and what little there may be of a mean, filthy, and unhealthy description.

Irregularity of meals, the use of injurious articles of diet, want of cleanliness, of clothing, and of pure air; absence of mother for the whole day, and consequently the want of the natural aliment, the system of drugging with laudanum, alcohol, and other poisonous agents, have a most baneful influence on infantile life.

One of the chief causes, I am convinced, is due to the prevalent custom of the abuse of intoxicating drinks. I will, instead of enlarging on this evil, which confessedly exists, give the result of my observation in the police office.

According to the calculation of Dr. Strang, the annual increase of the city is at the rate of 3*1*/<sub>5</sub>, which, applied to 95,000—as I believe the 55,000 have been stationary—would give a population at the present time of about 175,000. For the population of 175,000 the parochial board has appointed twelve medical officers, the labours of eight of whom are chiefly confined to the small space of a quarter of a mile, and to the population of 55,000.

In speaking of various methods of improvement, the reader said, amongst other suggestions,—

1st. In rural districts a highly-to-be-commended system prevails of giving small rewards, in money or otherwise, to peasants, for the best and most cleanly kept cottages. Were such a system greatly extended, and not confined to rural districts alone, but introduced into our cities and towns, it might ultimately, at a very small cost, have such an encouraging and stimulating influence on the character and habits of the people that the appearance of dwellings in low localities would be reversed; and, instead of, as now, finding nine-tenths of them in a filthy and unwholesome condition, that proportion would be distinguished for a clean, wholesome, and healthy character.

2nd. To invest the authorities with increased powers to enter dwellings in low districts, and, at the cost of the proprietor or the public, to have them put and maintained in such a state that they shall not continue, or again become, the centres from which emanate disease and death. A very small tax would suffice to do so; and, if it is considered advisable to attend to the sanitary state of the city externally, much more is there a necessity for a strict supervision over the interior of houses.

Mr. J. Watson read a striking paper on "The Measures required for Improving the Low Parts of the City, and the Value of Model Lodging-houses." He said there was perhaps no city in the kingdom where the abodes of splendour and refinement contrasted more strikingly with those of squalid poverty and wretchedness than the city of Glasgow. It was not to be concealed that there were certain portions of it in a most frightful condition, and which, like so many plague-spots, demanded investigation and called for legislative reform. There were narrow lanes or closes, running, like so many rents or fissures, backwards to the extent of sometimes 200 and 300 feet, in which houses of three and four stories stood behind each other, generally built so close on each side that the women could either shake hands or scold each other (as they often did) from the opposite windows. In many of these lanes and closes there were residing in each not fewer than 500, 600, and even 700 souls, and in one case he observed thirty-eight families, or nearly 300 persons, occupying one common stair.

Mr. Watson stated, that what must be considered very encouraging, that some model lodging-houses erected in Glasgow were paying 10 per cent. on the outlay.

Mr. David Smith J.P., Glasgow, read a paper on "The Necessity of a Building Act for Large Towns." After dwelling at some length on the mortality of large towns, he suggested the following remedies to be embodied in a Building Act:—

1. That every street or lane shall be at least one and a half times the wideness of the height of the house.

2. That every building shall retire at least once its own height from the front.

3. That there shall be no inhabited dwellings underground.

4. That a limit shall be put to the number of inhabitants that may enter by one close, and that a certain number of cubic feet, to be fixed by some competent authority, shall be allowed for each inmate in each apartment. These appear to be the principal arrangements necessary to be enforced. Others in reference to ash-pits, dust-bins, water-closets, drainage, and other matters may also, with propriety, be introduced. In an admirable report, made to the Architectural Society of Glasgow in 1852, several additional suggestions are made, such as:—That there be no back-houses; that the hack wall of any tenement, for houses in flats, be a space equal to the height of front wall from the lane; that the lane shall be 16 feet in width; that, in houses for working men, no roof shall be less than 9 feet high, nor any apartment contain less than 1,512 cubic feet, with 21 square feet of light. A space of 60 feet to be left from wall to wall, with a lane of 10 feet in centre, for workmen's dwellings. No dwellings in sunk flats. No concealed beds; all fixed beds to be of iron. The number of dwellings on each landing not to exceed three, making two houses of not less than a room and kitchen, and one house of a single apartment. Stairs to be scale stairs, and not less than 3 feet 0 inches in breadth. To be compulsory on landlords to light all public stairs with gas. He referred, in conclusion, to the sanitary moral and political objects which would be served by the enforcement of such rules.

The Chairman having invited discussion on the papers which had been read,—

Mr. Henry Roberts, F.S.A., took strong exception to a recommendation which had been given, that unfit houses occupied by the poorer classes should at once be pulled down without waiting for the provision of others, and stated the result of his experience on the subject in France.

Mr. G. Godwin confirmed what Mr. Roberts had stated, and said enormous mischief had been done by attempting to dispossess the poorer classes of their dwellings before finding them other houses. He had seen in London many such clearances, and the result had been that parts before greatly crowded had become much more so, and rooms let to one family had, in consequence, been made to receive two and even three. So that, where railway companies, improvement and other societies, were about

to take down houses fully occupied, it had been felt necessary to erect others for the labouring classes elsewhere. With regard to the papers, there were really so many subjects presented by them, that it was difficult to say anything in the short space of time at their disposal. What could be more frightful than the picture given to day about Greenock? They need not be surprised at the excessive mortality there: the wonder was that any person lived there at all. But for some extraordinary counteracting influence the evil agencies were sufficient in themselves to carry off the whole of the population. It was perfectly frightful. With respect to Glasgow, it might seem rude for a stranger coming freshly into a place to say anything disagreeable on the subject, but he could not resist making one observation. He had that morning been over some of the wynds and closes at the back of the Trogate and Saltmarket, and he felt bound to say, most impressively, that it was a disgrace to any civilized community—a positive disgrace, and the evidence of enormous ignorance and short-sightedness on the part of the citizens. He maintained that the inhabitants who permitted such a state of things to exist, simply because of the expenditure which the improvement would entail, were not merely damaging morality and sacrificing life, but injuring their own pockets, and perhaps bringing distress and sorrow into their own homes.

Mr. Mossman, Edinburgh, said, with regard to Mr. Smith's paper, that it occurred to him that it would be very beneficial, and tend greatly to further this movement, if the question of the 40s. freehold franchise was brought to hear upon it. It was a social question, and those gentlemen present from England would hear him out in saying that that measure had been a most beneficial one for the working classes. In Manchester, Birmingham, and Sheffield, the working classes had houses of their own, cottages with every convenience, situate in the most healthy localities, all brought about by this 40s. freehold system, which enabled a man, by small periodical payments, to buy up the property he possessed.

Mr. Salmon (of the Glasgow Architectural Society) thought that they must all sympathise and agree as to the necessity of erecting houses for the accommodation of the working classes, previous to taking down the old ones. He would just like to observe that houses had been erected of late years which were as bad as some of the houses built many years ago; and, until some measures were introduced to prevent the extension of the evil, he feared that there would be little abatement in the overcrowding of houses. He had just been making an examination of some of the houses erected during the last year, and he found that in one block, containing forty two separate houses, the square area allowed to each person was three square yards. In another block of houses built within the last seven or eight years, which accommodated thirty-eight families, all going up one stair, the square area allowed to each individual was two square yards. Now, in the very worst portions of the old town which had been referred to, the square area allowed to each person was  $1\frac{1}{2}$  square yard: that was the least allowed to each in the old town; and, generally speaking, it ranged from  $1\frac{1}{2}$  to 5 square yards; and yet here they were going on erecting houses with an allowance of two square yards to each inhabitant. With reference to the taking down of houses in the olden parts of Glasgow, he affirmed that the ground would be a great deal more valuable; and that, in a pecuniary point of view, the building of new houses on the sites of the old ones would prove a remunerative speculation to any capitalist who attempted it on a large scale.

After some further discussion, the Chairman said he might state that under the supervision of the police, in lodging-houses containing as many as 80,000 of a population, epidemic typhus had really been banished. Again, in a number of their cities they had reduced the death-rate one-third, chiefly by the abolition of the midden-steads. By introducing both of these improvements, the defects of the old buildings might be remedied in part, although

great evils still remained from over-crowding and other things. He thought too little was done in the way of visiting these places. He commenced his sanitary education twenty years ago in Edinburgh and Glasgow. He visited the wynds of Glasgow, and amongst other things found that they were utterly uninhabited at that time, although it was pretended they were. He was told by the people that he was the first clergyman seen there for some years. He recollected mentioning this fact to his friend the Bishop of London. "Well," said he, "it is very plain that if they took you for a clergyman, they had never seen one." In visiting the wynds of Edinburgh he gathered very much information with regard to the spread of intemperance among the lower classes.

Some papers were read on "Co-operative Societies" in another department to which we must refer hereafter.

On Wednesday, after Sir J. Kay Shuttleworth's address, a number of very interesting papers were read and discussed in the Health Department, but we must defer our notice.

It is to be hoped that what has been said will have the effect of directing the attention of the authorities to the necessity for immediate action.

#### SANITARY CONDITION OF ENGLAND IN EARLIER TIMES.

A SPIRIT which has been shown, in more than one quarter, to prevent, as we think without sufficient general inquiry, useful efforts which have been made to advance the social position of the people, may have some effect in retarding the progress of sanitary science, on which yearly depends the lives of thousands. The subject is a matter of life and death, and one on which the national strength and advancement greatly depend: it is therefore necessary to reiterate a few facts which will, we trust, be encouraging to those who are engaged in making more pure and healthy the atmosphere of large towns; and it should be borne in mind that, with marvellous rapidity, the country population is decreasing and that of the towns is largely on the increase. Towns not long since of small population are growing into large ones, and in the villages are being collected the cottage population, which was, less than a century ago, extensively distributed throughout England. This change of condition does now, and will, for a long time, require the greatest care and unremitting attention.

In glancing at the accounts of the various kinds of pestilence which have passed over this land, it is difficult, had as the present loss is, to form an idea of the old conditions. Not to refer to more ancient times, London was visited by pestilence in the year 679, and also in 764, 798; and in 801 fever carried off nearly the whole of the people of London. Some idea of its sanitary state may be formed by reading the condition of the London of that day. Slaughtering and burnings took place: the wholesome practice which had for long time been adopted by the Romans began to fall out of use among the Anglo-Saxons: the dead were left imperfectly buried close to the living; the wells became polluted; and, according to such accounts as have been left, the arrangement and condition of the streets, the enclosure of the town by walls, the necessity with those who had any wealth or possessions of adapting their houses to the purposes of warlike defence, and other causes, led to evil. Passing over some time without notice, we will remark that, in 1348, the first dread of the plague alarmed Cornwall. At this time it was reported that the disorder began at Carthage, in Asia, and then passed into Syria, Palestine, Africa, and Europe,—devastating Germany, Italy, Spain, France, and England. In the latter country so great was the destruction of human life throughout the whole land that grass grew in the streets of the once populous cities, the price of provisions and animals of labour decreased, in consequence of the want of buyers, to a remarkable extent; and, in some places, the living were not sufficient to bury the dead.

From all the accounts which can now be gathered, this visitation was general throughout the whole population. There were then few towns much better situated as regards sanitary arrangements than that which has become so great a metropolis. Worse drained and even worse supplied with pure water than in the days of the Roman occupation, the impurities of the soil increased, the houses were closely built together within the walls of cities, the odour of the slaugh-

ter-houses and other refuse was carelessly allowed to accumulate, the dead filling the grave-yards, and personal cleanliness was not so carefully attended to as it was even by the Saxon. Who can be surprised that Old England did not escape a visit from the plague? It is worth while to note how very similar the course which the plague is reported in the above year to have taken agrees with the route of the cholera in modern times. At this visitation of the plague 7,000 persons died at Yarmouth, in Norfolk; and, without referring to other places, it is stated by Stowe, that 50,000 were buried on the site of the present Charter House in London, which had been bought by Ralph Stratford, Mayor of London. If we put the population of the metropolis, at the date 1349, at 200,000, and there seems no clear proof for stating it at a greater amount, the number of persons buried here formed *one-fourth* of the entire population—carried away in a single year.

If we estimate the present population of London at three millions—it cannot be much less—a plague of the same malignity would have killed seven hundred and fifty thousand persons in London alone in less than one year, besides those who might fall from other diseases! Three quarters of a million of human souls perishing in this metropolis at the present day, in the time mentioned, would be a matter which would create wonder and terror throughout the civilized world.

In the Rev. Mr. Popwell's work, vols. 4 to 7, which may be found in the reading-room, British Museum, press 2,066, C—a work published about 1816—he urges, having had the advice of some of the most eminent authorities of that time, certain opinions as regards the health of the district of Cornwall, of which he is the historian.

He seems, as is natural with most historians of districts, anxious to place his subject in the best possible light. He writes of the salubrity of the air; of the place being bounded on each side by the sea, with elevated lands which cause the rapidly-running streams to carry away the offensive matter; also by that kind of land circulation of fluids, improving and purifying the air. Notwithstanding the plague raged in most of the towns of this county, the historian is anxious to clothe the neighbourhood which he is describing in the garb of health, but the notes which are frequently to be found, quoted from the books of various writers, show that no one should feel surprised, in spite of the wholesome, natural condition of the air, at the visits of epidemics. See the following quotation from an author of about two centuries ago—

"The great town of Bodmyn [Bodmin] is situated in a valley equally distant between two seas. It is of great length—nearly a mile—but of one main street and some ragged lanes; a small brook running through it, and through the churchyard, where dead bodies are interred, by reason whereof the water cannot be salubrious; and that no doubt maketh the town often subject to long and grievous infectious: unhealthful it is by nature, and more by the unclean keeping of houses. It hath been larger in receipts than it is now, as appears by the ruins of certain ancient buildings in decay."

This is an old note, but here are all the evil conditions which even in the most naturally healthy localities invite pestilence.

Again, Mr. Popwell, in 1816, states, on his own authority, that most of the dwellings in Cornwall, as in St. Keven's Church-town, have, to this day, pits at their doors: their beds are in general rotten and filthy, and they lie three and four together: in this state disease must spread, and too often has pervaded a whole family. At the same time benevolent neighbours are liberal of their wine, their brandy, and their beef; but attention is to the far more essential points has been neglected from ignorance. A few matters of clean straw, old sheets, and a bottle or two of vinegar, should be in readiness in every parish, and the parish authorities should be directed to have stagnant pools of filth immediately removed. The want of this sort of attention to the houses and bedding is not confined to the lower classes of the community: many of the farmers who can afford a better provision are shamefully mean in the furniture of their upper apartments, which, not to say the least of them, are filthy; and the paucity of inhabited houses seems to be the only means of exemption from many fevers and scourges.

Bad in a sanitary point of view as was this place in 1816, others must have been even worse in, say, 1487—a time when the graveyards were still being packed, and when no particular attention was paid to either the drainage, proper building, space, &c., of the dwellings. In this

year the "sweating sickness" broke out in England.

Although, in even more ignorant days than this, it was believed that the plague was regularly imported, by human means, in ships,—the sailors dying and then the pestilence raging—sometimes the dropping of a handkerchief has been believed to have spread the plague in towns,—nevertheless, it is not said that the "sweating sickness" was imported in this year, when,—

"Ere yet the fell Plantagenets had spent  
Their ancient rage at Bosworth's purple field,  
—A monster never known before,  
Rear'd from Locusts its portentous head.  
This rapid fury, not like other pests,  
Preserved a gradual course. He in a day  
Rush'd as a storm on the astonished Isle,  
And strew'd with sudden carcasses the ground."

To go, however, to Exeter. At the assizes, held at the Castle in 1585, when the prisoners were tried, "there suddenly arose such a noisome stench from the bar," that a great number of those present were instantly affected: of these died the judge himself, Sir John Chesterton, Sir Arthur Bessil, and Sir Bernard Drake, knight; one Robert Cary and Thomas Hison, esq., justices of the peace; three of the bench and eleven of the jury, who were empanelled to try the prisoners.

The cause of these deaths was attributed at the time to the imprudence of Sir Bennet Drake, of Ash, having taken a Portuguese ship, and sent his prisoners, who were ill of a contagious disease, to the high goal of Exeter. Undoubtedly in the condition the goals of this country were at that time, we cannot wonder at fevers being created, and spreading: overcrowded, filthy in the extreme, where were scenes of the most abominable vice and dissipation; who can wonder that "king fever," once having breathed into the place, would feed the particles of poisoned atmosphere on which miasma delights to loiter and prepare for the work, and that the grim and terrible monarch should have been triumphant. Can we wonder that disease spread, and the effects were made visible in the densely crowded and unwholesome courts of justice, close by the goals? Some of these are bad enough now, but neither the goals nor the courts are to be considered with those of the above old date. Notwithstanding, in years after the time above mentioned, the goal fever in the Old Bailey courts spread its pestilence in the close air suitable for its reception, and killed, in the same manner as at Exeter, judges, council, and jury.

We have no evidence that the goal fever was spread from goal to goal, although it is asserted that those afflicted with this disease who had, in consequence of these outbreaks, been discharged, and passed to their unwholesome homes, had there died, and that others had been attacked with a similar disease: the question for consideration is, were those cottages or dwellings referred to much better than the goals?

In rooms and places without sufficient space and ventilation, when crowded with the sick, it is impossible but that the health of others must suffer. Those who have watched even the best arrangements of the dwellings of this day cannot have failed to note, even in the case of little children, and those of older years who might be near death from consumption or other complaints, the peculiar effluvia which those accustomed to nursing recognize as the sure prognostic of death.

In the case of virulent fever, and in plague, when the body seems even before death to become partly putrid, when the air is filled with malarious influence,—without the best sanitary condition, without space and ventilation, without the most perfect attention to cleanliness, it is unlikely that the germs of disease will spread to those in such condition, and who may be naturally predisposed to it by bodily condition?

In these modern times the attacks of cholera have carried away numbers (fortunately small in proportion to the old plague). In this disease there seems to be no evidence of infection. We have seen hundreds of cases in the hospitals of the metropolis where the nurses were not affected. Here there were better space, ventilation, and other good arrangements. But a small proportion of the medical attendants who so bravely and with so much assiduity did duty both in the hospitals and in the miserable homes of many of the poor, were attacked; nor are those straggling cases to be wondered at when they were for hours, of both day and night, oppressed and fatigued, and kept in the very atmosphere which had been the means of producing this modern plague. Persons removed from ill-drained and unwholesome houses not only in the London district, but also in the provinces,

were not attacked, nor was the infection carried into well-drained houses and wholesome places by the surgeons or other persons.

At the last visit of cholera, a vast number of houses were suddenly attacked in the same night. Those who occupied these places were persons of different conditions,—some very poor, but others well off. We made most careful inquiry, and feel certain that the disease could not have been propagated by persons passing from place to place. Even the poisoned well, often referred to, could not apply to St. Ann's-court, for in this neighbourhood we had clear evidence that those affected had used for all purposes no other water than that supplied by the Company. Here, however, were open cesspools; others simply disguised with pans without traps; cesspools, in some cases three and more, in a small back garden, only covered over, but not emptied. Let those who have doubts upon the matter pay a visit to the cholera-stricken part of Deptford, with its total want of drainage, stagnant ditches and pools of water, creeks, &c., filled with poisonous mud, small rooms in which are families,—and where missionaries when they call are obliged to open the windows in consequence of the poisonous air. Here cholera, domestic fevers of various types, and small-pox, are far more fatal than in other places.

If we take a map of Newcastle-upon-Tyne, and shade the undrained part of the town, where, besides cesspools and other abominations, the pavements were rotten and unpaved, it will be found that there the cholera prevailed, and in some instances whole households perished: there fevers, &c., also raged. Those who visited the churches of Newcastle, and saw the large crowds of persons in respectable circumstances who were in mourning, and who knew the families attacked, must admit that it was not the poorness of living to which might be attributed the numerous deaths. No one will deny that poor and insufficient food predisposes to disease; nor can it be doubted that drunkenness and dissipation will have a similar effect; but it must be admitted, that the poor and dissolute are driven into the worst conditions, and that those more affluent, who have been exposed to live in undrained situations, have not escaped. In these attacks it is to be noted that the wealthy fly. In the case just mentioned, many families went to Newcastle, which, with North Shields, is connected with Newcastle by railway. Gentlemen passed daily from where the cholera was raging, but no cases are known to have been conveyed from one town to another. Tyne-mouth and North Shields had, at former times, been visited with this disease in a fearful manner. They have, however, been well drained; and as we have already said, the medical officers removed every fragment of filth that was possible before the downright alarm came.

The same was done at the barracks about a mile from Newcastle. Several hundred soldiers and their families communicated freely with the townspeople, but no case of actual cholera occurred. The malaria was evidently visible at both these places, for diarrhoea prevailed to a great extent: it did not, however, assume a malignant form, and yielded to mild treatment.

In looking at the accounts of the treatment of various kinds of illness in former times, the ignorance of many of those who practised medicine, who shut up fever and small-pox patients in close rooms, forbidding a breath of air to enter, who held for every disorder, all must see that the improvement of the general health is to be attributed, to a certain extent, to increased skill and intelligence of the medical practitioner, and to vaccination: this is not, however, sufficient to account for the great benefit derived from sanitary operations. It is not from this cause that the goal fever has disappeared, that other fevers have almost vanished from the model buildings and low lodging-houses, and that, in places where drainage has been made good, and ventilation has been carried out, virulent fevers cease even amongst the very poor.

#### EVIDENCE TOUCHING THE ARCHITECTURAL MUSEUM.

We continue our report of Mr. Scott's evidence:—

Chairman.—Do you think that the advancement of architectural art would be much endangered by the breaking up of your museum?—I think very seriously: it would be worse in some sense than if we had never formed it; because, where an object has never been attempted, people feel that, if they could possibly carry it out, a great public benefit would be effected, and they make efforts to start the thing; but where a thing has been tried and then stopped, you cannot get any one to help you again.

\* See page 602, ante.

those in that list are annual subscribers. Our annual subscriptions last year were 3161. We have spent altogether 4,000*l.*; besides having had extensive and valuable donations of casts and other specimens, we have now an enormous mass of most interesting specimens from India, which have been presented to us by Sir Bartle Frere, which are at present in the docks, because we have no room in which to keep them. They are the remains of a city, which, 500 years ago, was destroyed by an earthquake.

DESCRIPTION OF A NEW PRINCIPLE IN THE APPLICATION OF MALLEABLE IRON TO THE CONSTRUCTION OF BRIDGES.

HAVING, a short time since, had my attention directed to the construction of a bridge which should combine great strength and durability with economy of cost, the result of my consideration of the subject being to recommend a principle of construction, in the application of malleable iron to the purpose, which appears to me to be new, a description of such construction may not be without interest to some of the readers of your valuable serial; and I hand you the conclusions I have come to in the case referred to for insertion, should the same be deemed worthy a place in your columns.

After some consideration of the subject, I came to the conclusion that the use of malleable iron, and a principle of construction which I believe to be new in the application of that material—although the application of cast iron on a somewhat similar principle is not uncommon—would answer all the conditions required.

When I state that my design is a new application of malleable iron to the purpose referred to, I wish such assertion to be understood in the qualified sense of my not being aware of the same principle having hitherto been acted upon, and of my not having met with any suggestion of the application of malleable iron on the same principle to the construction of bridges. Mr. Dempsey, in his book on "Tubular, and other Iron Girder Bridges," p. 1 (Wentle's Rudimentary Treatise), alludes to a bridge, said to have been chiefly of wrought iron, as having been invented by Thomas Paine, the political writer, as early as 1787; but not having seen any description of its construction, I am unable to say whether it was, or was not, on the same principle as that which I am about to describe.

The principle of construction adverted to consists of a parabolic arch, in the spandrels of which are struts proceeding from the back of the arch to support a horizontal and longitudinal beam. The bottoms of the struts are connected with the head of the next succeeding one towards the crown by diagonal braces; and from the head of each strut from the springing of the arch is a vertical strut meeting a horizontal piece. These form one of the ribs or trusses of which an arch of a bridge is composed; and any number of which that may be necessary to support any required breadth of roadway are connected by transverse beams or joists notched into the horizontal and longitudinal beam of each rib; the notches being in both the longitudinal and transverse pieces.

The whole of the above-mentioned parts of the arch it is proposed should be of plate-iron.

Besides the transverse beams already spoken of, the ribs are further connected by tie-rods, of malleable iron, through the arched piece, below the junctions of the struts and braces. And, in order to maintain parallelism, these tie-rods should be shouldered at such distances as the ribs are intended to be apart, and secured by nut-screws or taper keys at their ends at the outer sides of two ribs in succession, which each tie-rod connects. It must be understood that, the several sets of tie-rods forming each transverse connection of the whole of the ribs of an arch, one tie-rod connects the first and second, another the second and third, and so on.

The direction of the struts is that of the diameter of curvature at the points in the arch from which the struts, at their mid-breadths, proceed. This direction, it may be remarked, is that of a perpendicular to a tangent to the curve at the point in the arch just mentioned; and the joints in the plates forming the arch should also be in the like direction, whilst those in the struts, braces, and crown-beam may be square or perpendicular to their directions.

The distances of the struts apart from each other should not exceed 9 feet; but any distance within that limit may be adopted that may accord with an equal division of the length of the arch.

The rise of the arch should never be less than one-tenth of its semi-span, which in general will be found to be sufficient; but, under particular

circumstances, a greater rise in proportion to the span may be required.

The proper direction of the joints has already been spoken of. The ends of the plates should butt to each other at their joints; and joints may be at any part of any member of a rib, provided a lower portion of a strut and of a brace be in one plate with a portion of the arch piece, and that an upper portion of a strut and of a brace be in the same plate as part of the crown beam. Over every joint there must be a covering plate, extending to a distance on each side of the joint at least equal to the breadth of the plates joined. These covering-plates are to be riveted on one side of the joint, and fastened with screw-bolts and nuts on the other; and wherever two or more plates, arranged parallel to each other, form any part or member of a rib, then between such plates pieces of plate, of a length equal to the breadth of the plates to be joined, and of a sufficient breadth to admit of two rows of rivets, are to be riveted immediately at the extremity of the covering-plates on the side of the joint fastened by bolts.

The transverse beams should be formed of two parallel plates, 6 inches in breadth, and half an inch thick, having wood 2 inches thick, and of the breadth of the beam between them, secured by bolts 18 inches apart, to which to spike deals to form the floor or roadway of the bridge. These transverse beams should be so notched into the crown beams of the ribs, that the backs of the crown beams and those of the transverse beams may be flush.

In bridges for ordinary traffic, the ribs should be 6 feet apart, centre to centre; but for carrying railways, the ribs should be so arranged, that the rails may be immediately above, and in the direction of the ribs. The transverse beams should be 6 feet apart, centre to centre, from each other; and when the bridge is only intended for light traffic, such as foot-passengers, a bridle-road, and roads in pleasure-grounds and farms, these members of the structure may be entirely of timber.

The abutments at the extremities of a bridge on the construction described will be properly of mason work, having the horizontal portion of the rib beyond the springing of the arch resting on cast-iron plates, or in spans of great length, on rollers mounted in strong frames; and the mason-work built up in the intervals between the ribs, leaving spaces for them to fit in loosely.

Should several arches be required to span a river or stream, the piers between the arches may consist of cast-iron columns and plates, on cast-iron screw piles, whenever the bed of the river or stream may be of a nature to admit of their application. If the bed of the river or stream be rock, or of such a nature as not to admit of the use of screw piles, recourse must then be had to stone foundations for the piers.

There should be as many piles in the transverse direction of the piers as there are ribs in the arch, and the piles should not be less than 4 feet in clear distance from each other in the longitudinal direction; so that, on each end of a rib may rest above a pile. When the piles have been arranged as just spoken of, their heads must be adjusted to a level, not only with each other in the same pier, but also to the level of the other pier. When the heads of all the piles have been adjusted to an exact level at a height of several feet above which the water in the river or stream may be expected, under any circumstances, to rise, there are shouldered cylinders, having one end fitting into the heads of the piles, and the other end passed through cast-iron plates 1½ inch thick, and about 3 feet 6 inches in breadth, to connect them transversely; and plates above the last-mentioned, of similar breadth and thickness, to connect them in the contrary direction; and the remaining length of the cylinder, after having passed through the two plates, to fit into the bores of the cast-iron columns forming the upper part of the piers. The two plates and the base flanges of the columns are then to be firmly bolted together, by means of not less than four screw bolts to each column.

Upon the heads of the columns there should be cast-iron plates similar to those already described as being between the heads of the piles and the feet of the columns; but the connection from the heads of columns through the plates will be unnecessary. The head flanges of the columns, the horizontal plates, and the base of the vertical plate about to be described, should all be firmly bolted together by screw-bolts and nuts. The vertical plates just adverted to should be of the same height as the end of the rib, which must rest on the transverse horizontal plate, and fit loosely into the groove on the vertical side of such upright plate. In order to protect the cast-iron

piles from injury, by floating ice and wreck, it will be necessary to have starlings in front of the piers, formed of timber piles, with sheet piling between them. The sides of the piers should also be protected by fenders formed of a timber pile driven between each two cast-iron piles, and strong transverse beams of timber notched into and bolted to such timber piles at 3 feet apart from the bed of the river or stream, upwards. The starlings and side fenders should be of the same height as the cast-iron piles: the starlings should form parabolic curves in their plan: the side fenders should be tangents to the vertices of the parabolas; and the whole should be covered with sheet iron, to prevent abrasion of the timber by floating bodies striking against such defences of the piers during floods.

The sides of the bridge may be fenced at the sides by plain palisades, or by an open parapet, ornamented to the taste of the designer. In either case there should be pilings over the piers, surmounted by lamp-posts. The material of the fences will properly be of cast iron, and their height should be 4 feet 6 inches above the level of the roadway.

The floor or roadway of the bridge may be formed of creosoted Baltic deals, 3 inches in thickness, spiked to the transverse beams, covered with a mixture of asphalt and chalk, and lastly with broken stone or gravel, with a small quantity of Portland cement or hot lime washed into such surface with water.

The principle being simple, a bridge may be constructed and erected at a comparatively small cost; and, being composed of pieces of a portable size, it may be constructed and fitted in this country, and then taken to pieces and transported to the colonies and foreign countries, where it may be erected with a trifling amount of labour, and may, therefore, become an important manufacture for export.

The following are suggestions for the dimensions of iron to be used in the construction of bridges for different purposes.

Foot Bridges.

Span of Arch.	Breadth of Plates.	Thickness of Plates.	Number of Plates.	Number of Covering-Plates at Joints.
Feet.	Inches.	Inches.		
Under 40	4	4	} two.. one.	
Above 40 .. 60	5	4		
— 60 .. 80	5½	4		
— 80 .. 100	6	4		
— 100 .. 150	6	4		
— 150 .. 200	6	4		

To bridges for light carriage traffic, such as on private roads in pleasure grounds and farm roads, the above scale may be applied; but having three plates, and two covering plates at the joints, instead of two and one respectively.

Bridges for Heavy Carriage Traffic, such as on Public Roads.

Span of Arch.	Breadth of Plates.	Thickness of Plates.	Number of Plates.	Number of Covering-Plates at Joints.
Feet.	Inches.	Inches.		
Under 20	6	6	} two.. one.	
Above 20 .. 30	6	6		
— 30 .. 50	6	6	} three two.	
— 50 .. 100	8	8		
— 100 .. 150	10	10		
— 150 .. 200	12	12		

To bridges for railway traffic the above table may be applied, but with the breadths of the plates and number of covering plates in the arch and crown-beam increased in the proportion of three to two.

The diameters of the rivets and bolts should be two-fifths of their lengths when such proportion exceeds three-eighths of an inch; and their distances apart, centre to centre, may be properly three times their diameter.

The diameter of the tie-rods may vary from one to two inches, according to the strength of the arches they are to connect.

The columns should have parallel sides: their length should not exceed twenty times their external diameter; and their thickness should not be less than 1 inch when the external diameter does not exceed 12 inches, and 1½ inch when above 12 inches.

SOCIETY OF ARTS EXAMINATIONS.

Prizes awarded to Candidates, 1860.

Arithmetic	1st Prize	£5	William Vaughan, aged 19, Sussex-hall Evening Classes. Clerk.
	2nd Prize	3	Michael Skilite, aged 17, Leeds Young Men's Christian Institute. Mechanic.
Bookkeeping	1st Prize	5	Francis Joseph Thomas Moore, aged 25, London Mechanics' Institution. Bookkeeper.
	2nd Prize	3	Robert Pearce, aged 20, Ipswich Mechanics' Institution. Accountant's Clerk.
Algebra	1st Prize	5	Thomas Hick, aged 19, Leeds Young Men's Christian Institute. Teacher.
	2nd Prize	3	Joseph William Mills, aged 17, Watt Institute, Portsea.
Geometry	1st Prize	5	Walter Robinson, aged 23, Leeds Young Men's Christian Institute. Mechanic.
	2nd Prize	3	Charles Herbert Ellerby, aged 18, Manchester Mechanics' Institute. Mechanical Draughtsman.
Mensuration	.....	..	No Prizes awarded.*
Trigonometry	.....	..	No Prizes awarded.*
Conic Sections	.....	5	Hugh Battle, aged 39, Leicester Church of England Institute. Missionary. No Second Prize awarded.†
Navigation and Nautical Astronomy	.....	..	No Prizes awarded.*
Principles of Mechanics	.....	..	No Prizes awarded.*
Practical Mechanics	.....	..	No Prizes awarded.*
Magnetism, Electricity, and Heat	1st Prize	5	Archibald Simon Lang Macdonald, aged 20, Glasgow Mechanics' Institution. Mercantile Clerk.
	2nd Prize	3	William Scott, aged 26, London Mechanics' Institution. Inland Revenue Officer.
Astronomy	.....	..	No Prizes awarded.*
Chemistry	1st Prize	5	William Scott, aged 26, London Mechanics' Institute. Inland Revenue Officer.
	2nd Prize	3	William Croudson Barnish, aged 20, Wigan Mechanics' Institution. Clerk.
Animal Physiology	.....	..	No Prizes awarded.*
Botany	1st Prize	5	Alexander McKinlay, aged 19, Glasgow Mechanics' Institution. Solicitor's Clerk.
	2nd Prize	3	John Gibbs, aged 37, Chelmsford Library and Mechanics' Institution. Wool-sorter.
Political and Social Economy	.....	..	No Prizes awarded.*
Geography	1st Prize	5	John Dix Suggett, aged 17, Lynn Athenæum. Banker's Clerk.
	2nd Prize	3	Charles Walker, aged 19, York Institute. Telegraph Clerk.
English History	1st Prize	5	Robert Clark, aged 22, Glasgow Athenæum. Clerk.
	2nd Prize	3	Charles Seed Roberts, aged 19, Bradford Mechanics' Institution. Cabinet-maker.
English Literature	1st Prize	5	Henry Simpson, aged 19, Birmingham and Midland Institute. Clerk.
	2nd Prize	3	Howard Shakespeare Pearson, aged 21, Birmingham and Midland Institute. Stationer.
Logic	1st Prize	5	Frederic Reeves, aged 19, Messrs. Chance's Library. Glass-cutter.
	2nd Prize	3	David Dalley, aged 23, Bilston Institution. Schoolmaster.
Latin and Roman History	1st Prize	5	John Naismith Russell, aged 24, Glasgow Institution. Assistant Teacher.
	2nd Prize	3	Charles Steer, aged 29, Croydon Literary Institute. Printer.
French	1st Prize	5	Abraham Shkelton, aged 30, Glasgow Mechanics' Institution. Book-keeper.
	2nd Prize	3	Andrew Farm, aged 39, Glasgow Mechanics' Institution. Pattern-drawer.
German	1st Prize	5	Walter Robert Clark, aged 20, Sussex-hall Evening Classes. Clerk.
	2nd Prize	3	No Second Prize awarded.†
Music	1st Prize	5	William Hugh Smith, aged 24, Glasgow Institution. Clerk.
	2nd Prize	3	John Walter Asquith, aged 31, Wakefield Mechanics' Institution. Teacher.

Prizes to Institutions.

One prize of £1. to the Sussex Hall Evening Classes, in respect of candidate William Vaughan, who obtained the first prize in arithmetic.  
 One prize of £1. to the Leeds Young Men's Christian Institute, in respect of candidate Thomas Hick, who obtained the first prize in algebra.  
 One prize of £1. to the Leeds Young Men's Christian Institute, in respect of candidate Walter Robinson, who obtained the first prize in geometry.  
 One prize of £1. to the Glasgow Mechanics' Institution, in respect of candidate Archibald Simon Lang Macdonald, who obtained the first prize in magnetism, electricity, and heat.  
 One prize of £1. to the London Mechanics' Institution, in respect of candidate William Scott, who obtained the first prize in chemistry.  
 One prize of £1. to the Glasgow Mechanics' Institution, in respect of candidate Alexander McKinlay, who obtained the first prize in botany.  
 One prize of £1. to the Glasgow Athenæum, in respect of candidate Robert Clark, who obtained the first prize in English history.

One prize of £1. to the Birmingham and Midland Institute in respect of candidate Henry Simpson, who obtained the first prize in English literature.  
 One prize of £1. to the Glasgow Institution, in respect of candidate John Naismith Russell, who obtained the first prize in Latin and Roman history.  
 One prize of £1. to the Glasgow Mechanics' Institution, in respect of candidate Abraham Shkelton, who obtained the first prize in French.  
 One prize of £1. to the Sussex Hall Evening Classes, in respect of candidate Walter Robert Clark, who obtained the first prize in German.  
 One prize of £1. to the Glasgow Institution, in respect of candidate William Hugh Smith, who obtained the first prize in music.

Prizes to Local Boards.

The prize of 10l. to the Local Board at the Glasgow Mechanics' Institution.  
 The prize of 5l. to the Local Board at Bradford.  
 The prize of 6l. to the Local Board at the Glasgow Institution.  
 The prize of 4l. to the Local Board at the London Mechanics' Institution.

\* No candidate obtained a first-class certificate in this subject.  
 † The candidate standing second in this subject did not obtain a first-class certificate.

APPOINTMENT OF ENGINEER TO THE LIVERPOOL DOCK BOARD.

MR. JOHN B. HARTLEY, son of the late Mr. Jesse Hartley, the former engineer to the Board, has been unanimously appointed to the same office, which indeed he has, *de facto*, filled for some time previous to and since the death of his father, whose assistant he was. The salary has been fixed at 3,600l. per annum, with efficient assistance. Mr. Hartley, it appears, has already suffered in health from the arduous nature of his duties.

ON ROUND CHURCHES.

THE following is the paper read by the Rev. T. James, at the meeting of the Northampton Architectural Society, reported in our last—

I fancy that there is no one who has arrived at the first stage of his architectural ecstasies who would not be able to answer how many round churches there are in England. The four round churches are almost as familiar to us as the seven wise men, or the nine wonders of the world, or any other conventional number of world-wide notoriety, which will always bear a little addition to their sum when critically tested, but

which, for a popular lecture, such as this is intended to be, will be found amply sufficient for working purposes.

A round church! People will at once go to see that who would pass by a hundred rectangular ones, partly, no doubt, because the form is rare, partly because it is connected with that little bit of archeology which the most modern student has picked up, of the relation of that plan to the Holy Sepulchre, and partly, I think, also, from the circular form in itself commending itself to our love of beauty and completeness, so that from the "round O" that children delight in above all the letters of the alphabet, to the globe which is our world, and to the mightier spheres which circle above us in the vaulted sky, all round things have a peculiar charm for us, symbolising, as they do, that eternity which the heart of man yearns to as his home.

It may be, I think, because the age of imagination has passed away, and that we are become, as most certainly we are, more prosaic, flat, commonplace, square-headed, and unideal, that the round form has evaporated from our architecture, and that we can now seldom catch its vanishing image, except in a Windmill or a Folly.

Men are said by civilization to become less an-

gular, and to have their individual points and peculiarities rounded off by rubbing against their neighbours; and if the architecture of the day is to symbolize the existing state of society (as is a favourite and not very false theory), we might expect to find all our buildings with all their angularities smoothed off, and all projecting points rubbed down to the fashion of most polished circles.

But I believe that it would be truer, both in fact and figure, to say that our polish and smoothness are all surface-work, little more than a glaze of varnish and a thin veneering, and that all the individual crochets and ugly corners still exist in the inner man as strongly marked as they do in the ground plans of our houses,—the angles, perhaps, a little *canted* off, but no well-rounded, complete character either in our men or in their buildings.

Indeed, it is remarkable that, whereas the old Roman described a perfect character as a smooth and perfect sphere—

"Totus teres, atque rotundus,"

round and tight as a cricket-ball—we moderns should take the most angular block in common use for our image of perfection, and call a good fellow "a regular brick."

That phrase would of itself imply that the day of round buildings has passed away, and yet with them, I think, the most beautiful of all forms, and the most perfect; if, also, the most ambitious.

For who can fancy the daring tower rising on the plain of Shinar other than a round building, tier above tier, reaching unto heaven? What are those round towers of Ireland, and those far more ancient towers and láts of India, the works of the early Buddhists, but emblems of the same spirit of aspiration, striving to express its craving after the Eternal and the Infinite by a form at once most lasting and limitless?

The earliest buildings of all nations are their tombs, and these, also, from the same feeling that erected them, are the best preserved. Love of father or mother, love of ancestry, love of child early snatched away, love of the departed, which is even stronger because they are departed, the wish to perpetuate the memory of fleeting spirit by enduring matter,—these motives have made our sepulchres the most enduring of our monuments, and those on which the earliest and highest art was bestowed. Leaving out the strange and isolated art of Egypt, the earliest existing tombs of old Greece and Etruria, and of the further North and East, are, for the most part, round; or, at least, domed and vaulted, and so partially in curved lines. I must omit references which I had made to them, and also to that much larger group of later Roman buildings, such as the Pantheon, the Temple of Tivoli, the Tombs of Cecilia Metella, of Augustus, Diocletian's Palace at Spalatro, the Church of San Vito (a tomb of one of the Tossia family), at Rome, and many other buildings in which the round form is distantly developed.

But to come to those circular buildings of which Time has spared both their forms and records, and which are immediately connected with the round Christian tombs, baptisteries, and churches, from which the Holy Sepulchre at Jerusalem and its kindred churches sprung.

I have drawn out a series of circular buildings all to one scale, the ground plans being chiefly taken from Mr. Fergusson's admirable "Hand-Book of Architecture," a book enough of itself to fascinate a reader into a student. This series will enable you to trace the growth of the round tomb, through a variety of phases, into the normal form of round church, such as our English architects adopted.

Passing from the classical period, and taking up the buildings of the Christian era of Constantine, we have the tomb of his mother, Helena, who died in 328; and that of his daughter, Constantia, now known as the Baptistery of St. Agnese. They are both nearly on the same plan. I have drawn that of the tomb of Constantia. You will observe an inner circle of double pillars supporting the central dome, a vaulted circular aisle and a further outer row of pillars, which is broken by the entrance or forum, which extended on both sides in front much further than I have shown it.

Of the fifth or sixth century is the much larger building (its diameter being 210 feet), now called the Church of S. Stefano Rotundo, at Bologna. The pillars are all taken from older buildings. This was probably a tomb or a baptistry.

In San Giovanni, at Perugia, we have almost the identical form, though of much smaller diameter (115 feet), and we here see the first additions to the simple round in the forms of the square porches. Up to this point there is nothing to in-

dicate any place set apart for the holy communion. The tomb of the saint, or the font, would occupy the central point, and though, from the tradition of the catacombs, the tomb might also form the altar, yet we find no divergence from the concluding circular wall for eucharistic purposes till we come to the budding chance of the Baptistery at Nocera dei Pagani (on the road between Rome and Naples), where a small intersecting circle forms a recess, at the entrance of which, or possibly on the chord of the smaller circle, the altar stood. The ground plan of this church, in which the type of our future round churches first comes distinctly out, is singularly like (and it may help you to remember it) that of one of those venerable watches which our fathers delighted to carry in their fobs.

The integral round being once broken, the expansion rapidly increased in various directions, the chance became yet more developed, and the octagon form, the intervening link between the square and the circle, which had already appeared in the central font, comes out into prominence, sometimes affecting the outer, sometimes the inner arrangement of the building, as is seen in the main ground-plan of St. Vitale at Ravenna, where I have omitted, for the sake of clearness, the accessory chapels, towers, and porches.

I have done the same in the plan of S. Lorenzo, at Milan, where I have retained only the central part of the original plan, which strongly marks the combination of the square with the circle, and the germ of those foliated geometrical forms which in after-times characterized the window tracery and wall panelling of the best epoch in Gothic architecture, but which were for many centuries confined to the ground plans of a series of the smaller class of churches and chapels, closely united, in motive and expression, to the earlier round churches. I give ground plans of the chapels of Planes, in France; Montmajour, near Arles, also in France; and of Ani, in Armenia.

It would be tiresome to give you a mere catalogue (and time would allow no more) of the many existing circular and octagonal baptisteries and churches still existing in Italy, and at rarer intervals in Northern Europe. Ferguson's Handbook, to which I have already referred, and the much larger French work, by Isahelle, on "Édifices Circulaires," though referring chiefly to classic instances, will supply ample examples to those who are inclined to exhaust the subject. The baptisteries of Florence, the Duomo Vecchio di Brescia, Pisa, and Parma, the campanile di Pisa, known as the "Leaning Tower," are familiar to us all, either by the engravings or still more faithful photographs which every traveller brings home with him. All combine, more or less, the rectangular with the circular form, and none of them very much exceed or fall short of the diameter of 100 feet, which may be taken as the average measure of this class of buildings.

It will illustrate better the history of our own churches to direct your attention to the ground-plan of S. Tomaso in Limine, near Bergamo, where the arrangement is almost identical with the original plan of the English examples. Travelling farther north, we arrive at the curious and important church of Aix la Chapelle, in which "more emperors have been crowned, and more important events happened within its walls, than have been witnessed within the walls of any existing church in Christendom." This was built by Charlemagne, and, though overpowered by the accretions of ages, still retains its main features complete. The nave is really a polygon of sixteen sides, but the shortness of each line brings it in effect to the character of a circle. Originally a circular niche, as in the baptistery of Nocera dei Pagani, formed the east end; the present chancel, terminating with a projecting polygonal or many-sided apse, which also has all the general effect of a round, was not erected till the fourteenth century. This church was, no doubt, a sepulchral one, and the parent of many similar buildings in Germany. The churches of Neimegum and Magdeburg seconded (in Germany) keeps to the true circle, both in choir and apse, and terminates westward with a large square tower. The baptistery at Bonn, which was of the eleventh century, has the rectangular part as a large western porch, instead of being inserted as a choir between the round nave and apse. I notice the hexagonal Chapel of Coborn on the Moselle on account of its rare form, and because, by the kindness of Professor Donaldson, I am able to exhibit very complete scaling drawings, which, in the elevation of vaulting, triforium, and clerestory, give you a good idea of the appearance which your own church of St. Sepulchre must have exhibited in its pristine integrity, though the plan of St. Tomaso, near Bergamo, furnished also by Professor Donaldson, shows this much more clearly. For many of the other ground-plans I have to thank Mr. Irvine, the intelligent clerk of the works at St. Sepulchre's, who carefully notes and preserves every relic of old times that is brought to light by the present alterations.

But it is time that I should say something of the Church of the Holy Sepulchre at Jerusalem, which, though by no means the first of round churches, as I have already shown, was yet the great progenitor of nearly all the round churches of the Middle Ages, and certainly of all our English ones. Mr. Poole's paper has already forestalled me in much which I might say, and into all the controversies on the authenticity of the site I am glad that I am spared from entering. It is enough, for an architectural view, that the pilgrims of the Holy Land, from the fourth century downwards, found a round church, or at least a circular enclosure, built over the reputed tomb of our Lord, and that the Crusaders of the Middle Ages, after that earlier church had been destroyed, still saw a church of the same form, though with many anomalous additions, raised over the same holy spot. It was in fond remembrance of that form, so strange to our insular precedents, that individual knights or religious societies built those memorial round churches, four only of which are left us to the present day.

The Holy Sepulchre itself, in its present state, is a small chapel, of about 26 feet long by 18 feet broad, in the centre of the rotunda, which is itself about 67 feet in diameter, and at the west end of the building. Beyond, to the east (not to complicate a very intricate plan with minor details) is the choir, presbytery, and apse. These are of much later plan than the original design; and of the walls and architectural details very little indeed remains of the older work. A fire, which occurred in 1808, destroyed the greater part of the old landmarks, and what has since been built is in the very worst taste (and one could not go lower) of Russian ecclesiastical architecture. The number of piers in the rotunda is eighteen (probably twelve existed in the original rotunda of Constantine), and the walls are divided in the usual manner, as your own church once was, into three stories, ground floor, triforium, and clerestory. Quaresimus, who wrote, I think, in the seventeenth century, describes the wall of the triforium panelled with sacred subjects in mosaic on a gilt ground, consisting of the prophets Ezekiel, Daniel, and Hosea—the Emperor Constantine, and on the north side the twelve apostles. I mention this as indicating the character of decoration which might be added if our rotunda were ever thoroughly restored. The roof was conical, formed of cedar beams, and the top of the cone was truncated by a circular aperture, open to the sky, which, as in the example of the Pantheon, appears to have been its only opening for the admission of light. Being placed upon a hill of most irregular surface, so great a difference of level existed between the outer soil and the floor of the rotunda, that the entrance door from the street on the western side opened into the triforium of the interior. The piers of the rotunda are in part circular (as ours are), in part square: the arches in this part were round; though traces of a pointed arcade, the work of the Crusaders, still remain in the choir and eastern apse, and a pointed arch doorway at one of the entrances. How this church grew up from the simple tomb hewn in the native rock to the present unsmooth conglomeration through ages of persecution and superstition, of good faith and of bad faith—how infidels desolated and defiled it—how emperors and patriarchs restored and sophisticated it—how Malomedians and Christians fought over it—and Christians, one with another—how legends and traditions obscured its genuine history—and rival churches and sects overlaid its primitive form—till the great fire in 1808 left little but fragments of the old walls remaining—would form a singular and instructive history, but one far too long to be even sketched in here. To us, its interest becomes greatest when, towards the close of the eleventh century, Europe was roused, by the preaching of Peter the Hermit, into that military and religious frenzy which resulted in the Crusades.

It was from this crusading spirit of mingled faith and glory, which took the cross-formed sword-hilt as the symbol of its creed, that the great military monastic orders sprang up which are so intimately connected with our round churches. The earliest was that of the "Brethren of the Holy Trinity," but far conspicuous above this and several smaller societies, were the two

great orders, often confounded, but strictly distinct and often antagonistic—1. "The Knights of St. John of Jerusalem;" and 2. "The Knights Templars." \*

#### THE GREAT PRIZE IN ARCHITECTURE, AT PARIS.

THE "Concours des Grands Prix d'Architecture" was on Saturday decided. The subject of the competition for this year is an imperial residence at Nice. It differs from a general style of grand-prix programmes, in being rather more practical. It happens that the member of the Academy who this year proposed the subject is M. Lefebvre, the private architect of his Majesty the Emperor; and there was some idea of his having to design this residence for him, and this may have influenced his choice. The difficulty this time was not to compose a design of enormous extensions, but to fill up a space of 80 metres square with all requirements of an imperial residence. An irregular piece of ground was given, surrounded on two sides by the sea, and in the south-eastern parts of the town. It was to be filled up with gardens, sea-baths, lodges, barracks, stables, staircases leading down the cliffs, and port for the imperial yachts. The drawings demanded were—1. A block plan, at a scale of 2 millimètres per mètre; 2. A plan of the palace, at 123 millimètres per mètre; 3. An elevation, at 2½ centimètres per mètre; 4. A section, to the same scale; and 5, 6, and 7. Two general elevations and section, to a scale of 23 millimètres per mètre.

The following is the award:—  
Premier Grand Prix.—M. Achille Toyan, of Nantes, atelier Quastel.  
Seconds Grands Prix.—1. M. Bédard, atelier Lebas; 2. M. Guadet, atelier André.

#### COMPETITIONS.

Stretford, near Manchester.—The designs for the new congregational chapel and schools by Messrs. Poulton & Woodman have been accepted.  
Preston Congregational Church and Schools.—Twenty-three designs were submitted: that by Messrs. Poulton & Woodman, of Reading, was unanimously adopted.

#### COCKBURN STREET, EDINBURGH.

THIS new street, projected by the "Edinburgh High-street and Railway Station Access Company," for the purpose mainly of providing a more direct route between the southern part of the town and the railway terminus than is at present afforded by the North Bridge and the Mound, is now in active progress.

The entire line of the street has been for some time cleared of the old houses which occupied it, and the roadway has been formed and opened for foot-passenger traffic. One block of new buildings at the north end of the street, facing Princess-street, and forming the right-hand portion of the view, is now almost completed externally; and the greater portion of the other blocks are commenced, and will be completed in the course of next summer.

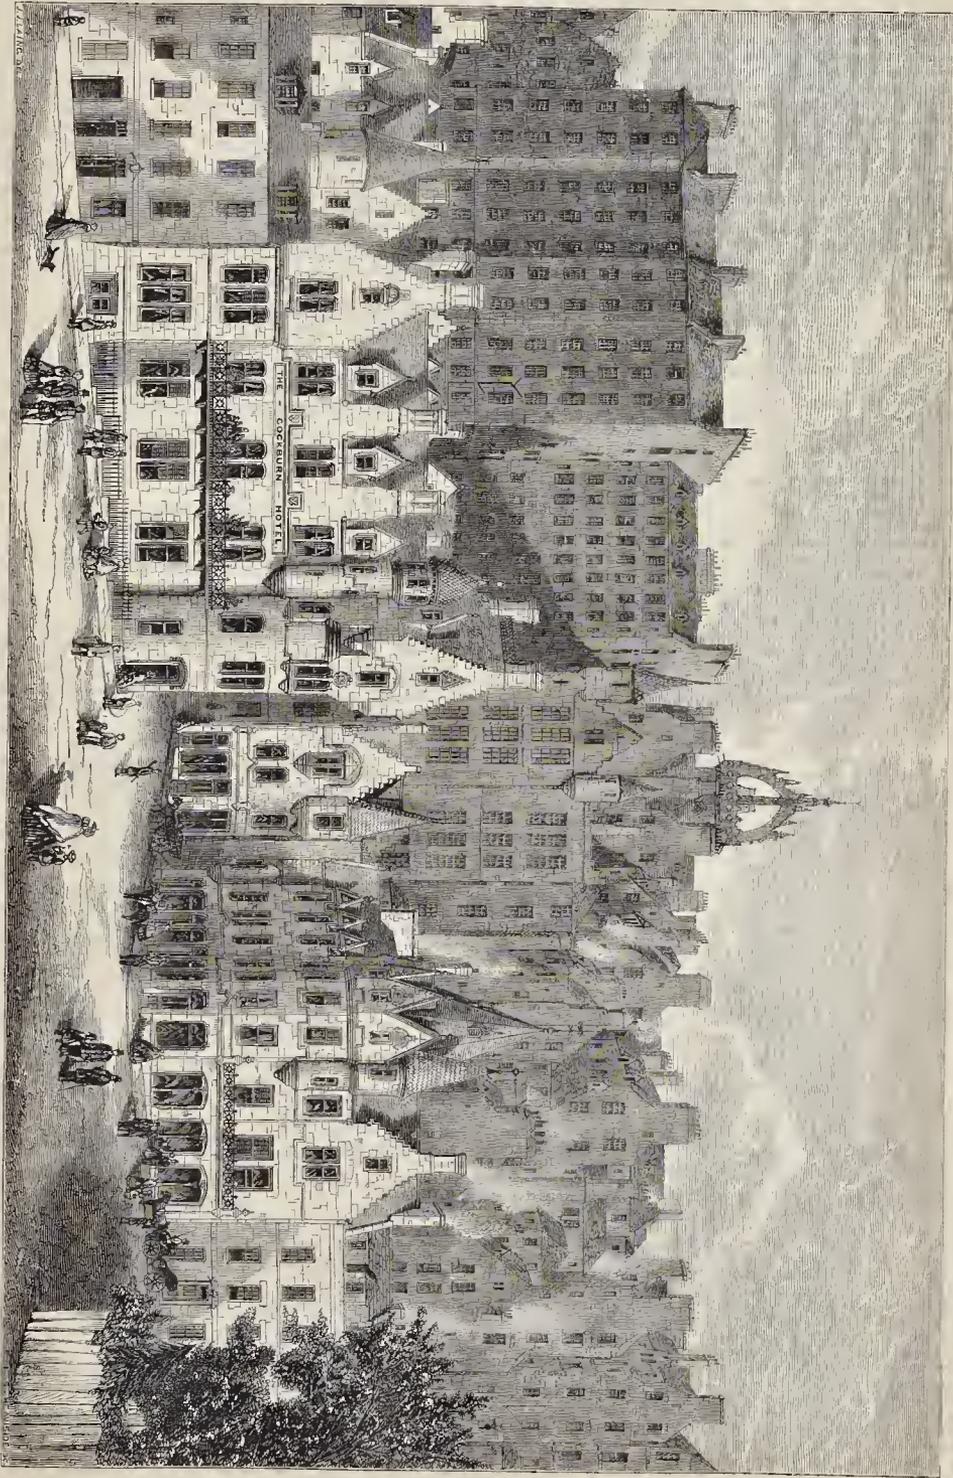

The street opens from the south end of the Waverley bridge, and, curving in the form of the letter S, winds up to the High-street, which it enters almost opposite Hunter-square. By taking this curved route, the gradient of the street is reduced to one in fourteen, being considerably less than any of the other streets from the railway terminus to the old town.

The buildings to be erected on each side of the street are in the style of those shown in the view,—the old Scottish domestic style, as it prevailed in the sixteenth and seventeenth centuries. The street-floor of the whole of the buildings (except that shown on the left-hand side of the view, which has been designed for an hotel), is devoted to shops, which will be provided with all the modern fittings, many having also large saloons behind, or on the floor above. The proprietors of the Scotsman newspaper have purchased from the company a site on the street for large new printing and publishing offices, which are now being erected.

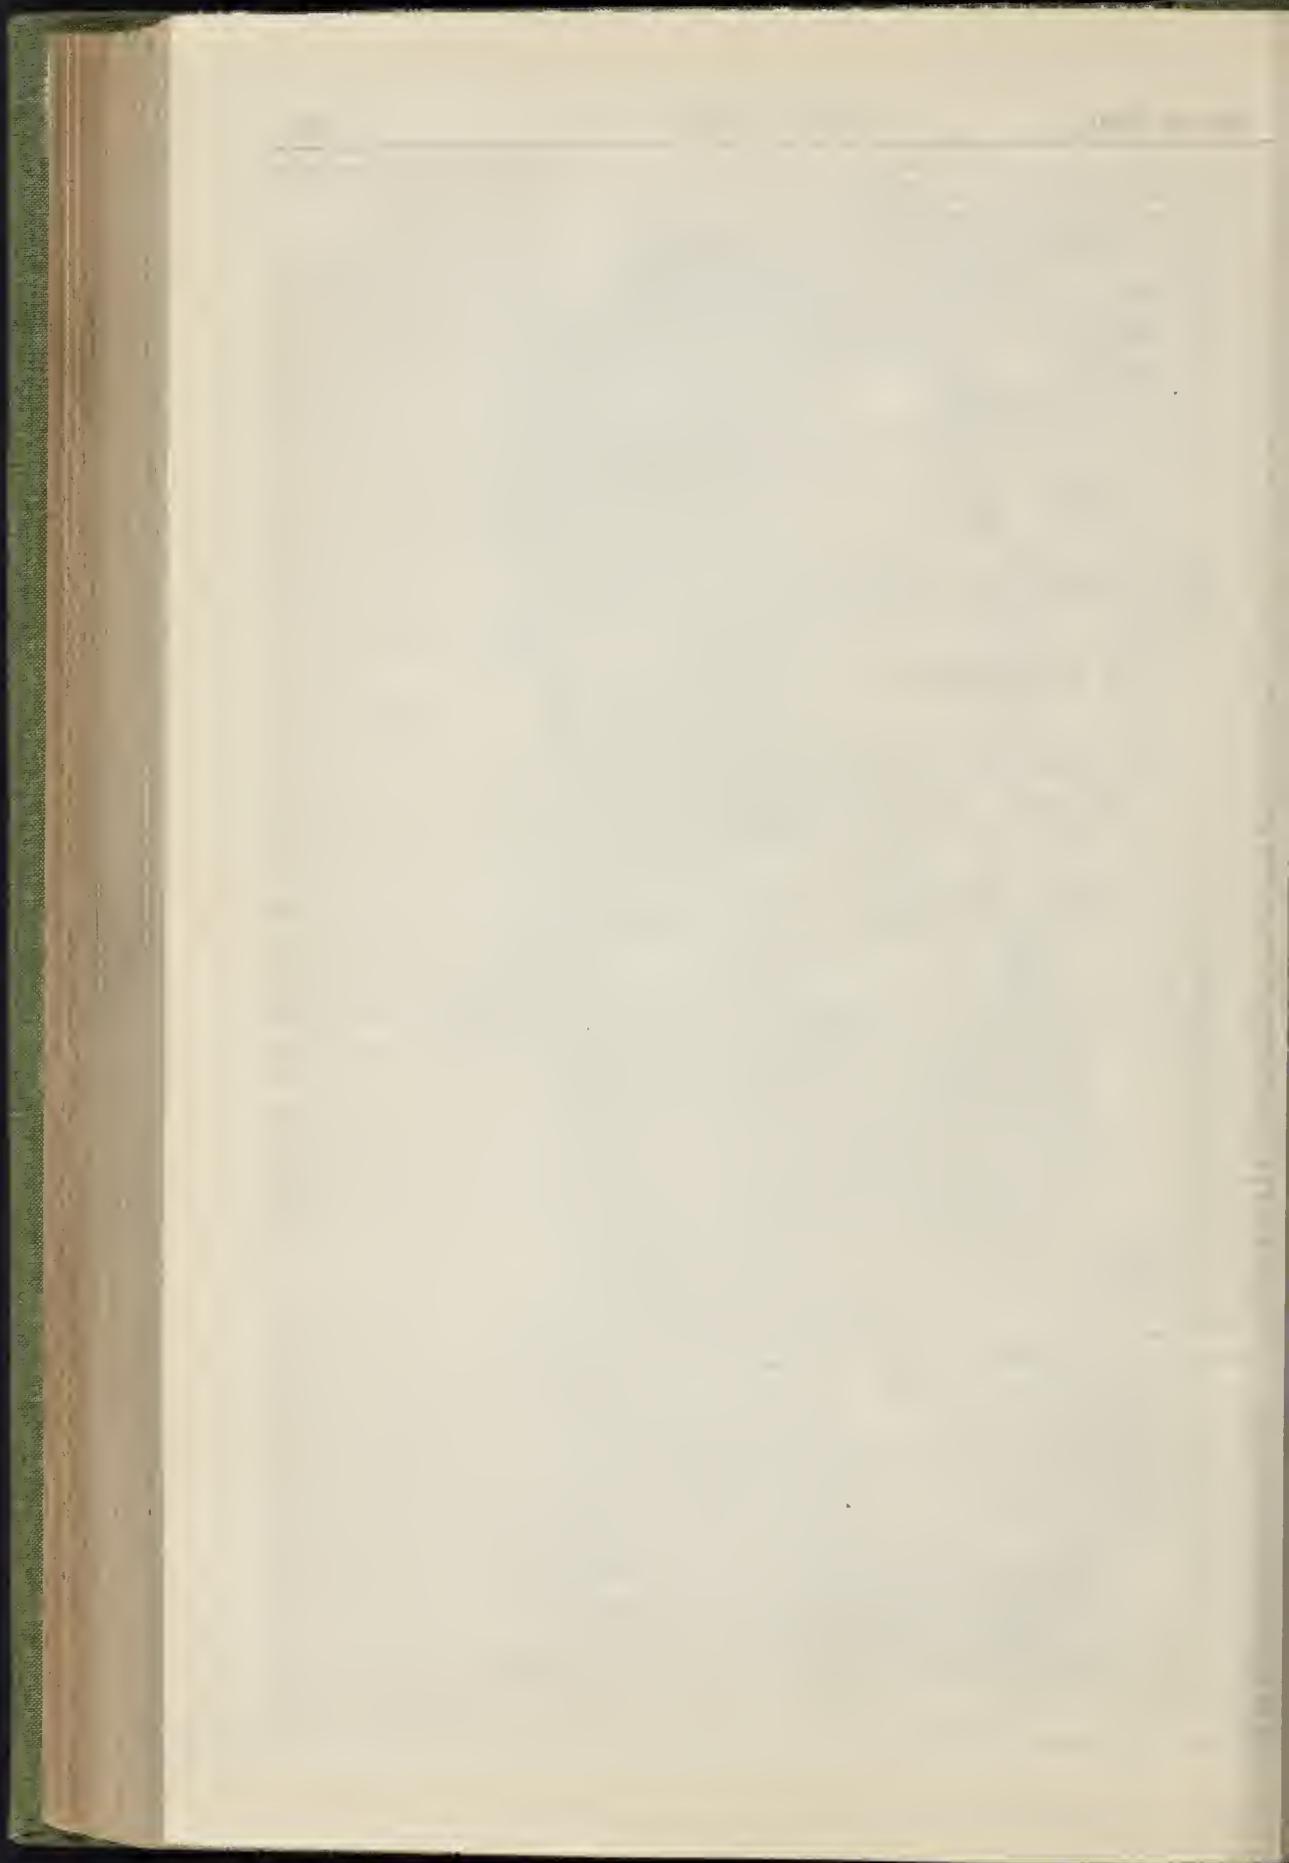

The whole of the buildings in the street are to be erected from the designs of Messrs. Peddie & Kinneir, the Company's architects.

In the background are seen the dark and ancient piles of the High-street, with the spire of the cathedral of St. Giles in the centre. The mass on the left is the Royal Exchange and City Chambers.

\* To be continued.

COOKBURN STREET, EDINBURGH.—MESSRS. PEDDIE & KINNAR, ARCHITECTS.

## THE CHARING-CROSS RAILWAY.

The company formed for the extension of the railway from London-bridge to Charing-cross had to sustain one of the many fierce parliamentary struggles which have occurred in the history of railways, the principal aid and most determined opponents being the governors of St. Thomas's Hospital, whose demands for compensation, as it was termed, although no portion of their buildings was to be touched, involved little short of a quarter of a million, and required the entire removal and rebuilding of the hospital at a considerable distance from its present site.

Passengers for the City will be set down at London-bridge, while those going westward will be carried on direct to Charing-cross. The extension will form a junction with the South-Western Railway, and thus complete the link of communication with all the southern lines; and by means of the South-Western and the bridge at Battersea, access may also be had to the whole of the North-Western and Great Western systems. The line is intended to be constructed on arches throughout its entire length, and they will be so built as to be readily adapted for dwellings, warehouses, or shops. Stations will be provided at each of the roads leading to the Southwark, Blackfriars, and Waterloo Bridges. The amount of local traffic upon these short distances which is expected has been calculated at not less than six millions.

The works, which have been commenced, have been, up to the present time, confined to the bridge across the Thames. A commencement has been made upon the Surrey side of the river by sinking cylinders for the construction of the foundations of the supporting columns. Progress has been made in the construction of the ironwork of the bridge. As at present designed, it will have a roadway for four lines of rails: the two existing piers of Hungerford-bridge will be retained, and six others will be required to carry the structure. The present suspension-bridge has been sold to parties who are about to re-erect it at Clifton; but the new railway bridge will still continue to give accommodation to foot-passengers, by means of projecting footpaths on each side of the railway road. The bridge will be 70 feet in width, and the footpaths on each side 7 feet wide. It will have eight spans of 154 feet each of water-way, and the height of the under side of the bridge, above Trinity high-water mark, will not be less than 25 feet. The width of the river at the point where the bridge crosses is 1,350 feet, and the depth of water at high-tide 30 feet. The bridge will be supported on cast-iron columns, sunk deep into the bed of the Thames. The contractor for the bridge and railway is Mr. George Wythes; but the ironwork of the bridge will be prepared by the Messrs. Cochrane, of Woodside, near Dudley, the same firm who are supplying the ironwork of the Westminster-bridge.

The cost of the line between the London-bridge and Waterloo stations, including land and compensation, and the cost of iron girder bridges over the streets to be crossed, are set down at 464,000*l.*, between Waterloo-road and the south bank of the Thames, 126,000*l.*; the bridge across the Thames, 160,000*l.*: this sum will be exceeded, as there will be four, instead of two, lines of rails, as originally intended; and for the Charing-cross station, including land, compensation, trade, and other matters, 320,000*l.*; making, together, an outlay of 1,070,000*l.*

## THE GOVERNMENT AND RELICS OF ANTIQUITY.

At the last monthly meeting of the York City Council the Town Clerk read a letter from the Secretary of State, notifying, as we have already stated, "that the Lords Commissioners of the Treasury have been pleased to authorize the payment, to finders of ancient coins, gold or silver ornaments, or other relics of antiquity, in England and Wales, of the actual value of the articles, on the same being delivered up for behoof of the Crown; and I am to request that you will instruct the police officers of your borough to give notice of the intentions of her Majesty's Government, and to inform all persons who shall hereafter make discoveries of any such articles that, on their delivering them to the sheriff, they will receive from the Treasury rewards equal in amount to the full intrinsic value of the articles. In all cases where it shall come to the knowledge of the police that such articles have been found, and that the persons having found them refuse or neglect to deliver them up, Sir George Lewis desires that measures may be taken for their recovery, and that information may be forwarded to him."

Mr. Wilkinson said he thought this was a very unjustifiable proceeding, and one that would tend to injure local collections. He moved that a copy of the letter be forwarded to the council of the Yorkshire Philosophical Society. Mr. Weatherley seconded the motion. Mr. Hargrave said that when this letter was read before the Watch Committee, it was thought that it would be very unwise to adopt the suggestion, and that it would be better for old coins, &c., found in this neighbourhood to be deposited in the Museum, rather than that they should be sent to London. The motion was carried.

## LILLE, FRANCE.

THE intended cathedral has made but small progress: a portion of the crypt, as we mentioned recently, has been completed, and an altar placed in one of the recesses, where Divine service is performed. The piers to support the superstructure are of brick, with stone quoins. Above a few of the clustered columns have been carried to the height of 10 feet.

The large church of St. Maurice is undergoing a complete repair, executed with care of the original decorative portion.

The Museum is being improved: a new gallery is being constructed for the modern pictures. The Wear Museum of ancient drawings is well arranged, and consists of 1,435 numbers, all framed. The drawings from the sketch-book of Michelangelo are the great feature of the collection. They are in number 198, and being on both sides of the leaves, are framed between sheets of glass. There is an autograph letter of Francis I., addressed to Michelangelo, expressing his desire to possess some of his sculptures. As his Royal Highness the Prince Consort has sent Mr. Bingham to photograph these drawings, of such high interest to architects, it may be hoped it will be for the object of their being circulated among the profession. The Museum also possesses sixty-seven drawings by the divine Raffaele, some of the highest beauty.

The Chevalier Wear, who formed the collection, and bequeathed it to his native city, was the agent appointed by the French Directory to collect the *chefs d'œuvre* of art for the Museum of the Louvre.

## BELGIUM.

Brussels.—The tower of the Hôtel de Ville has been restored to the base, and all the vacant niches filled with statues. A scaffolding now encloses a portion of the eastern wing for a similar purpose. In consequence of the abolition of the *petites*, all the gates have been taken away, and the ditch with the dwarf wall removed entirely where the ground is level to permit its being done. Excepting private houses there is nothing being done of any architectural character, and these are mostly here of anything decorative.

The triennial exhibition of the fine arts is now being held in the Palace, erected for the Prince of Orange before the revolution of 1830. The central saloon on the upper floor is the place of honour, and here is Sir E. Landseer's picture "Inundation," which was in the Exhibition of the Royal Academy. The other English pictures are "Past and Present," A. Egg, R.A.; "Titan making his first Attempts in Colour," W. Dyce, R.A.; "Marie Antoinette bearing the Sentence of Death read to her by Fouquier Tinville," E. M. Ward, R.A. These and some few pictures bearing obscener names, constitute the whole contribution of our school, and have not received very flattering encomiums from the Belgian press.

The total number of pictures, sculptures, drawings, and engravings exhibited are 1,114. All architectural drawings of actual buildings were ineligible, and although a gold medal is to be awarded to architecture, there appears but one candidate for the honour.—M. Joseph Schadde, of Antwerp, being the solitary exhibitor of six designs for Village Churches,—four of Byzantine and two of Gothic, all remarkable for plainness even to poverty, probably to meet the limited funds allowed for their erection.

The pictures of the Belgian school are of pleasing character, without much idealism, when of moderate dimensions; while the larger canvasses, on which some artists portray sacred or historical subjects, are of very mediocre quality. The best of the Belgian school fail to exhibit, and there are no pictures by Wappers, Galabé, De Keyser, Leys, and others. The German school is well represented, and the French school also tolerably.

Courtrai.—The town-hall, which contains the

two chimneypieces so familiar to us by L. Haghe's lithographs, has been completely repaired, and the original design throughout restored.

## NEWS FROM AMERICA.

THE State Lunatic Asylum recently erected in New Jersey, on a commanding site near the banks of the Delaware, is an important structure, with a façade of 750 feet in length. A hexastyle Tuscan portico, surmounted by a dome, occupies a central position, and the wings are finished with *campanile* open on all sides. The internal arrangements are very comprehensive, the main building being chiefly occupied by reception-rooms, chapel, apartments for the officers, with culinary offices in the basement; the right wing arranged for male patients, and the left for females. Accommodation is also provided for the quieter and more convalescent patients, distinctly separate from the refractory; and each ward has its own dining and bath-rooms, &c., those for the better classes having a spacious entrance, half-carpeted, and a parlour handsomely furnished. A lift apparatus conveys the provisions from the basement to the several departments; and the building throughout is heated by steam and lighted with gas. Each apartment has its air-fues communicating with upright foul-air shafts. Heated air is forced into air-chambers by means of a large fan, situated at the end of a tunnel some 350 feet in length. The washing is done by steam, and so is much of the ironing and the cooking.

A new hall is proposed to be built at Tammany. The hotel built by the Tammany Society, and the first opened on the European plan, has received two additions since first erected, and occupies an area of 83 feet by 57.

The total increase in the valuation of Boston this year is 12,910,900 dollars beyond the preceding year; and the rate of taxation on each thousand, 9-30 dollars. Last year it was 9-70 dollars.

The monument at Burlington commemorative of Ethan Alan has been erected. It consists of a round shaft of Vermont granite, 60 feet high, resting on a square pedestal, and with a suitable inscription.

The recently-furnished returns of the Treasury Department, New York, show that the value of hardware imported from England to this country during the year ending June 30th amounted to 1,048,896 dollars, of which 2,274,032 were for railroad iron; 2,150,625 for various iron manufactures; 1,185,441 for bar iron, and 1,049,200 for pig iron. Scotch pig iron is in fair request, and English bar inactive.

As a sign of returning prosperity, it is remarked, that most of the locomotive building establishments which survived the storm of 1857 are now in full and profitable operation.

The improvements now in progress at Canal-street, New Orleans, will, it is said, cause it to be the most magnificent street in the world, the length being eight miles, extending from Mississippi river to Lake Poulhartrain, and nearly 200 feet wide, with a parterre promenade in the centre, of 40 feet in width. At all the crossings are to be monuments or fountains. Clay's monument has been erected, and that to Fulton is being proceeded with.

## GOVERNMENT OFFICES, OTTAWA, CANADA WEST.

THE building for Government offices, at Ottawa, of which the corner stone was laid by H.R.H. the Prince of Wales, on September 1st, is similar in character to the buildings in the same city of which we gave an engraving on a former occasion, presenting towers, metal crests, parti-coloured arches, and high roofs. There are two blocks of equal size, though differing in design. They contain all the offices of the various departments of the Government service, together with rooms for the governor-general and his staff and the executive council. There are upwards of 300 rooms with corridors, safes, record-rooms, &c., and the buildings are grouped together, forming three sides of a quadrangle, 800 feet square; the area to be laid out with walks, shrubberies, and fountains. The architects are Messrs. Stent & Laver, to whom was awarded the first prize in October last.

THE GREAT EASTERN AND MR. SCOTT RUSSELL.—It is stated that the directors of the Great Ship Company intend to appeal against the award of 17,000*l.* or 18,000*l.* made by the arbitrators in favour of Mr. J. Scott Russell, who is said to have previously received some 14,000*l.* in excess of the contract price.

## ELECTRIC TELEGRAPH IN INDIA.

The telegraph which crosses the Kistna river, at Bezwarrah, in the Madras Presidency, is a galvanized iron-wire rope, 1½ inch circumference, and weighing, per foot lineal, 6½ ounces. It consists of three ropes twisted together: each rope has seven strands or wires, 1-16th of an inch in diameter. It is carried from rock to rock, and fastened to large posts of teak wood, built into the rock at about 400 feet above the surface of the water. The distance between the two points of support is six thousand feet, without any intermediate connection or support. It forms a beautiful curve, and at its lowest point is about 60 feet above the river. It has now been up more than twelve months, and the communication is very perfect.

The ordinary telegraph wire is 3-16ths of an inch in diameter, and weighs per foot run, 3½ oz. It is all galvanized.

EDWIN E. MERRILL, C.E.

## IRELAND.

The War Department require tenders for the erection of latrines at Birr barracks, in the Curragh district.

The Port of Dublin Corporation are seeking contractors for the erection of a beacon on the Alderman Rocks, Crookhaven, co. Cork, and a lighthouse tower on the Calf Rock, westward of Dursey Sound, co. Cork: time extended to 31st October.

A branch bank and manager's residence are to be erected at Ennis, for the Provincial Banking Company, according to plans by Mr. W. Murray, architect.

A new hotel is to be built at Bray, co. Wicklow, by the Dublin and Wicklow Railway Company. Mr. Wilkinson is, we believe, the architect. We desire to note the rapid improvement of this new favourite suburban locality. Building ground, not long since disregarded for its undesirability, brings large prices: a new town is rapidly springing up; important projects under Mr. Dargan's auspices are being matured: the Turkish baths recently erected are in working order: a new harbour is in contemplation; and dwelling-houses of various classes and designs are numerically increasing, in a proportion not exceeded in the metropolis.

St. Andrew's Church, Dublin, has been recently partly restored,—the mural monuments that had been covered with plaster are brought to view; the old Norman font (A.D. 1184) is placed within the church; the recumbent effigies of the Earl of Forster and his wife, and of a bishop of Kildare, previously exposed to the weather, are now under cover; the chancel window is filled in with stained glass; the tettering and unsightly vestry removed. It is further proposed (when funds permit) to re-roof the portions of the old buildings still uncovered, to save from utter ruin the clustered shaft pillars in the graveyard, and to effect various other desirable objects. In an appeal for pecuniary assistance, the committee remind the public that "this ancient church dates from Anglo-Norman times, and, if restored, would exhibit one of the choicest specimens of the architecture of the period, as attested by the monumental brasses, mouldering statues, and time-worn inscriptions, &c., &c., therein."

The report of the County Surveyors of Ireland states that, "though another year has elapsed, and the objects of the body still remain unattained, a powerful expression of opinion has been evoked, and a bill brought into Parliament, with a view of improving the position of the office." Further, that "the Committee entertain sanguine hopes that the subject will come before Parliament early in the next session, and an Act be obtained by the Government in redress of claims."

The new church of the Assumption at Wexford has been consecrated. It is almost identical with that of "the Immaculate Conception," at the north end of the town. The style is Decorated Gothic, and the plan comprises nave, chancel, and side aisles, with tower at western end, surmounted by a spire, attaining an altitude of 220 feet. Dimensions of church—150 feet in length, by 80 in width, including the aisles, which are separated from nave by an arcade of pointed arches, springing from cut stone piers with moulded capitals. The roof is of open timber-work, chamfered, stained, and varnished. Great millioned windows in the flanks, and great windows at the east and west end, light the church; several being filled in with stained glass, representing various subjects. The altar in the chapel of the Blessed Virgin is the gift of Mr. J. T. Devereux. A richly-carved

oak organ-gallery is placed at the western extremity of the church. The material for walling is red conglomerate, with granite dressings. We believe this church was originally designed by Mr. Pugin, but has been carried out under the superintendence of Mr. J. J. McCarthy, architect.

A new line of railway from Bird-hill to Nenagh, in connection with the Limerick and Castleconnell line, is projected, and will be about 12 English miles in length, at a probable expense of 5,000*l.* per mile.

## CHURCH-BUILDING NEWS.

*Milton-next-Sittingbourne.*—The new Congregational chapel recently erected here has been opened. The estimated cost of the chapel, which was built by Mr. Naylor, of Rochester, will be nearly 1,200*l.*, besides the materials of the old chapel.

*Hastings and St. Leonards.*—The foundation stone of the church of St. Matthew has been laid. The building is situated in the parish of St. Leonard, and about midway between Dobernia and Tivoli. The design is by Mr. Voysey, architect, St. Leonards. The contract is taken by Mr. George Edwards, of Luton, Bedfordshire. The building is to be of brick, with stucco facings, and will be 55 feet long by 27 feet wide, and accommodate 300 persons. The ground was given by the Rev. J. T. Cumberlege, and the building will be erected at his own private expense.

*Ilton.*—The church of Ilton, near Ilminster, has been re-opened. The interior has been restored, except the transept, which belongs to Mr. Hill, of Ilminster, who has promised to divest it, during the next spring, of the coats of whitewash which now "adorn" it. The window in this part is filled with stained glass. The nave and north aisle have been re-peved with seats of deal, stained. There has also been a new ceiling to the nave, divided into panels by moulded ribs, and the oak moulded ribs of the aisle roof, which were concealed with plaster, have been exposed to view, repaired, and cleaned. The Ham stone piers and arches have also been repaired and cleaned, and the walls re-stuccoed. The old oak pulpit has been cleansed from its numerous coats of paint, altered somewhat in shape and height, and fixed on a Ham stone base. The approach to it is through a small octagonal vestry, which has been thrown out on the south side, in the corner formed by the chancel and transept. The chancel has been rebuilt, and is separated from the nave by a low screen of Bath stone, with a pair of gates, made of iron and brass. The chancel, also, has a new ceiling of the same character as that of the nave, and with carved flowers at the intersections. The east wall, as high as the level of the sill of the window, is covered with Minton's tiles. The part over the communion-table is covered with glazed and enamelled tiling of various colours, and with the Canterbury tile on each side. In the centre is painted a vesica with a cross bearing the sacred monogram in colours and gold, and immediately above this is painted, in Medieval letters, the text, "Whoso eateth my flesh and drinketh my blood hath eternal life, and I will raise him up at the last day." The chancel is filled with two rows of oak seats, placed stall-wise on each side, the front ones having moveable book-stands. The whole are finished with carved poppy-heads, some carved foliage, and trefoil panelling immediately under the book-board, and cut and moulded bench ends. The floor is laid with Maw's encaustic tiles, that portion inside the communion rails being of geometric mosaic work, from which it is separated by two arches of Ham stone, filled in with a light open oak screen, having some wrought-iron work in each compartment, and finished by a light iron cresting, the whole being relieved by having the leaves, &c., gilt. This was made by Messrs. Wightman & Denning, of Clard. The two-light window on the north side has been filled with stained glass by O'Connor, of London. The subjects are Samuel and Eli, and Jesus Christ as the Good Shepherd. This window has been put in by the vicar. It is intended at a future time to fill the east and south windows with stained glass. The whole of the work has been carried out from the designs and under the superintendence of Mr. J. M. Allen, of Crewkerne, architect. Mr. Munden, of Ilminster, was the builder. The Ham-hill stonework was from the quarries of Mr. Joseph Staple, of Stoke, who presented the Bath-stone screen. The Caen stone monument, erected to the memory of the vicar's sister-in-law, was executed by Mr. H. Davis, of Taunton. The sum expended amounts to upwards of 750*l.*

*Yeovil.*—The new cemetery at Yeovil has been consecrated. The site is on the Preston road, immediately facing Ram Park, and about a mile from the borough. The grounds are entered by a pair of gates of oak and iron. There is an entrance-lodge on the left side, built in a style appropriate to the architecture of the chapels, which are approached from the lodge by a gravelled walk about 12 feet wide. These are built in the Italian Gothic style, of Yeovil stone, with Hamhill stone dressings, and each chapel will accommodate about fifty persons. There are two entrances to each chapel, one by an open porch which was intended to be the approach from a central tower, included in the design of the architect. This tower has not been built, from want of funds, but the foundations are laid. There is a stone central turret on each chapel. These turrets are about 30 feet high, and are carried up on four ribs springing from four columns, which rise from the interior of the chapels. The chapels are paved with tiles, inlaid with a mixture of Hamhill stone and stone from the Pisbury quarries, near Langport. The windows are filled with ornamental glass. A little more than eight acres and a quarter of ground were purchased for the cemetery for 1,050*l.* About four acres only, however, have at present been set apart—in equal portions between the Church and the Dissenters—for the purposes of burial. The cost of the chapels was about 3,000*l.* The sums thus expended were borrowed by the town council of the West of England Insurance Company, on the security of the rates for the next twenty years. The architect was Mr. R. H. Shout, of London. The building was entrusted to Mr. Wellspring, of Dorchester, and he has completed his contract. The clerk of the works was Mr. Sansom.

*Ottery (South Devon).*—Talatou Church, near Ottery, was reopened on the 5th. The edifice, having become ruinous, has been rebuilt, with the exception of the tower, which is a curious example of the Perpendicular style, there being seven or eight niches with saints and evangelists on the upper stage and stair turret. The old woodwork, as far as practicable, has been reconstructed in seating and roofs, and a small new aisle added, to compensate for the west galleries removed. Not the least interesting feature of the restoration is the re-erection of a third-pointed roof-screen, repaired with much labour by Mr. Ship, carver, Bristol, at the expense of the present rector, the Rev. C. A. Hoggan. There are five painted windows, by Mr. Hughes, memorialists to the late rector and Mr. J. P. Mathew. There is a rich oak pulpit, also by Ship. The chureh is covered with lead. The outlay is about 1,500*l.* Mr. Ashworth, of Exeter, is the architect, and the contractor Mr. Digby, of Ottery St. Mary.

*Llandaff.*—The *Bristol Times* states that Mr. D. G. Rosetti is executing for Llandaff Cathedral an altar-piece, a triptych. In the centre compartment is the Virgin, with her new-born infant in the manger. A kneeling angel presents a kneeling king and a kneeling shepherd, a ring of angels looking on the manger from the outside. On the left side is the youthful David preparing to fight Goliath; on the right, David in manhood, and a king, in the costume of a Medieval knight, playing his harp. The whole triptych measures about five feet high by nine feet long. The restoration of the edifice is progressing, and the dean and chapter have resolved to purchase a powerful organ, and have agreed with Messrs. Gray & Davison, of London, for one at a cost of 900*l.* Sir Frederick Gore Onley, regius professor of music, at Oxford, has been consulted as to its construction. The organ-fund, however, is considerably short of the required amount.

*Northallerton.*—West Rownton Church, near Northallerton, which possesses a fine Norman chancel arch and Norman doorway, has been restored under the superintendence of Mr. Pritchett, architect, and was re-opened by the Dean of York.

## STAINED GLASS.

*Romsey.*—Another stained glass window has been put up in the Abbey Church. It is the east window of the south-east side chapel. The subject, the Epiphany, was chosen for it, because the birthday of the person in whose memory it is put up fell on that festival, January 6. It was executed by Mr. O'Connor, the artist who made the three other windows already in the Abbey. At the bottom of the window, in the glass, is this inscription:—"To the glory of God, and the beloved memory of Elizabeth Painter, who was for 55 years a friend and servant in the family of the Hon. and Rev. Gerard Noel. She died December

15, 1859." The window is given by Mrs. Noel and Miss Caroline Noel, with other members and friends of the family.

**Harpurhey.**—Messrs. Edmondson and Son, of Manchester, have inserted a stained glass window in Christ Church, Harpurhey. The window is canopied, and consists of geometrical tracery. It appears to be placed to the memory of Jane Cheeseright. The window has been presented to the church by a near relative of the rector, in memory of his deceased wife.

**Shipley.**—The painted window in the chancel of Shipley church has just been completed by filling up the seven vacant lower compartments. There are now placed under fretted Gothic canopies full-length figures of our Saviour, St. John, St. Peter, St. James, St. Thomas, St. Andrew, St. James the Less, and (those now added) St. Matthias, St. Simon, St. Philip, St. Paul, St. Bartholomew, St. Jude, and St. Barnabas, the whole surrounded with the figures of the four Evangelists.

Besides, nine smaller spaces are filled with scenes from our Lord's history, namely, the Annunciation, Nativity, Presentation in the Temple, Disputing with the Doctors, the Crucifixion, Entombment, Resurrection, and Ascension. There are in the smaller lights in the upper portion of the window various devices represented. The work was done by Mr. Francis Barnett, of Leith. The total cost of the window exceeds 300*l.*, 100*s.* of which has been expended in the last executed portion of it. This 100*l.*, as well as the expense (300*l.*) of purchasing and laying out a new cemetery, was raised by means of aazaar lately held in Shipley.

**Worcester.**—It may be remembered, by some who took an interest in the subject (says the *Worcester Chronicle*), that, on occasion of the commission for filling a portion of the great east window of the Cathedral with stained glass being entrusted to Mr. Hardman of Birmingham, a Roman Catholic, without affording any chance of competition to Protestant talent, local or general, a correspondent of this paper stigmatised the procedure as something "like a job." When tenders were invited for the memorial window to the late Queen Adelaide by a committee, headed by the lord-lieutenant of the county, Roman Catholics were, as we thought very illiberally, excluded from the competition. To compensate we suppose for this piece of paltry narrow-mindedness, the committee, deputed to manage or assuming the management of the citizens' memorial window, jumped to the opposite extreme and assigned its erection off-hand to a Roman Catholic, without inviting competition to see whether Mr. Hardman might not be surpassed in excellence and cheapness. The window is now filled in, as far as the means of doing so at present extend. It is (continues the *Chronicle*), in every sense of the word, a great disappointment. The window is Early English, with five lights, and is divided across the middle into two distinct portions by the masonry. The coloured glass fills the five lights in the upper division, and the centre light in the lower, leaving four of the lower lights yet to be filled. In providing a design for this east window the artist ought to have taken into account the principal locality from which it is to be seen. The choir, in which divine service is daily performed, is the place where the visitors to the building are gathered together, and the design ought to have been such that its principal features should be distinctly observable from that part of the edifice. We would defy the keenest-sighted person to stand at the extreme east of the choir and discover what is meant by the window. Its leading characteristics are blueness in colour and haziness of outline. With a view of modifying this sensation somewhat, we obtained access to the Lady Chapel. Here we found it necessary to go pretty close to make out the subjects attempted to be illustrated. Judging by those in the lowest medallions, the scenes represented were the chief events in the life of Christ, but it was impossible to discover with readiness what was intended by the artist. The limbs of the various figures are covered with ridges of muscle running in nearly parallel lines from end to end, and the faces are so deeply furrowed as to resemble the tattooed visages of New Zealanders. Two men walking in front of the Saviour are so drawn that one appears to have four legs, and to wave the other's head growing out of his side in a most impossible manner. A female figure, with a bush of the most endearing hue, follows the Saviour. Whoever has had the good fortune to be in the Portland Gallery Miss Florence Caxton's (Choice of Paris, an Idyll) wherein the prophetic beauties are so smartly satirized, with the ridges and furrows of muscle, the strained or impossible attitudes, the distorted visages, and

general air of caricature there displayed, has seen nothing more *bizarre* or extravagant than appears in this medallion. The picture, by the ridiculous attitudes of the figures, might have been intended to throw mockery upon one of the most solemn and touching events in the history of our Lord, and we protest earnestly against the introduction of such grotesque Medieval foolery into a representation of that scene which the Christian Church for eighteen hundred years has regarded with sorrow, veneration, and awe.

**Rugby.**—The large wheel window in the new church at Rugby has lately been filled with stained glass by Mr. Holland, of Warwick, with subjects showing parables of our Saviour, viz, the Good Samaritan, Good Shepherd, Prodigal Son, Labourers in the Vineyard, Lost Sheep, Marriage Feast, Dives and Lazarus; as also angels hearing scrolls.

**Leamington Priors.**—Three windows have just been fixed in Upton church by Mr. Holland, of Warwick, with the following subjects:—one three-light window, Christ Blessing Little Children, and the Acts of Charity in four subjects; one two-light window, Raising the Widow's Son, Healing the Sick; and one single-light, of the Ascension.

#### FULLER'S EARTH.

NUTFIELD, a village to the west of Tillburston-hill, on the road to Reigate, has long been celebrated for the fuller's earth which has been for centuries dug up in the neighbourhood. The beds of the fuller's earth are dug from the top of the lowermost division of the Shanklin Sand, and occupy a line on the north side of a ridge that extends from the east of Nutfield nearly to Redstone-hill, on the west of Copyhold-farm: about two miles west of Nutfield, the earth was extracted from a stratum 6 or 7 feet thick.

In some of the pits there are two kinds of fuller's earth, one of an ochereous yellow colour, and another of a slaty grey.

The kinds of fuller's earth above mentioned are used for distinct purposes. The blue or slate-coloured is chiefly sent to Leeds and other parts of Yorkshire, where the finest cloth is made. The yellow earth has a much wider distribution, and is employed in the manufacture of every description of coarse woollen goods. It is not only in request over the West Riding of Yorkshire, but also in Lancashire, Cumberland, and Westmoreland. Some is sent into Scotland and North Wales. Norwich also receives a supply for its stuff manufacture. In some coarse goods a portion of the earth is left in the fabric, to give it substance. The whole of the earth exported from this neighbourhood is sent from London by sea, except a small quantity retained by the dyers and scourers. The district yielding the fuller's earth, which had been explored in 1811, was about two miles in length from east to west, and a quarter of a mile in breadth. The quantity of earth raised from the pits is about 6,000 tons annually, of which 4,000 are of the yellow colour.

#### "THE BUILDER'S" LAW NOTES.

**Portsmouth Barracks.**—By a recent Act of Parliament, the public right of way through Colworth Barracks, in Portsmouth, has been extinguished, as it was found to be injurious to military discipline.

**Manchester Cathedral.**—By a recent Act, the Ecclesiastical Commissioners are empowered to expend (or to authorize the Dean and Canon of Manchester to expend), in the necessary restoration or repair of the Manchester Cathedral or Collegiate Church, as much of the money paid to such Commissioners before the 1st January, 1860, under the Manchester Parish Division Act of 1850, as they shall deem fit; but the maintenance and future repair of the Cathedral are to be as by the said Act of 1850 is prescribed.

#### CURIOUS SMOKE-VENTS IN MILLOM CASTLE, CUMBERLAND.

A WRITER in *Notes and Queries* says,—On my last visit to the ruins of Millom Castle, about half a mile from the estuary of the Duddon, I observed (what had on several previous visits escaped my notice), a curious smoke-vent in the room, which had evidently been the great hall, and which is entered from the small court by a doorway, surmounted by a beautiful flamboyant arch. This vent is a hole of a shape nearly elliptical, the vertical axis measuring perhaps a foot, and the horizontal one about 8 inches (I speak from guess), cut through the wall, which is there some 5 feet thick, at an inclination of about 30 degrees to the horizon. This hole was so very much like

what I have sometimes seen in a village church, made to carry outside an iron tube passing from a stove, and then forming a chimney, that I at first fancied this might have been an early instance of this more useful than ornamental contrivance. On examining the outside, however, I found sufficient proof that this was not the case. The hole itself has evidently been the whole and sole chimney, as is proved by its being there bordered by a frame of cut stone surrounded by an ornamental finish (I fear my architectural nomenclature is very imperfect), all evidently of the same date with the building itself. Do any of your numerous readers know of any similar instance? Perhaps some of them may wish to examine for themselves this ancient smoke-vent, which I have attempted to describe. If so, I think they will thank me for pointing out the best way to get to the spot. If the intending visitor will take a tourist ticket to Coniston, such as are issued at the principal stations of the London and North-Western, the Great Northern, and the Midland Railways, available for a calendar month, at very moderate fares, he will find that he is at liberty to stop on the way at any of the stations between Caraforth and Coniston, and afterwards resume his journey at his pleasure. Let him then stop at Foxfield station, and ask for a ticket for Green-road. Then he will be directed to the Green, where he will find an unpretending but very clean and comfortable village inn. From this he can proceed by a very good road, affording views of most picturesque and varied scenery, the lake mountains, Scawfell, the Old Man, High-street, Hill Bell, &c., behind; the open sea in front; the Duddon estuary on the left, and Black Comb on the right. The distance is between two and three miles. Having examined the ruins of the castle, he will proceed to the church close by, which has been lately restored in very creditable style, considering the small amount of funds. He will notice a handsome Norman doorway now re-opened, a piscina window, a drawing of which appeared a year or two ago in the *Illustrated London News*, and in the interior some monuments of former Lords of Millom, among which are two wooden effigies, such as I have seen mentioned in the pages of *Notes and Queries*. There is a Druidical circle, nearly perfect, about two miles and a half from the Green in a different direction; and the foot of Black Comb (the view from which on a clear day is said to be the most extensive in England, embracing parts of Wales and Scotland and the Isle of Man, and occasionally, though rarely, of Ireland), is about three miles from the Green.

#### THE DONKEY-TRAP CRUELTLY.

In the *Builder* of March 10, p. 159, an appeal was made on behalf of the poor donkeys whose feet are so frequently trapped by the street water-plugs. All that was then stated has been repeatedly confirmed; but the unmentioned case has been brought to the notice of the magistrate of Lambeth, and deserves the utmost publicity. It seems that the suggestion in the paragraph to cover these holes has been adopted by the Lambeth Vestry, but the Water Company has neglected to comply with the order. Only a donkey, shareholders, tortured and killed by your negligence, whose distressed owner your officials laughed at! Your petted pony may not meet a better fate. At the police court, according to the published report,—

The applicant said that, while he was driving his donkey along the street, one of its hind legs dropped into a water-plug, and snapped in two, so that he was obliged to have the animal killed on the spot. On inquiry he found that the Lambeth Vestry had given orders for these plug-holes to be covered; but the Company had neglected to do so, and he wished to know how to proceed against them.

He had made application to the Water Company, but they only laughed at him, and said the donkey wasn't properly shod; but he went to the slaughter-house and obtained the hoof of the donkey to show that it was. The hole is 3½ inches across, and quite big enough to admit the leg of a good-sized pony.

Mr. Elliott advised the applicant to make another application to the secretary of the Company, and in the mean time he would look over the Act of Parliament to see how he could assist him.

Independently of the suffering of the poor donkey, the loss of such an animal to a costermonger may be more than he would recover for a year; and who shall estimate the distress to his family that may result from it? Costermongers are a most industrious, hardworking class; and, while you are building *social bridges* to enable them to cross the sloughs through which they have to struggle, care should be taken that their efforts are not thwarted by the negligence of parish authorities or the penuriousness of joint-stock companies.

J. B.

## CONDENSATION OF MOISTURE ON GLASS.

The inquiries of "G. W." on the "Condensation of Moisture on Glass" have been answered by yourself in principle, in recommending a "good system of ventilation;" but, if you deem it worth your notice, I would beg to bring before you a plan I have tried, and found to succeed to a considerable extent, and which I think will realize my expectations when the building is well dried out; for, when it is occupied for some time, the amount of evaporation usual in drawing-rooms will not be so great as that which takes place from new walls.

An air-flue, built parallel to the fire-flue, having an opening between the ceiling and floor of each story, takes up the vitiated and humid atmosphere through apertures dexterously concealed by the centre enrichments. I intend to extend this treatment in another case to the cornices, by forming them so as to admit of it, particularly at the inner angles.

I need scarcely mention, the above flue is carried from the ground joists as well, and by drawing air from the ventilation in the base keeps the same in a perfect state. X. Y.

A correspondent of yours wishes to know how to get rid of the condensed water from window sashes, so I will let him know of a plan which I have lately adopted with success. I have the top edge of the bottom sash head sloped off towards the sash. The water, which always runs over this head, and down the paint and paper, now runs between the head and the sash, and so outside the window. But when the sash fits close to the head, then I have a small piece cut out of the former, so as to let the water escape from the channel which has been formed. This plan of mine also answers for casements which open outwards. G. T.

## PATENTS IN CONNECTION WITH BUILDING.\*

**ARTIFICIAL MARBLES.**—*R. C. Videgrain*, Rue Lafayette, Paris. Dated January 6, 1860.—1. Iron rendered inoxidizable in bars, or in strips. 2. Sulphate of lime. 3. Lime. 4. Ochres of all kinds. 5. Wood and coal ashes, mixed (these substances must be employed more particularly in marbles intended to bear great heat, such as chimney-pieces). 6. Alum powdered at the time of mixing, being put in a furnace and reduced to powder with alabaster or plaster. The liquids used to mix with the powder to render them into a paste are:—1. Aluminous ferruginous water. 2. Gum water. 3. Silicate of potash water. 4. A small quantity of rectified sulphuric acid (about 1 pint to 150 pints of water). The proportion of the various liquids must vary according to the object to be obtained. The principal point to be observed is, that the paste be thoroughly kneaded, and of a complete homogeneity.

**LOCKS FOR DOORS.**—*J. Fowler*, Waterford, Ireland. A communication. Dated January 6, 1860.—For the purpose of this invention the locks are formed to admit of the key at opposite sides, though at different parts of the key at opposite sides, though at different parts of the key, so that the opening for the key on the one side is not opposite that on the other, and when locked by the key being introduced on the one side, the key must act from the same side to unlock it, and the key when in the lock on one side is not accessible on the other side. According to one arrangement the key acts on the tumbler or tumblers and bolt on the one side (say the outside) as in ordinary locks, but when locked from the opposite side (say the inside) the key cannot be removed from the lock without the bolt being withdrawn or unlocked. According to another arrangement the key may be withdrawn from either side, though the bolt must be brought back, that is to say, unlocked by the key being put in at the same side by which locking was effected.

**"CUTTING DOVETAILS."**—*W. E. Newton*, Chancery-lane, London. A communication. Dated January 31, 1860.—The object of this invention is to obtain a machine for cutting dovetails of the ordinary form, which extend entirely through the work, and are used for securing together the sides of boxes and similar other articles. The invention consists in the employment or use of rotary cutters, arranged with movable beds, on which the work is placed, whereby the dovetails may be rapidly and perfectly formed, thus rendering them applicable to cheap work, such as common boxes, to which they could not hitherto be applied by reason of the expense of forming the dovetails.

**SUN-BLINDS.**—*J. Jeffreys*, Richmond, Surrey. Dated Jan. 28, 1860.—The patentee employes asiers

\* Selected and condensed from the *Engineer's Lists*.

of frames of galvanized iron or tinned wire soldered together; these are suspended by cords from a blind-case fixed at the upper part of and outside the window to which the blind is fitted. The suspending cords are so arranged, that the frames may hang horizontally, or nearly so; their inclination may, however, be varied. Pieces of canvas or other fabric of suitable form are attached to the outer edge and two sides of each of the frames, and the piece of canvas or fabric so attached to either of the frames is also secured to the inner edge of the frame next above it, except in the case of the highest frame, and in this case it is attached to a wire carried by the suspending cords at a suitable distance above the upper frame; the pieces of canvas or fabric are thus stretched diagonally from frame to frame. In order to raise the blind, two cords are employed: they are each attached at one end to the blind case, and they then pass downwards in front of the inner edge of each of the frames, and afterwards they return upwards to a roller fixed in the blind-case. By winding up these cords, the frames will be in succession lifted by their inner edges, and will thus be thrown into a vertical position, and when they are fully raised, they enter a blind-case by which, when out of use, they will be sheltered from weather.

## Books Received.

**Construction of the Great Victoria Bridge in Canada.** By JAMES HODGES, Engineer to Messrs. Peto, Brassey, and Betts, contractors. John Waele, Holborn, London, 1860.

We confine ourselves, on the present occasion, to announce the publication, by Mr. Waele, of Mr. Hodges' elaborate and elegant book on the Victoria Bridge, constructed for the passage of the trains of the Grand Trunk Railway across the river St. Lawrence. In the dedication to the Prince of Wales, Mr. Hodges describes the book as an "attempt to explain and illustrate some of the difficulties and labours encountered by Her Majesty's subjects in the accomplishment of this important work," the Victoria Bridge. It includes 21 illustrative plates, and 40 engineering plates, giving all the details of construction. It is beautifully got up, and is altogether a worthy record of the extraordinary undertaking it describes. The lithographs and chromolithographs are by Messrs. Kell, Brothers.

We shall take an opportunity to go fully into the subject.

**A History of Wimborne Minster.** London: Bell & Daldy, 1860.

THE ancient collegiate church of St. Cuthberga and King's Free Chapel, at Wimborne, is an interesting edifice. It has recently been restored and reopened; and it was in connection with this restoration and the traits and relics thus brought to light that the present volume was prepared and published. The objects aimed at have been to give a correct account of the building as it now stands; to place on record all that is known of its history; to register the results of the late explorations and draw fair conclusions from them; and to rescue from oblivion any collateral facts, unimportant in themselves, but indirectly bearing on the history. These objects seem to have been very well carried out; and the volume, which is illustrated by sketches, views, and plans, gives a good account of the minster and its history. The names of the builders of the present church have disappeared, as well as those of its benefactors: the fondness is almost mythical; and generation after generation has lived and died without leaving any memorial of the progress of the sacred precincts; which, to a certain extent, therefore, have been left to speak for themselves; but in this instance they have been fortunate enough to have a good interpreter; who, besides, has managed to fish a good deal of additional information after all out of historical and local records.

A terrible calamity befel the church in the year 1600. For many years before that date fears had been entertained for the safety of the spire, which crowned the central tower. As far back as 1547, masons had been sent for to inspect it, and repairs of various kinds had been made at intervals from that time to this. But things were getting worse and worse, notwithstanding that iron bars had been introduced to support it but a short time before; and at last, on a Friday morning, the market day, when the church was more full of people than usual, perhaps to hear the lecturer, it fell. Strange to say, no one was hurt by it; and equally strange, no direct mention of the disaster is to be found in the accounts, though we find collections made for

repairing the ruins of the church, and for carrying away stones and rubbish during the next few years. Its fall is thus quaintly described by a contemporary writer, the Rev. John Coker:—

"Having discoursed thus longe of this church, I will not overpass a strange accident, which in our dayes beinge thus full of people at some of clock service, likewise the streets by reason of the market, a sudden mist arising, all the spire steeple, being of a very great height, was strange cast downe, the stones battered all the lead, and brake much of the timber of the roots of the church, yet without ains hurt to the people; which ruine is sithence commendable repaired with the church revenues: for sithence hath not yet swept away all, being assisted by Sir John Hamham, a neighbour gentleman, who, if I mistake not, enjoyeth revenues of the church, and hath done commendable to covvert parte of it to its former use."

Few incidents worth recording occur in the history of the church and school after this time.

The churchwardens' accounts contain some curious and illustrative items. Extracts from these, from so far back as 1475, and for 200 years thereafter, are given in an appendix to the volume under notice.

The venerable saint, "Cuthberga the Virgin," however mythical, must surely have had some relationship, no less mythical it may have been, to St. Cuthbert of the beds (though the Virgin could not have been Mrs. Cuthbert, of course); for we find that respectable old gentleman represented by an image, among the "goods" of the church, with 100 pair of "bedys stones, silver and gilt." Were they *real* St. Cuthbert's beds? and was the image supposed to keep count of its paternosters thereby? St. Cuthbert probably stood side by side with St. Cuthberga; for we observe, about the same time, an item of expenditure for a clue of worsted to make a decent apron for St. Cuthberga, and even for four yards of greensilk for her heehof. These "goods" existed shortly after 1475, when a note of them was taken. A little further on, mention is made of a new "epicaustrorium." What was it?—a hypocast for warming the church? The author under notice queries whether it were not a "boiler;" but for what purpose, unless it were for heating water wherewith to warm the church? It occurs along with "stone and sand" (sabbion) from Kingston, a cartload of "aler pyles," and "casytry dome de lapid."

Candlemas in those days was really Candlemass; for we find, alongside of one of the perpetual items of payment for "mending the orgonys," an expenditure for 46 lbs. of wax at 8d., "for making of lyghts against Candlemas." We have also items for "wex agensit Cuthbroggyde, to make our lady lights and ij torches." A mysterious entry often occurs in the shape of an acknowledgment of value received of "the two wyves for cakys,"—of "the wyfe of the town for cakys," and of "the wyfe of the land" or "the landwyfe," and "the wyfe of the country," for the same edible. The author guesses that these may have been two women "who made and sold cakes for the benefit of the church, in the same way as the heer was sold," the profits being handed over to the churchwarden.

"Paid for ij bokes of prayers for envadinge of the Turk" seems to have constituted a very early, but rather a hopeless, endeavour, however meritorious, to convert the Turk. But what Turk? The Turk in the abstract? or Lord Bateman's individual Turk,—*"This Turk?"*

Not one whit less odd and obscure is,—*"Pd for greaso to greaso the Bear."* Was it not rather a supererogatory act of kindness to "greaso the Bear"? The bear was not worth his keep if he did not supply greaso to greaso the churchwarden. Our author sheds a little spark of light on this mystery, however, by suggesting that the "bear" was the "hier," which was, probably, even then a wheeled vehicle.

But we cannot dwell longer on these topics, and must conclude by reminding our professional readers that, while these merely occupy an appendix, the utility of the volume is comprised in a full and detailed account of the architectural and archaeological features of this well-known minster, and of its recent restorations, to all of which we have already occasionally given attention in the *Builder*.

**A Handbook for Travellers in South Wales and its Borders, including the River Wye. With a Travelling Map.** London: Murray, 1860.

THE general features of South Wales during the last twenty years have undergone great changes in social, commercial, and even geographical points of view. The enormous development of mining enterprise and the opening of new railways have peopled districts which were formerly uninhabited. New towns have arisen: new harbours have been formed; and the picturesque counties of South

Wales, particularly those of Gwent and Morganwg, have woken up to a new phase of existence.

It is pleasing and satisfactory to find Mr. Murray persisting in the issues of his approved handbooks to districts of our own fair land. These books cannot but tend to turn the tourist stream away from its continental meanderings, even in spite of his own continental handbooks, and to promote the desire for home tours which has of late arisen amongst us.

The editor of the present Guide has, it appears, lived the greater portion of his life in the district which he has endeavoured to delineate; so that it ought to be a dependable one; as, indeed, it is, so far as we have noted. The information is said to be brought up to the present day in the hope that it will really guide the tourist to what is most worth seeing; but there is no such book without occasional inaccuracies, and the editor, frankly confessing the possibility of this, takes the next best course, short of a perfection not attainable, by soliciting a correction of possible misstatements.

Besides its cathedrals (Llandaff and St. David's; and, as a border edifice, Hereford) and (a very few) of its churches, there are many other objects of architectural and archaeological interest in its Medieval abbeys and castles, its ancient cromlechs and stones, camps, and British and Roman roads. Interest of another kind attaches to its stores of coal, iron, and lead, and its iron works and copper-smelting establishments. Nor is the district unattractive in its social aspects, and its curious customs and superstitions, its kindly inhabitants, their Celtic language, their tall peaked or conical hatted and red flannelled "witches," and their watted and beguiling music, in some of which, doubtless, we have still the entrancing strains of the rapt Druidical harpers who "sang the night songs" of the hyperborean god.

Mr. Murray is piling up a mighty cairn to his own memory. It is formed of red volumes.

### Miscellaneous.

**BAD VENTILATION AND DRUNKENNESS.**—It has been related, remarks the *Labourer's Friend*, by a person employed by the City Missionary Society of London, whose duties lead him among the inhabitants of St. Giles's parish, that there was scarcely any one of them who might not obtain a comfortable livelihood if he could leave off gin. But it had been shown that many of these persons had been driven to this liquor as affording a temporary relief to the feelings of depression and exhaustion caused by living in a noxious atmosphere; and instances have been known of individuals who, when they were enabled to reside in a less crowded and healthier locality, where pure air was attainable, spontaneously abandoned the practice of gin-drinking. Adopting this view, the number of gin-palaces which flourish in the metropolis not only show a tendency to tipping, but also point out the condition of the habitations of the great bulk of those who frequent these gin-shops.

**DRUNKENNESS IN FRANCE AND ITS CAUSES.**—While we are introducing French wines to the notice of the lower classes, in the hope that drunkenness may be diminished by their substitutions for worse liquors, the mayors and statisticians of France are crying out—"Shut up the wine-shops," because, according to M. Jules Simon, who has investigated the subject, "drunkenness is the beginning and the end of French industrial life." Considering the character for temperance which the working classes in France have hitherto borne with us, this is somewhat surprising. It appears to be considered, however, by M. Simon and others, that the wine-shops are not to be blamed, at least primarily; but the squalid, uncomfortable homes of the people in the manufacturing districts, where, chiefly, the drunkenness prevails. And nothing can be more likely in such a case, than that—there as here—ill ventilated, close, and unwholesome dwellings, will lead those resident in them to an unnatural craving for stimulants. By reaction, too, of course, drunken habits must render dwellings still more squalid and unwholesome. The testimony of M. Simon applies to England no less than to France, although it is questionable whether the evil and its concomitants be not even worse in France than has long been known to be in England. If some of the liberal subscriptions which are (figuratively, if not literally) sent to Borrioboola-ga were expended in the improvement of dwellings at home, the money would not only be reproductive of cash profit, but of profit to humanity a far more important kind.

**A CEMENT FOR GLASS.**—A transparent cement for glass, it is said, is made by dissolving one part of indiarubber in chloroform, and adding six-tigest parts, by measure, of gum mastic in powder. Digen for two days, and frequently shake the vessel in which these substances are contained. The cement is applied with a fine camel's-hair brush.

**KENT ARCHEOLOGICAL SOCIETY.**—On Thursday before last the council of the Kent Archeological Society held a meeting in the council chamber of the Guildhall, Canterbury, under the presidency of Mr. E. Foss, F.S.A. Several new members were elected, and it was proposed, but not finally settled, that the congress should be held at Maidstone in 1861. It was announced that the Society's journal, profusely illustrated, would be in the hands of the local secretaries for distribution among the members in a few days.

**NEW WATER ELEVATOR.**—An improved apparatus for raising water has recently been exhibited,—the invention of Mr. Robert Nelson, of America. It consists of a large cylindrical receiver underneath, which is attached to the suction-pipe. The vacuum is produced by the combustion of volatilised hydro-carbons. The principle is said to be so simple that a child may employ the machine, which may be kept in full play by the withdrawing and replacement of a valve every six or seven seconds.

**THE MAGNETIC TELEGRAPH COMPANY.**—The facilities for sending messages by telegraph appear to be gradually approaching the conveniences of our postal system. The Magnetic Telegraph Company are now issuing small adhesive stamps for franking messages throughout their lines in the United Kingdom. The principle is precisely similar to the postage stamp system. A message can be written wherever convenient, and, after affixing the necessary stamp, it can be sent either by post or messenger to the nearest magnetic telegraph station, and thence forwarded to its destination. There is said to be a liberal discount on these stamps in order to assist in bringing them into general use.

**FALL OF A CANAL BRIDGE AT MANCHESTER.**—Across the Rochdale canal, in the Oldham-road, at the bottom of Prussia-street, and connecting that street in Potts-street, is a narrow wooden-floored iron girder bridge. During some holiday doings, a great number of girls from neighbouring factories proceeded to cross the already-crowded bridge, and a police constable ascended the steps on the Potts-street side to clear the bridge. While doing so, a sudden creak was heard, and immediately afterwards the bridge fell into the canal beneath, carrying with it upwards of 150 persons, chiefly young women. The bridge snapped the stone clean off on the Prussia-street side; on the Pott-street side it moved a mass of stone weighing about two cwts. out of its place, while the bridge fell in an upright position, the centre breaking after it had reached the bottom of the canal, and the crowd upon it were kept standing by the iron railings. A number of men dashed into the water, and the affrighted, half-drowned people were extricated: only one life was lost—that of a child.

**AN AGRICULTURAL HALL FOR ISLINGTON.**—A company, with limited liability, has been formed for the purpose of erecting an important public edifice at Islington, at a cost of 20,000*l.*, raised by 10*l.* shares: the building will be mainly of glass and iron, and will serve not only for the fortnight's cattle-show of the Smithfield Club, who are its chief promoters, but, it is hoped, as a permanent and attractive exhibition, mainly of an agricultural character. In reference to this project, the *Islington Times* says,—"We fear, however, the directors are about to commit a very awkward *faux pas*. Dixon's Lairs is a well-known spot of ground, having a large frontage on the Liverpool road, whilst its eastern extremity looks toward Islington-green, from which it is separated by a number of old rickety buildings. Intrinsically, of no value, their position on the main thoroughfare of the parish yet gives them a worth sufficiently great to render them an obstacle to all but such an undertaking as we are considering. The removal of these unsightly sheds, for they are little better, would open up a second frontage of far greater importance than that which exists on what was long known as 'the Back-road.' Yet, so it seems, the directors of the new Agricultural Hall are either so ignorant of the locality, or so blind to the interest of the undertaking they represent, that they have not yet seen the wisdom of placing the main entrance in the great northern thoroughfare that runs through this parish, and in the centre of our shops. They purpose placing it on a road which directly leads nowhere."

**AUCTIONEERS LENDING ON FURNITURE.**—A firm of auctioneers at Birkenhead has been fined 12*l.* 10*s.*, for lending 7*l.* 10*s.* on a quantity of furniture, and receiving interest thereon, not being licensed as pawnbrokers. The gentleman who appeared on behalf of the Inland Revenue said the full penalty was 50*l.*, but as defendants, he believed, had acted in ignorance, he only pressed for one-fourth of that amount.

**IMPORTANT TO WORKMEN.**—A wages case has recently been heard at Warrington. Thos. Hart had been employed for a number of years as a worker in iron at the Callum Forge Foundry, near Warrington, conducted by Messrs. Neild & Co. It is Messrs. Neild's custom always to retain one week's wages in hand. On Saturday, August 26th, there was 1*l.* 5*s.* due to Hart. On the Monday following, Hart, while at work, in a state of intoxication, assaulted the foreman with an iron bar and rendered him insensible. Next morning, the Messrs. Neild summarily dismissed Hart, and refused to give him any wages. He summoned them for the wages due for the week previous to that in which the *fracas* had taken place.—Mr. Marsh, for the Messrs. Neild, quoted the law bearing on the case, as laid down by Lord Denman and Mr. Justice Coleridge, which showed that "if a party hired for a certain time (whether by the fortnight, month, quarter, or any other period), so conducts himself that he cannot give the consideration for his salary, he shall forfeit the current salary even for the time during which he has served." Mr. Justice Coleridge had also laid it down that "under circumstances of gross misconduct the workman cannot recover *pro rata*." The case was dismissed.

**SUFFOCATION TO DEATH IN A GAS MAIN.**—The Imperial Gas Company are running a large three-foot main from Sloane-street across Hyde-park, a portion of which, about 90 feet in length, passes under the Knightsbridge-road, near Albert-gate. The joints of the mains are first caulked with pitched yarn as tightly as possible: upon this caulking a thick coating of molten lead is run, which is hammered close into the joint by a peculiarly-shaped chisel. With the view, however, of making the main gas-proof, there is a further process of filling the inside portion of the joint with Roman cement. To enable the two operations of cementing inside and lead jointing outside to be carried on simultaneously, the man who cements is obliged to work several "lengths" up the main, beyond where the outside work is going on, so that the blows of the hammer wedging in the lead will not shake the cement by percussion, which may be the case if the two kinds of work were being done too near each other. The main is made up of 12-feet "lengths," and the cementing men will sometimes be working a couple of hundred feet from the open end of the street. It was while so engaged that the gas man was suffocated. The coroner's jury returned a verdict that the deceased was suffocated by the inhalation of coal gas, and adopted a suggestion of the coroner, that men should not be allowed to work inside more than six lengths of pipe in future.

**THE DEBUSCOPE.**—A small instrument has lately made its appearance, which it is said will be of great utility to designers and others engaged in the ornamental and decorative arts. It is of French origin, and, as described, consists of two silvered plates of great reflective power, put together in a framework of cardboard or wood, at an angle of 70 degrees. On being placed over a small picture, or design, of any kind, no matter how rough, or whether good or bad, the Debuscope, says a contemporary, "will reflect the portion immediately under the eye, on all sides, forming the most beautiful and elaborate designs, and, being slowly moved over the picture will multiply new designs to any extent. No matter what the subject is on which the instrument is placed: the result is marvellous: there is produced, from the most unlikely objects, such as scraps of paper-hangings, blots of ink, leaves, flowers, bits of lace, &c.,—an endless series of new and really beautiful designs. Although of the same species, it possesses an advantage over our old friend the kaleidoscope. It gives the design, and that in such a manner that it can be made stationary at pleasure, until copied as new patterns for draughtsmen, calico printers, dyers, paper-hangers, painters, or others. Setting aside the utility altogether, it can be made the means of gratification in the drawing-room, and will doubtless soon assume its proper place, along with the microscope and stereoscope, as a source of amusement at once innocent and instructive." Could not the patterns in some such instrument, and even in the kaleidoscope itself, suitably formed, be readily copied, and fixed as photographs, by aid of the camera?

**CHAMOUNIX AND ALBERT SMITH.**—A new English church has been consecrated at Chamounix, and the first monumental tablet that decks its walls is an *in memoriam* to Albert Smith.

**DEATH OF MR. INGRAM, M.P., PROPRIETOR OF THE "ILLUSTRATED LONDON NEWS."**—We regret to learn that the melancholy fact of Mr. Ingram's death by drowning, as reported, on the sinking of the *Lady Elgin* steamer, while on an excursion in the American lakes, is now past any doubt, the body having been identified by two gentlemen who have been many years in his employ, one of whom has at the present moment the custody of the body on its way to England for interment. The body of his son Herbert has not yet been discovered.

**FALL OF HAY AND FEATHERS, GOSWELL-STREET.** Sir: The surprise in this matter is by no means lessened as the house has been mentioned as an example of good workmanship. Would not a better tie be got for corner buildings by allowing in such cases timbers to lie in walls? Had the party well been connected with the accident it would most probably have pushed the building into the street.—A BUILDER.

**THE COURT CASE.**—Every one knows how deeply the country is indebted to the family of Henry Cort, "the father of the British Iron Trade." A poor pension was at last meted out to Mr. Richard Cort, who is now not far off eighty years of age; but this aid is quite inadequate to relieve him of expenses incurred by his long and tedious efforts to bring the country to a sense of what was due to his father's family, especially in the midst of adversity. It has been decided to raise, if possible, a sum of 100*l.*, for the purpose of setting poor Mr. Cort free from all dunning on this score in his extreme old age, and we earnestly hope the attempt will be successful. The names of numerous supporters of the "Cort Claims," including sixty M.P.'s and 100 other eminent authorities, iron manufacturers, and engineers, may be seen recorded in the library of the Institution of Civil Engineers.

**MANCHESTER ROYAL INSTITUTION: EXHIBITION OF PAINTINGS.**—The exhibition of paintings at the Manchester Royal Institution for the year 1860 comes before the public under the auspices of the recently-formed body, the Manchester Academy of Fine Arts, as well as through the arrangements of the council of the institution; and as a consequence of the infusion of new blood into the executive, says the *Courier*, the beaten track of former years has been departed from so far that the exhibition has much more the character of an exposition of the state of art generally than it had a few years back. The last two or three catalogues have shown a regular increase of French names; but now instead of having the works of foreign artists dotted up and down the rooms among those of Englishmen, so much of expansion has been given to the liberality noticeable in late years, that we have at last small but complete collections resulting from the labours of "our own commissioner" and other connoisseurs, illustrating the present characteristics of the German, Belgian, and French schools, as well as those of our own.

**CURIOS ALLEGED DISCOVERY IN FLORICULTURE.**—It is said that Maylor Tiemann, at his paint factory at Manhattanville, has accidentally made a discovery which threatens to revolutionize horticulture. One of the factory hands having thrown some liquid green paint of a particular kind on a flower-bed occupied by white anemones, the flowers have since made their appearance with petals as green as grass. The paint had in it a peculiar and very penetrating chemical mixture, which Mr. Tiemann has since applied, with other colours, to other plants, annual, biennial, and of the shrub kind, "the result being invariably that the flowers so watered took the hue of the liquid deposited at their roots." By commencing experiments early next year, during seed time, and applying different colours, we shall no doubt soon be enabled to "paint the lily." For the truth of this wonderful discovery, the *New York Tribune* is responsible. This, however, we can personally testify,—that charcoal put to the roots of dahlias and other flowering plants will render them vividly, flowers nearly white being thus turned to a deep red, sometimes altogether, and sometimes mixed with the lighter hue in half-a-dozen varieties, from one and the same root. Since noting this curious fact in our columns some years since, it has been repeated, and with success, for several seasons in France, having admittedly been tried there in consequence of reading the paragraph quoted in the *Builder*.

**INDIAN-RUBBER SEATS.**—Garden-seats, made of vulcanized Indian-rubber, have been introduced as an improvement: their elasticity saves discomfort to the sitter.

**CUTTING GLASS.**—Alexander Taylor writes as follows to the *Photographic News*:—"In treating of glass, I may give you another way of cutting bottles, shades, or any glass vessel the neat thing you wish, and that is to get a rod of iron heated to redness, and having filled your vessel the exact height you wish it to be cut, with oil of any kind, you proceed to very gradually dip the red-hot iron into the oil, which, heating all along the surface, suddenly the glass chips and cracks right round, when you can lift off the upper portion clean by the surface of the oil. This never fails, and many a couple of servicable bell glasses have I made in this way from a six-pouud confection bottle."

**HAMMER FOR SHAPING METALS.**—An improved hammer, applicable to the manufacture of globular articles, and the formation of borders upon articles of sheet metal, has been patented by Mr. William Spurrier, of Birmingham. He fixes a hammer-head or swage upon the long arm of a lever turning upon a horizontal axis. The short arm of the said lever is operated upon by means of cams, or teeth upon the periphery of a wheel, made to rotate by steam or other power. A rapid reciprocating motion is given to the hammer or swage by the said wheel, and the metal to be shaped is hammered thereby. The metal operated upon is supported on sand in hags or dies, or in some other convenient manner.

**MILLSTONE MASONS.**—It appears that there are in London a certain number of masons whose special avocation it is to prepare for use a peculiar kind of millstone, known as the French burr. This stone consists essentially of flint. The "picking" of the "burr" is effected by a steel chisel struck by a hammer, and every stroke is attended by a flash of light and a cloud of dust and small particles of stone. Having seen many of the men as patients at the Victoria-park Hospital, on account of chest affections brought on by their employment, Dr. Peacock was led to make extended inquiries at the places of work, the results of which he embodied in a paper in the *Medical Times*. The subjoined are the principal of his conclusions:—1. That the average age of those engaged in this occupation is very low indeed. Of twenty-three who had been apprenticed to it the average age was only 21-1 years; and one of the foremen stated that the longest period he had ever known a man to work at it was thirteen years. 2. That the fatality among these men is directly due to their inhalation of particles of silex; but that the injurious influence of the latter is much aggravated when the men are intemperate. 3. That the form of the disease induced may be either chronic bronchitis or phthisis, according to the predispositions of the patient. 4. That the presence of the silicious particles in the lung-tissue may be proved by chemical examination.

**TENDERS**

For road and drains on building land, on Alceon's College estate, belonging to W. Phillips, Esq., between Forest-hill and Sydenham hill. Messrs. Banks & Barry, 27, Sackville-street, architects:—

Walker	£959 0 0
Dearis	855 0 0
Potter & Love	892 10 0
Porter	789 0 0
Neave	772 0 0
Constable	731 0 0
Clarke	728 11 6
Colson	686 0 0
Morris	680 0 0
Becton	663 0 0
Strickson	660 0 0
Stacey	610 9 9
Hartland & Bloomfield	627 0 0
Ladd	609 0 0
Hare (accepted)	585 2 6

For alterations and additions to Biscot Park, Surrey, for Mr. Carew Gibson. Mr. Henry Clutton, architect:—

Mansfield	£7,949 0 0
P'Anson	7,775 0 0
Pitchard	7,748 0 0
Brass	7,334 0 0
Foster	7,216 0 0
Myers	7,089 0 0

For works at Tulse-hill. Mr. Eales, architect:—

Clemence	£215 0 0
Batterbury	879 0 0
Airey & Bellingham	785 0 0

For erecting a house in Long alley. Mr. J. Tanquer, architect. Quantities supplied:—

Taylor	£653 10 0
Elston	570 0 0
Maers	497 15 0
Cass	497 0 0
Brooks	485 0 0
Green	422 18 0

For works at No. 18, Cork-street. Mr. Eales, architect:—

Fish	£1,796 0 0
Batterbury	1,556 0 0
Airey & Bellingham	1,755 0 0
Conder	1,747 0 0
Cowland	1,676 0 0
Sanders	1,568 0 0
Longmire & Barge	1,543 0 0
Smith	1,485 0 0
Rudkin, junior	1,455 0 0

For new Baptist Chapel, Derby. Messrs. Hine & Evans, Nottingham, architects:—

G. Myers	£6,301 0 9
Simpson & Lyham	4,996 0 0
Robinson & Freeman	4,950 0 0
R. Dennett	4,925 0 0
J. Wood	4,850 0 0
R. Young	4,800 0 0
Edw. Thompson	4,800 0 0
Thompson & Fryer (accepted)	4,590 0 0

For the erection of the Ladies' Invalid Home, St. Leonard's-on-Sea. Mr. Francis H. Fowler, architect. Quantities taken up by Mr. Smithers:—

Myers	£3,550 0 0
Ayers & Co.	3,762 0 0
Wheeler	3,659 0 0
Kenwood	3,635 0 0
Hughes & Hunter	3,567 0 0
Howell	3,394 0 0

For altering the Literary Institution, Southwark, into a vestry hall for the parish of St. George the Martyr, Southwark.—The tender of Mr. Thos. Rudkin, jun., was accepted by the Vestry Board, from the quantities supplied by Mr. John M. Bryson.

For erecting brick-hut accommodation for 100 soldiers at Hounslow barracks, for the War Department, under superintendence of the Commanding Royal Engineer of the district.—The tender of Mr. Jennings was accepted by the Director General of Contracts, from the quantities supplied by Mr. John M. Bryson.

For cottage at Titchmarsh, near Reading, for Mr. Wm. Blandy. Old materials from present house and farm-buildings in addition. Messrs. Poulton & Woodman, architects:

Laker	£1,956 0 0
Wheeler	1,935 0 0
Woodroffe	1,800 0 0
Orton & Child (accepted)	1,593 0 0

For hall and committee-room for West-street Institution, Reading. Messrs. Poulton & Woodman, architects:

E. Strong	£830 0 0
Orton & Child	822 0 0
Leach (accepted)	751 0 0

For the erection of national schools and master's house at St. Leonard's, Aston Clinton, Bucks. Mr. Frederick Gatto, architect:—

Fanshidge	£1,042 0 0
Honour	703 19 0

For first portion of the new buildings at Ford, Liverpool. Mr. E. Welby Pugin, architect:—

Farrell & Ledger	£1,859 0 0
Denver	1,639 0 0
Yates	1,550 0 0
Steel	1,444 0 0
Glester (accepted)	1,420 0 0

For a cottage residence at Hartley, near Plymouth, for Mr. Richard Hicks. Mr. O. C. Artlur, architect. Quantities not supplied:—

Ellott	£1,480 0 0
Norbeck	1,460 0 0
Call & Pethick (accepted)	1,395 0 0
Letbridge	1,335 0 0
Marshall	1,291 0 0

For three new warehouses, Booth-street, Manchester. Mr. Thos. Bird, architect. Quantities supplied:—

Terras	£1,687 0 0
Thompson	1,583 0 0
Nell	1,592 0 0
Tully	1,558 0 0
Penk (accepted)	1,549 0 0
Jaffrey (accepted)	157 0 0

For three villas at Higher Broughton, Manchester. Mr. Thos. Bird, architect. Quantities supplied:—

Penk	£3,799 0 0
Terras	1,769 0 0
Harrap	1,733 0 0
Farrell & Ledger	1,659 0 0
Tully (accepted)	1,576 0 0

For a drapery establishment, Chorlton-upon-Medlock, Manchester. Mr. Thomas Bird, architect. Quantities supplied:—

Nell	£2,916 0 0
Thompson	895 0 0
Savage & Geuney	810 0 0
Clark & Jones	805 0 0
Metcalf & Waterson	819 0 0
Vickers	810 0 0
Penk	798 0 0
Terras (accepted)	727 0 0
Tully (too late)	795 0 0

For three houses at Dartmouth Park, Forest-hill, for Mr. William Rendle. Mr. Thomas Fred. Franklin, architect:—

	£	s	d	Total
Macey	2,380	145	2,525	
Gannon	2,259	121	2,380	
Downs	2,128	146	2,274	
Crabtree	2,079	724	2,400	
Rider	2,660	105	2,166	
Thompson	1,988	140	2,128	

# The Builder.

VOL. XVIII.—No. 922.

*The Metropolitan Main-Sewerage: the Northern Outfall Sewer.*

IN the course of the past week, according to original arrangements, tenders were to be received by the Metropolitan Board of Works, for the Northern Outfall Sewer. An advertisement in our present number, extends the time to the 15th inst. It will be recollected that this portion of the general work of the sewerage of London, upon which the success of the whole of the operations on the north side of the Thames, excepting only what is called the Western Division, will depend, is complicated and difficult from features of the district to be traversed, and the nature of the soil. In the account of the scheme for the metropolis, which we gave some time back, we specified the principal obstacles that would have to be surmounted at the commencement of this particular sewer, within a distance of little more than a mile. The remainder of the line (making the entire length for the sewer, 5 miles 1,400 feet), passes through that very treacherous ground, the marshes, between West Ham and Barking Creek. Eighty borings have been taken along the whole line, to ascertain the nature of the soil; and the results are shown on three sheets of the drawings.

We have before expressed a high opinion of the completeness of the preparations, by the engineering staff of the Board, for subsequent works, at least in whatever is comprised under drawings and specifications; a completeness which has contributed to that efficiency of superintendence which also we have acknowledged. The details in the present case are even more deserving of notice than were the corresponding preliminaries for the contracts in hand. Of these, the chief points interesting to those who would visit the works whilst in progress, and points that might subsequently be referred to as precedents, have been all duly laid before our readers. But it may be well to state once more, for information of distant readers, that on the south side of the river, there are now in progress, works of the High-level Sewerage and of the Outfall Sewer, besides portions of the Low-level Sewer,—for which last the general drawings are not yet finished,—and that the engines and other machinery for the Depford pumping station are in hand,—the Low-level Sewer, and the pumping machinery and reservoir at the outfall below Woolwich, being thus the only divisions of the work of which the details have to be furnished; and that on the north side of the river, the works in progress (some of which may be regarded as complete,) include those of the High-level Sewerage, the Middle-level, with a storm-water outfall passing beside the Serpentine and across Hyde Park, and what may be considered the upper portion of the Western Division. It should also be recollected that the Hackney Branch, which is included with the contract for the High-level, will intersect the line at Old Ford, and pass southward to join eventually the Low-level Sewer. After that portion of the scheme which we are about to describe, there will remain for particular design, the works, on the north side, of the Low-level Sewer, of the pumping machinery, of the reservoir at the outfall, and those generally of the Western Division.

The difficulty which there is for us, in presenting in moderate space, the interesting and useful points to be noted in examination of the drawings and specification now before us, will be supposed from a mere statement of their bulk. The form of contract, which embodies the specification as well as a schedule of prices for possible extras or omissions, fills eighty-five printed pages, besides six pages of an index; and the drawings occupy seventy-five large sheets. The specification contains 267 clauses. The details we have to notice will be understood best if we here give, as succinctly as we can, the particulars of the course the sewer will take.

It will be well remembered that the works comprised in the contract for the Northern High-level Sewer terminate at the western bank of the Lea. These include a portion of the outfall as well for the Middle-level as for the High-level division. The Northern High-level and the Middle-level Sewers, after a junction at the overflow-chamber, so often described, westward of the North London Railway, proceed in separate and parallel channels to the point from which the works now to be noticed commence, the before-mentioned western bank of the Lea, where, also, and slightly divergent on plan from the upper channels, there are two outfalls at a lower level, for storm-waters. The parallel channels of the upper level or main outfall, (two sewers, in fact,) are to continue, crossing several different watercourses and branches of the Lea, and intersecting the Eastern Counties Railway and the Stratford-road, to the site of the intended pumping station and junction of the Low-level Sewer, which is just westward of the branch known as the Ahney Creek of the Channelsea River, itself a portion of the waters of the Lea. Thence to the Thames, just westward of the mouth of Barking Creek, the Northern Outfall Sewer, so called, will continue as three channels,—except at the outfall itself, and excepting in one or two other places where it has been necessary to divide the flow into a greater number of courses. The general line is easterly or south-easterly, except at the outfall for rather more than 800 feet from low-water mark, in which distance the line has turned to the south. The sewer will have a uniform inclination of 1 in 2640, or 2 feet per mile, to the end of the general construction, where the invert appears to be about 1 foot below high-water level, after which there are a tumbling hay, nine lines of sewer, and lastly campsheating, together falling about 18 feet in a length of 400 feet to near low-water mark. The ground over the sewer or sewers will form a continuous embankment and a new line of road. The line intersects, in the following order, the main branch of the Lea, the East London Water-works Feeder; at an acute angle, the Pudding-mill River and Marsh Gate-lane; similarly the Eastern Counties Railway and the City Mill River close southward of the crossing of the latter by the former; afterwards the Water-works River and the Stratford-road; Abbey Mill-lane; Ahney Creek, and the Channelsea River close together; the North Woolwich Railway at the intersection of Marsh-lane, the Bow and Barking Railway, Balaam-street in the town of Plaistow, Barking-road, and many lanes and water-courses requiring special provisions. The line crosses East Ham Manor-road just south of the church.

Each of the channels, two, or three, of the sewer, will be 9 feet in the span of arch, or the clear width between the curved sides, and 9 feet from the invert to the soffit; and excepting for about one-fourth of the length, or the portion eastward of the church just named, where cross walls or piers of concrete are used and arches, and excepting where the channels or culverts will be on foundations slightly below the present level of ground, and of course excepting the crossings, the brickwork will be placed on a continuous substructure of concrete, which, in some places, will be not less than 14 or 15 feet in depth from the bottom of the sewer, and 50 to 60 feet transversely at the base, in addition to what is carried up as continuous counterfort to the sides of the sewer. There may have been

good reason which is not apparent, for the adoption of the imbedded piers of concrete with arches, for support in one case, and the solid embankment of concrete in the other.

It will be understood that in all the crossings, as of railways, roads, and streams, over or under them, the 9 feet in clear height of culvert, plus a roadway above, had to be provided for; and that thus the difficulty of crossing was increased. The requirements of the "Metropolis Local Management Act, 21st and 22nd Vict.," are stringent as to the non-obstruction of the navigation of the streams. In most of the cases the construction is of iron, and the drawings are very elaborate. Of course provision had to be made for contraction of the iron, without allowing sewage to escape. The mains of the Water-works Company also entailed special contrivances. The land on the line from the Lea, of the width of 100 to 150 feet, has been, or will be all purchased by the Board.

In construction of the main portion of the line, a good foundation is to be first obtained by excavating; and the concrete is then to be deposited with sides at a slope of 1 to 1, finishing along the sides of the sewer within 2 feet 6 inches of the soffit of the arches. The inverts and side walls of the sewers, the former 13½ inches thick, and the latter 2 feet 3 inches for the external walls, and 18 inches for the internal parallel divisions, will be built in Portland cement; whilst the arches and continuation of the side walls above the springing, will be in Roman cement. The former cement is to be of not less weight than 106 lbs. to the bushel of four pecks, and the Roman not less than 73 lbs., the Portland to be mixed two of cement to three of sand, and the other in equal parts. The concrete, so far as the embankment aboveground is concerned, is to be composed of four measures of approved ballast, one measure of sharp grit sand, and one of the best description of Dorking, or other stone lime of equal quality to be approved, the whole to be mixed in a pug-mill, and thrown in from the greatest practicable height. But, for the foundations of piers of bridges, and brickwork over streams, as also where to be used below present surface of the ground, the same proportion of ballast is to be mixed with two measures of sand, and one of freshly burnt lias lime. All the lime is to be delivered in lump, and ground upon the line of works. The ordinary bricks are to be the best description of picked stocks; but the inside of each sewer is to be faced with "shippers or paviors," to be according to samples at the office of the Board. Joints of the brickwork are not to exceed 3-16ths of an inch in thickness next the interior surface; and the external joints are to be raked out and pointed with neat cement. Hoop iron of 1 inch in width, and 1½ lb. to every 10 feet length, is to be used in the outside walls of the sewers, four widths in every fifth course, also at the bridges; and at the outlet near the river, there are to be two widths for every brick in thickness. The facing of the soffit of arch and top of invert, is to consist of half-brick rings on edge, and particular directions are given for the work of the side walls, in old English bond, for the wetting of the bricks, and for the immediate carting away of old or rejected bricks; and no broken bricks are to be brought on the works. In all cases where excavations are made for brickwork, embankment or otherwise, the trench is to be filled with concrete, and wherever the drawings indicate "made ground," concrete is to be used. Where the concrete piers are used, we observe that they are to be only of the width, 37 feet 6 inches, required for the width of the three lines of sewer. The space apart, or span of the arches springing from them, and carrying the sewers, is about 18 feet; and the thickness of the arches is 18 inches. Each ordinary pier, of concrete, will be the 37 feet 6 inches by 4 feet on the plan; and is to be estimated as about 16 feet in depth from the present surface (which has about the same level as the line of springing of the arch), down to the surface of gravel or foundation of good ground. Every sixth pier, however, is 6 feet across, instead of 4 feet. The backing of the

arches is made up with concrete, wherein 3-inch pipe drains are laid to the ditches outside the line of sewer. The continuous counterfort of concrete to the sides of the sewer, as will have been understood, is not provided in the portion of the work just described. The external faces, however, of this portion, as well as of the concrete slopes of other portions of the line, are to be covered by outer slopes of 1½ to 1, with dry rubbish or other material, well rammed in layers of not more than 6 inches in thickness, with an iron punner of not less than 10 lbs. weight,—the top of the embankment, or roadway, finishing 40 feet in width, and 2 feet 6 inches above the crown of the arches of the brickwork. Each ditch at the toe of the embankment, will be 3 feet 6 inches wide at the top, and 1 foot 6 inches at the bottom, and about 2 feet 6 inches deep, and will discharge into the present open ditches. Before the roadway is formed, 12 inches in depth of clay-puddle will be placed along and over the top of the brickwork, and down to 1 foot below the top of the concrete slopes. The external slopes are to be faced with turf of not less than 4 inches in thickness; or where the land is arable, particular directions are given for sowing with grass seeds; and the kind of quicksets for the hedges, and manner of planting also are specified. Culverts of brickwork in Portland cement are to be built in the open ditches met with and intersected. These works, in 1½ brickwork, alone amount to 520 feet of 7 feet by 6 feet; 620 feet of 6 feet 6 inches by 5 feet; 820 feet of 4 feet by 3 feet, and 500 feet of 2 feet barrel. Numerous side entrances and air-shafts will be required. The latter will be of the common form, and the others not greatly different from it. Where the side entrances occur, openings will be formed in the division-walls of the sewers, to allow of access from one to the other; and in each opening, double flaps will be placed.

Besides the work in raising Balaam-street, Barking-road, Prince Regent-lane, Blind-lane, and East Ham Hall Manor Way, and the lowering of Marsh-lane and West Ham Abbey-lane, there will be forty "occupation roads" to be formed, to lead to the lands on each side.

The more important works in the construction of aqueducts or bridges, include the bridge over the Lea, of one span; the bridge over the Waterworks Feeder, of two spans; that over Marsh Gate-lane, Pudding Mill River, and (Knob's Mill) Marsh Gate-lane, of four spans; that over the City Mill River, of one span,—each of these carrying the double line of sewer; the bridge over the Waterworks River, of one span, carrying four lines of sewer; that over Abbey Mill-lane, of one span, carrying a double line; and that over Abhey Creek and Channelsea River, of two spans; that over the Bow and Barking Junction (intended) Railway, Marsh-lane, and the North Woolwich Railway, of three spans; and that over the Bow and Barking Railway main line, of one span (besides certain bridges of one span, over occupation roads), all carrying the triple line of sewer. In some of these cases, the construction is repeated: but separate designs and sets of drawings have been required for the bridges of the Lea, the East London Waterworks Feeder, and the Waterworks River near Stratford-road; for the works adjoining the latter and crossing the road; and for the bridge over the Bow and Barking main line, as well as for the crossing over the Waterworks main, and the method of passing under the Eastern Counties Railway, and of crossing Balaam-street and other roads. The outlet into the Thames, the tumbling-bay, nine culverts, and other works, also are the subject of distinct drawings and clauses of the specification. In our present limits, we cannot do more than say that each of these features in the design of the Northern Outfall Sewer displays much ingenuity in contrivance, and great variety of construction; and much experience of corresponding varied character, as well as large resources, will be necessary in whatsoever may be the contractor.

The contractor is to provide for works which may be required or deducted, 200 rods of brickwork in Portland cement, 10,000 yards of blue lias lime concrete, 10,000 of the con-

crete of Dorking lime, 500 feet of Bramley Fall stone, the largest block not to exceed 30 cubic feet, the outer faces, beds, and joints to be dressed; 500 feet similarly of Aberdeen granite, the largest not to exceed 30 feet; and 1,000 yards of 3-inch tooled and squared York stone, heddled, jointed, and laid. In the schedule of prices, such brickwork as that mentioned, in blocks or otherwise, is set down at 15*l.* per rod, that with "shippers or paviers" being 17*l.* The concrete with blue lias lime is priced at 7*s.* per cubic yard, and that with Dorking lime at 5*s.* 3*d.*, but where ballast is got out of the trenches, at 3*s.* 6*d.* Under the head of stonework, Bramley Fall stone, tooled, squared, and bedded, is priced at 4*s.* 9*d.* per foot cubic, and the 3-inch York stone, at 9*d.* per foot superficial,—2½-inch being 7*d.*, 4-inch 1*s.* 6*d.*, and 6-inch 2*s.* Digging, including every expense of shoring, watching, carting, and so forth, and filling in and punning, are priced 2*s.* 6*d.* per yard, and without cartage, 2*s.* But in the case of foundations of piers of bridges, the same kind of work, including carting, is put at 7*s.* 6*d.* per yard, to defray every expense of keeping the work clear of water, a matter which may possibly involve, as in the recent case of work connected with the Low-level sewer on the south side, extraordinary difficulty and attendant expense. Timber, Memel or Riga, left in trenches, is to be charged per foot cubic, 2*s.* 6*d.*; and used as sheathing, piles, and similar works, 5*s.*, with the necessary caps and shoes; 12 feet planks left in, are to be 3*s.* 9*d.*, and 1½-inch deal is to be 3½*d.* per foot super. Cast-iron work in side-entrance flaps, will be 18*s.* per cwt.; in gully and ventilating grates, 12*s.*; and in covering plates, girders, pipes, and columns of any pattern, 10*s.* Wrought-iron work as in ladder-irons, will be 3*d.* the lb. Clean Thames ballast will be 4*s.* 6*d.* per yard. Labourers will be 3*s.* 9*d.* the day of ten hours; excavators, 4*s.* and 4*s.* 6*d.*; whilst bricklayers and other workmen, except engineers, who are 7*s.*, will be 6*s.*

In the general conditions upon which the works described are to be performed, besides such usual clauses as that the decision of the engineer as to meaning of the specification, is binding, it may be noticed that in case of any suit against the Board, or any of their servants, in respect of damage from the execution of the works, the Board may compromise the action, and at the same time claim indemnification from the contractor. The contractor is not to assign the contract, nor to make a sub-contract with any workman for any part of the brickwork, earthwork, masonry, or work connected with these; and under pain of a forfeiture, he is not to give a gratuity to any officer of the Board. Weekly accounts of extras and omissions ordered, are to be delivered. When improper materials directed to be removed, are not sent away in twenty-four hours after orders, they may be removed at the expense of the contractor, who may also be made to forfeit as damages, 5*l.* for every day's delay. Obstruction to footways entails similar damages on the contractor. Coins and other articles of value, are to be delivered up. The works are to be finished within two years after date of the order to commence; or 50*l.* per day will be claimable as liquidated damages; but in the event of strikes or combinations on the part of the workmen, the engineer will allow such additional time as he may deem fair and reasonable. Moneys payable to the Board by the contractor may be sued for and recovered on the contract, or may be retained out of moneys due or to become due, even though the sum to be retained may be unascertained at the time of the withholding. The sum of forty thousand pounds for extra works, is to be included in the tender. Advances are to be at the rate of 90 per cent., as the works proceed, until one-half the contract is completed, when a further 5 per cent. will be advanced upon the amount of work executed. Similarly, 90 per cent., and 5 per cent. will be advanced, as regards the second half of the works, and also the remaining 5 per cent. upon the approximate value of the first half. But such advances are not to be made oftener than monthly; nor are they to affect any subsequent question, or

to be taken as admission of any particular work. A further advance of 2½ per cent. will be made in three months from completion of the works; or one of 1½ per cent. at six months; and the balance will be paid at the end of twelve months, provided the contractor shall have given a full account of all his claims, and the engineer shall give a certificate. Two surties, jointly and severally in 20,000*l.*, are to be found by the contractor; and no member of the Board is to be personally liable; the payments being to be made out of the funds in the control of the Board. Mr. Edmund Cooper will be the resident engineer, under Mr. Bazalgette.

The least difficult portion of the work, so far as foundation is concerned, would seem to be at Plaistow, where the hard gravel is reached within two or three feet, and where the invert of the sewer for about 2,500 feet of length, will be below the present surface level. In other cases, as near the Lea, where the greatest height of embankment will be required, there is made-ground to a considerable depth.

#### ON ROUND CHURCHES.\*

The Knights of St. John were so named, in the first instance, from their patron saint, John the Patriarch, and they were called also Hospitaliers, from their early connection with the hospital, or hostel, or hotel (for it is the same word), attached to the St. Sepulchre at Jerusalem, for the reception of pilgrims to the sacred places. Originally they were Brethren of Mercy attending on the sick, the poor, and the stranger, and rendering them the offices of hospitality and charity. But about the year 1113, when the disturbed state of the Holy Land drove them from these works of peace and love, the lay members of the society drifted themselves off into a new order, under the name and guardianship of St. John the Baptist, taking the three vows of poverty, chastity, and obedience, and making the defence of the holy places and their visitors the main object of their union. These Knights Hospitaliers of St. John, being first called of Jerusalem, were afterwards known from their possessions and change of domicile, successively as Knights of Cyprus, of Rhodes, and of Malta, at which last place many vast buildings and unceded records yet remain. Their dress was a black cloak, with white cross, in contradistinction to that of the Templars, which was white, with a red cross. They became exceedingly powerful and numerous in England, and at one time, after they had acquired the possessions of thir-dissolved Templars, they had as many as 53 establishments or "commanderies" ("preceptory" was the name assigned to the Templars' houses) in this kingdom, of which I may mention one—Dingley, in this county, in the cellars of whose modern houses there are yet, I believe, remains of ancient vaulting, as early as the time of the Knights' proprietorship of the place. Long after their occupation was gone they lingered on, a rich and dreaded body, who might longer have stood their ground, and kept their own, had not the sweeping revolution of Henry the Eighth whirled them along in the wholesale destruction of all kindred societies. However, they had spirit enough to "die game," and our native historian, Fuller, speaking of their dissolution, says:—"The suppression of the Hospitaliers deserveth especial notice, because the manner thereof was different from the dissolution of other religious houses, for manfully they stood it out to the last, in despite of several assaults. The Knights Hospitaliers (whose chief mansion was at Clerkenwell, nigh London), being gentlemen and soldiers of ancient families and high spirits, would not be brought to present to Henry VIII. such piling petitions, and public recognitions of their errors, as other orders had done. Wherefore, like stout fellows, they opposed any that thought to enrich themselves with their ample revenues, and stood on their own defence and justification. But Barabas-day itself hath a night, and this long-lived order, which in England went over the grave of all others, came at last to its own."

And this last grave of its last prior is yet to be found in this county. In the parish church of Rushton (removed, I believe, from the destroyed church, which stood in the last century close to the hall), is the beautiful monument of Sir Thos. Fresham, in his robes of prior of the order of St. John of Jerusalem. Though Henry VIII. suppressed the order, Queen Mary revived it on her

\* See p. 623, ante.

attainment to the throne, and appointed St. Thos. Tresham, well regarded for his adherence to the unreformed faith, as the head and prior of the order in England. He died shortly after, and this most unique and curious, but little known, monument (of which I am enabled, by a friend's kindness, to exhibit a most faithful drawing), remains a singular memorial of the last brief revival of this ancient society; though I have an indistinct recollection of seeing, on the walls of the Royal Academy, either this or last year, a full-length portrait of Sir G. Bowyer, M.P., in the robes of the prior of the Knights of Malta.

Still grander monument of the order, and in closer connection with our present subject, is the round church of Little Maplestead, in Essex, the most perfect of all the crusade churches in England, and which, by the cruel irony of Time, though still a parish church, has passed from the patronage of the world-known and dashing Hospitallers into that of an obscure and feeble sect of Sabatarians.

Founded within a few years of the same time (1118) was the order of the Knights Templars, who were of a more exclusively military character, and effected no deeds but deeds of arms. Nevertheless, the rule of discipline was strict, and after St. Bernard's rule. They took their name from a palace adjoining the Temple at Jerusalem, which was appropriated to their use by Baldwin I. Their dress was a tunic of chain-mail, with a long white cloak, on which a red cross was subsequently engraved, and became their well-known badge.

They came to England in Stephen's reign, and first settled in Holborn, whence they removed to the site nearer the Thames, which, though the arms have yielded to the gown, and the long white cloak of the soldier to the long black robe of the lawyer, still retains the name of the "Temple," and rejoices in that round Temple Church, which exhibited almost the first noble, though still imperfect, example of the spirit of church restoration which has since so widely spread. The pride and haughtiness of this order brought it to an early fall, and though the name of the Templar is more popularly known than that of the Hospitaller, the existence of the former society was of far shorter duration, the Templars having been, with great severity and cruelty, suppressed in the thirteenth century, and their lands passed over to their more fortunate rivals. Of their domains, of which the Hospitallers took possession, I may name as places probably familiar to most of you, Temple Bruern, in Lincolnshire (described in the volume of our architectural reports for 1858), Temple Balsall, in Warwickshire, and Rothley Temple, in Leicestershire. I do not find that they were ever established in Northamptonshire, and I am told to-day that they had possessions at Hardwick.

The ground-plan of the Temple Church is the least elegant of all that remains, the round being smaller in proportion to the rest of the building, and forming rather a vestibule than the chief feature of the church. It differs from our own church in having twelve instead of eight piers, and so far has closer resemblance to the plan of the original. In its triple arches, opening from the rotunda into the chancel, it follows its Northampton sister.

We have, then, the round church of the Temple built by the Knights Templars, the round church of Maplestead by the other great society of the Hospitallers, while in the other two round churches, of Cambridge and of Northampton, can be traced no connection with either order; but they sprang, in all likelihood, from the unaided bounty of individual benefactors; that of Cambridge from some unknown pilgrim or crusader, whose name has perished, though his good work remains; that of our own town, from indirect but very convincing evidence, may almost surely be attributed to the first great name in Northampton annals,—Simon de St. Liz, first Norman earl of this county, the founder of the castle, and of St. Andrews, twice a pilgrim to the Holy Land, and whose name has become so identified with Northampton as to have gained a settlement in the racing card of the spring meeting.

Twice, at least, after the erection of this church, was the town of Northampton prominently connected with the Crusades. On the 14th of September, in the year 1189, within a fortnight of his ascent to the throne, Richard Cœur de Lion assembled a council, at the neighbouring Abbey of Pipwell, of all the English and Irish Bishops, the Abbots and Priors, and lay nobility, to organize a crusade for the recovery of the Holy Sepulchre;—and, no doubt, the now remote site of Pipwell was selected, both for its central position as regards the whole kingdom, and its contiguity to the neighbouring commandery of Dingley. After

his return to England in 1193, Richard kept his Easter with great pomp in this town, and, we may hope, knelt in thankfulness in the round church of this town, so suggestive of the object for which his wars and his perils had been undergone.

Again in 1240, the twenty-fourth year of Henry the Third's reign, a gathering of nobles took place in Northampton, previously to their setting out for Jerusalem; and again on Midsummer-day, 1267, in the fifty-second year of his father's reign, Prince Edward, with upwards of a hundred knights, here assumed the cross, previous to their departure for the Holy Land, in the presence of the King and the Queen Eleanor, who was afterwards to be so gracefully bound up with the associations of Northampton in the beautiful cross which is the finest architectural monument it can boast.

There are other slighter connecting links between Northampton and the Crusades, which I pass over, not professing to have made any research into the subject beyond what may be found in the commonest histories of the place. You may expect me, however, before I conclude, to refer to the past and existing state of your own church, though that subject has been more fully and faithfully treated by Mr. Poole this morning. I need hardly tell you how sadly the original form has been marred, even in times to which we have generally given the credit of knowing better. Originally consisting only of a round and an apsidal chancel, the present round pillars were some 2 feet lower than they now are. They supported an open gallery or triforium, and above that was a circular clerestory (not octagon, as we now see it), crowned by a conical roof. The circular aisle (if I may so call it) running round the pillars was groined over. There were round-headed windows, alternating in position in the aisle and triforium, some of which yet remain. Probably, in the fourteenth century, the roof and vaulting had decayed, and the restorers in those and subsequent days thought it cheaper to pull down the whole of the vaulting, turn the two lower stories into one, raise the piers, put up pointed arches, insert large windows, add chancel aisles and two more arches into these new aisles, turn the round clerestory into an octagon, and otherwise mar the original design. Subsequently the tower and spire were added at the west end; and then, in still more recent times, followed the abandonment of the chancel and its aisles, the accumulations of galleries and pews, stoves and pulpit, into the round: so that it has been said, and I know it to be a literal fact, that strangers have gone into St. Sepulchre's to see the round church of Northampton, and have come out again conceiving that they had mistaken the building, so utterly is its characteristic form obliterated. Now, whether we shall ever restore it to its original form, whether even it is desirable to attempt to do so, to make it again "as round as the O of Giotto," I will not undertake to say. When we have placed the congregation in the new nave beyond it, and the choir in the new apsidal chancel, still further eastward, it will be time to see what can be done with the round. It will, at any rate, be a vestibule to the church, at the same time that it forms a most noble baptistery, with the font in the centre. The plans before you will show that, in round churches, the round was not always the nave, as it was originally here and in all the English churches. Sometimes it formed merely the vestibule, sometimes the nave; sometimes was placed between nave and chancel, sometimes formed the chancel itself, or the apse, eastward of the chancel. Sometimes it was an attached chapel, sometimes a detached baptistery or tower. But in all these churches, which were distinctly imitative of the rotunda of the Holy Sepulchre at Jerusalem, it formed the western or nave portion.

Symbolically, the Round church has its significance; imitatively, its associations; and, aesthetically, its beauty; but its circular form is not fitted—never was fitted—for devotional and congregational purposes.

There is one case only in which it is well suited for liturgical use, viz. for the administration of the sacrament of baptism. To this the round form was early devoted: to this it should have been confined. For a ceremony admitting many spectators, directed to one central object, no form could be more beautiful or more convenient. But it is not suited for the Holy Communion, nor for prayer, nor for preaching. Your own experience in St. Sepulchre's, and its present anomalous arrangement, prove that it was a bold thing, therefore, for a lecturer in this town, not long ago, with such an example close at hand, to advocate the

round form for English churches. There are fashionable watering-places where the experiment has been tried, and octagon chapels were once becoming popular in London, but even as mere preaching-houses their form is inconvenient, and still less is it adapted to the Liturgical services of the Church of England.

It is well, therefore, that you propose to give up the Round for congregational purposes, and place the worshippers in the rectangular portion eastward, reserving the round as a most noble vestibule, and most appropriate and serviceable baptistery, in the centre of which a font, worthy of the position, may, I hope, soon be placed as a memorial to the late Marquis of Northampton, who took so much interest in the church, built by the first Norman earl of the same title. When the contemplated extension of the church is completed, and the present cumbersome fittings of the round swept away, I can conceive no interior more picturesque and unique than what St. Sepulchre's will furnish to a spectator standing under the western tower, which will then constitute an outer porch. I feel sure that there will not be one contributor to its enlargement and restoration who will not feel that, whatever he may have given, it will have been more than repaid him even by the architectural effect produced.

Before I conclude, I would briefly sum up the inferences which may be drawn from the very cursory and imperfect statements I have made on the very wide and as yet unexplored subject of Round Churches. You will at least have seen that our four round churches are only a small remnant of a much larger number which once existed in England, and that of the Templars or of the Hospitallers, though probably in almost every case (the round chapel of Ludlow Castle perhaps being one exception) with some crusader, or pilgrim to the Holy Land, and therefore constructed in imitation, more or less direct, of the Rotunda of the Holy Sepulchre at Jerusalem; in all which cases, as I have said, the "round" constituted the nave or western portion.

But from the earliest Christian ages, and linking on by subtle but unbroken chain, with ancient Rome and Greece, and indeed with the monumental history of almost every people, there existed a series of tombs, towers, temples, baptisteries, chapels, of circular or curvilinear form, which had no connection with the Holy Sepulchre (except that it was itself one link in the general chain), and which, quite irrespective of any imitation of that sacred building, are to be traced in the round portion, wherever situated, of the ecclesiastical buildings of the Middle Ages, and which received their greatest and final development in the manifold and unlingular apses, which constitute so striking and beautiful a feature of the finest continental churches.

In contradistinction to the use of the rest of Europe, England kept steadily, as a rule, to a square east end, and though at Canterbury and Tewkesbury, and in a few other noted examples, the circular form appears, yet often, with obstinate and hardly excusable persistence, as at Peterborough and Westminster, she capped the curved apse with a rectilinear addition, protesting, as it were, against the foreign element, and reserving the round form for the western end. Round apses have been a favourite re-creation with modern architects, and where, as in the new chancel of St. Sepulchre's, they can give the reason why, there can be no objection to their introduction, but a new round church we can never hope, never wish, to see again: the reason and the feeling for it are past; and its form, which was ill-suited even for the unreformed church, is doubly so for our own. As a baptismal vestibule, nothing can be grander; but in these days we want too much room for our congregations to be able, in a new church, to throw away so much space on mere architectural effect. The more incumbent upon us, therefore, is it to preserve that unique and beautiful feature, when we find it here. The fifth round church in England we shall never see; but we may yet make ours the most remarkable of the remaining four. There is more of the original in Maplestead, more completeness in Cambridge, more splendour of decoration in the Temple; but for size and usefulness, for correct arrangement and artistic effect, for local association, and, above all, for supplying the urgent spiritual wants of a daily increasing parish, the work which your committee has taken in hand will, if carried out in its integrity, yield to no church restoration, whether of round church or square; and will, when finished, become the glory, as it has hitherto been the shame, of Northampton. That work is now thrown upon your

hands, and I fully believe that you will accept the responsibility, and carry it out. Don't trust to great men, or to rich men, or to strangers; but do you, the middle classes of Northampton, hold it to be an honour that you have such a church to restore and enlarge, and enlarge and restore it accordingly.

SOCIAL SCIENCE IN GLASGOW.\*

EACH morning's business of the Social Science Association was opened with an address in the City Hall to the whole body, from the President of one of the Departments, and then the members dispersed themselves to the various sectional meetings to hear and discuss papers. These sectional meetings were held in the College Schools, which have but one entrance, and that close to the platform, so that they were very inconvenient. On Thursday, the address in the City Hall was read by the Hon. A. F. Kinnaird, M.P., on Punishment and Reformation; on Friday, Sir James Emerson Tennent spoke eloquently on Social Economy; and on Saturday, Mr. Edwin Chadwick discoursed on "Public Health." These presidential addresses have been fully reported in the journals. We must confine ourselves at present to the papers and discussions in one or two of the departments which more specially belong to us, but shall refer hereafter to Mr. Chadwick's address. Of some of the papers and remarks on "Trades Unions and Strikes" we shall also make mention under a separate head.

Returning, then, to the proceedings on Tuesday, a paper was read by Mr. John Watts, Ph. D., on

Co-operative Societies,

which the writer thus concluded:—

Although the possibility of great success and of great usefulness is now demonstrated, the further spread of these societies is not likely to be barren of failures any more than will future individual enterprises; but a few failures do not stop general trade, nor will they stop the progress of co-operation; nor is it likely that, with ordinary prudence, the Court of Chancery will be often troubled to wind them up. They are, of course, open to the common danger of a business entrusted to management,—the danger of dishonesty; but, where all the assistants are shareholders, and working under superintendence, and obliged to deposit security either by private bond or by the policy of a guarantee society, a greater danger than dishonesty is deficient judgment in the selection and purchase of goods. A well-conducted co-operative store is a large business with a guaranteed round of customers and cash payments, and therefore with very little risk of bad stock, and none of bad debts. But if inferior goods are supplied, or more than the average market price is charged, the general public first comes to buy, and then the members, one after another, draw out or sacrifice their shares in preference to paying more than market price, even with the prospect of getting a portion of it back again as profits. So, in a co-operative manufactory, if well conducted, it is not only a safe place of work, but it is a land and building society and savings bank combined. Every workman, being interested beyond mere wages in the success of the concern, will endeavour not only that a full day's work shall be done, but also that it shall be well done; and the result will be that the yarn, or twist, or cloth of that mill will command the market; but if the manager be not a good buyer, and so gets inferior material to work up; or if the workpeople have not confidence in the manager and his assistants; then the goods will deteriorate in quality, and the market will be lost. A few years ago a co-operative manufactory concern was started at Fallowfield, in Lancashire, and at first made good progress; but in course of time too many of the workmen wanted to be overlappers, and they came to quarrelling. They had invested about 7,000*l.* and were owing about 9,000*l.*, a sum which continued to increase very soon have covered; but during the quarrel one of the shareholders broke into the mill at night, and cut out a large proportion of the wares from the looms. The creditors, looking forward to a certain loss by such proceedings, came at once upon the estate and realized, and the shareholders lost the whole of their money. Another manufactory was started in Pendleton (Manchester), and from similar causes had the same kind of result. But the rocks which wrecked these attempts are now marked on the map of co-operative progress; and, it is hoped, sufficiently marked to be avoided in future. And instead of wondering at the progress of these efforts by working men, to secure a larger share of the fruits of their own toil, we shall begin soon to wonder why strong existing organizations do not adopt the principle; why, for instance, the 20,000 members of the Amalgamated Engineers' Society do not apply their 100,000*l.* stock to the establishment of a co-operative steam-engine manufactory, a boiler manufactory, or a nail and locom manufactory; why the masons do not use their trade funds in working contracts on their own account; why the bricklayers, joiners, and painters do not build and finish houses, either by contract or for sale; and why, in any case of dispute with employers, such as led to the great strike at Preston, or in the late case of the building trades in London, or the strikes at Coventry and Colne, the workmen, instead of striking work and the country, do not continue to work, and, by increasing their subscriptions to the trade society, in due time gain the power of the pence in establishments of their own. Such a course would increase, instead of decreasing, the wealth and comforts of society; would raise instead of demoralising the men; and would bring a new element into the competition of employers, showing them that, whilst the utmost cheapness of production consistent with the welfare of society is desirable, it is necessary at all times to consider the connection between the amount of wages paid and the possibility of an intelligent man bringing up a family thereon.

Sanitary Legislation.

On Wednesday, in the department of Public Health, Mr. Mouteith, of Carstairs, presiding,—Dr. Lankester made a spirited and telling address on the results of recent sanitary legislation in the metropolis, and described the working of the Metropolitan Management Act. One of the great functions of civil government, he said, was to protect the life in the community out of which it sprang. This was necessary to its religious and moral existence. It was only as the health of the body was protected that it became a fit and proper receptacle of the mind; and that was a general position which should be held prominently in view. The sanitary affairs of the people were generally entrusted to small boards or vestries; and these could not be easily convinced that disease and death among the people was an expensive thing. They did not think in the same way of their cattle, just because animal life was a marketable commodity. Amongst the blacks in America, the money worth of a human being was better realised. Now the money value of lives in this country was of much greater value, though this was overlooked. Supposing the life of a human being were worth 100*l.*, and that the rate of mortality of any locality were found to be very high, such as had been shown to be the case in Greenock; they could easily see the vast amount of money that was squandered away by the neglect of sanitary laws, and which might be turned to a much better account. They should try to realise the value of a human being in a money point of view, and they would see that disease and death were very expensive things. Speaking of the duties of the medical officer of health and the sanitary inspector in London, he said he himself had been called, a short time ago, to the Marlborough Police Office, and had found the cells there in a very dangerous condition from the want of proper ventilation. Churches and theatres had been found to be very badly ventilated; and the influence of the public officer had been found to be of great value in remedying these buildings. Workshops, too, were often found to be in a very bad state from the same cause, and employers were not so ill to deal with as the prejudices of the workpeople themselves. Amongst them there appears to exist an impression that a workshop could not be properly ventilated without being dangerously cold. The people could not be impressed with the value of fresh air in their apartments. Every room must be imperfectly ventilated the windows of which did not come down at the top; and yet people could only with the greatest difficulty be induced to go to the expense of having their windows so constructed. In towns where the death-rate was fifty in the thousand, that was murder; and he hoped the day would come when corporations who showed such a rate would be arraigned for it criminally. The kitchens of old houses there, which were underground, were generally occupied by families, and were found to be a very great source of disease. He found from a paper, which had been read in reference to Glasgow, that in some places people lived where there was only a space of a yard and a half to each person. People would not keep the inferior animals in such a space. A cowkeeper would never dream of adopting such a course with his cows. He referred to the original bad construction of Burlington Arcade, where the death-rate had been thirty in the thousand; but the roof had been raised, and a better state of ventilation introduced.

One of the worst-drained houses in the metropolis had been that of the Bishop of London; and, during the absence of the bishop, he had visited the house, and introduced some alterations, which would have a beneficial effect, he hoped, on the health of the bishop for the future. He would like to see an organization, having for its object the improving the public health. They had lately seen what had been done in the great volunteer movement; let them organise, in the same way, a system by which they would have healthy mothers and healthy children to form these volunteer corps. The speaker concluded by recommending, to the notice of all, the efforts of the Ladies' Sanitary Association.

Architects and Sanitary Arrangements.

Mr. Chadwick impressed upon the meeting the necessity of getting returns of the disease and death rates of the community, by which they could at once see upon what portion of a town there was the greatest necessity for operating sanitarily. He had sent down to Glasgow to ascertain the death rate, but found there were no available data. There was no measure of economy so profitable as enforcing such a return. It was easy to be got, and would be sure to be followed with good results. Architecturally, sanitary science was a department which ought to be cultivated. Medical men should be enabled in these times to send their prescription, not only to the apothecary, as they had been in the habit of doing, but to the architect. He thought that architects were scarcely doing their duty in this respect, or houses would not be built as they were, with all the old defects and inconveniences. If architects were paying attention to these matters, he hoped Mr. Godwin would tell him so. As to hospitals also great improvements were needed. Mr. Godwin said he could not allow Mr. Chadwick's inquiry to pass without stating on the part of architects that they had, unfortunately, nothing whatever to do with the great mass of habitations erected in the United Kingdom; and that, even where they were employed to design private houses, the question of expense, and dislike to novelties felt by employers, prevented the introduction of new inventions and arrangements. With respect to hospitals, what had been done for many years past in this country was most unsatisfactory; but he believed attention had been awakened to the advantages of what was known as "the pavilion principle," which he and others had been advocating for some time. It was distressing to see what had been done by the Government. As to the great hospital at Netley, where thousands were being spent, he had pointed out, in the *Builder*, when the first stone was laid, the error of the plan, and asserted that, if so carried out, it would destroy more than it cured. This view had been confirmed by Miss Nightingale and others to the fullest extent.

A paper by Mr. G. W. Muir, on "Sewers and Sanitary Reform," was read, in the course of which it was argued that the present system of connecting the water-closet with the common sewer should be given up. The writer advocated the use of a Dry Closet (D. C. *versus* W. C.), wherein earth was used as a deodorizer. A model was exhibited.

Mr. John Carrick, Superintendent of Streets and Buildings, Glasgow, read a report on the

Drainage of Glasgow,

in the course of which he said:—

"In 1816 five miles of common sewers had been formed. At the present time there are sixty miles of sewers, nineteen miles of which have been formed since 1848.

All the sewers are, with one or two exceptions, of brick-work, varying in size from 2 to 8 feet diameter, and, at present there are no fewer than 13,000 water closets upon the water, the bottoms being formed to the curve of heavy freestone (which is plentiful in the neighbourhood) or moulded blocks of glazed ware, all set in hydraulic mortar or cement.

The water-closet has now become universal in the dwellings of the upper and middle classes, and also in the better description of houses for the working classes. At present there are no fewer than 13,000 water closets within the city, in connection with dwelling-houses, and many of the factories and warehouses are provided with them.

The amount of drainage from the various manufactory, distilleries, chemical works, dye works, &c., is very great. Excluding the water of the Kelvin, it is estimated that 40,000,000 gallons of sewage are daily discharged into the Clyde.

The Clyde and its tributaries have become exceedingly foul and offensive in summer weather, and various schemes have been laid before the authorities having for their object the purification of the river and the profitable disposal of the sewage. Mr. Manning proposed to precipitate and deodorize the sewage. This scheme was reported on at great length by Dr. Anderson, Professor of Chemistry in the University of Glasgow, Mr. Bateman, of London, Engineer for the Water Supply of Glasgow from Loch Katrine. Experimental works were erected

by the Town Council, at a cost of several thousand pounds, near the outlet of a most noxious common sewer, and experiments were conducted in the direction of these gentlemen by Mr. James Napier, a practical chemist of great experience. The result of their investigation was embodied in a report addressed to the Sanitary Committee of the Town Council.

In the discharge of my official duties my attention has been directed to the improvement of the drainage of Glasgow, and the purification of the sewage of these gentlemen by Mr. James Napier, a practical chemist of great experience. The result of their investigation was embodied in a report addressed to the Sanitary Committee of the Town Council.

A system of public water-closets has been adopted during the last few years, the contents of which are removed daily, and not allowed to pollute the drains and sewers; and the local authority is now enforcing the adoption of an improved older closet and refuse bin in various districts of the city, the general adoption of which will go far to ensure the comfort of the inhabitants.

The Rev. William Arnott read a paper on "The State of the River Kelvin in the neighbourhood of Glasgow," wherein the ludicrous and the horrible were mingled. Through the romantic valley of the Yarrow, he said, flows a stream of about equal value with the Kelvin. The manufacturers below have acquired the right and the power of strong water in the great natural basin of St. Mary's Loch, towards the upper part of the valley, in order to equalize this supply during a period of drought. For that purpose they diminish the flow during the night and the Sabbath, but a clause in the engagement firmly binds the parties to keep a certain amount of water always flowing, and never leaving the bed of the river at any part for a moment dry. Why? Because there are trout in the stream, and every security is taken for preserving them alive. Ah! if we had trout in the Kelvin, or if we who live on its banks were trout, there would be a law binding all the millers on its borders to keep a perennial flow of water in its bed. The inhabitants of the west end of Glasgow might be addressed in the classical apostrophe, slightly altered in accommodation to circumstances, "Flesh, flesh! Oh, wert thou fishified!" But as only the lives of men and women are at stake we must take what comes.

Mr. J. Newlands read a paper on "The Sanitary Statistics of Liverpool." He adverted to the evils attendant on overcrowding of houses and the bad construction of houses—the result of a gross, if not a criminal parsimony. In Liverpool, in one very bad district, they had grappled with the overcrowding evil, though it had cost as much as 88. per square yard. Having referred to the overcrowded state of certain districts in Liverpool, he detailed the means taken to lessen the evil, by means of house visitation by sanitary officers, who ordered cleansing operations. He exhibited a table showing the sanitary improvements which had taken place in this city within the last twelve years, together with its increase.

Mr. Bateman, C.E., described the difficulties which attended the drainage of Glasgow, and detailed how useful McDougall's disinfectant powder had been in deodorising the sewage of Carlisle, and also of Tavistock sewer, London; and said that at a cost of 5,000, or 6,000, the whole sewage of Glasgow could be purified for a year.

Dr. Lankester objected to trusting to deodorisation, but would rather have sewage kept out of rivers, and said that so bad was the Kelvin, that he would forbid any one connected with him from walking near its banks.

*Dwellings of the Working Classes.*

In the Department of Social Economy, Mr. H. Roberts read a paper "On the Progress and Present Aspects of the Movement for Improving the Dwellings of the Working Classes." He began by directing to some of the recent Acts passed having reference to the improvement of the dwellings of the working classes; and then stated a number of facts connected with the condition of dwellings in Ireland, and showed that it had been estimated that there were no fewer than 135,580 single-room cabins in that country. He remarked that a great step had been taken in the right direction by Parliament, in having during last session voted 30,000, for the accommodation of unmarried soldiers. Mr. Roberts alluded to the operations of various building societies in London and various parts of the country, and dwelt on the advantages that had been derived from them, both financially and otherwise. In one instance, on an outlay of 13,200, in providing accommodation for about 125 families, there was a clear return of 55 per cent. He thought that, even for self-interest, the parochial authorities in towns ought to encourage the building of such houses. The number of new buildings of this description in London was but as a drop in the bucket compared

with what the extent of its population required. He then referred to the improvements that had been made in the domestic arrangements of many persons in London, as the results of the efforts of the Female Domestic Mission, which was carried on by 130 agents, combined together to promote the physical, moral, and spiritual well-being of the lowest classes of the population.

Mr. Roberts afterwards gave "Examples of Efforts in Scotland to provide Improved Dwellings for the Working Classes." He said that his recent sojourn for a few days in the capital of Scotland, a city unrivalled for picturesque beauty, and remarkable for the classic elegance of so many of its modern buildings, had revealed to him what he had not seen on former visits,—a degree and extent of wretchedness which has exhaled more painful feelings than all that he had witnessed of a similar character during a long residence on the Continent. Even amidst all the misery and degradation which might be seen in the back slums of Paris, Genoa, Rome, and Naples, the vice of drunkenness rarely outraded itself, and was certainly but to a very slight degree, as it was with us to a very considerable extent, both the cause and the consequence of the miserable state of the dens which so many of things were called their homes. Such a state of things was a reproach to our country and to our Protestant Christianity. The Pilgrimage Buildings, Leith-wall, were the first of that description erected in Edinburgh. The construction of these houses originated with a number of gentlemen who were accustomed to visit the district in which they were situated, with a view to the spiritual and the temporal improvement of the labouring classes. Besides these, there were in Edinburgh and its suburbs eight distinct blocks of dwellings, either completed and occupied, or now in progress; three belonging to associations, and five to individuals, one of whom was a lady of property. Mr. Roberts concluded by referring to the efforts that had been made in Dundee and Aberdeen, and stated that the financial results had been on the whole satisfactory.

Mr. James Salmon read a paper "On Working Men's Houses:"—

In the investigation of this subject it is difficult to point to any circumstance more aggravating and alarming than the fact, that the houses built for the working classes some fifty or sixty years ago, especially in the suburbs, were much better adapted for securing the health, comfort, and morality of their tenants than those generally erected now. To verify this fact, we have only to visit Bridgeton, Calton, Tradeston, and other suburbs, where the streets are wide, the houses two stories high, and behind each an ample court or green. Unfortunately, distinguished from this, we find, increasing in every direction, tenements of houses of four and five stories in height, besides sunk stairs, with scarcely as much space around them as furnish a dim light to the tenants. Trying these two classes of houses by the test of square area, it will be found that these old suburban two-story tenements were so constructed as to provide each inhabitant with from 20 to 30 square yards of area, while many of the modern tenements too often provide little more than from two to three. As for many of the older portions of Glasgow, on both sides of the river, the census of 1841 revealed the startling circumstance, that the square area on which they stood did not admit of more than from one to two square yards of space to each resident. The importance of this fact as a test of health or salubrity will be better understood when contrasted with the square area which has been provided for the upper and middle classes of Glasgow districts occupied by the working men, and in those occupied by the middle classes, from twenty and forty square yards provided for each inhabitant. Let even the worst houses above ground in any ward or vennel of Glasgow be removed to an open locality, where it can share the sun and wind of heaven, and it will be infinitely more healthy and desirable as a residence than the best provided house we have, if squeezed into a place of Gorbals or High-street close. Indeed, I am convinced that the whole of this great subject is bound up in the question of "space or area." Provide what other requisites you please for our workmen's houses, nothing will compensate for the want of light and air. With this knowledge it is lamentable, as already stated, to know how many houses for the industrial classes are still building on principles which set this law of existence at defiance. In England, a very large proportion of the labouring classes inhabit self-contained houses, each family having their own entrance and their own back yard. But what will our friends from the South think when we tell them that, on the space which answers for five or six of their houses, the people of Glasgow erect a lofty tenement to accommodate from sixteen to twenty-five families? What I am at, in the first place, is to correct the erroneous principles on which in Glasgow the houses for the industrious classes have been blocked off and erected. Mr. Salmon here called attention to a plan upon the table, exhibiting four sections of dwellings-houses as they exist at present in four different localities of Glasgow. One was a dwelling-house of the upper classes in Sauchiehall-street, another a middle-class house, a third a working-man's house in Anderston; and another in Gorbals. For the first, for each inhabitant a space of 60 square yards was provided; for the second 40 yards; for the third 20 square yards; and for the fourth 14 square yards. This crowding of human beings into these breathless continuities accomplishes its mischief in too many ways to be easily understood. Permit me now to refer to one or two of the causes which have led Glasgow into its present unfortunate position. As for the older portions of the city, it may be supposed that a good deal of the crowding arose from sheer thoughtlessness. The naturally brings me to refer to what has now become the

great cause for this perpetuation of confined courts and narrow lanes, and this building up of five or six stories of human beings one above another. That cause is the high price of ground. At this moment in Glasgow, ground in what would be reckoned a convenient site for work-houses, cannot be purchased at a less rate than 100,000 pounds per acre. At that amount as it absolutely necessary for the bare necessities of health and morals, there would be imposed a mean yearly rent on each small dwelling of 5l. before even a single stone of the building was erected. The arresting and gradual healing of these frightful evils appear to me to lie chiefly in four directions—viz. in the efforts of philanthropy, in the efforts of speculative enterprise, in the efforts of extensive employers, in the efforts of the legislature. Speculative enterprise could do much, especially with the older portions of the city, where the plague is blackest. Extensive employers of working men could do much to assuage the evils. Requiring, as these great firms do, to erect their works in the suburbs, for the sake of cheap ground, what hinders them to purchase a few acres more than required for business, on which they themselves, or others for them, might erect houses for their workers? On ground costing from five to ten hundred pounds per acre, such employers could build workmen's houses, with everything necessary to insure health, morality, and comfort; and, while giving them to their workers at moderate rents, would realize a fair return for their invested capital. Let the conditions be simply these—"And be it enacted, That, after this date, all new houses erected for the accommodation of the industrial classes of the kingdom shall provide a superficial area of not less than seventy square yards for each individual house or dwelling, including the back yard and the half of the street; that not more than six families shall approach their dwellings by one entrance or one stair; that not more than one family be permitted to live in each house; that no family occupying a house of 100 rent and under be allowed to accommodate lodgers without a license; and, finally, that each house, besides the living-room and its adjuncts, shall contain three sleeping compartments, well aired and lighted by large wall windows." Let such an enactment as that be obtained, and you will do more to stem the surge of demoralization which is sapping the health and morality of the people, than any other means which our humanity has the power to employ.

*The Meeting of Working Men.*

Wednesday evening was appropriated to this; and a most remarkable sight did the City Hall present, being crowded in every available spot with more than 3,000 earnest, attentive men, averaging as it seemed to us not thirty years of age. They were admitted by tickets at sixpence each, and it was understood, represented no fewer than 30,000 who had applied to be present. Foreign gentlemen who talk about the invasion of this country should see and contemplate such meetings as this of our hard-handed sons of toil. It had been arranged that each resolution should be seconded by a working man named by the working men, and very able representatives they selected. The first resolution was proposed by Lord Brougham, who presided, and whose reception was tumultuous; and was seconded by Mr. Wilkinson, in a clear and forcible address. He said, at the commencement of it,—"We are asked by this resolution to perform two things, viz.—firstly, to give in our adhesion to the objects of this Association; and, secondly, to furnish facts within our reach bearing on the different social problems under discussion. In seconding this resolution I am anxious in the outset to impress the fact that this labour sought for will be productive of important results. There is one naked and imperishable truth that should never be lost sight of by the working classes, viz., that there is only one step between us and the lake of hell, and that step on which we rest is broken, and the chances are that we ourselves go to swell the numbers in the workhouse and our children to augment the ranks of the criminal population. But give us health—surround us with those sanitary influences that will produce strength of body and soundness of mind—and at the same time let our conduct be regulated by those great moral principles on which we are all agreed; and, with these essential auxiliaries, bad as the world is, and Heaven knows that to us, who have to fight its hard battles, it is bad enough; yet, notwithstanding its corruptions and its commercial and manufacturing competitors all working against us, give us health and moral rectitude, and with these two accompaniments, we are prepared to fight the battle of life successfully. One of the objects of this Association will be to stimulate the necessary means and exertions to build suitable dwellings in suitable localities for the working classes.

Much excitement was caused by the speeches of two French visitors, M. Garnier Pagés and M. Desmartez, both warmly eulogized by the president. Mr. Kinnaird, Dr. Lankester, Sir John Pakington, and Mr. Fawcett, of the members, and Mr. McFarlane and Mr. Cullen, of the workmen, also addressed the meeting.

*Poverty and Disease.*

In the Public Health Department, on Thursday, Mr. J. A. Easton, M.D., read a paper on this subject, not omitting, in showing its various bearings, the results of the huddling together and

the over-crowding found in the dwellings of the poor.

"It has been well remarked," he said, "that of all the circumstances affecting health none is so important as the condition of the air we breathe. On it, more than on any other, depends the purity of the body. Let it be impure, and all the organs of the body are affected. It is well known, also, that in every portion of the oxygen which we breathe, in every drop of the water which we drink, and in every particle of the food which we eat, there is contained an equal volume of carbonic acid gas sent forth from our lungs; and thus, if dwellings be overcrowded and imperfectly ventilated, this deleterious gas corrupts the vital air of heaven. Hence the prevalence, in overcrowded localities, of typhus and other zymotic diseases. For it has been proved that, even with free ventilation, health and strength cannot be maintained in a space of less than from 700 to 800 cubic feet for each individual; and that to live and sleep in a space of less than from 400 to 500 cubic feet is dangerous to life, even though there be not, as there generally is, in our wynds and long narrow lanes—well-named lanes—the superadded evil of extraneous noisome emanations. Now, when the 'subjects' literally 'gather themselves together,'—when ten or twelve human beings are huddled into a space which only two should occupy,—when each miserable occupant, instead of having 800, has only 90 cubic feet to live in, and have his being,—can we wonder at the ravages of disease under circumstances so favourable to its propagation? In proof of the prevalence of disease in overcrowded dwellings, I submit the following facts:—The area of the city parish of Glasgow embraces 1,924 imperial acres, or about three square miles; and I have ascertained that, during the twelve months which ended on the 31st of August, 1859, there were 7,500 applications for medical relief among the necessitous poor who resided within the bounds just given. But the important circumstance is, that 1,592, or more than one-fifth of the whole applications, came from a portion of High-street, from Salmaker, Bridgegate, New, Old, and Back Wynds, which cover about a fiftieth part only of the area of the whole parish. Now, by actual measurement, and should be witnessed by the district surgeons, and witnessed by myself, it was found that the average space for each individual in some of those places just named was 210 cubic feet; and thus my own experience as a district surgeon, five and twenty years ago, confirmed by recent personal observation and the testimony of some of the district surgeons of the present day, attests that overcrowding still continues in these wretched localities, making them the hotbeds whence, during epidemic visitations, typhus fever may spread again, as it has often spread before, through the whole of Glasgow. No doubt there are other places, here and there, in which sanitary, as well as greater reforms, are much required: at the same time it is undeniable that the plague spots of Glasgow are concentrated in the district which I have just named, and that, on account of those, the whole city has been denounced for general insalubrity. But, while I regret that there is in the midst of this great community so compact an aggregation of morbid agencies, and should rejoice at their removal, I am glad to be either just or generous to characterize Glasgow in the aggregate as pre-eminently insalubrious, when it can be proved to the satisfaction of every reasonable and unprejudiced person that small, circumscribed, and exceptional portions only deserve that unenviable distinction. But, even in these pestilential districts, improvement is visible; and, as this has resulted from what I conceive to be some of the modes of dealing with similar evils wherever they exist, I shall conclude this paper with a mere enumeration of a few of the remedies which either have been or might be applied. In the first place, the municipal authorities should exercise a vigilant supervision over all lodging-houses in the denser portions of large towns, and should insist that the space already spoken of as being essential to health and strength should invariably be provided. I am glad to notice that the police in Glasgow are attempting to root out this clamant evil, and that offenders have been brought to justice and punished. Further, an Act should be obtained, applicable to the United Kingdom, for regulating buildings, and for the licensing of dwelling localities. During the last thirteen years the Corporation of Glasgow has been acquiring, destroying, and rebuilding on old and unsuitable property in some of the worst parts of the city,—slowly, no doubt, and to a limited extent; but perhaps as well as the want of compulsory power and of a special rate will allow."

#### Drainage and Rivers.

In the Health Department, on Friday, Mr. Edwin Chadwick read a paper "On the Pollution of Rivers and the Economy of Sewage." Alluding to the charges brought against him in the House of Commons with reference to the system of sewage for London, and the use of the river Thames in connection therewith, the reader proceeded to explain the nature of his views on that question, applicable, as well, to all similar cases, and to defend the same against the propositions advanced by his opponents. By the adoption of the plans advocated by him in certain localities, he stated that the death-rates had been reduced one-third, and, in another instance, the pestilence, so well known in former times as the jail fever, entirely removed. While pursuing his investigations on the question of sewage, and before publication of his plans, he had had careful abstracts drawn out of those localities in the London district where epidemic diseases were most in the habit of appearing, from and upon which his report was founded. From these it appeared that notwithstanding the indignation of those who had raised such an outcry about the pollution of the Thames, it was immeasurably to be preferred, as a general system, that excremental matter should be at once carried off than allowed to remain till decomposition had commenced, under or contiguous to human dwellings. It was proved by statistics that the representations as to the noxious effects of the river had been very much overstated; as an example of which he would

adduce the rate of mortality amongst Custom-house tide-waiters, whose life was almost wholly spent on or beside the river, as against that of the Guards in barracks, altogether away from such a nuisance. In the former case, the rate was ten or eleven in 1,000; in the latter, twenty in 1,000. In his opinion, the fundamental principle in establishing a system of sewage was to have the excremental matter removed as rapidly as possible before decomposition or fermentation had set in; not, as under the old method, to allow it to remain to be carried off at some subsequent period. In concluding his paper Mr. Chadwick remarked that all plans for decolorizing sewage on a large scale had been found failures, and were now abandoned; and insisted on the necessity, according to his own theory, of its immediate and complete removal from human habitations.

We must now, however, hasten to a close, not stopping to speak of the *concretions* in the Galleries, in Sanchiehall-street, where the corporation have a large collection of pictures, or the banquet in the City Hall, on Friday, which was brilliantly attended, and passed off with great satisfaction. Enthusiasm prevailed up to the close of the congress, and it may be hoped that what was said and done will not be without good fruit in due time.

#### CONCRETE BUILDING IN THE COLONIES.

Mr. B. H. BARRAGE having sent a notice of the concrete employed by M. Coignet (an imitation as we have elsewhere shown of an English process), and having occasion to enlarge a building in Australia, made trial of it, and gives the following as the result of his experience, which he thinks may be useful to others, especially in the colonies. He says:—

The internal dimensions of the concrete building I erected are 21 feet long and 8 feet 9 inches wide in the clear; the walls are 6 feet 9 inches high; and the roof consists of a concrete arch 9 feet 3 inches high at the crown. One of the sides is formed by the garden-wall, which is of cob, 15 inches thick, against which a lining of concrete, 1 foot thick, was built. The opposite wall is of concrete, 18 inches in thickness, as is one of the ends; the other end abuts against a cob building, which was also fortified by a thin wall of concrete. The concrete roof is formed inside with a pointed arch, consisting of two segments, 6 feet 9 inches in radius, the rise at the crown being 5 feet, whilst externally it is dressed off to a double slope, like a common roof. The thickness of the arch is 11 inches at the crown, 1 foot 10 inches at the springing, and 6 inches in the thinnest part, which is at about two-thirds up. I have been particular in giving these dimensions, because no concrete roof of this form has, as far as I am aware, been hitherto constructed.

The foundations were dug out in the form of a trench, 18 inches wide and 18 inches deep, and filled in up to the surface of the ground with ordinary concrete consisting of one part of North Adelaide lime and seven parts of gravel and sand, taken from the bed of a creek. Upon this foundation a durable frame about 2 feet 6 inches high, and 10 feet long, similar to those used for making *piés* work on the Continent, was fixed, the sides 18 inches apart, into which the concrete for the walls was thrown, and well rammed in layers of about 1 foot in thickness. This concrete was made according to the proportions adopted by Coignet, and was mixed in the following manner:—Seven parts of sand and gravel and three parts of common earth were mixed together, and formed into a ring, inside of which one part of unslacked lime was put. Sufficient water was then poured in to slack the lime and convert it into a paste. After being allowed to stand for an hour or so, the whole heap was thoroughly mixed together, and more water added if necessary, so as to make the concrete sufficiently moist to run into all the corners of the frame. After being turned over with shovels it was thrown into the frame and rammed.

The concrete for the arched roof was formed of the same proportions as that of the foundations—namely, 7 of gravel and sand to 1 of lime, thoroughly mixed together in the same manner as the concrete for the walls. The ribs for the centres were made of 1½-inch deal, and were 4 feet apart, 1½-inch planks being laid upon them in layers like arch stones, and brought to the slope about 1½ feet of the arch was built first, and the centres were then struck and shifted forward to

build the remaining portion. The feet of the ribs were supported by wedges in order to allow of the centres being gradually eased.

That portion of the concrete of the walls which was made during the warm weather set sufficiently to allow of the frames being shifted on the following day; but, during wet weather, it was found necessary to leave them for two or three days. In order to tie the walls together at the angles, two pieces of 2-inch hoop iron, 3 feet long, were built horizontally into each wall at the corner, and were riveted to the corresponding pieces of the wall at right angles, making a kind of grid-iron in the angle; the further ends of the hoop iron were turned up for about an inch, to give them a better hold in the wall. Only one set of these ties were put in; but if I were making another building I should be inclined to put them in about every 5 feet in height.

The concrete of the arch, being made with a larger proportion of lime, set quicker than the concrete of the walls; but I did not think it safe to stack the concrete before three weeks had elapsed from the completion of either portion of the arch. On both occasions after easing the wedges and finding that the arch evinced no signs of any settlement, I proceeded at once to remove the centres.

It has been justly observed, that very often more is learned from a failure truly described than from a successful experiment; and, as my object in going into these details is to enable any one who may be inclined or obliged to become his own builder, I will proceed to point out the mistakes I made in not sufficiently supporting the middle portion of the centres, and in making the concrete for the first portion of the arch far too wet. Being accustomed to arches of stone and brick, in building which it is an object to key them in as soon as possible, so as to relieve the centres from a portion of the weight, I pushed on the concrete of the first 14 feet of the arch, so as to complete it in two days; the consequence was that the centres settled a little at the crown, and the weight of the wet concrete slightly pushed out the 18-inch wall, cracking it at the angle, and thus suggesting to me the use of the hoop-iron ties, which I adopted in the next portion I built. In settling, a slight crack was opened in the outside of the arch, at about 2 feet above the springing. A very few days sufficed for the concrete partially to set, and no more movement took place; but, as a matter of caution, before striking the centres, I built two concrete buttresses, 2 feet square and 6 feet high, against the 18-inch wall to support the thrust of the arch. The other wall, consisting of 15 inches of cob with 12 inches only of concrete, was not affected by the settlement, and I did not, therefore, build any additional supports to it. I believe that the 18-inch wall would have supported the arch very well without the buttress, but I was afraid to risk it in a first attempt. After the centres were struck, which was done in three weeks and a half from the completion of this arch, not the slightest appreciable settlement occurred. Warned by my experience with the first length of the arch, I took a week to the second one, and built hoop-iron ties, as above described, into the walls just below the springing. This portion of the arch was built during the wet weather, but it has set equally well with the first portion, and the centres were removed after standing the same time, namely, three weeks and a half.

The cracks on the outside of the arched roof were pointed with mortar made with blood instead of water, which set very rapidly; and a thin coat of common mortar was spread over the two slopes of the roof to make them smooth, which I intend to cover with a whitewash made of blood and lime, to enable it the better to resist the rain. The concrete arch was commenced on the 19th April, and completed on the 26th of May, and the centres finally removed on the 13th of June, so that it has had some very unfavourable weather to contend against; but, since the cracks were pointed, it has completely kept out all the rain. Both the concrete made with a mixture of earth after Coignet's receipt, and that made only of gravel, sand, and lime, have set very well, and promised with time to become as hard as a rock. I believe that concrete walls properly made, not the mortar walls used in Norwood, &c., are more solid and durable than the ordinary stone and brick walls in use in this colony, while a concrete roof has the advantage, not only of being fireproof, but of being, what is of great importance in this climate, exceedingly cool. In making larger buildings in this way I should advise the introduction of light iron tie-rods to assist the walls to resist the thrust of the arched roof, and I should

have no hesitation in making buildings of more than one story, in which case the floors should be made of a concrete arch with iron ties, and might be faced with cement and painted in oils in the Italian fashion so as to do away with the necessity for carpets in the hot weather. Concrete affords great facilities for introducing buttresses and other projections in building; and has, moreover, the great advantage of affording a surface to which stucco adheres so intimately as to become a portion of the wall itself, so that there is no danger of its peeling off as it sometimes does from a stone building.

In point of economy there is no comparison between concrete and other buildings. My walls cost 2s. 6d. a square yard for labour and materials, whilst for even a cobb wall I paid 3s. 6d., and an 18-inch stone wall costs 8s. a square yard. The economy of a concrete roof is also striking. My arched roof cost 2l. a square yard, being less than half the expense of a shingle roof; and, of course, considerably cheaper in proportion than either iron or slate. I should, however, state that I did not take the expense of the wooden frames, or the centering, into the calculation, as the same ones might have been used for a dozen other buildings. I should also mention that I had only half a mile to go for sand and gravel; but, on the other hand, as a set-off, I had to send six miles for the lime.

Settlers at a distance from towns, who find it difficult to procure skilled workmen, I strongly recommend to try this economic building; and even for stations in the Bush when, as often is the case, limestone is to be found. Concrete buildings would be nearly, if not quite, as cheap, as log huts; and, whilst being infinitely more comfortable, they would, being fire-proof, set at defiance all the attempts of the blacks to burn them, and thus, in case of an attack, enable their inmates to hold out until help arrived: in fact, to parties about to build, I say, try concrete.

#### MR. HERBERT INGRAM AND ILLUSTRATED LITERATURE.

Of late the hand of death has fallen heavily on men of mark in many walks. Some have dropped with great suddenness, and the public have been startled and surprised. In no instance, however, do we remember a more painful impression recorded than that which has been caused by the accidental death, the well-known originator and successful proprietor of the *Illustrated London News*. Mr. Ingram's career is encouraging to those beginning life; and he is worthy of honourable mention, as well for the good which he has done in advancing illustrated literature for the multitude, as for the energy and perseverance that distinguished him.

In 1811, Mr. Ingram was born in a humble home in Boston, in Lincolnshire. Here he received a useful amount of education, and was then apprenticed to a general printer. In that position he would be more likely than in a large metropolitan establishment to get a knowledge of the various branches of his business,—an advantage felt by many in this and other trades who are brought up in the provinces. On finishing his apprenticeship he removed to Nottingham, where he commenced business as a printer, bookseller, and newsagent. In the news department of a comparatively small but thriving establishment Mr. Ingram showed activity and judgment, and he managed to supply periodicals with a quickness which sometimes surprised his neighbors.

This shop brought him a certain amount of prosperity; and, in course of time, Mr. Ingram was induced to embark in the manufacture of a patent medicine—a "life-pill,"—by which some-what questionable means a large sum of money was made with extraordinary rapidity. While thus engaged, the idea of an illustrated newspaper, originating, it is said, in the success which had followed an illustrated handbill, was conceived, and the idea of it so matured, that, on the 14th of May, 1819, upwards of eighteen years ago, No. 1 of the *Illustrated London News* made its appearance, mainly with a view, originally, it has been asserted, to assist in making popular the life-pill. Much diversity of opinion was expressed respecting this venture, but at the time many thought that it must end in failure. Artists of skill were difficult to be had for the execution of the subject needed; and, as we have before said when alluding to the growth of our periodical literature, box-wood of sufficient size was not to be readily obtained: the system of steam-printing, too, was not then so perfect as it is now, and there were no organised means of obtaining sketches of events from distant parts of the country or from abroad.

In a well-written announcement in the first volume of the *Illustrated London News* it is stated that it was "determined to pursue the great experiment with boldness, and to associate principles with a purity of tone that may secure and bold fast for the new journal the fearless patronage of families,—to seek in all things to uphold the great cause of public morality,—to keep continually before the world a moving panorama of all its actions and influences."

It is curious to refer to the commencement of attempts which have led to success, and it is with interest we look at the illustrations of the first number of this periodical. On the front page is the same heading which is still used, and a small ill-executed view of the great fire at Hamburgh: the fashions of the day are ill-given; and, over the heads of various kinds of intelligence, are emblematical designs: the police reports are illustrated with rather coarse and humorous designs; there are besides some rather rough comical cuts with appropriate letter-press: on the last page there is a view of 200 men passing the Bank of England carrying placards announcing the publication of the "*News*." A marked improvement may be seen in each week's cuts: they become larger in size, and more hold and spirited in execution. A *l'al masqué* given by the Queen and other events were well engraved: notwithstanding, however, the sale did not advance; and the writer has been told that so greatly had Mr. Ingram's resources been exhausted, that it was feared it would be necessary to stop the publication. Mr. Ingram was, however, strongly impressed with the idea that there was no staying the advance of art into all the departments of our social system. It had begun in a few isolated volumes, stretched itself over fields of natural history and science, and penetrated our general literature. At one plunge it was in the depth of the stream of poetry, working with its every current, partaking of the glow and adding to the sparkling of the glorious waters, and so refreshing the very soul of genius, that even Shakespeare came to us clothed with a new beauty, while other kindred poets of our language seemed as it were to have put on festive garments to crown the marriage of the Muses to the Arts. Then it walked abroad among the people, went into the poorer cottages, and visited the humblest homes in cheap guides—and, perhaps, in roughish forms,—but still with illustrative and instructive principles strongly worked upon and admirably developed for the general improvement of the human race. Lastly, it took the merry aspect of fun, frolic, satire, and badinage, and the school of the *Charivari* began to bleed itself with the *gambol* of Henry's Cyclopaedia and Saturday Magazines. He, therefore, persevered; and, on the occasion of the Queen's first tour in Scotland, so great was the general enthusiasm and so novel were the illustrations, that a great demand was created, and from that time the publication might be said to be firmly established.

Although not endowed with a very great or refined knowledge of either art or literature, Mr. Ingram had the faculty of selecting what was interesting to the general public. He was liberal in his treatment of those whom he had occasion to employ, and strictly punctual in his arrangements with artists and others. This and the advancing reputation of the publication made the supply of news and sketches more regular: Mr. John Gilbert (who did much to advance the paper) and other artists of ability were employed, and no cost was spared in sending competent persons to places where extraordinary events were occurring.

During the long period wherein Mr. Ingram kept the management in his own hands, he showed that perseverance which is so often the means of success, in very distinctly keeping his publication to the illustration of the passing events of the day. Respecting the correspondence, he was carefully particular; and in the production of fine-art blocks which had a reasonable interest he did not begrudge any expense.

As the circulation of the *Illustrated London News* grew, Mr. Ingram showed much administrative ability in the arrangement of his now extensive establishments. Old buildings were purchased, demolished, and rebuilt in a substantial form; powerful engines of the best description were purchased; and the whole business was arranged with remarkable regularity. In the midst of this success Mr. Ingram showed the praiseworthy wish to stand well in the estimation of the dwellers in his native place. He purchased land in the neighbourhood, fostered useful institutions, directed attention to sanitary matters, and used surprising exertion in improving the railway communication of the town of Boston and the neighbourhood.

In 1852 the electors of Boston did credit to themselves and honour to him who, as the school-boy and printer's boy, had so often, in simple guise, unnoticed and undistinguished, rambled through their streets, by sending him to represent them in Parliament. In 1857 he was again returned without opposition. Moreover, Mr. Ingram was appointed a magistrate of the county of Herts, where he had considerable property; chairman of the Boston and Sleaford Railway; and deputy-lieutenant of the county of Lincoln. To such distinction had Mr. Ingram arrived by diligence and with energy pursuing a straightforward and useful course.

In future histories of self-made men Mr. Ingram's name will take a prominent place; while his sad fate, at the age of forty-nine, when fortune and position were realized, and he was regarded as one of the "lucky men" of the day, may be made to point a moral, and teach moderation in success and contentment with apparently had fortune.

#### REPORT OF FALL OF IRON FOOT-BRIDGE IN MANCHESTER.

We mentioned last week the fall of an iron foot-bridge over the Rochdale Canal. At the inquest held on Wednesday, the 26th ult., Mr. E. T. Bellhouse, of the Eagle Foundry, Manchester, read the following report:—

"Agreeably with instructions received yesterday, I have carefully examined the foot-bridge which crossed the canal at Prussis-street, Salughton. The clear span of the bridge was 37 feet 6 inches, in addition to 3 feet 6 inches which was taken up by a projecting mass of masonry connected with the stone steps on one side. The width of the path was 3 feet 6 inches. The bridge consisted of two compound trussed girders, of cast and wrought iron, which form the railing or parapet on each side of the path. The structure has been in existence a long time, and was designed at a period when the construction of iron girders was not so well understood as it is now. The combination of wrought and cast-iron trussed girders was proved to be bad in principle at the time of the fatal accident which occurred on the railway near Chester, from the failure of a trussed iron girder bridge. In the present case the construction is decidedly faulty, inasmuch as the cast iron is in tension and the wrought iron in compression, whereas the very opposite should be the case with these materials. The corrosion of the wrought-iron uprights near the bottom materially weakened the girders, as the great majority of them were completely rusted away. These uprights formed the suspension bars, by which the pathway of the bridge was hung to the wrought-iron curved pieces, so that, by their being rusted away, the very principle of the trussed girder was destroyed. When originally made, the bridge might have been strong enough to bear the heavy test to which it was subjected at the time of the accident; but, in its corroded state, it certainly could not have been expected to bear such a test. The overhanging masonry from which the bridge commences on one side is decidedly objectionable. At the time of the accident there may have been a weight of ten tons distributed over the surface of the bridge. This would be equal to a weight of 2½ tons on the centre of each compound trussed girder. I should consider half this weight sufficient load for the girder in its original state."

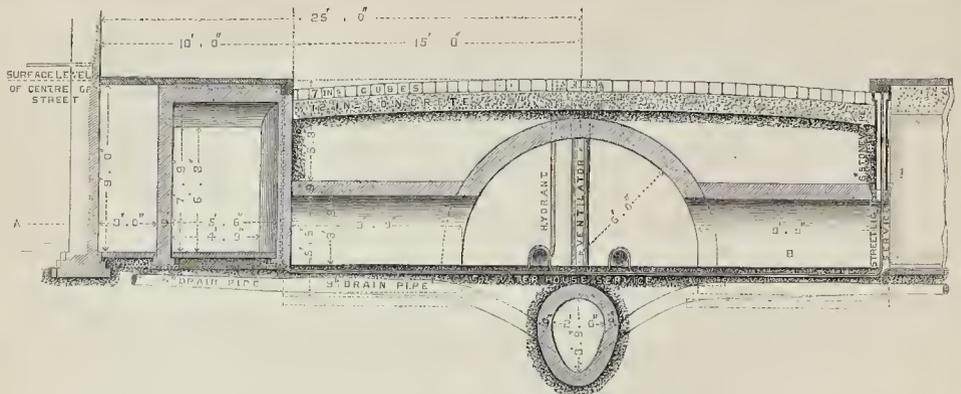

The jury, after a few minutes' deliberation, returned a verdict that the cause of death was accidental; at the same time suggesting that the Rochester Canal Company should replace the bridge by one on an improved principle.

#### THE PUBLIC HEALTH.

By the Health Act of 1858 the Privy Council are empowered to cause inquiry to be made, when they see fit, in relation to the public health in any place; and a medical officer, Mr. Simon, is attached to the Council, and superintends such investigations. His report of the proceedings of 1859, which has recently been issued, deals with several subjects of great interest. Among them is that which has still to be called "the Thames nuisance."

In a paper communicated by Mr. Ord, that gentleman describes the symptoms of a poisoning of the nervous system which occurred very generally in the summer of 1858 among persons employed upon the river, and observes that in 1859, when extensive disinfecting operations were carried on at the mouths of sewers, the sulphuretted hydrogen gas was not in proportion sufficient to the production of the symptoms; and he remarks, that if the emanations of a river in so foul a state do not actually originate disease, and, on the other hand, percolations from cesspools into the soil and wells is proved to be highly injurious, then even this stage in the process of purifying London must be accepted as an improvement upon its previous condition. The putrefactive matter, instead of adding in a thousand places as a focus of disease, is brought into one large aggregate, where it may be more readily submitted to disinfecting processes, and where it finds in the water of the receiving stream elements which appear to disarm it of much of its destructive influence. Happily this source of disease is destined in a very few years to a much more complete banishment.

The state of "the diarrhoea districts of England

THE SUBWAY IN THE NEW STREET TO COVENT GARDEN.

is one of serious import. Dr. Greenhow was commissioned last year, as a temporary inspector, to inquire into their sanitary condition. The towns selected were Coventry, Manchester and Salford, Nottingham, Birmingham, Dudley, Leeds, Wolverhampton, and Merthyr Tydfil. In all of them Dr. Greenhow found it coincident with one or other of these two circumstances—the habitual drinking of impure water, or the tainting of the atmosphere with the products of organic decomposition, especially of human refuse. In other words, in the districts which suffer from high diarrhoeal death-rates the population either breathe or drink a large amount of putrefying animal refuse. He traces street by street, showing how diarrhoea, visiting cleanly districts but slightly, is especially grouped round those spots where there is an accumulation of nightsoil infecting the air in the midst of a dense population, or so placed that the exhalations permeate into the houses, or can be but slowly dispersed into the general atmosphere. The comparative immunity of other districts resembling these in all respects, save the absence of this focal impurity, is found to be so constant, that it seems impossible not to admit the relationship as one of cause and effect; and the medical men affirm that diarrhoeal disease is not only more prevalent, but also more unmanageable, in ill-conditioned places. Dr. Greenhow remarks that the occurrence of epidemic epochs may arise from peculiarities of season giving greater efficacy to local causes, or possibly from the products of decomposition at such periods being different from those at ordinary times. How preventible this disease commonly is may be judged from the success of sanitary improvements in almost all those very districts in reducing the local prevalence of diarrhoea. But, though much has been done, the report shows that it is very far from enough; and it may surely be hoped that the authorities of these towns will take means for removing from their administration “the reproach of preventible but unprevented disease.”

THE SUBWAY IN THE NEW STREET FROM CRANBOURNE-STREET TO COVENT-GARDEN.

The Metropolitan Board of Works has published the plans for the subway in the new street to Covent-garden (commencing at the junction of Long-acre and St. Martin's-lane), which were prepared for them by Mr. Marshall and Mr. Bazalgette, their architect and engineer. We have already briefly described the work as in progress, and now give an engraved section that will sufficiently illustrate it. The following report accompanies the drawings:—

“Having been directed by the Committee on New Streets to prepare a design for a subway under the new street leading from Cranbourne-street to Covent-garden, in which the pipes and mains for gas and water might be laid in such a manner that easy access could be had to them at all times without disturbing the surface or roadway, we now beg to submit the accompanying plans, which we believe to embrace all the desiderata of such an arrangement in the simplest form and at the least possible expense. The plan consists chiefly of a central continuous passage or subway, extending the whole length of the new street, of sufficient dimensions (12 feet by 6 feet 6 inches) to admit of the deposit of any requisite number of gas and water mains, with ample working room for alterations, additions, or repairs. Under the centre of this

passage runs the sewer, to which means of access by man-holes are provided at convenient distances, as also ventilating shafts, gullies, &c. Side-arched passages communicating with the central way will be constructed between every two houses, in which the service-pipes will be carried from the mains into the open areas in front of the houses, and open channels will be left in the footings of the walls dividing the house-vaults, through which the service-pipes will be passed, without any interference with the structural arrangement, and these channels although of small dimensions (4½ inches by 3 inches), being always left open, will act as drains for the admission of air from the open areas into the central passage, which, in conjunction with ventilating shafts at convenient distances into the roadway, will secure an ample current of air for all the purposes of ventilation. An entrance to the main passage will be provided in Rose-street, similar to the ordinary side entrances, but of such dimensions as will allow of the ready admission of the main pipes for gas and water, which, as all the service pipes will be laid in sunken channels, can be readily carried to any required point on a small truck kept in the subway for the purpose. Provisions have also been made for the hydrants or fire-plugs, and for the service of the street-lamps, but these are matters of detail which would doubtless be subjects for final arrangements with the different companies.

Careful estimates have been prepared, showing the cost of the private vaults to the houses, the paving of the foot and carriage ways, and the cost of the ordinary sewer, including dipping, side entrances, ventilating shafts, gullies, &c., by which it appears that the extra cost of constructing the subway as now proposed will not exceed 2½ ds. 11d. per foot run, or about 14. per foot frontage on each house, which, together with the cost of the vaults, sewers, and road, might either be charged at once on those taking up the ground-rents, or be added as an annual charge, in addition to the ground-rent, and which would of course form a part of the annual rental to be sold when the Board should think fit to realize the ground-rents. The estimates in all cases are given at so much per foot run on the frontages, so that the charge on each house may be seen more readily.”

It will be remembered that premiums were offered by the Board for the best designs for a subway, and we may conclude that the plan adopted was the result of careful consideration of all that were submitted.

The following is the estimate given:—

	Quantity.	s.	d.	dec.	£.	s.	d.
<b>SEWER.</b>							
Excavations, Carting away, &c. . . . .	cubic yds.	0'42	2	6	1'05		
Brickwork . . . . .	cubic ft.	4'66	0	11	4'97		
Junction Blocks, 9 in. pipe		..	..	..	0'05		
<b>SUB-WAY.</b>							
Excavations, &c. . . . .	yds.	2'272	2	6	5'98		
(Central Passage) Brickwork . . . . .	cubic ft.	13'160	0	11	12'05		
Excavation, &c. cubic yds. . . . .		0'300	2	6	0'76		
(Side Passage) Brickwork . . . . .	cubic ft.	2'140	0	11	1'95		
<b>CELLARS.</b>							
Excavations, &c. . . . .	cubic yds.	3'554	2	6	8'93		
Brickwork . . . . .	cubic ft.	22'930	0	11	21'02		
Pitching (brick on edge) . . . . .	sq. yds.	0'525	3	6	1'54		
Paving, area 2½ days, yds. . . . .		6'924	4	10	15'85	1	13 3
<b>FORMING OF STREET.</b>							
Excavations . . . . .	cubic yds.	1'02	2	6	2'55

Per foot run . . . . .		..	..	..	0'16		
Total cost per foot run of frontage . . . . .		..	..	..	24 19 9		

THE “PROMOTER” LIFE ASSURANCE OFFICES, FLEET STREET.

THESE premises occupy a plot of ground, No. 29, Fleet-street, about 20 feet broad by 50 feet deep, and the rear is in close proximity to the Temple Church. The front is executed entirely in Portland stone, excepting where enriched by polished granite and marble.

On the ground floor there are three openings in the front, two of which are the windows of the public office, and the third (which is the western) the doorway; these openings have stone arches, supported by four red granite columns, which stand on Portland stone pedestals; and between these pedestals are the basement-windows: the capitals of the granite columns are each carved in a different design, one being the grape, another the hop, and a third the rose. The spandrels of the arches are filled in with green marble and red granite, in patterns, the key-stones being bunches of fruit and flowers, which hang over a dentilled string above the ground story, at the ends of which are carved lions' heads. Over this string are three elliptical panels: the outer ones are filled in with red granite, and the middle one with green marble, upon which are carved the name of the office, and the date of its establishment (1826); between these panels is a hand of red granite, with diamond centres filled in with marble.

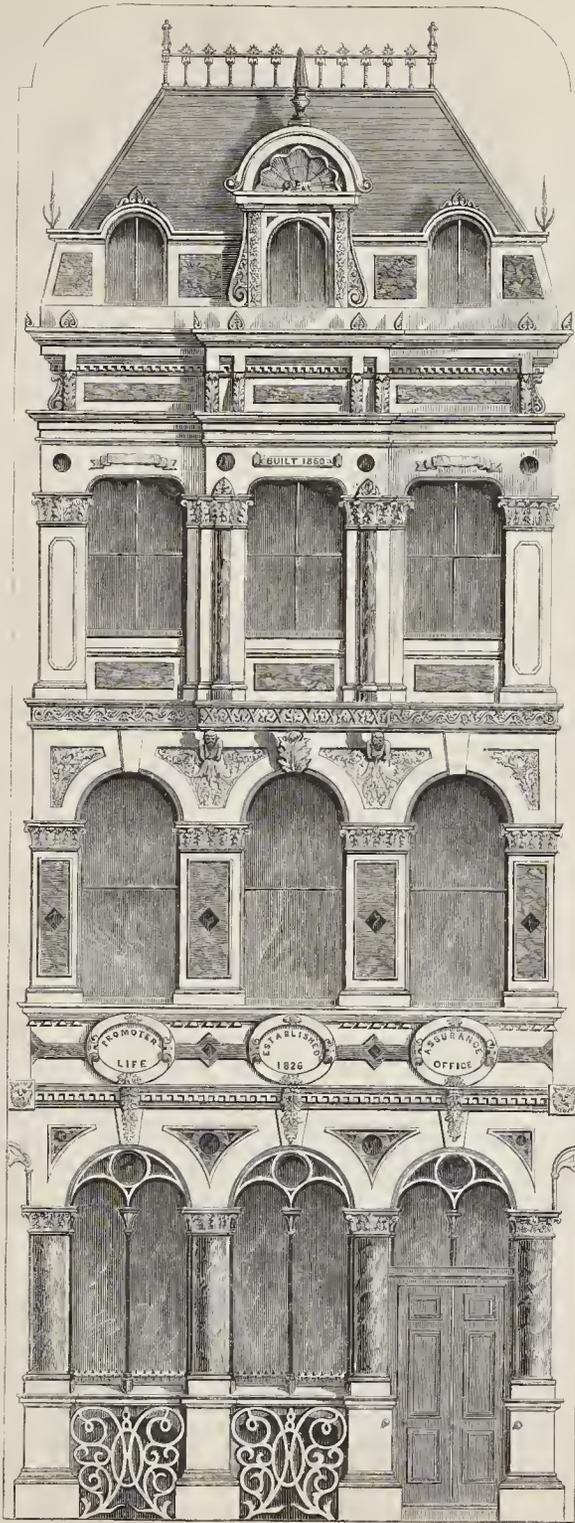

The first-floor openings are divided by stone pilasters, the panels of which are red granite, with green marble diamond centres. The capitals of these pilasters are also all of different design. The arches of these openings are Portland stone, and the spandrels elaborately carved: two of the key-stones are quite plain, and the centre one carved. The sill over first-floor window is supported by two carved figures, projecting forwards.

The openings in the second floor are divided by pilasters, the two end ones being panelled; and in front of the two centre ones stands a slender red granite column, above which are carved bands bearing the date of the erection. Above these is a frieze, upon the string course of which stand consoles, and eary blocks, which form part of the principal cornice, and between these consoles are panels of red granite, set projecting. Above the cornice are the attic windows, between which are slabs of red granite. These windows are arched over,—the capping continued over them: the centre window, which projects, has a cornice and circular pediment, in which there is a carved shell, and in the centre of the pediment is a finial.

The entrance lobby is paved with encaustic tiles, and communicates with the stairs, and by a door to the public office, the sides of which are ornamented by pilasters with enriched caps and frieze. Behind is the secretary's office. The ground floor is constructed of Fox & Barrett's fire-proof flooring. In the basement is a living-room, with a bedroom in the rear; and in the front are lavatories, &c. for clerks, while in the centre is a fire-proof room.

On the first floor is the board-room in front, and doctor's room and lavatory are at the back.

The architect of this new building is Mr. W. G. Bartlett, and the builder Mr. J. Wilson, of Southwark. The work has been carried out by Mr. Allen, the clerk of works. The carving has been executed by Mr. Forsyth, under the superintendence of the architect.

THE "PROMOTER" LIFE ASSURANCE OFFICES, FLEET STREET.—MR. W. G. BARTLETT, ARCHITECT.

APPRENTICESHIP TO TRADES.

LOOKING at a large number of important manufactures and other works in town and country, a great change will be found to have taken place in respect of the training of apprentices to the different branches of trade.

Formerly, in nearly every establishment it was the custom to take a number of apprentices in proportion to the men engaged. This arrangement differed in various trades. In blacksmiths', brass-fitters', cabinet-makers', and other shops in which works were carried forward on an extensive scale, the boys were distributed amongst the men, who for a certain payment taught them their business. Now, however, it seems that, in some of our chief establishments, where hundreds of skilled workmen are engaged, no employment is afforded for apprentices.

At Maudslay & Field's there are no boys; at Messrs. Pellatt's glass works, neither in the cutting-room nor in other parts are there apprentices. Thirty or forty years ago there would have been a large number. In carrying forward great building operations, amongst carpenters, bricklayers, and stonemasons, particularly in the metropolis, scarcely a boy is to be seen; and it would be easy to mention a hundred other instances of this remarkable change.

Year after year works are increasing in extent, and small workshops are becoming more scarce. This naturally raises the question as to how a supply of skilled workmen is to be kept up, and it is also a question what is to become of the boys? This is now a difficulty among the working classes and persons of limited income who have a number of children. From the ages of thirteen to sixteen there are various ways in which boys can get employment which enables them to earn from 5s. to 6s. or 7s. a-week. The nature of their occupation—work in printing-offices, potteries, filling situations as errand-boys, &c. &c.—does not fit them with the means of gaining a livelihood after they have ceased to be boys; and it is owing to this that so many youths, just at the time when their labour ought to become of greater value, are thrown out of work: the skill they have acquired is useless to them: fresh boys are coming into the field with the same miserably prospects.

Although this phase of our present social system has not met with much attention, it is of vast importance, and must, before many years have passed, cause much difficulty and lead to much mischief. It demands the consideration of all who are interested in the matter.

MANCHESTER WAREHOUSE ARCHITECTURE.

We have often asserted that there are duties, that there is a responsibility, incumbent upon all, both as regards the cultivation of their own perceptions, and their influence upon the tastes of others. And we rejoice that this belief appears to have spread beyond the ranks of artists to others who are quite as important in their place—the capitalists who employ their money in building. The *Manchester Review* on this head says,—“Our mercantile and manufacturing towns have hitherto been concentrated within themselves almost everything that could make human habitations repulsive. The lowering smoke, the sulphurous air, the river blacker than Styx, the dire array of coal wharves, the endless lines of sooty brick, are features more or less common to them all. Yet why should the same spirit of trade, which has conjured up places of beauty on the shores of every sea, enumber England with so much unattractive ugliness? No doubt the circumstances which surround business in Venice, Milan, or Florence, were very different from those by which it is attended now. Trade is no longer in the hands of exclusive guilds, or mainly controlled by a few wealthy and educated merchants. It cannot now be conducted without generating volumes of smoke, which reduce all things in heaven and earth to one dingy funeral hue. And, above all, the economy of space and material, enforced by the pressure of competition, might seem to forbid the pursuit of any enterprise loftier than the desperate scramble for existence. But we have already ample proofs that these difficulties are not impossibilities; and we rejoice at the unmistakable signs of a better spirit which may now be observed in our streets. We cannot, indeed, undertake to maintain the correctness or good taste of all that has been done; but there is, at all events, an effort in the right direction; and, in some cases, not always in those of greatest pretensions, considerable success has been achieved. Even if we are to look upon some of these warehouse fronts as only equiva-

lent to the ornamental and fantastic advertisements which are thrust before our eyes everywhere in these days of competition, we should hail with pleasure the spreading conviction that, on the whole, it will pay better to show some respect to the desire for beauty, which we all share more or less, than utterly to set it at defiance. But though such a feeling undoubtedly has its weight, yet we cannot believe it altogether excludes a higher motive. Let us hope that, as Manchester merchants have never been slow to recognise their responsibility for the vast influence which their commerce exerts upon the world at large, they have begun also to feel that no one has a right to use his capital for the purpose of encumbering the world more immediately around him with monstrous forms of ugliness. This is the position which we should like to see more generally taken up. Surely if, as we are assured on high authority, eating and drinking may be done to the glory of God, there is nothing very extravagant in the idea that any one who overshadows a public street with a pile of buildings ought to feel some responsibility for its effects upon passers-by. What right have half-a-dozen rich capitalists to drive us melancholy-mad by hedging up our way with their acres of dirty brick-wall? What right have thieving traders to insist that the increase of our misery shall be commensurate with the increase of their business? Yet this must necessarily be the case wherever a city is swallowing up the country round, unless the men for whom the city mainly grows feel some responsibility for the sights by which they surround us. We rejoice, therefore, that better ideas than of old are manifested in the warehouses of Manchester.” We have often before spoken of these buildings.

“AN ADDRESS TO BUILDING OPERATIVES AND WORKING MEN OF THE WEST RIDING.”

UNDER this title John Plummer, of Kettering, believing that it is “the bounden duty of every person, no matter what may be his station in life, who may possess any experience or information relating to the questions at issue, to speak out frankly and boldly, so that the expression of his honest opinions and convictions may aid the endeavours of those who seek to devise some method of preventing” the repeated contests between labour and capital, or mitigating the baneful influence which they have so often exercised in our attempts at social progress, has issued another little pamphlet, which deserves the consideration of his fellow-operatives.\*

Speaking of the nature of the relations which subsist between the employers and the employed, he says—

“Nothing is more common than the error that the employers can regulate the rate of wages at will, or that they can alter the established customs of a trade at their own pleasure; consequently, the men, as a rule, deem it but just, that they should curtail their power as much as possible; and, in various methods, *deplete* the rate of wages, hours of labour, &c. The men have a perfect right to state on what terms they will work for the employer, and the employer has an equal right to accept or refuse those offers. But if others are willing to work for the employer, on the terms refused by them, then they have no right to interfere farther; otherwise they are guilty of injustice and wrong. Labour is a marketable commodity like anything else, and is worth what it will fetch in the market, and no more. Some kinds of skilled labour may be worth 60s. per week, while other descriptions may be dear at 10s.; but that is no reason why the purchaser of the labour at 10s. should be censured for not giving 60s. for it. Suppose that the grocers of Leeds are selling sugar at 2d. per pound, and they take it in their heads that this is too low a profit, considering the risk and labour involved in the retailing of it, and that they accordingly raise the price to 6d. per pound. What an outcry would arise against them! Well, suppose again, that the purchasers of the sugar, feeling dissatisfied with the increased price, encouraged some tradesman to procure a hogshead of sugar, and sell it at the original rate, and that the combined grocers, hearing of the circumstance, ‘struck’ selling any articles to their customers until they refrained from purchasing of the cheap sugar dealer. Would not the working men of Leeds and the West Riding be the foremost in denouncing such conduct as tyranny and coercion, and hold up to public execration the names of the combined grocers? Yet what is this but the very principle of the present strike amongst the masons of Leeds? The grocers have a perfect right to place any price, say 5d., 9d., or 1s. per pound, on their wares, but they have no right to coerce the public into buying at the increased rates; and the same principle applies exactly to the purchase of labour by the employers. The price of the sugar is regulated by the state of the market: if the stock of sugar be small the prices will be high; and if the stock be large the prices will be low. If the wholesale price of sugar be 10s. per pound, and the grocer sell it for 12s. per pound, he will soon find himself on the road to ruin, for all his dealings will be conducted at a loss. Should the wholesale price rise to 12s. per pound he will not sell so much as former, because the increased price will lessen the demand for it. The same will labour. If the employer gives an increased rate of wages, without raising the price of the labourer’s produce, his profits will fall

in proportion; and if he does raise the price of the produced article, the demand will diminish in exact proportion to the increase of price, and a less amount of labour will be employed.”

On the question of *piece-work* the writer says:—

“We shall have to ascertain whether piece-work is injurious or not to the interests of the operatives. If it is not, then there is an end of the question; and if it is, then we must inquire into the advisability of a strike for the remedy of the same. In paying for labour performed, it will always be found that, as a rule, the industrious men will receive more wages than the indolent. We may suppose the labourers to be paid for their work by the piece, or by the day. If by the piece, it must be clear that those who do most work will receive most wages; if by the day, those who work the larger number of days will receive more than those who work the smaller. Or, if, while each laboured the same number of days, some, by greater assiduity, executed more and better work; so soon as this difference was clearly ascertained, the effort among the capitalists to secure the services of the most efficient workmen could not fail to establish a difference in their wages.\* Now, what the reasons desire to establish at Leeds, Halifax, and elsewhere, is a uniform rate of wages and hours of labour; so that the industrious and skilful operative shall receive no more than the indolent and unskilful. Now it is not reasonable to suppose that an industrious man will care about labouring so hard as the less industrious one, if there be no difference in the amount of wages received by both. Consequently, the quantity and quality of the work performed will deteriorate in proportion to the attempted equality of wages. Good labour will always find a good price, if there be any market for it. The great objection of the employed to piece work is, that it tends to cheapen wages; that a man, who made by time work two articles for a penny, would, under the piece work system, have to make three for the same price. Now is this belief really based on fact? Does the extension of piece-work tend to cheapen wages? I believe that, with a few exceptions, it does not do so, and I will quote the words of Mr. James Howard, the agricultural implement manufacturer, of Bedford, from a lecture delivered by him at Northampton. He says,—“I like the system, as it enables the workman to obtain higher wages, and the master pays for no more and no less than is done. I never had any difficulty in letting a job by piece-work. I hear there are difficulties in other trades, but I think they would vanish when the system came into operation. It is worthy of remark and consideration that those trades have made the greatest progress where piece-work is the rule. It gives the industrious and skilful man a great advantage over the lazy and unskilful one. And such is the result of my own experience. I generally find that, where time-work is used, the inferior workman has to pay for the loss occasioned by the employment of the indolent and incompetent; and that it is the inferior workman who, as a class, desire time-work; while the superior men prefer to labour by the piece. Possibly the increased skill of an intelligent and industrious man may occasion him to produce articles at a quicker rate than formerly, and that he, consequently, may be enabled to do them a little cheaper, so that, by the increased demand, he may be enabled to increase the net total of his weekly earnings; but this does not operate more injuriously—allowing such to be so, which I do not admit—on the interest of the employed, than does the practice of time-work.

Should the men persist in refusing to accept piece-work, then employers at a distance, labouring under no such restriction, would be tempted to accept the offered contracts, and send their own men to perform the labour lost to the others. The enforcement, therefore, of the rule, that piece-work and sub-contracting be prohibited, would tend to seriously cripple the trade of Leeds, and to inflict much suffering and misery on the operatives.”

THE WESTHAM DISTRICT SEWERAGE WORKS.

A REPORT recently made by Mr. Rawlinson states that the whole of the works comprised in the original plan have been let, and are either completed or in hand. The annexed statements show the particulars and cost of works finished, and the particulars and estimated cost of works remaining to be done. The sewers throughout the district have been designed with a view of obtaining the best practical gradients, more especially for tributaries. In some cases, however, it has been necessary to lay the mains with a fall of not more than 1 in 3520, or 18 inches per mile. All sewers terminate at the least practicable depth to ensure proper falls for house drains. A system of ventilation has been adopted which prevents the road dirt falling through the ventilating gratings and impeding the flow in the sewers. An intervening screen, filled with charcoal, filters all the sewer gases, so as to render them innocuous. The outlet sewers in Canning-town have been laid level, to allow of their being used as depositing and deodorising tanks.

There are 27,311 yards, or about 15½ miles of public sewers completed, varying from 3 feet 3 inches by 5 feet 6 inches, to an earthenware pipe of 9 inches in diameter. The cost of such sewers, including manholes, lamp-holes, junctions, &c., has been 38,064l. 13s. 5d., or an average of about 2,450l. per mile. The greatest cost has been 34,10s. 7d. per lineal yard. A portion of tunnel heading, in Barking-road, cost, complete, about 90s. per lineal yard. The cost of sewer, 9 inches in diameter, laid 10 feet deep, is 6s. 10d. per lineal yard.

There remains to be executed a length of 27,025

\* Phenomena of Industrial Life.  
† The first contract was taken in June, 1858.

\* Kettering: Thomas Waddington, Printer, High-street.

yards \* of public sewers, from 3 feet by 2 feet, down to earthenware pipes of 12 inches diameter, at an estimated cost of 26,971*l.*, or an average, including manholes, lampholes, &c., of about 1,800*l.* per mile. The greatest cost per lineal yard will be for sewer in Romford road, about 40*s.* The cost of a 12-inch earthenware pipe laid 8 feet deep will be 7*s.* 3*d.* per yard. In the sewers executed there are 213 manholes, or a means of access to the sewers for flushing and cleansing, and 100 lampholes for means of inspection; making, on an average of the entire length, one opening to the sewers from the surface of the street or road at about each 87 lineal yards. The manholes have step-irons, flushing grooves, and movable covers complete, and about 100 have ventilating chambers, charcoal strainers, and ventilating grates. The ventilation and safety of the sewers and house drains will be secured by 200 points of permanent ventilation, where all sewer gases will be disinfected so as to render any accumulation or emission of foul air impossible, and 9,000 side junctions will be provided for house, yard, and other drains. No system of sewers has been executed up to this time with the same amount of facilities for permanent working and ventilation.

#### PUBLIC BUILDINGS IN THE PROVINCES.

**Boss.**—At a meeting of the committee for the erection of the Ross Corn Exchange, public rooms, and markets, Mr. Nicholson, of Hereford, architect, two tenders were sent in. The first was from Messrs. Hayes & Son, of Gloucester, for the whole of the works, at 2,912*l.*; the other was from Messrs. Pearson & Son, of Ross, at 2,638*l.* Messrs. Pearson & Son's contract being 27*l.* less than the other, it was unanimously resolved that it be accepted. Each of the builders who tendered offered to substitute a Bath stone front for one in cement, should the committee deem it desirable, for an extra sum of 150*l.* It was decided to make an effort to obtain a Bath stone front.

**Dartford.**—The new cattle-market for this district has just been completed and opened for business. Mr. Bray, the landlord of the Bull, obtained plans from his father, which were submitted to a committee; and, being approved by them, the works were accordingly determined upon. The place selected was contiguous to the Bull yard, and the building was entrusted to the Messrs. J. C. & T. Waller, of Dartford, Mr. Bray, sen., acting as architect. The new building will accommodate about 300 oxen and 1,500 sheep. The market is so arranged that the beasts are placed round, the sheep being in the centre in iron pens, constructed by Mr. Howe, agricultural implement maker. The total cost of the erection was over 600*l.*

**Midsomer-Norton.**—The new market-place here has been opened, and a monthly market inaugurated. Messrs. Fosters & Wood, of Bristol, prepared the plan of the market-place; and the contract for the erection of the building was let to Mr. Shearn, of Midsomer-Norton, and Mr. Stamp, of Dunkerton. The market-house, which has been erected in the centre of the town, has two fronts, one towards "the Island," and the other towards the road to Stratton. It is Italian in character, and built of the yellow lias stone of the neighbourhood, with freestone dressings, and band courses of Pennant stone. The doors and windows being arched heads; the upper windows being in ranges, and supported by freestone columns, with carved capitals. The market-place occupies the whole of the ground-floor; and a public-room, committee-room, and clerk's office, are on the first floor over it. A separate entrance on the Stratton-street side leads, by a flight of stone steps, to the public-room, which is calculated to accommodate about 300 persons. It has a coved ceiling. The whole is lighted with gas. The gas-fittings were supplied by Messrs. Davis & Son, of Bath.

**Cambridge.**—The tender of Messrs. Bell & Son

\* The completed sewers, and those to be completed, will measure together about 30 miles. The commissioners' scheme would have measured only 12,157 yards, or rather less than seven miles, and was estimated to cost 20,000*l.*

for the new Townhall has been accepted, and a beginning, according to the local *Chronicle*, will be made at once. It is hoped that in a year from this time the new rooms will be ready for use.

**Loughborough.**—The new Police Station, which was to be opened on the 27th ult., comprises a general classification. All the apartments and conveniences, excepting the bed-rooms, are arranged on the ground-floor. Next to Wood-street is the main entrance to the building and courthouse, on the right of which is the clerk's office and magistrates' retiring-room, communicating with each other as well as with the court or bench. On the left is arranged the residence for the superintendent of police. The building throughout has been fitted up with gas, the court being lighted with three ornamental star-lights. The magistrates' court and cells are heated from hot-water pipes by Mr. Messenger's triangular tubular boiler. The buildings are executed of red and white brick with Bath and native stone dressings, with rusticated base. The frontage next Wood-gate is 47 feet, side front facing the right of road 190 feet. The style adopted is the modern Italian. The architects were Messrs. Bellamy & Hardy, of Lincoln. The same architects have been engaged by the Savings' Bank Committee for their proposed new bank. The works of the Station have been executed by Messrs. Pepper & Dolman, of Spalding; the ironwork by Messrs. S. Frisby & Son, of Loughborough. The clerk of the works was Mr. John Savill.

**Manchester.**—The corporation of this city have accepted the tender of Mr. James Hayward, jun., Phoenix Foundry, Derby, for the new market about to be erected in the London-road, from the design of Mr. J. L. Lynde, city surveyor. The same firm recently supplied the cast-iron ornamental entrance-gates to the Queen's Park.

**Salford.**—Rapid progress is being made with extensive additions to Salford Town-hall, but in the rear of the building. There will be a frontage of more than 200 feet to West Market-street, of two stories high. Outside, the building will be plain; inside, some care will be bestowed on decoration. Mr. Evans, the district surveyor, prepared the plans. Mr. Sothorn has the contract, the amount being about 6,000*l.* The new building will provide offices for the town-clerk, the surveyor, committee-rooms, large room for the Court of Record, with retiring-rooms, &c., and a new council chamber, 52 feet by 28 feet, and about 22 feet high.

**Derby.**—The foundation-stone of the new Corn Exchange, in Albert-street, has been laid by the mayor. The new building will stand about fifty yards from the Royal Hotel, in Albert-street at the junction of the great frontage in Princess-street, having its greatest frontage in Albert-street, leading to the Market. At the junction of the two streets is the principal entrance. The ground plan consists of a circular vestibule, 26 feet in diameter in the clear, having three large entrances from the two streets already named, and all verging to one centre. From the central vestibule are entered the various offices; the telegraph-office, ante or cloak rooms, the large concert-room, and the principal staircase to the rooms above. On the Albert-street frontage, owing to an irregularity in the site, various offices are obtained, together with cloak-rooms and entrances to the large hall. A private entrance for reserved seats is also obtained, having cloak-rooms on each side of it, and possessing separate entrances from thence into the large hall. These front offices are only proposed to be one story in height, with a lead flat roof and stone parapet, so that windows are obtained in the hall above them. There will be two news-rooms, one circular, 26 feet in diameter, lighted by three stone windows, and communicating through sliding doors with another room, 20 feet by 17 feet. The dimensions of the large hall are 110 feet by 55 feet. The committee decided upon adopting designs recommended by Mr. Wilson, for the interior, at an increased cost of upwards of 300*l.* This will the Corn Exchange, and other purposes, there being in this case a double instead of a single roof, a ceiling divided into compartments, which are again sub-divided into domes, the flat surface at the top being filled with glass, and the sides covered and divided into ornamental panels, starting from a moulded plaster cornice, which is supported by ornamented plaster corbels sprung from the sides of the hall. The gallery runs up the two sides parallel with the walls, but is not opposite the orchestra is semi-circular, and it is capable of seating about 400 persons. The exterior will be erected with bricks and stone dress-

ings, in the Italian style of architecture. Mr. Benjamin Wilson furnished the plans and design. The tenders for sewerage works in Derby having been opened by the Sewerage Committee of the local Board of Health, Mr. William Hyslop's, amounting to 1,468*l.* 8*s.* 1*d.*, being the lowest, was accepted.

#### SCOTLAND.

**Galashiels.**—There has been a grand Masonic demonstration here at the laying of the foundation stones of the Galashiels Public Hall and Corn Exchange. The public hall will be, externally, 75 feet long by 45 feet in width, and it will have a spire. The plans were designed by Mr. Lessells, architect, Edinburgh, and the builders are Messrs. Herbertson & Son, their estimate being 2,368*l.*, which includes the plaster and plumber work. The hall proper is on the second story, the lower part being set apart for sheriff and police-court rooms, committee-room, kitchen, and other necessary accommodation. The dimensions of the public hall are 70 feet by 40 feet. The building is of freestone in front. The windows of the hall are arched with cornices above, and the roof is to be finished with a block cornice. The orchestra gallery will be placed in a recess in the centre of the south wall. The large hall will accommodate 500 people seated at dinner. The Corn Exchange, erected by Messrs. B. & A. Stirling, of this town, is a plain erection. The length is 59 feet, and the width 30 feet; height 22 feet to the tie joists. The roof below this is open, and of dressed wood, which will be stained and varnished. It is lighted entirely from the roof, and like the other erection, has a freestone front, the back part and side walls being of the common blue stone of the greywacke formation of the district. This building also contains a committee-room and other accommodation for the use of the farmers and grain dealers, and it can be let for public meetings, concerts, &c.

**Leith.**—Some time ago competitive plans were obtained for a new Corn Exchange for Leith, and the competition resulted in the adoption of designs by Messrs. Peddie & Kincaid. Contracts have now been entered into for the work, and the erection of the building will be proceeded with immediately. The site is the angle between Baltic-street and Constitution-street. The building is in the Roman style, and includes a corn-hall or exchange, 110 feet in length, and 70 feet in breadth. This apartment has a roof of one span, supported on semicircular ribs of laminated timber. Light will be admitted entirely from the roof, and the hall will be so finished as to afford accommodation for public meetings, &c. This hall occupies the rear of the building. That portion of the structure fronting Baltic-street includes offices in connection with the exchange, and five or six suites of chambers for merchants. Externally, the building comprises a large octagonal tower, placed at the junction of the two streets. This tower rises one story above the other elevations of the exchange, and is finished by a dome surmounted by a small octagonal lantern: the rest of the building is of two stories, each areaded. The whole will be executed in polished ashlar, Kilmurree stone being used. The contracts, which amount to 4,000*l.*, are several hundreds below the architect's estimate. The contractors are Mr. George Lorimer for the mason-work, and Messrs. Henderson & Wilson for the wright-work.

#### CHURCH-BUILDING NEWS.

**Ipswich.**—The south aisle of St. Matthew's Church was, at the commencement of the present year, extended as far as the east end of the chancel, and the latter restored and benched, the new part being also filled with open seats. The old part of the church is of a Late Perpendicular date, and the additions are carried out in the same style. The roof of the new part of the south aisle is of a low pitch, with moulded tie-beams, supported by corbels carried by angels. Pierced tracery fills in the space above the tie-beams, and carved bosses are placed at the intersection of the intermediate timbers. The mouldings are ornamented throughout with four-leaved patras and other carving. More funds were collected than required for these works, and it has now been decided to hench the nave and north aisle with square-headed benches, and to build a new south porch. The total cost of the works will amount to between 1,100*l.* and 1,200*l.*, and the increased accommodation will exceed 200 sittings. The contractor for the general work is Mr. Garnham; for the pulpit and reading-desk (of carved oak and stone bases), Mr. Ringham; for the stone work, Mr. Newton; for the plumbing and glazing, Mr. Manning; and for the henching of the nave and north aisle, Mr. Bacon,—all of Ipswich.

Messrs. Hart & Son supplied the brass gas standards and altar railing. The architect is Mr. R. M. Phipson, of Ipswich.

**Brighton.**—The chief stone of the Church of St. Michael, situated in the Montpelier-road, opposite the Temple, has been laid by the Vicar of Brighton. The founders of this church are two ladies, who have contributed 4,500*l.* Mr. Pabian was the contractor. The edifice is of brick, and will have 550 sittings, 350 free. The site cost 1,250*l.*

**Upper Sapey (Herefordshire).**—The parish church of Upper Sapey has been closed for some months, in order that it might undergo a renovation and improvement; and it has now been reopened. Previously to its restoration the church consisted of chancel, nave, south porch, and western bell turret. The church being in a very damp, dilapidated, and unseemly state, and the turret and roof showing unmistakable signs of giving way, Mr. W. J. Hopkins, of this city, says the *Hereford Times*, was called to report upon the best method of effecting a thorough restoration of the edifice. The plans prepared by him were subsequently adopted, and the work has been carried out, under his superintendence, by Mr. Warner, of Leigh. As much of the old church as possible has been preserved, including the greater portion of the walls, the doorways, and original windows. The chancel arch, being inconveniently small, has been removed to the west end, where it forms an opening into the tower. The latter is entirely new: the belfry stage, of wood, is surmounted by a shingled spire. A three-light middle-pointed window has been inserted at the east end, and a two-light window of the same style on each side of the nave. Stained glass for the east window is being prepared by Mr. Preedy. The single light in the north wall was transferred thither from the west end. The roofs are open, that in the chancel being of oak, and the nave roof of deal. There is a lofty pointed chancel arch, formed of alternate courses of light and dark tinted stone. The open seats in the nave are of deal, of a simple design. All the woodwork is simply varnished. The floor of the nave is laid with Maw's red and black tiles. Minton's tiles, the gift of the Rev. E. Addenbrooke, are used in the chancel: they have a blue and white border. In front of the altar is a row of memorial tiles, bearing inscriptions to the members of the Addenbrooke family, many of whom are buried in the church, and to whose memory were some stone slabs, for which the tiles are a substitute. The stained window is given by Mrs. Newman. The exterior of the walls has been relieved of the plaster and whitewash, and pointed and drained. The roofs are covered with Broseley tiles. The total cost of the renovations will approach 1,000*l.* Sir Thomas Winghamton, Bart., gave the sum of 500*l.* towards the restoration fund: the recently-appointed rector, the Rev. Phipps Onslow, gave 150*l.*; Mrs. Newman, 100*l.*

**Corris.**—Corris and Machyulleb are two scattered hamlets, which generally go by the simple designation of Corris, and are situated in a wild and romantic spot at the south-east extremity of the county of Merioneth. Here a new church has been erected. The style is Early English. The windows, which are nine in number, are of the concrete form, and the one in the chancel is of stained glass. The roof is of stained pitch pine, and the floor is of flags, obtained at the adjacent quarry at Genwern. The edifice was erected at the cost of Lord and Lady Vane, to the memory of their relative, the late Sir John Edwards, Bart.

**Wrexham (Denbighshire).**—The chancel of the new church of St. Mark, Wrexham, has lately been decorated in polychrome. The prevailing tone is murrey. The central panel over the altar, on a light green ground, presents the sacramental emblems, the eorn and vine, in a cruciform arrangement, encircling a white cross, interlaced with the sacred monogram, on a crimson ground, diapered in gold. On the right of the central panel are the Creed and Lord's Prayer; on the left the two tables of the Law in old church text, emblazoned in gold and colours, and surrounded by borders. Above these in gold medallions are the emblems of the four evangelists in panels, which contain also representations of the Lily, surrounded by a border of light grey. The designs were furnished by Mr. Fisher, of the firm of Harland & Fisher, Southampton-street, London, and executed under his direction.

**Lutterworth.**—The church of Ashby Magna, near Lutterworth, has been restored and reopened. In the present year a public subscription, amounting to something like 400*l.*, having been raised, it was determined to restore the church as far as the funds would allow. Mr. Firm, of Leicester,

was appointed to carry out the alterations, and under his management, and that of Mr. Clifton, who has supplied the woodwork, the restoration has been partially completed. The windows on the south side have been altered, and a new one inserted in the place of the southern porch. The gallery has also been taken down, and open deal varnished seats have been substituted for the pews. The church will now accommodate nearly 300 persons. Something has also been done to the walls, columns, and arches, the whitewash having been scraped off, and the original stonework exposed to view. A carved pulpit of Bath stone has been erected, and a font of similar design, together with a new vestry adjoining the chancel.

**Horsley.**—The work of church restoration, now so busily carried on in Derbyshire, has been brought to its completion as far as Horsley is concerned. The old church, dedicated to St. Clement, has undergone a thorough renovation, and been formally re-opened for Divine worship. The total cost of renovation has been about 2,000*l.* The work has been carried out by Messrs. Kerry and Allen, of Smalley, the contractors for the stone and wood work. The vicar has been engaged in carrying out the architectural details. The principal portion of the cost of the work has been defrayed by Miss Eliza Sitwell and other members of the Sitwell family.

**Rochdale.**—The new church recently erected at Norden, near Rochdale, has been opened for Divine service. The church is a plain structure, with a spire, a nave, and a north aisle separated from the nave by arches. The seats are open stalls, and will accommodate 600 people. The cost has been between 2,000*l.* and 3,000*l.* Mr. Slaw, of Saddleworth, was the architect. A small stained glass window, at the north end of the church, was presented by him, in which are inscribed the names of the chief promoters of the undertaking. Another small stained glass window, in memory of the Rev. Mr. Hodgson, has been presented by Mr. T. Ferrand Dearden, who has also presented the church with a baptismal font.

**Colne.**—The cemetery at this town has been completed, and was lately consecrated by the Bishop of Manchester. The cemetery contains about six acres of sloping ground, and the Board have erected two chapels, each 30 feet by 16 feet inside, with tower and spire between them, 80 feet high; also a lodge at the entrance gates. The whole has been designed and carried out by Mr. Pritchett, of Darlington, whose design was selected in competition about a year ago.

#### ST. PATRICK'S CATHEDRAL, DUBLIN.

A WRITER in *Scander's News-Letter*, commenting at some length on the letter in our pages signed "Medievalist" (p. 597), denies its correctness, and calls it "an ebullition of ill-temper and envious feelings." In the interest of architecture and our national antiquities, we have one question to ask for ourselves,—are the works under the direction of a properly qualified and experienced architect?—a question we have before now put. We have the greatest respect for the fairness and good intentions of the *News-Letter*, and have no doubt it will assist in obtaining for us a distinct reply. The works ought not to be allowed to go on at St. Patrick's, without satisfactory guarantee that they will be executed with skill, conscientiousness, and loving care.

In our notice last week of works progressing in Ireland, the fifth paragraph should commence, "St. Audeon's Church, Dublin, has been recently partly restored." The printers turned it into "St. Andrew's." St. Andrew's is at present a ruin, having been destroyed by fire, as already noticed.

#### TORQUAY INFIRMARY.

A WING has lately been added to the Infirmary in this town, for the reception of fever patients. Plans were advertised for, and those sent in by Mr. Edward Appleton, architect, of Torquay, were approved, and have been carried out. The new buildings consist of rooms in the basement, for offices, &c., not yet to be fitted up: on the ground-floor level are two convalescent wards, closet and lavatory, entrance-porch, and a room for the surgeon.

The upper floor is occupied by the fever wards, two in number, with nurses' rooms, lavatories, and water-closets; the two latter in a separate building, with the lavatories placed between the wards and the water-closets, and thorough ventilation provided for in each.

Upwards of 1,500 cubic feet of space is allowed for each patient: the wards are 24 feet wide and

16 feet high, with windows carried up to within a foot of the ceiling on three sides, and the fourth side is provided with ventilating screens of perforated zinc, controlled by flaps: in addition to this an exhausting-shaft passes over each line of beds, above the ceiling, with ventilators at intervals; and these communicate with a flue carried up in the chimney stack.

The heating is by open fireplaces. The probable cost, including fittings and furniture, will be about 90*l.* per patient. The walling is of limestone, hammer-dressed, with tooled main quoins, &c.

Mr. John Harvey, of Melville-place, Torquay, is the builder.

#### TRAMWAYS ON ROADS WITH CARRIAGES PROPELLED BY MANUAL LABOUR.

SIR,—Both publicly and privately I have long suggested the adoption of tramways for roads as well as for streets, from one end of the island to the other. My plan was only adopting that which has been so long and successfully tried in Friday-street, Cheapside, the Commercial-road, up Reigate-hill, &c., viz., by laying down a double line of the long granite kerb-stone of the streets in a double line for the wheels of all carriages to run on. This plan is cheap, safe, practicable, and humane,—dispensing with half the horses. The produce of the land they consume would afford employment and bread for all unskilled labourers, disbanded militia, discharged and discarded prisoners without end. Well, Sir, an ingenious American has at last persuaded us, at Birkenhead, and at Burton-on-Trent, to adopt the tramway of New York and Boston, on two lines of iron; but surely these are both expensive and perishable, compared with granite. No matter: only give us a rail; and I have great pleasure in presenting to the public three or four earnings, easily worked by manual labour, promising them both health and pleasure. I have amused myself with the subject, and, from experiments made on common roads, am pretty certain that on rails they will lay the foundation of improvements that may, ere long, supersede, in a degree, both steam and horses. I anticipate the return of much traffic and pleasure, now lost, on our public roads.

D. F. W.

#### A BRIEF HISTORY OF THE GREAT BELLS.

SIR.—Upwards of four years have passed away since the first great bell, called "Big Ben," for the clock at Westminster Palace, was cast; and many readers will remember that, while he was temporarily suspended from a beam at the foot of the tower, in October, 1857, he received a death blow. During the month of May, 1858, his successor, Big Ben the Second, was produced; and, having been raised to his chamber in the clock-tower in October, and subsequently fixed to the large iron beam, he proclaimed the hour at the bidding of the clock on or about the 12th of July, 1859. But on a certain day in the month of September, in the same year, he was silenced also. So much for the performances of the two Big Bens.

A few days after the latter occurrence, a suggestion from a correspondent appeared in the leading journal to the following effect:—"Let the clock strike the hours, *pro tem*, upon the largest of the four bells, intended for the quarter chimes; the other bells being mute." Time, however, still rolled on silently; and thus it has continued up to this moment; so that about twelve months have elapsed since the clock struck—a space of time more than sufficient for designing, casting, and hanging out of the finest peals of twelve bells in the world.

With respect to the condition of the great bell, the "Reports" by Dr. Tyndall, Dr. Percy, and the Astronomer Royal, may be interesting so far as they relate to the cavities, cracks, and composition of the bell. But, whatever may be the opinion of these eminent professors as to whether it may again be made use of without any risk of breaking, the all-important question is,— "What is the condition of the bell in a musical point of view?" I must say, then, that it is by no means satisfactory; for, though we may perceive no jarring, nor grating of surfaces of the cracks; and though the note of the bell may have been called pure, it is defective, very dull, and, in my opinion, incurable. The truth is, that, since this Big Ben the Second was fixed in the clock-tower, he has never given out his "fundamental note" with its proper complement of "harmonics;" and this is the reason why the sound emitted does not "ring" like that of a perfect bell. In other words, this suggests the reason why the sound which strikes the ear is destitute of grandeur and richness of tone. Nevertheless, for the

## Miscellaneous.

**HOSPITAL CONSTRUCTION.**—The second note in Dr. Combe's plan for a hospital (p. 606, ante), should stand thus:—"The latest, and, as far as I know, the best and completest detail of these principles is to be found in the various papers by Mr. Robertson, of Manchester; in those which have appeared in the *Builder*, especially three in August and September of 1858; and in the papers by Miss Nightingale which were read to the Social Science Association at Liverpool." The omission by the printer of the words "in those" attributed to Dr. Robertson, erroneously, the authorship of our leaders of August and September, 1858. Next week we shall give some observations on Dr. Combe's plan. It should be quite superfluous to say that we do not necessarily agree in all the views the statement of which by correspondents we insert. Out of differences and discussion come certainty and truth.

**IRON BRIDGE AT BORDEAUX.**—This bridge rests upon ten piers about 230 feet apart, and is formed of enormous iron tubes. The columns which compose the piers are 75 feet high, and terminate in a handsome capital of entirely new design, rising some 60 feet above the ordinary level of the river. Many difficulties which were thought to be well-nigh insuperable have been overcome by the use of hydraulic rams, and some very ingenious apparatus invented by Mr. Nesven, the engineer in charge of the works. The bridge was commenced in 1858, and it is hoped that the present year will suffice for its completion. An engraving of it from a photograph appeared in the *Illustrated Times*.

**EPSOM SALTS.**—The spring of mineral water at Epsom is said to have been first noticed in Queen Elizabeth's days. It seems, however, to have had an older origin, and to have been found by one Henry Wicker in the year 1618. Its property as a purgative was first ascertained, according to Aubrey, about 1630. Its virtue depends on the presence of sulphate of magnesia, which was obtained from this water by chemical processes, and sold under the name of Epsom salts. The water is colourless and pellucid; it has no odour, and but a slight saline taste. The quantity of saline matter held in solution in this water is variable. Dr. Lister obtained from a gallon of the Epsom water taken up during a dry season one ounce and a half of solid substance; while Dr. Lucas, on evaporating a similar quantity of the water, procured but five drachms and one scruple of residuum.

**BRANCH OF LADIES' SANITARY ASSOCIATION FOR MANCHESTER.**—A meeting has been held in the Manchester Townhall, at which Mrs. William Fison, of Brighton, read a paper, and urged the formation of a branch of the Ladies' Association, established in London four years ago, mainly for the improvement of the homes of the poorer classes. The Rev. James Bardsley, M.A., introduced Mrs. Fison to the audience. The Association, she said, was formed by a few ladies who desired to alleviate the physical condition of the poor, and to popularize information on sanitary subjects. It was most important to provide counter attractions to the beer-shop and gin palace; and, wherever practicable, newsrooms should be established, where the working man could see the papers and have a cup of cheap coffee, like a gentleman at his club, without being driven to more objectionable places for them. Mrs. Fison pointed with sorrow to the sad violation of the Creator's immutable laws amongst the poor, and put to shame those landlords who sacrificed precious life and health by ill-ventilated dwellings, possessing neither pure water nor good drainage, so essential to life. She quoted the emphatic words of Professor Owen:—"It is proved to be practical to make those garments, the frail bodies of the population, last fully ten years, or probably one-third longer, in the wilderness of this world." Dr. Southwood Smith asserted with confidence that the cause of the depression which induced the poor to drink was bad air. Crime was not the necessary attendant of poverty or low wages; but it was most abundant in crowded towns and ill-drained localities. The encouraging fact was mentioned that the Religious Tract Society was about to publish a sanitary series of tracts. The cheap pamphlets of the Ladies' Sanitary Association, she remarked, deserved the widest publicity. The titles of a few, from a halfpenny to twopenny in price, are, "The Worth of Fresh Air," "The Use of Pure Water," "The Value of Good Food," "The Cheap Doctor," with others devoted to the feeding and clothing of infants. In Brighton and other places the happiest results had followed from these sanitary labours.

**BAZAARS AND LOTTERIES.**—It has hitherto been not unusual for the articles left unsold at bazaars, held for building or charitable purposes, to be disposed of afterwards by lottery. It appears, however, that that method of dealing with them is quite illegal, and, if practised in future, may be attended by unpleasant results. The Solicitor of the Treasury has just pointed out to some promoters of a bazaar at Stourbridge, that their proposal to hold a lottery would render them liable to heavy penalties, and it has been found necessary to abandon the scheme.

**PUBLIC OPENING OF THE VICTORIA TERMINUS AND THAMES BRIDGE.**—The new terminus at Finsbury and the railway bridge across the Thames, near Battersea Park, with the lines of rail in connection with the Crystal Palace and Brighton railways, were all opened to the public on the 1st instant. Progress, we may here note, is also being made with another railway bridge a little above Battersea and Cremorne, by means of which and the connecting lines of rail the railways on the south side will be brought into junction with those on the north through the short West of London line. Great changes in the railway conveyance centering in the metropolis are thus on the eve of occurrence. Further progress is also being made with the foundation cylinders of the Charing-cross railway bridge on the Surrey side.

**HOUSE BUILDING IN CHINA.**—The erection of a house is well worth watching, though to be next door to one is dreadful, as the workmen keep time to a barbarous, monotonous, drawing tune the whole time. A scaffold of 14 feet having been erected, a dozen boys mount upon it, and by means of a heavy stone drive down a row of piles in order to make a firm foundation. Now it is this pile-driving that is so objectionable. The leader of the gang keeps time by singing a song which no pen of mine can describe. Attached to the stone are ropes, so that they (each holding one) can drop it on the head of the pile. After five blows they join in chorus—such a chorus! At ten strokes they stop, waiting for their leader to sing a verse solo; then the chorus and ten thumps; then a solo and a rest. And so they keep on from five a.m. to five p.m.—*The Englishman in China*.

**THE GLASS TRADE.**—Messrs. Sowerby & Neville, of Gateshead, says the *Gateshead Observer*, are recorded among the patentees of the month. Their patent is for "moulds for making pressed glass." This invention consists in holding the body of the mould down to the bottom thereof by means of pins or trunnions, which enter suitable holes made for their reception in the bottom; and in forming a flange on the top of the plug to determine the thickness of the glass at the top or rim: the inventors are thus enabled to dispense with the top ring, upright hinge, and catch.—The workmen of Messrs. Sowerby & Neville's flint-glass trade have come to an arrangement with their employers yet, and are therefore still out on strike.—The representatives of the Belgian glass-trade have been proposing to the French government, since the treaty with England, that French glass should be admitted into Belgium *duty free*, on condition that Belgian glass, on its importation into France, should pay a duty of not more than 9 per cent.

**THE NEW CAMBER DRY DOCK FOR PORTSMOUTH.**—The foundation stone of this new dock has been laid. By the Act obtained for its formation, the council were empowered to borrow 30,000*l.* upon the security of the borough rate; and the contract for the construction of the dock was taken by Messrs. Bottomley and Hanson, at between 28,000*l.* and 29,000*l.* Since the undertaking was commenced the contractors have dissolved partnership, and the work is now being carried on solely by Mr. William Hanson, under the superintendence of Mr. C. W. E. Pineo, the engineer to the Corporation. The dock is to be 345 feet long, by 70 feet wide, and there is to be a concrete foundation of 4 feet 6 inches thick. The greatest depth will be 23 feet 6 inches; and it is calculated that the dock will hold a vessel of upwards of 2,000 tons. The materials, &c., required for the work are as follows:—Granite from Cornwall, 10,700 cubic feet; Roach Portland stone, 101,000 cubic feet; Purbeck stone, 12,000 cubic feet; Memel timber, 500 loads; excavation to be removed, 25,000 cubic yards; clay for dam, 1,700 cubic yards. Only about one-third of the bottom of the dock has yet been completed. Up to the present time about 2,000 tons of worked stone is on the ground, varying in weight from six tons downwards. The unfavourable weather which has prevailed during the late summer season greatly retarded the progress of the works, and the excavations, in consequence, were made with great difficulty.

**PROJECTED RAILWAY IN JERSEY.**—A number of gentlemen interested in the establishment of a railway between the towns of St. Aubin and St. Helier met last week in the town of St. Helier, to consider this subject, when a committee was formed, and the States of the Island, it is said, are to be pressed to facilitate the undertaking.

**HEREFORD OLD TOWN-HALL.**—Mr. Clayton states that the block with the use of which we were favoured was made from his restoration,—a restoration founded on the present remains and an old vignette engraving on the corner of Price's Map of the City. Mr. Clayton adds a long letter denying the correctness of Mr. Anthony's statements. We do not find in it, however, sufficient matter of general interest to justify the devotion of the space it would require.

**A NEW CHURCH AT PADDINGTON.**—The foundation-stone of the church of St. Michael and All Angels, in the district parish of St. John, Paddington, has been laid. Mr. Hawkins, of Stanhope-street, is the architect of the edifice, which is designed to be a chapel of ease, capable of containing about 1,000 free seats.

**THE LATE MR. J. C. WELLS, ARCHITECT, UNITED STATES.**—We have to mention the death of this gentleman, a prominent architect of New York, on board an English steamer, bound for his country, of which Mr. Wells was a native. He died two hours before the vessel reached land. He designed several of the public buildings of New York, including Dr. Phillips's church on the Fifth Avenue. Various large stores, and a court-house at Wilkesbarre, Pennsylvania, also illustrate his skill. He held the office of treasurer in the American Institute of Architects.

**THE LATE MR. THOMAS MOTLEY, C.E.**—This gentleman died at Washington, U.S., on the 13th of July last, aged seventy-six. He was formerly of Bristol, and was the projector of the design of the wrought-iron arch bridge over the Avon from the rocks at Clifton, a model of which was exhibited many years ago. He went to America about seven years since, in hope of getting his plans adopted in that country. Last year, in consequence of the severity of the previous winter, he became affected with a disease of the hand, underwent the amputation of three of his fingers, and seems never to have thoroughly recovered from the shock. He was interred in the Friends' burial-ground at Washington, and his remains were attended to the grave by the mayor of Washington, several official persons connected with the Government works, and a number of friends and acquaintances, by whom he was highly respected and much regretted.

**THE LATE MR. JOSEPH LOCKE.**—The *Daily News* gives expression to the opinions of many who say,—"So long as Joseph Locke lived and laughed and laboured amongst us, there were obvious reasons why we should abstain from challenging the neglect which he experienced in high quarters, and his exclusion from office, court, and coterie. When we think of the rubbish which lofty places are filled, of the imbeciles and impostors we are annually called on to pay for doing mischief or doing nothing, and who are daily jobbed into every species of public preferment, we cannot feel surprised that the presence of a hard-beated, clear-sighted, independent-minded man like the late Mr. Locke should have been deprecated diligently, and carefully avoided. If posts of power and responsibility were once thrown open to middle-class men who have proved themselves fit for them, the craft of the Ephesians would be in danger, and the great imposture would fear to be set at naught. But the sordid prudence which exigently seeks to preserve power and emolument in close monopoly hardly requires that the impudent and dishonest rule should be applied as strictly to other matters. Social courtesies and personal marks of distinction convey, indeed, to none but the most ignorant the idea of recognition of public service. A profligate or a fool, if he be ever sprung from the right loins, is certain of either or both. Usefulness, perseverance, consistency, energy, inventiveness, talent, or the universal respect of the community, are, we will understand, but dust in the balance where the broad ribbon of the Bath or the rank of Privy Councillor is in question; and as for haronecties, they are professedly given as prizes for the greatest number of hedges and ditches of which the contributors can show themselves to be the owners, great works and great virtues having nothing whatever to do with the matter. For engineering services rendered to France, Mr. Locke was decorated in that country with the cross of the Legion of Honour; in England, where he had earned ten times the gratitude and reward, the rule of the Government is to spurn and ignore such men."

**THE MASONS' STRIKE IN LEEDS.**—We are glad to learn that there is some probability of this strike being shortly brought to a termination, as the masters and the operatives have agreed to submit the matters in dispute to arbitration.

**EMPLOYMENT OF WOMEN AT THE GREAT NORTHERN RAILWAY.**—The abandonment of the coal trade by the Great Northern Railway Company is the occasion of some stir at King's-cross. The directors have given up the business to others, for whom they have recently built offices in the station. The circulars now issuing are said to have required the united labour of twenty-six clerks (all of whom are young women) a full fortnight to fold and address them, while the postage-stamps alone have absorbed £257.

**ESSEX ARCHÆOLOGICAL SOCIETY.**—The annual general meeting of this society was held on 27th ult., in the Old Castle, Colchester. It was the first occasion for opening the new museum of antiquities in the Roman Chapel, which has been granted by Mr. Charles Gray Round, and a large number of the gentry and clergy of Essex attended: a great many ladies also were present. The Rev. Charles Merivale, B.D., read a paper entitled "Notes of the Roman Conquest of Essex." Mr. Merivale controverted the statement of Professor Airey, that Julius Cæsar landed in Essex, and endeavoured to show that history and popular belief were right in fixing upon Kent as the place where the Roman conqueror landed. The Rev. J. H. Marsden next read a paper on "Greek Coins found in Colchester." Mr. Duncan, in a paper on "The Roman Topography of Colchester," pointed out the several localities where the tessellated pavements and other Roman antiquities had been discovered. The visitors inspected the antiquities of the town, and dined together at the Cups Hotel.

**STATUES AND MONUMENTS.**—The Government is said to have refused to give metal for the statue to the late Sir John Franklin, proposed to be erected at Spilshy.—Tenders have been accepted for the enclosure of the Nelson Monument at Yarmouth. Mr. E. O. Johnson, of Yarmouth, undertakes the stone-work at 188*l.*, and Mr. Barnes, of Norwich, has contracted for the iron-work, at 117*l.*—The statue of the late Mr. Robert Hall, M.P., is now finished, says the *Leeds Intelligence*, in the studio of Messrs. Dennis, Lee, & Welsh, Woodhouse-lane. It is a representation of the deceased gentleman in his robes, as the recorder of Doncaster.—A monument to the late Mr. H. A. Littlehale has just been erected in the church of Bolton-by-Dowland. The style is Perpendicular Gothic. The façade comprises an arcade of three double sunk ogee arches, standing on moulded base and plinth, the spandrels being filled in with open tracery. These arches are flanked by two buttments, having canopied buttresses, and filled in with tracery and armorial bearings, the whole being crowned by a moulded cornice (with carved vine-leaves), surmounted by a broken battlement of open tracery. Within the arcade is placed the gravestone, with an incised crosslet, surrounded by a nimbus, and standing on a calvary of four steps, and the incision is filled in with blue cement. At the back of the tomb is the inscription.

**ELECTRO-TELEGRAPHIC PROGRESS.**—The Pneumatic Despatch Company have commenced laying down their pipes in Throgmorton-street.—About 1,000 miles of telegraphic cable, manufactured by Messrs. Glass, Elliott, & Co., are, it is said, to be used between Rangoon and Singapore. The distance is 800 miles, but allowance has to be made for "slack," and for any casualties that may arise. It has not been finally decided, however, that the cable shall be laid between these points, although the idea of submerging it between Falmouth and Gibraltar appears to have been altogether abandoned by the Government, from the uncertainty of success to which so many failures with deep sea cables have naturally given rise. We are not aware that any vital improvement has been made by Messrs. Glass, Elliott, & Co. in this new (?) scheme.—Two lines of land telegraph from the Atlantic to California are now in rapid progress. The most northerly, which passes through Kansas and Nebraska, is expected to be so far completed in November that the remaining gap will be only about 1,000 miles.—The aurora borealis is said to produce a remarkable effect upon telegraph lines. The auroral current has even been used, it appears, for transmitting and receiving telegraphic despatches, on the American Telegraph Company's line between Boston and Portland, and upon other American lines.—The line named has been worked in this manner more than two hours; and, when the aurora subsided, the batteries were of course resumed.

**MEMORIAL DRINKING-FOUNTAIN AT SOUTHAMPTON.**—The ceremony of laying the first stone of the monument to the memory of the late Mr. Alderman Richard Andrews, in the public park of this town, took place on the 1st inst., in the presence of thousands of spectators. The design is a drinking-fountain, surmounted by a pedestal and a statue, 9 feet high, of Mr. Andrews. The whole building will be above 25 feet in height, will stand on a high spot of ground, and will be visible at a long distance. The architectural building forming the fountain is described as being in two stories, and of a triangular form, the style being Provencal Romanesque. Each of the three faces will be sheltered by a deeply recessed arch, below which will issue the fountain with double jets, each crossing each other under the crown of the arch. The fountain will be adorned with inscriptions and carvings commemorating and illustrative of the life and character of Mr. Andrews.

**KITCHEN BOILER EXPLOSIONS.**—Accidents of this kind are not infrequent, and something should be done, in perfecting kitchen arrangements, to obviate such risks. A safety-valve, opening in the side of the boiler, next the fire, so as to prevent weights from being set upon it, and to obviate scalding with the steam, might do. An explosion of a kitchen-range boiler has just taken place, we observe, in a house at West Derby, Liverpool. The accident, which was of a very dangerous character, was occasioned by one of the servants inadvertently turning the tap of the feed pipe, by which the water-supply was stopped. In a short time the boiler became overheated, and the expansion of the steam caused it to explode with fearful violence. A large portion of the kitchen wall was blown completely out: the kitchen-range and fireplace were shattered to pieces; and the furniture was thrown into a promiscuous heap.

**BRISBANE, NEW SOUTH WALES: OPENING OF A CHAPEL.**—In June last, a new Independent chapel was opened for divine service at Brisbane, in Eastern Australia. The chapel is situated near Government House, on the rise of the hill. The walls, according to the *Brisbane Guardian*, are of brickwork stuccoed outside and in, and the mouldings and water-tables are run in Portland cement. The entrance is in the second bay on the south-east side of the building, and is protected by an open-timbered porch. On the opposite side is a vestry of similar design to the porch. The roof is finished at the south-west end with an open turret. The gables are filled in with windows of open tracery: that at the south-west end is circular, and at the north-east triangular, the tracery being executed in cedar and painted. The lateral windows and those in the south-west gable are lancet shaped, and finished with hoodmoulds with foliated terminations. The roof is open timbered, and constructed of Queensland pine: it is supported on six pairs of principals with curved ribs, each forming a pointed arch. The interior is not quite finished, as it still requires a coat of warm colouring on the walls. The pulpit is of varnished cedar. The seats are of pine, stained. The style is the transition from the Early English to the Decorated. Mr.iffin, the colonial architect, provided the design, and contributed his services in the erection of the edifice.

**A NEW ROMAN CATHOLIC CHURCH,** dedicated to St. Anthony, has been opened at Walko, near Newcastle-upon-Tyne. The nave is 100 feet long by 30 feet wide; and the church, when completed, will altogether comprise about 850 sittings. The nave, south transept, and baptistery, containing accommodation for 600 people, forms the portion already completed, at a cost of a little more than 1,700*l.* The remaining additions are a north transept and a bell tower. Stone is the material used in its construction, and the woodwork in the interior is stained and varnished. The cost of the whole, when finished, will be 2,100*l.* Instead of the usual east window, the chancel is lighted from above by a flat light of stained glass, fixed in the highest point of the roof, throwing a red, subdued light on the altar and chancel. On the exterior, the place of the east window is occupied by a carved niche, to contain a life-size statue of St. Anthony, the patron saint of the church. The roofs, which are very high, are of open timber-work of simple construction, and, like all the other woodwork, are stained and varnished. A gallery for the choir, which, however, does not project into the chureh, is constructed in the transept. With the exception of a rose window in the transept, there is no attempt at ornamentation. A presbytery now in course of construction adjoining the church, is also included in the designs of Mr. Archibald M. Dunn, the architect. The contractors are Mr. W. Foggin for the masons' work, and Messrs. Waite & Howard for the carpenters' work.

**ALUMINIUM WORKS.**—Extensive works for the manufacture of aluminium and aluminium bronze have recently been erected at Washington, says the *Newcastle Courant*, and are likely to be kept in active and profitable employment. Mr. Bell has secured the sole right to use the patent for making this new metal, from Professor Deville; and, under the superintendence of Mr. Henry Brivet, the works (the only ones in this country as yet) have been erected.

**GAS.**—The owner of the gas-works at Whitby, Mr. Anthony Atkinson, M.A., is erecting new works, at a considerable outlay, on a site between the river Esk and the railway. It is expected that they will be completed before the end of this autumn. The railway company has contracted with the proprietor for the supply of gas for fourteen years. The price of the public lights has been reduced, and a uniform charge of 5s. per 1,000 cubic feet is made to private consumers, instead of 6s. 8d., as heretofore.—The Plymouth and Stonehouse Gas Company, from the 20th September, have reduced their price to 3s. 4d. per 1,000 cubic feet.

**TENDERS**

For consecrated and unconsecrated chapels to the cemetery now being formed at Halifax, Yorkshire. Mr. Chas. H. Edwards, architect. Quantities supplied by Messrs. Pearson & Dougherty:—

Whitely, Brothers.....	£3,100 0 0
Myers.....	2,540 0 0
Drake & Co.....	2,700 0 0
Evans, Brothers.....	2,485 0 0
Charnock & Booth.....	2,467 0 0
Robinson.....	2,400 0 0
Bancroft & Son.....	2,361 0 0
Pickard & Co. (accepted).....	2,287 0 0

For Plumbing.

Lees.....	185 0 0
Walsh.....	178 14 0

For rebuilding the Red Lion, Brompton, for Mr. Lathbury. Mr. G. A. Burn, architect:—

Piper.....	£2,593 0 0
Myers.....	2,360 0 0
Turner & Sons.....	2,320 0 0
Downs.....	2,170 0 0
Laurence & Sons.....	2,134 0 0
McLennan & Bird.....	2,045 0 0
Stimpson.....	2,045 0 0

For Barnby Dun Church. Messrs. Hadfield & Goldie, architects:—

Messrs. Anclay.....	£1,258 0 0
Hopkins & Read, Seales, Dod-worth, and White.....	1,173 4 6
Stimpson.....	1,122 0 0
Chadwick & Son.....	1,099 0 0
Richardson (accepted).....	1,095 12 0

For a passenger station at Marske, Yorkshire, for the Stockton and Darlington Railway Company. Mr. Wm. Peachey, architect:—

Bulmer.....	£1,563 0 0
Bulmer.....	1,257 9 7
Arncliffe.....	1,115 3 10
Pearson.....	1,060 10 0
Chapman.....	1,044 10 0
Kemp & Abildgaard.....	1,029 13 6
Arwin (accepted).....	1,015 1 4

For a pair of cottages, at Colney Hatch. Messrs. Richard Tress & Chambers, architects:—

Deards.....	£90 0 0
Powder.....	94 0 0
Hawkes.....	93 0 0
Eley.....	88 17 6
Pearce.....	87 17 0

For two new dwelling-houses, Percival-place, Tottenham, Middlesex, for Mr. Orme. Mr. James Dudley, surveyor. Quantities supplied:—

Chessum.....	£350 0 0
Humphreys.....	835 0 0
Brett.....	820 0 0
Turner & Sons.....	797 0 0
Cushing.....	757 0 0
Baldock.....	730 0 0
Clarke (accepted).....	748 0 0

Received by the vestry of Chelsea for the supply of

<i>Broken Granite.</i>	
Messrs. Fernings.....	s. d.
Mowlem & Co.....	13 6 per ton.
Messrs. Marnelle (accepted).....	12 11 "
<i>Flints.</i>	
Smeed.....	4 0 per yard.
Tyler.....	4 6 "
Tuff.....	4 6 "
Hart.....	4 5 "
Baldock (accepted).....	4 5 "

*Sewerage Works.*  
G. Todd, Jun. 2*½* per cent. discount from price in schedule. King & Howe's 10 per cent. ditto.

*Mason's Works and Materials.*  
Robinson..... Referred to a  
Nowell & Robson..... Committee.

\* Accepted.

# The Builder.

VOL. XVIII.—No. 923.

Hospital Construction.

R. COMBE invites criticism on his plan of a regimental hospital, which we published in a recent number,\* and we hope, therefore, any remarks we may make will be taken simply as an attempt to further elucidate sound principles of hospital construction. It is most gratifying to see army surgeons again turning their attention to this question, and it will be well for the army and for the nation if such attention be continuous. The names of Pringle and Lind will be more and more revered as the sound doctrines they enunciated and enforced are practically applied, and the spirit of their teaching is acted upon in the army and naval medical schools. Miss Nightingale has shown, by her evidence before the Army Medical Board, as also by her writings generally, that, in practice, sanitary science has been and is most sadly neglected. The army and naval death-rates are sufficient confirmation. Argument is an idle waste. The figures to be found in published returns are facts beyond dispute. Let any one compare the death-rates for the whole period of the Crimean campaign, contrasting the state of the British army and the British hospitals, month by month, with the state of the French army and French hospitals in parallel months, and he will see that as sanitary works and regulations were put in force in the British army and hospitals, the death and sickness rates were reduced; whilst, in the French army and hospitals, they increased to the termination of the war. It has, in fact, been said that the terrible mortality in the French hospitals (at the rate of 5,000 per month for the last three months of the war), necessitated, on the part of France, a speedy peace. We have a high respect for Dr. Combe, because he has evidently been studying sanitary science; but we are not able to approve fully of his plan for a regimental hospital, for reasons to be given.

In the first place let us say "model plans," like model rules, seldom work in every-day use, if rigidly applied: there may, however, be an alphabet of sanitary science, and a grammar; and the better these (the alphabet and grammar) are learned, the more wisely the science will be applied, and so much the more beneficial will be the results. With respect to hospitals and barracks for the British army, who shall devise a model plan and model rules suited to all climates, sites, and subsoils? British soldiers are expected to do duty amidst the winter snow of Canada, the tropical heat of Central India, and all the intermediate gradations of climate. It must, therefore, be clear that a model plan for hospital or barrack, to be always followed, would be a model nuisance. One law of nature must be attended to—the law of constant change of air within rooms inhabited by men. Fresh air and sunlight must be rendered available, with pure soft water, and fresh food in wholesome variety: clothing, work, and exercise, that is amusement, must also be attended to. Any medical officer must not only act, but must first think and feel for the men under his charge; and, as the result of experience, we will answer for it that such medical officer will receive his reward in the gratifying respect and esteem of the men under his care.

Dr. Combe recognizes the pavilion plan, but

does not fully express it in his arrangement. The word "pavilion" implies unity—a tent, a room under one roof; and it ought, in future, to be understood, when applied to hospitals, as meaning a separate building. This is certainly our idea of it, and also the idea Miss Nightingale has embodied in her Liverpool papers. Each ward must be one pavilion, and in its arrangements complete. A building planned so as to present three wards in radii, with a central block and closed angles, is not on the true pavilion plan. The hall, with glass roof, would be found a costly nuisance. Glass radiates heat, and condenses moisture: if the framing is of timber, this decays rapidly; if of iron, there are constant expansion and contraction, and "joint" leakage. Top lights of large area, acting also as a roof, are not often advisable, excepting for covering plants, when dropping water cannot do much injury. The idea of large areas covered by glass, is more poetical than practical. Ask the tenants at the Crystal Palace their experience. The ward dimensions given by Dr. Combe are not what we should recommend,—100 feet by 22 feet by 15 feet, for twenty-eight beds, or 1,178 cubic feet per bed. Such room would be too narrow by at the least 3 feet. Miss Nightingale gives 111 feet 6 inches by 30 feet by 17 feet, for thirty-two beds, or 1,760 cubic feet per bed, with closets, bath, &c., at the end. Dr. Combe cannot give the cubic space indicated by Miss Nightingale, because of a recent army regulation as to hospital accommodation. Dr. Combe has placed closets in the middle of the length of his model ward on one side, and a scullery opposite. The results would be that the scullery so placed would become a mere gossiping place for patients and orderlies. As to the soil-pan closets projected from the side, there is evidence to show that a taint would be driven against and through the windows by every side wind,—modified, no doubt, and reduced in intensity, but still sufficient to carry, with certain states of the atmosphere, an actual and sensible cause of smell into and through the ward. The continuance of a stream of foul gas, at times, is very curious. It has been known to continue perceptible to a human nose, in the open air, for a full quarter of a mile. As to the arrangement of the separate apartments or rooms, thirty, if we mistake not, are shown for ninety-two ward-beds. Now, in military hospitals, as in civil hospitals, separate rooms should be reduced to a minimum. Rooms have holes and corners to harbour dust. They are additional places to clean, and also to skulk in.

The two small wards shown for four beds each, have neither light nor means of ventilation sufficient. Dr. Combe, it is true, gives a qualified approval of such wards, but he counts the eight beds to make up ninety-two. Small wards are specially objectionable for ophthalmic cases. They become nests of disease, and aggravate rather than cure. Further, the administrative offices are scarcely so planned as to facilitate administration. The hospital sergeant is placed at too great a distance from the wards. An hospital sergeant ought to overlook his ward by day and by night. Military hospitals should be places to cure the sick, not to be married in. The sewerage and drainage, as shown on Dr. Combe's plan, would be extravagant: "external and in right lines," certainly, but with the greatest possible lengths to do the least possible good. Sewers and drains should remove subsoil-water from the covered site, surface-water, and roof-water, as also waste and soil-water from within the hospital. Sewers and drains may run parallel to buildings, but external, so as to remove subsoil-water, to the full depth of such sewer, from the area covered by any building.

As to a general hospital, Dr. Combe appears scarcely to have apprehended the idea of a "general hospital," as he seems to consider it necessary to "agglomerate" sick together in order to realize a "general hospital." The pavilion plan of structure, rightly understood, is recommended expressly in order to make "a general hospital" possible without any one of the risks of "agglomeration."

There are general hospitals at this moment with fewer sick under one roof than Dr. Combe

proposes to put in his. "Segregation," which he justly insists upon, will, we are told, be effectually carried out in the new military hospital about to be erected at Woolwich; if by segregation he means placing a small number of sick in each building, and isolating each such building, so as to form houses much more separate than houses are in a street within a town. The new hospital at Woolwich is not to be an agglomeration of regimental hospitals, but a general hospital under the new regulations. With regard to the site selected for the new hospital at Woolwich, we are assured that it has not a clay subsoil, but is geologically known as the "Woolwich pebble bed;" a mixture of shingle and loam resting on clay. This site will be sewered and drained; and, to obviate any risk even of subsoil-damp, the floors will be isolated by a basement above the level of the ground. The authorities, it is asserted, have used their utmost exertions to secure the best available site. The hospital question deserves to be fully discussed, and needs to be. Dr. Combe evidently feels this: hence the last paragraph in his paper; and he will not be angry with us for showing him where we differ.

With respect to sites and climates, we may offer a few remarks, the result of a tolerably wide experience, and we are bound to say that sites are more rarely in fault than defective structures, overcrowding, and bad management. A few feet elevation from the ground will mitigate the evils of a damp subsoil. Sidelong ground, that is, a steep hill-side, is about the most difficult site to manage safely, because there is the temptation to level a site by excavating and embanking, and the excavated portion becomes a sort of cellar dwelling, damp, cold, and a reservoir of stagnant air. In all climates, houses half buried in sloping ground are liable to promote excess of disease. Dr. Sutherland noticed this fact in the cholera epidemics in England; Mr. Rawlinson has pointed it out in his sanitary report on Alnwick, 1849; and physicians on the Continent, have independently remarked the same fact. The huts of the 79th regiment, forming part of the garrison of Balaclava in the spring of 1855, present a noticeable example, as may be seen on reference to the Report of the Sanitary Commission in the Crimea. There are, of course, "best sites," such as dry gravel; and, "worst sites," such as a marsh or wet clay. There are also healthy climates, and unhealthy climates; but the wonderful mechanism and power of adaptability in man, which enable him to live in health amidst the frosts of a Polar winter, where mercury becomes a solid, and to breathe air having a temperature which roasts dead meat, certainly have the power of adaptation within ordinary ranges of heat and cold from 50 degrees to 90 degrees Fahrenheit. The prime necessity in each case is abundant oxygen, or ever-changing air. In a hot climate there must be an artificial current or change of air created, and in a cold climate there must be artificial warmth; but no room should ever have its temperature raised by animal heat. In a cold climate, animal heat must be preserved by suitable and sufficient food and clothing; in hot climates, heat-producing food should be avoided, and a more rapid change of air should be provided for. With respect to cold the Chinese have a saying, namely, that "only fools and beggars feel cold." The one have not wit to clothe adequately, the other are too poor to provide necessary clothing. Neither our army authorities, nor the general public, sufficiently consider this. Man is a warm-blooded, and, therefore, in a civilized state, clothing animal, and man also requires pure air. The clothing is a matter of adaptation. There is, however, only one reservoir of pure air, and that is beneath the all-encircling canopy of heaven. Fresh air is external, and that will be the best hospital plan which admits it in the most direct manner. Elongated flues, complicated chambers, patent-heating apparatus, and artificial means of change, seldom answer alone. A punkah may be needed in India, but no form of air-fan can be needed in a British winter.

In the army, as in civil life, cost must ever

\* See p. 606, ante.

be an important element in hospital, in barrack, and in house construction. But this element of cost should be considered in all its bearings. First cost is one element,—working, or administering cost, is a second element, and in any calculation,—and the proportions amount of health or sickness is a third element, and, at present, most unfortunately by far the most important element of cost in hospitals. It could be shown, in figures, that many hospitals have destroyed more money value in human life, in one year, than would have made up the difference betwixt a bad and a good plan, supposing a best plan, in all cases, to be more costly than a bad plan,—a statement we do not allow.

Dr. Combe remarks, justly, that cubical space necessarily bears some relation to other things; especially to the rapidity with which the air is changed. This is true; but only to a limited degree. Any inclosed space, to be inhabited continuously, night and day, as hospitals are, must have large cubic capacity in proportion to the number of inmates. The means of ventilation should be abundant, and the action certain, constant, and requiring the least amount of human care, and there should be a fixed amount of permanent ventilation as little as possible under any servant's or patient's control. Windows with double sashes—both sashes hung—will be best for cold climates, and louvered openings, beneath verandas, for tropical climates. Where double sashes are required for winter-cold, one set may be made removable for summer use; because, in such a climate as Canada, there is an Arctic winter with a tropical heat in summer. Windows with double sashes would probably save their cost in fuel alone, even in the climate of Great Britain; and, as judiciously managed, the intermediate air-space would be a means of ventilation and of economizing the heat of the room at the same time, by opening the inner sash at the top and the outer sash at the bottom. Air passing out would give a portion of its heat to the air entering, and the inner glass would retain something of the temperature of the internal air.

In hospitals, each ward should contain such a number of patients as one head-nurse may overlook: Miss Nightingale names thirty-two, Dr. Combe twenty-eight. The width of such a room should not be less than 25 feet: Miss Nightingale prefers 30 feet. The windows should be at regular intervals, on both sides, and opposite: soil-pans, sinks, lavatories, and hath should be at the farther end; the room for superintendent and nurses at the entrance end, with internal windows so arranged as to command a view of the ward night and day. Vitreous substances, such as glazed bricks, tiles, marble, flags, or asphalt, should not be used within the ward, as these absorb and conduct heat rapidly, and, in damp weather, condense moisture. Marble halls sound romantic, and do to dream of, but would make most objectionable hospitals. For the same reasons, metal structures should be avoided. Permanent hospitals, built of brick or stone, should have abundant means for window and door ventilation: temporary hospitals should have abundant means of ridge-ventilation. Any material like patent felt should be used with judgment. Huts must not be made air-tight, like extinguishers, as those at first used in the Crimea were made. The one prime requisite for all hospitals, in every variety and range of climate, is FRESH AIR: to secure this with comfort to the patients and economy of administration is what is wanted. Hospitals may be made places in which the sick may have a chance of recovery rather than an almost certainty of death. Cobbett said of writing, "That is the best writing which the greatest numbers can most easily read." We would say of hospitals, that is the best planned hospital in which the sick can be placed and nursed at the least cost of money and labour with the certainty of the greatest proportion of recoveries throughout the year. The true pavilion system may be one ward or many wards; but each ward must be a complete unit, securing at all seasons means of cheap and efficient nursing; as, also, of sunlight and fresh air.

#### TRADES' UNIONS AND STRIKES.

In the department of Social Economy, at the recent Glasgow meeting,

Mr. EDMUND POTTER, President of the Manchester Chamber of Commerce, read a paper on this subject. He said, in the course of it,—

Strikes I consider as the action and the almost inevitable result of commercial bargaining for labour. They will always exist, but their operation will be softened and rationalized by education and sound views. When intimidation or force is used to compel a bargain by either side, it becomes criminal, and ought to be treated as such. Labour ought to be bought and sold, and be considered as a mere purchasable article, and the bonest fulfilment of contracts should be adhered to. Where the unions are the strongest, there the men are the most unthrifty and the population most degraded. Where, also, labour forms a large component part of a trade and there is least mechanical power and capital, the same spectacle is exhibited. Here the speaker gave a recent instance of the working of trades' unions for utterly selfish purposes. It was that of the Coventry workmen and the Blackburn Union. The power of the trades' unions then robs the worker of his right to work, and robs the capitalist of his right to purchase. The union does what in the individual would be dishonesty, and I am not yet willing to think that, by counteracting unions of masters, such things should be prevented. All protection combinations arise from jealousy, fear, or weakness; and how is this caused? The labourer does not save as he might do; hence he is dependent. I would wish him to have power, based upon free thought and self-respect. Strikes would not have much of their misery, were the labourer saving. And yet it is possible that many workmen, such as builders, could be saving, and they should not be obliged to appeal to their fellow-workmen for aid. If it was right to take the step of striking, it should have been prepared for by saving. In 1857 and 1858, thousands in certain districts were working on short time, and yet there was no misery, for the workmen could draw upon the savings' banks. Many of us could look upon the restrictive influence of trades' unions on individual progress, and many men have sacrificed the advancement of a life to the narrow subjection of a trades' union—some from honourable motives, but in most cases from bodily fear and a want of moral courage. Many have consented to abide by a uniform rate of wages, and many might have become masters. In regard to the alleged indifference of the masters as to the cause of strikes, I believe this arises from the conviction that the fact of his being a purchaser of labour ought not to subject his transactions to the special interference of third parties. The condition and education of the present generation of working men should make them, if they choose, as honestly independent of the master-class as does competition between buyers and sellers of other commodities. The success of all private concerns, and more particularly of those larger ones which are constantly looked upon by the unsound philanthropist class as those which ought to be shared in by the workman, is mainly owing to the energetic employment and the working of saved capital, and not to large profits. If the workmen choose to use their small savings, they can now avail themselves of partnerships in almost every trade, under the Limited Liability Act. I do not say this with a promise of success, as I do not think they will be successful in competing with individual energy and capital. Unsoundness must attach itself to every purely trade union, whether it be a burial club, a society for the regulation of wages, or for the enforcement of partnerships. The executive, supported by the mere majority, that majority the least educated, will offer a retarding influence. Further, no trade union ever encouraged invention. Hundreds of inventions are not used because trades' unions are strong enough to prevent them. This is shown in the case of brick-making machines, and thus millions of bad bricks are annually made, and thus society is injured. Unfortunately, the working man continues, in almost every trade—in policy or feeling at least—the unionist. To my mind, one of the most mischievous fallacies of the day is the idea that labourers have the power to form successful and useful combinations, and that masters will voluntarily give in all that had hitherto been tried by force to obtain from them; and that between employers and employed the relations will be those of voluntary partnership. There is a strong distinction between associations for competitive trade purposes, or for national ones, and trades' unions, which are so many unsound monopolies.

Associations are voluntary: unions are entered into from class feeling, from fear, and for restriction. No trade union, no protective monopoly, has ever really benefited a people. It may have benefited, temporarily, a small class, but it injures the mass. My opinions do not tend to shelter my class—the masters—by combination against competition. We advise competition. We say, education and industry are the best securities for individual and national progress. The conclusion I come to are,—that trades' unions are founded for an unsound purpose; that consequently their moral effects are bad; that society can be best aided by free and open competition; and that education and forethought alone can secure to every one his fair reward.

Mr. A. K. Hunter, of the Council of United Trades, Glasgow, read a paper on "The objects of Trades' Unions." He wrote to rebut some of the mislaided of allumies which have been uttered, contemned, and believed against them; and said the object of trades' unions was the moral and social improvement of their members. They aim at this elevation by endeavouring to obtain for them as much of the means of living as can be had by fair means. We may be met by the political economists who hold the doctrine that bare sustenance is all that labour requires, and that to violate this law is against political economy. While it may be true that labour only requires sustenance, it does not follow that the labourer should not receive more than what will keep body and soul together. This would be more than slavery. We know that some men think that all paid-for labour may be looked on as so much withdrawn from the trading power of the nation, and consequently would keep down wages, in order that such persons be not impaired. Such persons are alarmists of the worst kind. Their counsel breeds discontent, and, by indicating strikes, are a curse to the country. Labour may receive and retain command of a greater share of the profits of trade, and the country be nothing the worse, the money still being available for trading purposes: no matter who gets it, if they who get it spend it. National wealth may be owned by all the nation, and the greater the better. Then we would have a people industrious, contented, loyal, and conservative. Working men are determined to be greater sharers in the profits of labour, and make a better use of them than hitherto; in proof of which, we refer to the gigantic schemes of co-operation that are wrought successfully out in our day. A change in our social relations is impending, and we think that the starvation doctrines of those political economists already mentioned have done much to bring about such a change. It is the object of trades' unions to make men independent,—something more than mere hangers-on, wanting, nay begging of their employers to toil. Were trades' unions better supported, we believe it would be for the advantage of ratepayers. The most thoughtful men were unionists, the most careless non-unionists. It was the object of trades' unions to prevent that undue reduction of wages that has so often followed the introduction of machinery. If that was not attended to society would be composed only of millionaires and paupers. While we admit that all the acts of trades' unions are not what we could wish, we venture to predict that in our own day they will be as well conducted as any other popular institution. Mr. Hunter adverted at length to the struggles of the operative hakers of England and Ireland, and concluded by saying that men not in union were generally in the lowest state possible, both as regards wages and position. Carlyle had said with great force and beauty,—"Yet ten men united in love were capable of being and doing what ten thousand singly would fail to accomplish. Infinite is the help man can yield to man." That was the condition on which we take our stand; otherwise there would be what Carlyle calls a "community of drudges."

On the next day a report of a committee appointed by the Council of the Social Science Association was brought up and read. The suggestions and observations with which it concluded are as follows:—

1. That trade societies have of late years increased in number, and that an increased number of working men have become members of them.
2. That societies composed of workmen who are engaged in the same trade in different parts of the country have shown a disposition to unite; that societies connected with different trades in the same town have also shown a disposition to unite.
3. That the principles upon which trade societies regulate their proceedings are more moderate, and that discussions between the workmen belonging to them and their masters have been managed in a fairer spirit than in the times before the repeal of the laws against combination.
4. That the workmen belonging to these societies form

a better estimate now than heretofore of the condition of their respective trades; that they are less unreasoning in their expectations of obtaining increased wages; that they understand better the necessity of submitting to arbitration, and that they generally overcome the prejudices which they once entertained against machinery; and that their leaders are men of high character and intelligence.

6. That the strikes, though more frequent, are conducted with less violence than in former days.

7. That these changes are owing in a great measure to the increased publicity which has been given to the rules of the societies, and to the action of public opinion upon them since they have ceased to be illegal.

8. That among the causes of improvement in the general temper of the working men must be reckoned the establishment of joint stock associations in different parts of England; these associations having contributed both when they have succeeded and when they have failed, to increase their experience, to show them that there are fluctuations in trade over which the masters have no control, and to teach them the necessity of self-control and self-sufficiency.

9. That there are still in many trade societies rules, some acknowledged, some concealed, which interfere with the freedom of the masters and the men, within as well as without the bodies that impose them, and which are inimical to the interests of political and social economy must utterly condemn.

10. That trade societies have secured the co-operation of many prudent workmen by undertaking to provide maintenance for those who are casually out of employment, or who are seeking for work by means of the agencies of benefit societies, occasionally by promoting emigration, or establishing reading-rooms or libraries.

11. That the union of purposes adds to the attraction of these societies, and seldom enables a majority of their members to be in an unwilling minority in strikes and all their consequences.

12. That the teaching rich societies experience in finding a profitable investment for their funds, often increase greatly the temptation to employ them in strikes and all their consequences.

13. That disastrous as have been the immediate results of most strikes, to masters as well as to men, they have often been without their use to both, by inducing wiser and more reasonable concessions on one side, and less unreasonable demands on the other.

14. That minor questions connected with trades, which often produce serious visitation, might be advantageously referred to a tribunal of masters and men, but that in the opinion of a majority of the committee it would be over sanguine to hope for the removal of the more direct and serious causes of strife from such arrangements.

15. That the rate of wages must be settled between the masters and the men; and that the intervention of third parties, unless specially invited by both, and possessing a very high degree of the confidence of both, can be of no avail.

16. That the Legislature may do much good service to workmen, by providing an easy and cheap remedy both in law and equity to meet the case of disputes between trades' societies and the masters, especially in respect to the application of benefit funds.

17. That the slightest return to the old policy of prohibiting combinations would be most mischievous, and that a majority of the committee think that no legislative measures for preventing strikes and lock-outs could be devised.

18. That combinations of masters and of men have always tended to become tyrannical, when their rules, disputes, and modes of action have been kept secret; and that the wisest course is to expose them to the public in the best manner they can give, and that they are not engaged in plots which are dangerous to the public.

19. That the improved education of masters and of workmen is a good reason to hope, doing more to avert collisions between them than any other arrangement, whether voluntary or enforced; that the experience of the committee has convinced many of the employers that not to care for the education of their men is to promote their intellectual and moral ruin; and that the employment of uneducated slaves, without temperance and self-government, they must regard as a whole land, that the more they respect their own interests the less they will be at war with every other.

The President said they had now heard the report, and he would now call upon Mr. Hughes to move the adoption of the report *pro forma*. Mr. ("Tom Brown") Hughes then moved that the report be received. He believed for himself that the action of trades' unions was to stop strikes—not to create them. He believed it was the duty of the Legislature to provide for the regulation of wages in a dispute. One of the great employers in Yorkshire had suggested that this very meeting of the Social Science Association, a society should be formed to get masters and men to arbitrate.

Sir Archibald Alison, in course of a long speech, said—No one has any conception of the magnitude of the devastation caused by these strikes. I do not think it is possible to exaggerate the evils attending strikes. I have been brought into the country, officially, as public prosecutor and as arbitrator, with five or six great strikes in this country, and I am sure I am within bounds when I say that each of these strikes has cost the labouring classes of Lancashire not less than 500,000,000. It was not sustained merely in wages: it was divided by them with the persons with whom they dealt, and who depended upon their labour for their own employment. For every one

that strikes there are, at least, six or eight other persons thrown into distress who have never struck—who are advised, perhaps, to strike, but who, nevertheless, are the innocent participators in the sufferings it produces. Now, gentlemen, in contemplating this subject, there are two facts, which appear to me to be of vital importance, with the view of showing how these evils which we deplore may be remedied. The first of these is the great and growing improvement which has taken place of late years in the mode by which strikes are conducted. I think that is owing, not so much to the change made in the law in 1825, when trades' unions were legalized, as to the growing influence of public opinion. I think trades' unions in themselves are not only a proper but a necessary balance in the fabric of society. I think that without them capital would become far too powerful, and workmen would be far too much beaten down. I wish now to point out a mode in which they may avoid the character which their former conduct has caused, and gain their legitimate objects. In the first place, I agree with the report that nothing tends more to conciliate the working classes, and remove hostility between master and tradesmen, than kind intercourse with them. I would recommend, also, that trades' unions should attend to the circumstances under which a strike will be effectual, and my advice to those trades' unions, who have consulted me has always been—"Don't strike except when prices are rising: never strike when prices are falling." The propositions were discussed by numerous other speakers at considerable length, but no resolution was come to.

THE RESTORATIONS AT WARKWORTH.

A CHARM, both architectural and literary, attaches to Warkworth. Here, the divine Williams,—as the French savant designates Shakespeare,—laid the scene of the principal part of his drama of Henry IV. The rock-been hermitage that suggested one of Bishop Percy's reliques of ancient poetry, "the hermit of Warkworth," is close at hand; and the fringe of sea-coast is that described by Sir Walter Scott, in "Marmion," when the abbess of Whitby's "cloistered pite" voyages to Lindisfarne,—

And now the vessel skirts the strand  
Of Coquet-Isle northbermerland.  
At Coquet-Isle their heads they tell,  
To the good saint who own'd the cell;  
Then did the Abbe attend him claim,  
And Warkworth proud of Percy's name.

All who have recently travelled to Glasgow from the south, using the York and Berwick Railway, must have noticed the castle, prominent with its watch-tower; and other southerners who have not seen Northumberland, may know the castle through Turner's picture of it, in the Water-Colour-room of the Brompton Museum.

On the crest of the hill, up whose gentle acclivity the one wide street is built, stand the remains of the once mighty castle; at the foot is the church. The term, "remains," in connection with the castle, must not be construed to mean a pile of ruins; on the contrary, the shell of the keep is nearly entire; nor is it till we are close upon the structure, that we can perceive any marks of decay in the curtain-wall, which, strengthened with several mural towers, surrounds the bailey beneath the south and west fronts of the keep. The picturesque neighbourhood is thus described in the Elizabethan survey made by Clarkson:—"The castle is environed on three parts with the sayd ryver (Coquet); and of the north parte, in an angle within the said water, is situate a towne, called the boroughe of Warkworth, and the parish church, and at the north end thereof a bridge over the water, and a little towne buyld on th' end of the sayd bridge, wher bridge, with th' litle tower at the end thereof, are still standing; and it is of the good stewardship of those upon whom the charge of them is present devolved, that we are going to tell.

Both church and castle have been restored: the former, thoroughly; the latter, partially. The old chroniclers relate that the church was originally founded by the Saxon monarch, Ceowulph, and that he insured the immortality of his name by founding many churches, and resigning his kingdom, and taking the monastic vows and habit of the monks of Lindisfarne. All honour to their veracity! In the course of the recent restorations, the oldest portions of which are Norman, were uncovered the foundations of a Saxon edifice. They were 4 feet thick, and the lowest corner-stone was found

hollowed for deposits, as in modern times. It was with regret we learnt that the Normans had been beforehand, and left the receptacle empty. There are some minds that refuse to credit the statements of the monastic chroniclers; but here, to support their testimony, is an evidence that has been buried nearly eight hundred years; and, as if this were not corroboration enough, a small Saxon cross, carved with a basket-work pattern, was also brought to light. On the decay, or, more probably, demolition of this church, the Normans proceeded to build a nave and chancel over the same site, though not, as we have seen, upon the same foundations. About a century later an Early English tower was added at the west end. There are suggestions of a slight renovation having been effected in the Decorated period, which are most home out, perhaps, by a niche in the chancel arch. Then, in the Perpendicular period, a thorough rearrangement must have been organized. The south wall of the nave was taken down and replaced by columns, and a south aisle added, which was lighted by the large windows characteristic of the Perpendicular period. The pointed roof of the nave was also condemned to give place to the prevailing mode: so the walls were heightened, clerestory windows inserted, and a flat roof thrown across, leaving a tall-tale mark of the apex of the old roof still visible on the tower. Subsequently a wrought ornamental iron altar-rail was fixed, *tempo* Queen Anne. After this Georgian churchwarden did their best, or worst. They voted it high pen pews, plenty of whitewash, large sash windows in lieu of the Norman lights, and a bran new gallery, supported on iron posts. Then came a long season of complacency and inaction, till at last the pews began to rot and harbour mice and insects, and the fabric fell a prey to damp. The rain found its way through the roof, and the work of so many centuries was threatened with utter ruin.

To avert this catastrophe the worthy vicar set on foot a proposition to restore the edifice, when he was met with the usual amount of preparatory opposition. On these occasions there are always some people who think decayed churches very nice and interesting as they are; others, who believe that to touch them would end in spoiling them; others, who are more difficult to be convinced than any, that if there is to be an expenditure of money, it would be better to build a new church than to patch up an old one. Strong in the labour of love, the vicar waved all objections, and commenced his task. When once fairly in hand, support and aid came from all quarters; showing, beyond all words, the catching influence of a lovable work if only set about. Gifts of stained glass, and other objects of ornamental art, were freely promised: thus encouraged, the vicar brought the good work to a successful termination—the handsomely renovated church being opened for divine service on the 16th ult.

As the church was originally Norman, the selection of the Norman style, as the basis for the restorations, was considered correct. The care of the nave was entrusted to Mr. Dobson, of Newcastle; while Mr. Christian, as architect to the Ecclesiastical Commissioners, was responsible for the chancel. The flat perpendicular roof over the nave was taken down, and superseded, in its turn, by an open timber one; the sash-windows were removed, and the Norman lights replaced; the high pen pews dismissed, and open benches substituted; the gallery demolished; and the old plank-pannelled pulpit and reading-desk replaced by new. In the removal of so much of the perpendicular masonry as was rendered necessary by the determination to return to the high-pitched roof, numerous fragments of Norman sculpture were found built up in it: corbels of the usual grotesque character, portions of mouldings, and of shafts. This operation laid bare the Norman corbels that had borne the weight of the original roof, consequently the identical starting-point might have been chosen; but, for some reason, these corbels are left standing out from the wall, and the new roof is carried on others at a slightly increased altitude.

The chancel still boasted its Norman stone groined roof, although the Norman east lights had been displaced for one of the churchwarden's neat sashes; so it remained for Mr. Christian to re-open the Norman triplet, and to see to any needful repair of the ancient groining. All this, and more has been done. The triplet is filled with stained glass, from the studio of Messrs. Clayton & Bell, the subjects of which are depicted in medallions, with much religious sentiment and some harmony of colour.

A small memorial window by Wailes, in the north wall of the nave, and another in the circular opening over the chancel arch, have been inserted,

besides a large, six-light, perpendicular window in the west end of the south aisle, representing the whole army of martyrs, elaborately executed by Messrs. Clayton & Bell.

Tearing from the church, and climbing the steep street, we see the proud, grey, lieben-tufted castle, with the bold bas-reliefs of the Percy lion sculptured on its towers, grand, impressive, and heart-stirring, like the strains of martial music. We pass through the entrance-tower "with our heads full of the ancient Percys," as Wordsworth said, and find ourselves within the bailey. Through the green sward rise the bases of clustered columns, fragments of an intended collegiate church, whose founder did not live to carry out his purpose. Here and there hillocks reveal the burial-place of fallen masonry, and all the towers are roofless, and bestow glimpses of the sky through the frayed and mullioned window openings; but the wide stone steps that lead up to the entrance-door of the keep, are new and white, and neatly squared, and as the eye takes further survey it finds the windows of the south-west tower glazed, with new stonework all round about them, and a new ribbed lead roof also visible. This is the tower lately restored and furnished in Medieval style by his Grace the Duke of Northumberland. Of a surety we can subscribe to all the royal surveyor said, when he wrote, in 1538, that this was "a marvellous proper donjon."

The plan of the keep is a square, out of the four sides of which advance four additional towers. It contains, besides private apartments, a fine banquetting-hall, which had a dais and music-gallery, a chapel with oratory, a mighty kitchen, with butteries, cellars, large tanks for water, oven and boiler. The masonry, as we have said elsewhere, is in good preservation; but the timber of the floors and roof, with the lead, have been abstracted; regarding which, a document, still extant, shows that they were presented to one of the auditors of the family, by the Countess of Northumberland, in 1672, as a contribution to a house he was building for himself at Chenton.

The southernmost of the eight towers is that which has been chosen for restoration; it has been roofed in, floored and fitted with oak, hung with stamped Venetian leather, and furnished with ancient carved oak furniture,—making, when the Oriental carpets are unrolled, and the sideboards set out with choice specimens of ancient ceramic art, a very cabinet picture of an interior in "ye olden times."

Descending to the bank of the river, we trace its shining course till we see upon the opposite shore a high sandstone rock, pierced with a doorway and loop-lights. This is the Hermitage. A ferry-boat assists us across the twinkling, salmon-haunted stream. "My tears have been my meat day and night," wrote the hermit over the inner doorway, and every detail of his cell was pervaded with the same intense and passionate expression. It is divided into three chambers, of which the principal is the chapel. Here he seems to have lavished his solitary labour. He wrought the roof into groined compartments, divided by ribs, which terminated in pillars resting on the ground. He ornamented the windows with tracery; he begrudged not the tedious and scrupulous exactness required for mouldings; he hewed out an altar, a piscina, and a lavatory. But more than of his soul on the recumbent effigy of his lady-love, "My tears have been my meat day and night" must have been the heart-rending chant to which he attained the strokes of his chisel, as he lingered tenderly over this part of his task. By a lynxoscopic arrangement he contrived to obtain a view of this monument from his sleeping couch in an outer apartment. He also furnished a smaller chamber with an altar, an aumbry, and a confessional. Traces of a kitchen are not too obliterated to be altogether discredited; while a flight of rude steps, hewn on the outer surface of the rock, conducts us to the patch of ground above it, which the hermit cultivated as a garden. On the road thither we pass his well. The breeze from the river dissolves the old-world charm with which we have been enthralled, and we get sceptical as to the diet of tears—the kitchen, the garden, the well, the river, teeming with salmon, force suggestions of more substantial and less saline fare upon us. This state of mind leaves us open to the conviction that modern antiquaries entertain, viz.—that Bishop Percy's pretty lullaby was a mere fiction, and that this interesting excavation was a chantry, hollowed out at the direction of the third Earl Percy, of Alnwick, and that the effigy represents Mary Plantagenet, his departed countess.

It is delightful to know that a feeling akin to

the old fervour that dictated the erection of these buildings animates their present possessors, and that while the public are permitted to enjoy the beauties of both castle and hermitage, they are well cared for and maintained.

#### SUBWAYS FOR GAS AND WATER MAINS: REGENT STREET, &c.

EVERYBODY knows that in London our water and our gas are conveyed to our houses by pipes which pass under the streets. Yet few persons are at all aware of the labyrinth of this pipework that lies under the surface of some of our great thoroughfares, unless they may perchance have peeped down some transverse opening that gas, water, or sewer work had caused to be dug in any leading street, and seen a section of the pipeage laid bare. Take Regent-street as an example: there are nineteen lines of mains, of various calibre, from the 10-inch bore down to about 3-inch, that thread their course through this street, the progressive accumulation from time to time as consumption of gas and water, and competition, have increased. With such a multiplication of pipes alterations or repairs to some or other of them must necessarily be of frequent occurrence; and what with this and the circumstance of altering service connections consequent on the consumer changing the source of his supply from one company to another, or from one kind of gas to another, there is a perpetual breaking up of the street, to the annoyance of all that have to pass, and the serious loss of the parish on which devolves the charge of maintenance of this most costly bit of road. Nor will the operation of the New Gas Districting Act diminish the evil, the only charge effected here by this being that one company will light the entire of the west side of the street, whilst the other retains the east. For the last few years the representative vestry of St. James's has committed the keeping of this road to a committee of their own body, consisting of a few active tradesmen. And the vestry,—concurring in opinion that it is not only to the advantage of those of their fellow ratepayers who occupy in the street, and also to the interest and credit of the parish generally; but, taking a more enlarged view of the case, by regarding the street as one of not the least attractive of the metropolitan ornaments, that its roadway should be kept in the most perfect state of ornamental repair,—has ever conceded to the committee great latitude of action, and ample funds for their purpose; yet with all this power the committee has ever found itself frustrated in the endeavour to maintain a good road, in consequence of the constant disturbing of the surface by the openings out to get at gas or water mains. A little more than two years ago the committee employed Mr. Cary to lay down in the street an entire new road on his improved sub-sension principle; but sections of the work were scarcely out of the hands of the workmen, ere other workmen commenced the digging of holes to get at gas or water mains, and the committee had the mortification of seeing their new road, which had cost 6,450*l.*, thus destroyed bit by bit. In the space of some twenty months, no less than 359 trenches had in this way been dug in it; and scarce a piece of road, of a dozen years' run, then existed that had escaped the infliction of a trench. In April of the present year the committee called to their assistance another professional gentleman, one of the most experienced and eminently esteemed of the metropolitan roadmakers, and under his direction a vast expenditure on the street has been going on ever since; the intent being, in this instance, to attain an entire new 10-inch surface crust of Maadnam of great compactness, by means of the simple process of a series of layers of granite of from an inch and a half to two inches thickness, each succeeding layer being allowed time to thoroughly bind and consolidate before the next spread. Six months having been patiently occupied in the pursuance of this process, at an expenditure of 5,800*l.* (less, however, by the cost of cleansing the street for one year), the surface is just arriving at a state of great perfection; perhaps as fine a bed of Maadnam as ever was laid down—thanks, however, in this instance, to the partial cessation of trench-cutting consequent on the pending of the new Gas Bill,—and gives promise that, with fair play, it could be maintained for some years to come at a comparatively small outlay. But now again steps in this abundant gas-work excavating—a wholesale affair this time, that will destroy at one fell swoop all that has been gained by these six months' patient work and outlay. The Chartered Gas Company has just intimated to the vestry that they are about to lay down in the street two new mains of great

dimensions, in place of two that had become of insufficient size for their business, which work implies the breaking up of the roadway from end to end by a great trench excavation some five or six feet wide being cut right up the centre of the road.

The companies, it is true, are bound to make good, and do reimburse the parish the expense of so doing; but the amount received for restoration in these cases, though covering the actual expense occasioned, yet no more compensates for the damage inflicted on the road than does the payment of the chimney-mender's bill of 6*l.* per rivet by the housemaid who has broken her mistress's Sévres vase.

On the receipt of this vexatious intimation the vestry, taking under review the constant source of annoyance this breaking up of Regent-street has ever been, and the little probability there seemed that in the continuation of existing arrangements there could ever be any abatement, turned attention to the consideration of the propriety of seeking to bring about the formation of an accessible subway, after the plan of the one now being laid down in the new street near Covent-garden, to receive all the necessary mains, as the only apparent means of permanent relief from the evil; the proposition being that such subway should be made at the joint expense of the parish and the several companies whose mains pass through the street, in contributions proportioned to the amount of saving each would derive on the practical working of the arrangement. These bodies are,—1, the parish; 2, the two gas companies; 3, the Waterworks Company; 4, the Electric Telegraph Company; and lastly, on the ground of its being a public improvement, the metropolitan general rate.

The vestry instructed their Works' Committee to seek a conference with the directors of the Chartered Gas Company, with a view to induce delay in the commencement of the proposed works in Regent-street, in order to allow time for a fair consideration of the sub-way project, as also to induce their co-operation in the furtherance of the scheme. The conference came off on the 13th ult., when the committee put forth their case, urging all the points adverted to in the foregoing. The directors admitted the convenience and economy that would accrue on the use of the sub-way, and promised to report without delay to their Board. The Board has entertained the subject of the proposal, and declined to take action upon it; whereupon the vestry determined to withhold their permission to the company, to break up the street for laying down their new mains until the practicality of their being laid in a properly constructed sub-way shall have been fairly tested. The company, however, assert their power (Gas Works Clauses Act, 1847) to proceed without parish permission; but, backed by clause 109-10, of the Metropolitan Local Management Act, 1855, the vestry has resolved on resistance by going, if need be, for an injunction to restrain their proceedings.

Regent-street presents most favourable circumstances to the successful application of the sub-way, and will well repay for being done, even if it remained an insulated example of the provision; but it is quite certain, that one general connected sub-way system throughout the great leading central lines of thoroughfare of the metropolis is what must be come to before many years. No constructional difficulties stand in the way of the appliances in Regent-street. The whole course of the carriage-way is uninterrupted by vaults or other underground impediments, and ample space exists above the sewer for the introduction of a tunnel of any requisite dimensions. The time for carrying out the work, too, is now opportune since but little more breaking up of the street and little more interruption of traffic, would be occasioned by the construction of a sufficient sub-way than will be caused by the laying down of these ponderous gas mains. The only apparent difficulty in the matter is about the source of the ten or twelve thousand pounds, the probable cost of the work.

The saving to the gas companies by the use of the subway would be incalculable. Under existing circumstances they incur enormous expense in the maintenance of the conducting pipes. For instance it is calculated that the two gas companies pay the vestry of St. James's about 150*l.* per annum for reinstatement on account of Regent-street alone, which, if their own costs of opening, &c. be added, which latter at a moderate estimate may be put down at 250*l.*, gives an annual outlay of them of 400*l.*, all of which would be saved to the by their mains lying in a conveniently accessible subway, an amount which capitalized would allow

produce a principal sum sufficient to complete the necessary constructions. Besides which in their favour there would further be the saving by the avoidance of loss from leakage, through defective joints, &c., which the facility of detection and repair would enable them to effect,—a loss which is said to amount to 22 per cent. of all the gas sent out. Nor would the simplification of their piping be a small matter in their working economy, since the necessity of the system of service, or secondary, mains would be dispensed with: a single main, it is apprehended, would suffice for the business of each gas supply, and one also would serve for the water distribution; and thus the nineteen mains now in use in Regent street might be reduced to less than half a dozen.

A principal object of this communication is a hope to draw public attention to the subject of the subway generally; though, in the foregoing, the reference is to one particular street alone; yet the evil existent in Regent-street prevails in a greater or less degree in all the leading thoroughfares; hence the subject is of more extended interest.

An inspection of the plan of the subway now proceeding in the new street—the Covent-garden approach, as illustrated in the last number of the *Builder*—shows the simplicity and economy of the arrangement so manifestly as to insure its adoption in the laying out of any future newly opened thoroughfare; but whether the appendage be adaptable to existing streets so as to eventually become a comprehensive, connected system, embracing all the central trunk lines of communication—the “consummation devoutly to be wished”—seems not so certain. The settlement of that question, however, might be much furthered by the subject getting a little ventilation in the *Builder*. Nor in the consideration of the subject should the one fearful drawback be overlooked, viz., the possibility of the occurrence of explosions.

Some of the able, practical, and scientific correspondents of the *Builder* might render good service in the consideration, by throwing enlightenment on the several points. In conclusion it may be observed that, if the advantage of the subway principle be the reality anticipated, the opportunity ought not to be lost of providing the accommodation in such of the leading streets as are now about to be taken up for the formation of the main drainage low-level sewer. Here at least there would be no constructional difficulties presented; and if executed in connection with that greater work, it would be accomplished at greatly diminished expense, and cause no additional public inconvenience during the process. F. C.

#### MANUFACTURING ART AND MACHINERY.\*

The course of Lectures on Manufacturing Art and Machinery, which I have had the honour to be elected by the Council of this College to deliver to the students in the department of Applied Sciences, may, I think, be prefaced by an introductory lecture, which will give me an opportunity of laying down a general outline of the topics which I propose to discuss, and some idea of the method of discussing them which I propose to pursue; and I think it may afford some little aid to the students in the future pursuit of their studies, if I impart to them a few hints gathered from my own experience in fighting the battle of life; and if I encourage them to press forward, without wavering in the difficult although interesting task which they have set themselves to perform, by bringing under their notice the names of those men who have begun their education at the same fountain-head, and who are now occupying responsible posts, and executing some of those improvements which are attracting the notice of the scientific portion of the community, and which will, undoubtedly, serve as an example and incentive to future enterprise and invention. For the proper comprehension of these principles, then, I am sure, feel themselves indebted to the course of instruction which they received in the class-rooms of this excellent institution; and I venture to hope that I may be successful in leading those now placed under my charge to emulate the meritorious endeavours of those to whom I am about to refer, and to inspire them with appreciation of mechanical and manufacturing art, which is on all sides acknowledged to be so eminently beneficial.

Many of those gentlemen who have now come up here with the object of studying the Applied

Sciences, have, I dare say, already made up their minds as to the particular calling or profession which they intend to educate themselves for, and which they afterwards purpose following up. Many others, I dare say, are here studying, and at the same time feeling, as it were, their way to find the particular branch which suits their tastes, and waiting till they find the path which lies the most open for them before they finally determine upon the exact course which they intend to pursue in future. I think that I may be allowed to tell each of these classes of students that they are wise; for those who have already made up their minds as to their intended calling or profession may rest assured that if they are determined to adhere to their choice and to persevere in their task, they will overcome all obstacles, and speedily attain to excellence in the profession which they have chosen; while those students who have not yet determined upon the exact course which they intend to pursue after leaving the college, may be confident that if they study well there will be abundant opportunity for them to turn their knowledge to account one way or another either in England or abroad; for they must remember that subjects such as mathematics, applied to physics, together with chemistry, geology, and the development of machinery, are the means of daily adding to our national wealth; that as our wealth increases, so there is every probability that our resources will be developed; and that as our sources are developed, so there will be a continual demand for the services of those men who made it their study to understand scientific principles, in order that they may direct and guide others in the performance of the manual labour which it may be thought necessary to bring to bear upon the object to be attained.

Indeed, the course of study in the Applied Sciences prescribed to be followed, is such that, supposing a student upon entering his name has made up his mind to follow up a particular profession, and supposing that at the termination of the time of his probation here, unforeseen circumstances compel him to give up his original intentions, and necessitate his entering upon another calling, I do not see that he could have followed up any other course of study which would have afforded him such facilities for making a good change as that of the Applied Sciences. Supposing, for instance, that a student had come here with a promise of obtaining a commission in the army by the time of his completing his studies in the military department of the Applied Sciences, and supposing that circumstances subsequently arose which disappointed him in procuring his commission (a disappointment which often occurs), how easy it would be for him, with the knowledge he had obtained of mathematics, natural philosophy, chemistry, geology, art of construction, geometrical drawing, manufacturing art, and machinery, and the variety of knowledge which he here has the opportunity of acquiring,—I say how easy it would be for him, having mastered these subjects, to change his intentions of being a military officer, and to become a civil engineer; or, supposing he had intended to be a civil engineer, how easy it would be for him, if desirable, to become the manager of some important manufacture. I do not think, gentlemen, that another set of subjects for study, like those which form the curriculum of the Applied Sciences, could be framed together which would give the student such an opportunity of deviating, without injury to himself, from the path which he originally proposed to follow, but from which uncontrollable circumstances compel him to depart.

Now the section of the department of the Applied Sciences which it is my province to lecture upon is one which, although it treats of common things—that is, treats of the preparation and the method of manufacture of things which are in daily use with almost all of us,—and explains constructions and contrivances which are continually being brought under our notice, yet it must be remembered that improvements in arts and machinery have wrought greater changes in the condition of mankind than any other power or influence; and it is the knowledge of these arts and of these contrivances which gives to civilized nations the superiority which they possess over the ruder and less enlightened people of other lands. It is scarcely necessary for me to bring under your notice, as an illustration of the great social changes which have taken place, owing to the development of the mineral wealth which we have been enabled to obtain by the scientific and beautiful improvement by Watt in the steam pumping-engine (which remains to this day nearly as he left it); the changes which have arisen through the formation of railways, of which Stephenson is commonly

called the father, and with the theoretical principles of which the name of Moseley is so intimately connected and justly celebrated; or of the changes which have resulted owing to the diffusion of literature, which has to a great extent been brought about by the improvements of Cower in the printing-machine; and lastly, the changes consequent on the invention and improvement of the electric telegraph, which appears, I think, to ordinary minds the greatest marvel of them all, perhaps on account of the rapidity with which the researches of Continental philosophers, of Faraday and of Daniells, have been brought into practice by the work of many minds directed to the same end, and in which the intellect of Wheatstone played so important a part. I am sure that every one who is in any way connected with King's College must feel proud that four out of the seven distinguished names which I have just mentioned are those of gentlemen who have been professors here; two out of the four are not with us now, but we cannot recall their memories to our minds without feeling that they have, by their individual talents and by their brilliant discoveries and inventions, advanced us as a nation in our national greatness.

And now, gentlemen, to revert more especially to the professional point upon which I have the honour to address you, and begging your kind patience for a few minutes, I will venture to call your attention to a few facts and premises which may perhaps be of interest to you.

The principle of a given manufacture may be explained to, and is easily understood by, any person of ordinary education; yet it does not follow from such explanation, however perfect it may be, and however thoroughly understood by the person who receives it, that the process can there and then be gone through, and put into practice, for there may be many little minute points, many little difficulties of manipulation to be attended to, which can only be ascertained and carried out by a number of years' continual application and training, beginning, perhaps, from the early infancy of the operative, who will have to devote the greater part of his lifetime to the special handicraft in which he excels.

Labour performed by the hands of man, without any other assistance, would be extremely limited in the usefulness of its application; and in order to carry out any great work, some means must be found for uniting the exertion of several men, or else of increasing the power of one man: the combinations and contrivances which effect this unity of exertion or increase of power are called machines.

The labour of cultivating the ground or tilling the earth, which is the earliest form of work with which we are acquainted, requires in its primitive form but little skill and no machinery. Regularity and uniformity in the work are not necessary in turning over the surface of the soil; the rudest and simplest forms of tools may be used; the seed may be scattered by the hand without any external guide or practice; it may be covered with earth in the same manner as it is sown, and requires no further assistance from the labourer. Nature now lends her aid: the highest degree of skill is brought to bear upon the seed; it germinates, sends forth its roots, its stems, its leaves, and grows into a thriving plant, which absorbs its nourishment from the earth, the air, and the light, always keeping in truthful balance the atmosphere in which it lives, performing functions by day and by night which are continually aiding in supporting the life of the man who sowed the seed from which it sprang. The plant flowers and bears fruit, it yields seed a hundred-fold, and in due time man returns and with his unskilled labour gathers in the produce and prepares it for his sustenance. We cannot help comparing the small amount of skill which is required of the man to perform his part of the work with that unbounded wisdom and intelligence which are displayed in the changes which are wrought in the seed after it is once in the ground. We cannot but admire the providence exhibited in the admirable contrivances, the delicate functions, the adaptation of every part for the service which it has to perform. The eye is gratified by the beauty of the colour of the leaves and of the flowers, and with their variety and graceful outline of form, and the reasoning mind wonders at the economy of material and its perfect distribution: with this evidence before us of our utter incapacity, we cannot help admitting the existence of an all-powerful hand immeasurably surpassing us, whose works we can at best but attempt to imitate; and the more we study the superlunary accomplishments of Nature, the more we feel impressed with the short comings of our ability in

\* Introductory Lecture to a course on Manufacturing Art and Machinery, delivered at King's College, London, on the 4th of October, before the principal, professors, students, and visitors, by Professor C. Percy Blyssie Shielley, C.E.

approaching that degree of perfection which is one of its own attributes.

There is not to my mind any labour to which man at his origin could have been appointed which would have given him such a wide field for his intellect, such an unlimited boundary to his inventive faculties, which has formed such a firm basis for the science and theory of the present age, and leads us to put confidence in that Higher Power by which all things are created for our good and pleasure, than that of tilling the ground.

[Here Professor Shelley referred to several leading and recent inventions which owed their origin to students of King's College, and mentioning the names of several who had distinguished themselves by their scientific acquisitions, proceeded to say,—]

In the former part of my lecture I alluded to the importance of theoretical knowledge: but this alone is not sufficient for those who intend to put the Applied Sciences into practice. To the theoretical knowledge taught in the class-rooms must be added the practical knowledge which is only to be obtained in the laboratory and workshops.

In the laboratory the hand will be trained to manipulate with delicacy; the eye will be taught to distinguish, with facility, the various changes of colour and the effects of reactions upon the substances under examination, and that all important difference between dirt and cleanliness, in experimenting, will be better impressed upon the student by one failure through want of attention to it, than by a whole course of lectures on this particular subject.

Chemical cleanliness can, I think, be only learnt in the laboratory; and, in like manner, that which is technically called "truth," and the difficulty of approaching it, can only be learnt in the mechanical workshop.

I have casually referred to some of those former students in this department who have distinguished themselves by the important works they have carried into effect in after-life, and I might add to these many more who derived their education from the same source, and who are deserving not only of the highest praise, but of great public commendation, for the assistance they have lent towards the progress of science, and the appliances they have brought to bear upon the requirements of the age. This, however, time will not allow me to do, but I trust I have said enough to encourage the just emulation of those whom in future I shall have the pleasure to meet in the class-room, and to convince them that the difficulties which must necessarily be experienced in this, as in all scientific occupations, may be easily overcome by the exercise of that patience, perseverance, and application which I feel sure I shall meet with amongst those I see around me.

WAGES AND BUILDING NOTES IN THE TIME OF HENRY III.

AMONG the records deposited in the Public Record Office, one has been lately discovered by Mr. Burt, entitled "A Roll of Payments of Wages, and of Purchases for the Works at Westminster, 37 Henry III." Professor Willis, considering it a perfect specimen of this class of documents, gives the following account of its contents in the *Gentleman's Magazine*.

It contains the entire accounts of the building works during thirty-two continuous weeks, beginning with the first week after Easter, which, in that year, 1253, fell on April 20; consequently the works in question began on Monday, April 23, and the last week of the roll ended with Saturday, December 6. The account for each week is complete in itself, but no day of the month is mentioned, neither are the weeks numbered continuously, although for convenience I shall designate them as if they had been.

The first six weeks are indicated as first, second, &c., after Easter (Ehd' prima post Pasche, &c.). The seventh week was Whitson week, and was evidently kept as a holiday, but is not mentioned in the roll; the week next following, the sixth after Easter, being termed the first after Pentecost, is thus actually the eighth week from the beginning of the account roll. This enumeration continues to the fifteenth week, which is termed the eighth after Pentecost. The sixteenth week begins a new series, termed the first, second, &c., "after the agreement for wages for eight weeks" (Ehd' prima post pascione' stipendiator' pro' viij' Ehd'). This enumeration continues through two weeks, and carries us to the end of the twenty-seventh week of the roll. The

twenty-eighth is termed the first week after the feast of All Saints, and the succeeding second, third, &c., concluding with the "Ebdomada viij'" or thirty-second week of the whole, which closes the account.

At the head of each week one or more saints' days are sometimes mentioned in a peculiar manner. Thus, to begin,—the complete title of the first week is—

"Ehd' prima post Pasche' conditio factum Apostol. Philipi et Jacobi p' die' Jovis quod est d'ni Regis et festo' Inventionis s'c' Crucis p' die Sab' quod est cent'ar'."

"First week after Easter, containing the feast of the Apostles Philip and James on Thursday, which belongs to the King, and the feast of the Invention of the Cross on Saturday, which belongs to the masons." The second week is similarly said to "contain the feast of St. John ante portam Latinam on Tuesday, which belongs to the King;" and the third week is "sine festo." Thus, throughout, the roll feasts occur, sometimes two in a week, but generally only one. Fourteen of the weeks have none. Whatever feasts are mentioned, however, are assigned alternately to the king and to the masons. The only intermission of this rule is in the twenty-seventh week, where the feast of SS. Simon and Jude ought to have been given to the masons, but is assigned to the king, apparently because of the fact, stated in the title of the week, that it is the first day of his regnal year.\*

It may be presumed, therefore, that the feast-days thus assigned to the masons were kept as a holiday, and that they worked on the feasts assigned to the king, who in this roll is the employer of the masons.

I am not aware that this curious custom has been noticed by any previous writer. I have set down in the note below the list of the saints' days selected.† It is probable that in other years some other principal saints would have been also included which happen in this year to fall on a Sunday.

Having now discussed the titles to show the mode of designating the weeks, we may examine the accounts themselves. They are placed, for every week, under two heads, the wages and the purchases, or employees. The sum of each of these is separately stated, as well as the total. The nature of these payments will be best understood by giving a translation of one week complete; for, generally speaking, the workmen, the materials, and other items recur nearly in the same order in every week. There is a great advantage in this; for as the same terms are repeated, it happens that in some cases they are written more at length than in others, or spelled in a more intelligible manner, and thus the collection of so many examples of the same word greatly assists the interpretation of the unusual or technical expressions.

\* Second week after Easter, containing on Tuesday the feast of St. John ante portam Latinam, which belongs to the King; :—

To wages of 39 cutters of white stone, 15 masons, 26 stonemasons, 32 carpenters with John and his partner at St. Albans, 20 painters with an assistant, 15 polishers, 19 smiths, 14 glaziers with four plumbers, 15<sup>o</sup> 10<sup>d</sup> 10<sup>o</sup>. [This will give an average of 1s. 10d. per week.]

To wages of 176 inferior workmen with overseers and clerks, and two two-horse carts daily, 9 17<sup>o</sup> 2<sup>o</sup>. [About 9d. a week.]

\* This is the title of the twenty-seventh week :— "Ehd' xij' conditio festi Apostolorum Simoni et Jude quod est d'ni Regis anno Regni Regis Henr' xxxvij' inclinate et festo' octium s'c'or' p' die Sab' quod est cent'ar' . . ."

To Henry of the bridge for iron nails and wheelstones, 10s. 8<sup>o</sup>. To Benedict for carriage, portorage, and weighing of 23 cartloads of lead, 9s. 4<sup>o</sup>. To Richard for litters, 15s.

Sum total of emptions, 277. 12s. 10<sup>o</sup>d. Sum total of the week, 53s. and 14<sup>o</sup>d.

This week may be taken as a fair specimen of the whole. The first part informs us of the number of workmen of each kind that were employed in daily labour: the second part gives the materials and their carriage. The number of white stone cutters was gradually increased from 39 in the first three weeks to 78 in the fifteenth week, and diminished again to 35 in the last weeks. The masons, about 16 in the first eight weeks, were suddenly increased to 49 in the ninth week, who remained at work till the eighteenth week, and then were suddenly reduced to 31, and went on diminishing to 7. The stonelayers vary from 35 to 4. The 32 carpenters working in the first seven weeks are then reduced gradually to 9 only. The polishers are about 15, and the smiths 18 throughout; but about 14 glaziers employed in the first ten weeks are suddenly reduced to 6 for a month, and then to 2 for the remainder of the time. The inferior workmen vary from 220 to 37. The gross amounts are: stipends, 696<sup>o</sup>. 8s. 7<sup>o</sup>; emptions, 89<sup>o</sup>. 9s. 5<sup>o</sup> 1<sup>o</sup>; giving a total of 1,657<sup>o</sup>. 18s. 0<sup>o</sup>d.

From these particulars the nature of the work may be surmised; but, unfortunately, there are very few exact indications of the actual buildings upon which the workmen were employed. The only evidences of this kind that I have detected are the following, numbered to correspond with the weeks in which they occur: (1), tables or planks for the CHAMBERS of the king and queen; (2), panels for the king's bed, and for a table in the king's chamber; (3), 100 tiles provided for the entrance of the CHAPTER-HOUSE (It., p' tasc'h' iut'ij' capituli l. s.). From the nineteenth to the twenty-sixth and thirty-first weeks charge occurs in nearly every week for nails for the CHURCH AND BELLRY; and in the twenty-fifth week Roger the plumber is paid 10<sup>o</sup>. and 5<sup>o</sup>. 13s. 4<sup>o</sup>d. for taskwork at the belfry (belfrydam). This was probably the detached belfry of the Abbey church, which is known to have stood on the north side, upon the site of the existing Sessions-house.

Stukeley gave drawings of it in the *Archæologia*, vol. i. p. 39, under the name of the *Sanctuary*, but states that it was still called the *Belfry*. Stow relates that Edward III., about 1347, built to the use of St. Stephen's chapel, in the little sanctuary a "cholebard" of stone and timber covered with lead, &c. Widmore (History of Westminster Abbey, p. 11) found it mentioned for the first time in a charter of Edward I. (1290). "It was then called the belfry and continued to be used as such, or at least to go by that name till the present towers of the church were built by Abbot Iselp." The roll we are now examining shows that it was in course of construction and apparently covered with lead in 37 Hen. III. The building represented by Stukeley is of stone and in two stories, of a form well adapted to serve as the substructure of a lofty timber-framed tower, similar to that of Salisbury, destroyed by Wyatt, but preserved to us in the drawings of Price. The wooden tower had disappeared long before the time of Stow, and the stone substructure was pulled down, in 1750, to

\* In the Westminster Rolls (printed by Smith, Author, of Westminster, p. 182, and Brayley and Britton, Hist. of Houses of Parliament, vol. 151, 153), "Hurdles for the scaffolds of St. Stephen's Chapel" occur 4 Ed. III., &c., with beams, and poles, and leather thongs to the said beams and hurdles together." The original latin is not generally given in these publications, but in one case Smith (or rather Hawkins), p. 184, has "twenty-four hurdles pro eis super dictam scaffolam," which explains the use of the hurdles to serve in lieu of the planks we now employ.

† Henr' de Ponte p' clavij ferri et pressis' . . . xixs. But in the previous week we have "Henr' de Ponte p' gress ad Martella acuedu'." Duncane gives "gressus p' cassis Silax. gall. gress." (i.e., sandstone or grit). The gress for sharpening the picks or stone-hammers is therefore, not the English word gress, as it might appear, but a whetstone. ‡ "LITERIA, stramentum."—Duncane.

\* PACATIO . . . pactum, conventio.—Duncane.

make way for a new market-house. It had been for a long while occupied as a cellar for the Quakers' Tavern in Thieving-lane. The market-house was in turn pulled down about 1770, and the present Guildhall built as nearly as possible upon the site of the old building.

In the second week Magister Albericus is paid for task-work of the *form-pieces* ("pro tascha formarum"), that is, for window tracery, probably of the Abbey church, and also 6l. 9s. 10d. in the twenty-fifth. On the back of the roll it is recorded that on Tuesday of the fourth week after Pentecost,\* on the morrow of the blessed Thomas the Martyr, Master Albericus with three associates began the task-work of three windows. Also that on the Monday after "ad vincula S<sup>i</sup> Petri" (that is to say, in the fifteenth week of the roll) two parcels of coloured glass, valued at 12s. 2d. a parcel, and two of white glass at 6s. each parcel, were delivered to Master Henry, to be employed in the task-work of the windows, charging per foot wrought of coloured glass 8d. and of white glass 4d.

Another memorandum records that on Monday, the morrow of St. Bartholomew (August 25), the work in the king's quarry began.

Attached to the roll in the sixth week is a letter from Robert de Brumele to Master John de Oxonia,† informing him that he has despatched a boat-load of marble by William Justice, to whom five mares and a-half and 10s. are to be paid for freight. He also promises to send another boat-load before Pentecost, and a third if he can find a vessel to convey it. Similar letters are attached to the second week and to the twenty-second.

The *emptios* in each week's account include, in the first place, pieces of freestone cut by task-work into various shapes required for doors, windows, arches, vaults, or other portions of the structure, and made ready for setting. These are sometimes separately enumerated by name, as in the second week above, and furnish very curious illustrations of Medieval nomenclature. But in the latter part of the roll such pieces are all entered in the general form, "In diversis modis france petre ad taschan cisse," "to various shapes of free-stone cut by task-work," and similarly for marble. Next occur stones from the quarries, probably in a rough state, or at least only fit for walling. These are "Came stone" (Caen stone); "Reygate stone," generally from Roge de Reygate, and sometimes described as freestone, "franca petra," e.g. (8), "Roge de Reygate p<sup>r</sup> et ad di<sup>o</sup> France pet<sup>r</sup>, xxxv. ixd." Grey stone, "petra grisea," (6), "pro. ii. navatis grise pet<sup>r</sup>," and chalk for the *pendentia*,—"creta al pendencia," the latter being the term universally employed in Medieval documents for the vaults that rest upon the ribs. In (24) we have "p<sup>r</sup> marmore apud Cerne xvij<sup>i</sup> xix<sup>i</sup>." Beside these, other materials for building occur, as (1), "maccoc ferri tenacis de gloueria, iiii<sup>i</sup> xij<sup>i</sup>;" iron from Gloucestershire, and in (18) the spicemen well inserted above. In some of these entries we obtain names of trades which are of unusual occurrence. Thus (6), (21), and (12), "Ade Meremunia pro bordis et lateis," i.e. Meremunia, a timber-merchant from Meremium. Ricardus *Californarius*, the lime-burner (from Californium or the French *Chalfournier* occurs throughout. In (4), (13), (25), Ricardus *Cuparius*, or *Cuvarius*, the cooper, from *Cupa* and *Cuva*; in (1), Jacobo *Junar* p<sup>r</sup> panell<sup>r</sup> ad lectu<sup>m</sup> d<sup>i</sup> Regis junij<sup>i</sup> &c.

The masons' terms for shaped stones are for the most part the same that I have discussed in my "Architectural Nomenclature,"§ in the fifth edition of the "Oxford Glossary," 1850, and elsewhere, but they furnish a variety of spellings which are often instructive. I subjoin a list of those which appear to require explanation. They are arranged in alphabetical order, and the numbers in brackets prefixed to each word indicate the weeks of the roll in which it occurs:—

- (1, 3, &c. &c., &c.) *Ascetors*, or ashlars stones.
- (3) (2). "1. assis p<sup>r</sup> assise v<sup>r</sup>d." (5). xxi. *Assis*,—stones prepared for covered masonry, from the French *assise*.
- (2) (3) (5). "ix. ped de bossus." xxxiiij. ped de bossus"—the carved stones placed at the intersection of the ribs of vaults, which are still called *bosses* (vide "Arch. Nom.," p. 43, and "Glossary"). They were sometimes termed *keys*, or *claves*, of which the present roll has an example in (6), "ii. Clavinus et vij. Capitrel."

- (4). "... xli. buscell<sup>r</sup> p<sup>r</sup> buscell iij<sup>i</sup>." (7). "p<sup>r</sup> xi. 'busch', xix." Will. Jacobo p<sup>r</sup> cc and q<sup>r</sup>tr<sup>a</sup> 'busch' v<sup>r</sup>. vij. ob." (16). "... q<sup>r</sup>tr<sup>a</sup> busch', ix." The first entry is in a list of stones shaped by task-work, and I know no other instance of this use of the word.

But in another list of stones (3) we find "xvi. ped et di et di<sup>o</sup> q<sup>r</sup>tr<sup>a</sup>. de grossis rotundis," which seem, for want of a technical name, to be simply called *great round stones*; and in (2) "xxij. ped *maignanz*," which appear to be merely large stones (*magnum*), from the old French *maigne*. It may be supposed in the same way that the "bushel stones" above were round stones, suitable for a column, which were so distinguished for the moment because they happened to be about the size and shape of a bushel measure (about 18 inches across and 8 inches thick).

The other two examples of the word *bushel* are at the end of the emptios, amongst hurdles, "hokettes," &c., and are probably bushel baskets, or bushel measures of some article not mentioned.

- (3). "xi. ped de *Chapem<sup>t</sup> bowe*" occurs but once, with nothing to indicate its meaning.

(2). "xliij. *chamberand*." (3). "xviij. *cham<sup>r</sup>and*," also (4) (5). I have found this word repeatedly in the accounts of King's Hall, Cambridge. Thus in 6 Edward IV. in the form *chamberkint*, and in 6 Henry VI. as "xix. ped de *chamercans pro magna porta*," and soon after, "xxij. ped de *jaubles*." In 4 Henry V., "laxid<sup>r</sup> vocat *chamys*," and in 5 Henry V. "*jambye*." I have also found it in other account rolls, and in my "Nomenclature," art. 81, have given another form apparently of the same word, namely, *chameres*, which I supposed to be *jammers*, or stones for the *jamb*s of doors or windows. The spelling of the above examples appears to show that this word is the same as the French *chambreante*, the ornamental border or set of mouldings about a door, window, or chimney, and in these early examples was used for the molded stones of the jamb, if not also for the archnolds, or at least for the hoodmolds.

(2). "cxlvij. ped. *serches*." (9). "cxlvij. ped. de *serches*." *Chercho* and *serche* are old French words for circular arcs, and are used by workmen for convex or curved pieces. In this place they may mean convex stones such as would be employed in building cylindrical piers.

(2). "lxvij. ped de *escus*." (3) also (9). "iij<sup>i</sup> x<sup>i</sup> et di<sup>o</sup> ped<sup>r</sup> de *scutis*." (5) "xvij. ped de *escut*." These are *skew-stones*, i.e. stones cut with a level edge. Similar terms occur frequently in masons' accounts. (Vide *Skew*, *Skew-table*, &c., in "Arch. Nom.," and "Glossary.")

(2) (3) (9). "Folsuris cum fillo." (4). "*Rotundis*, folsuris cum fillet," i.e. *voussoirs* with a filleted molding.

(1) (5) (3). "Rotundis folsuris," i.e. *voussoirs* with round moldings.

(9). "iij<sup>i</sup> v. folsure chanferete" i.e. chamfered *voussoirs*. *Chanferain* means also chamelled or furrowed, and therefore we may include *voussoirs* with moldings under this expression. All these are *voussoirs* for molded arches or ribs, and as they occur in company with "chalk for the vaults and bosses" (*creta ad pendencia*), are intended for their ribs.

(5). *Formellis*. (3). *Formellis*. The same as "form-pieces," namely, the stones cut for tracery, ("Arch. Nom.," p. 48, and "Glossary.")

(6). *Lothenges*, stones cut into the form of the heraldic *lozenge*, perhaps for paving.

(6). "I<sup>r</sup> Roge de Tri pro iij. *orbilons* xxxij. sol." This word only occurs in this example, and here in small number. We may guess the thing to be a carved boss or bracket of a globular form; or, as *orbile* is the rim of a wheel, they may be stones in a ring form for tracery.

(2) (3). "... *perpens*, *parpens*, or through stones.—(Vide *Perpent-stone* in "Glossary.")

(1). *Seutcheon*, or *seenthon*. This is a word which frequently occurs, with varied spelling, in Masonic documents. (Vide "Seutcheon," in "Arch. Nom.," p. 37, and "Glossary.") It is always used for stones with an obtuse external angle.

(3). "c. et iij<sup>i</sup> ped. de *tablements*,"—string-courses. ("Arch. Nom.," p. 25, and "Glossary," art. Table.)

ROB. WILLES.

THE CRIMEAN MEMORIAL NEAR WESTMINSTER ABBEY.

The Medieval column of granite, about to be erected in the Broad Sanctuary by "Old Westminsters" in memory of those brought up in the school, who fell in the Crimean war, is at last rising above the boarding. An engraving of it will be found in our volume for 1858 (p. 694). The group of St. George and the Dragon, which will surmount the column, erroneously attributed in the daily papers, is being executed by Mr. J. I. Clayton. The exigencies of the position (the necessity of obtaining a columnar outline) have enforced a peculiar treatment of the group; but it promises to be an interesting production. It is about 10 feet 6 inches in height. Mr. Scott is the architect; and the work, generally, we believe, is in the hands of Mr. Philip.

HOSPITAL NURSING.

The various opening addresses have been delivered at the great Metropolitan Schools of Medicine. These addresses were all more or less marked by desire to elevate the position of the rising generation of medical men, and administer to the sufferings of humanity. In some of them it was said that earnest endeavours are now being made, and not before it is time, to provide proper nurses for the sick. Mr. R. D. Grainger, at St. Thomas's Hospital, remarked that he had great satisfaction in stating, that, owing to the wise munificence of one whose name would find an echo in every English heart, and who belonged to that noble, self-sacrificing band already illustrious by a Marguerite d'Angoulême, a Lady Rachel Russell, a Louisa of Prussia,—Florence Nightingale,—one of the greatest wants in the management of the sufferers from accident and disease, skillful and tender nursing, promised to be supplied. There were, at that time, in the wards of St. Thomas's Hospital, fifteen nurses, supported entirely by the "Nightingale" foundation, who had been selected with great care, and who, after proving themselves qualified by examination, would be sent to public institutions to minister to the sick. Already persons of a superior rank, prompted by Christian charity, offered their services; and there was reason to hope that an entire revolution in the system of hospital nursing,—indeed, of the whole class,—would be the result, at no distant period, of this philanthropic measure.

At King's College it was mentioned that Dr. Todd and the late Bishop of London were the originators of St. John's House Training Institution for Nurses. This institution supplied the hospital with a very efficient staff of nurses and lady sisters; and the hospital in its turn afforded to St. John's House the means of training its nurses, many of whom were annually sent out to private patients in all parts of the country. This movement is in operation both in town and in the provinces, and must, before long, lead to beneficial results.

BODELYWYDDAN CHURCH.

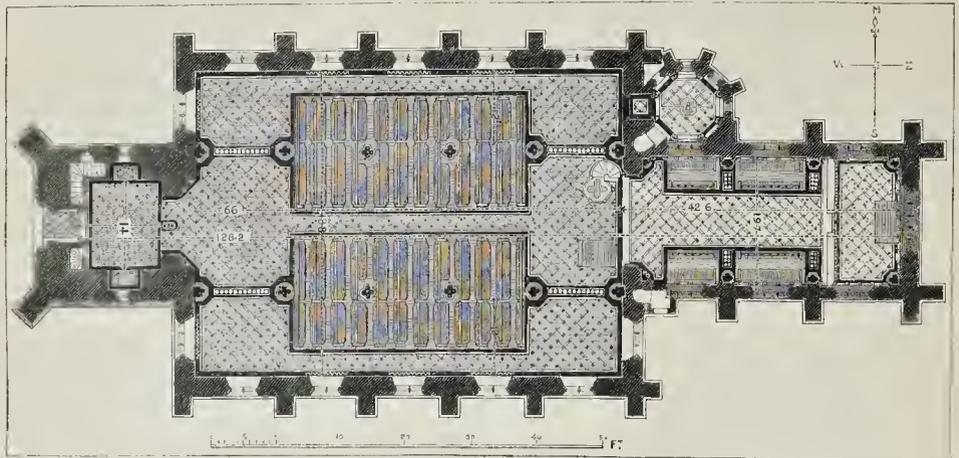

St. MARGARET'S, Bodelwyddan, near St. Asaph, of which we give some illustrations, is, internally, if not externally, one of the most elaborate of recently-built Gothic churches. It was consecrated on the 23rd of August, having been commenced on the 21st July, 1856. The church has been erected at the expense of the Dowager Lady Margaret Willoughby de Broke, in memory of her husband, the late Lord Henry Peyto Willoughby de Broke. It stands near to the north front of Bodelwyddan Hall, the residence of Sir Hugh Williams, Bart., and Lady Willoughby's native place, in one of the most picturesque parts of the Vale of Clwyd. Here a parsonage-house, schools, and cottages, also have been erected. Our view shows the exterior of the church; and we also give the general plan, and plans of the tower and spire.

The church, it will be seen, has the usual form on the ground, with addition of an octagonal vestry north of the chancel. The chief dimensions are figured on the plan, which also shows the arrangement of the fittings and heating apparatus, and gives some idea of the decoration of the chancel, and of the flooring of the whole church. The small cut shows the tower and base of the spire in plan, at four stages. The material of the main portion of the fabric is the Bodelwyddan stone, or hard limestone, similar to that of Anglesea, rough or dressed, according to position; whilst the plain-facing to the interior of the nave

\* L. the eleventh week of the Roll.  
 † Join of Oxford occurs in the Westminster Rolls published by Smith, p. 134; s. Edw. 111.

INDURATION OF THE EXTERIOR OF THE NEW MUSEUM, TRINITY COLLEGE, DUBLIN.—We learn from the *Dublin Builder* that Messrs. P. S. Barff & Co. have now completed the induration of the Portland stone work of the Museum, Trinity College, with Ransome's patent solutions. We mention it that the result may be noted.

## BODELWYDDAN CHURCH: GROUND PLAN.

is from the Talacre quarries of Cheshire, a cream-coloured stone. There is no plastering. The nave piers have the clustered shafts of Belgian red marble, the blocks 6 feet 4 inches in length, and 2 feet 4 inches in diameter, on bases of the native stone. The capitals, richly carved with the passion-flower and oak and ivy leaves, are in the native stone, except the abacus, which is of the Belgian red marble. Above the piers, in the spandrels, are shafts of Belgian red marble on corbels. Each corbel of these is foliated, and otherwise enriched, and exhibits a coronet and one of the letters of the name of Lord Willoughby de Broke. The intermediate shafts are carried also by enriched corbels, these forming the apex of each label of a nave-arch. The several shafts carry springers of the open timber roof. There is, however, a band which might be called clerestory, of small trefoiled openings, not showing in the exterior, to light up the nave roof; and the same object is furthered by the lucarnes at a higher level, which appear in our view. The nave and aisles are covered over in separate spans, with arched principals and collars (hammer-beams also in the nave), with cusped spandril spaces, the whole in oak. The external covering is of slate, cut in patterns. The internal height in the nave, from the floor-line to the top of the wall-plate, is 23 feet 9 inches; and thence to the apex of the roof, internally, is 16 feet 6 inches. There is a gallery in the tower. It is carried at the front by two arches, springing in the centre from shafts coupled transversely, and has an open-work front or parapet.

In the chancel there is a more ornamental character in the whole of the details. Ogee crocketed canopies, rising from shafts and corbels, and projecting to form niches, run along the three sides, more elaborately enriched where the reredos occurs. Alabaster, varied in tint, is used for backs of the niches at the sides, Langueooc marble for shafts, and picked white alabaster for the capitals and corbels, the bases being Parbeck marble. The arcades or niches at the sides have the canopies of Caen stone, whilst alabaster is used for those at the reredos. Much carving is introduced, as in crockets and the half-flower, that at the reredos being in alabaster, and that at the sides in Caen stone. This carving has been executed by Mr. Harmer, under the architect's direction, Mr. Field having contracted for the general marble-work and carving. Beyond the extra richness given to the reredos in the points already named, it has a diaper at the back, and foliated instead of plain capitals. The centre panel has the monogram IHS, with wheat and vine, and the diaper carved with the passion-flower. The fly is much used in the canopies. The roof principals in the chancel are carried by clustered wall-shafts. These last are of grotto red marble, with a thin fillet of Irish black marble in each hollow to separate the red lines of the shafts. Irish black marble also is used in the necking and the abaci of the capitals, and in the hands of the shafts. The facing of the chancel is of the Bodelwyddan stone in lieu of the Talacre, only enriched, as described, with the shafts and other features in the decorative

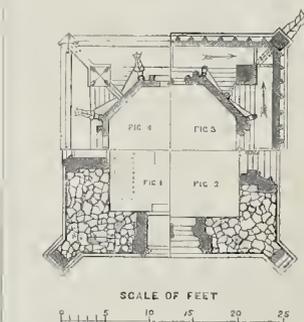

Fig. 1. Quarter Plan of Clock-chamber.

- " 2. " Bell-chamber.
- " 3. " Base of Spire.
- " 4. " Spire above Flying-buttresses.

marbles. The chancel arch is carried on red marble shafts, which rise from corbels. The latter, carved from the native stone, represent angels holding books: with the carving of the nave, they were executed by Mr. Henry Smith. The chancel ceiling is formed into square panels by moulded ribs, with rosettes and bosses at the intersections, and springs from an enriched cornice of which the lower mouldings are carried down to the capitals to form a square head or label, with spandrels over the wall arches above the windows. Each arched principal rib is formed with a cusped trellis work filling-in of what may be called the web, and with mouldings and the half-flower on the inner edge, corresponding with the projection of the capital from which it springs. The chancel is seated stall-wise, and the nave has open seats, in each case with appropriate panelling and ends. The roofs and seats in the nave were executed by Mr. Grey, of Leamington. The general carved woodwork,—including the pulpit presented by the Misses Williams, sisters of Lady Willoughby, (which has kneeling figures), the reading-desk, the stalls, and the bosses to the chancel ceiling,—was by Mr. Earp. We should add that the commandments are lettered in gold, on panels of dove marble, in the proper places.

The east window,—one of five lights, with geometrical tracery,—is filled with glass by O'Connor, who executed the glass for the windows next to it. These last mentioned are memorial windows with subjects. There is a circular window at the east end of the north aisle, over the entrance to the vestry; and the western window is also circular, and is filled with geometrical tracery, and surmounted externally by a high crocketed canopy or label moulding, with pannelled tracery and coat of arms in the tympanum. The glass for both these windows was presented by the Misses Williams. There is stained glass also in the north

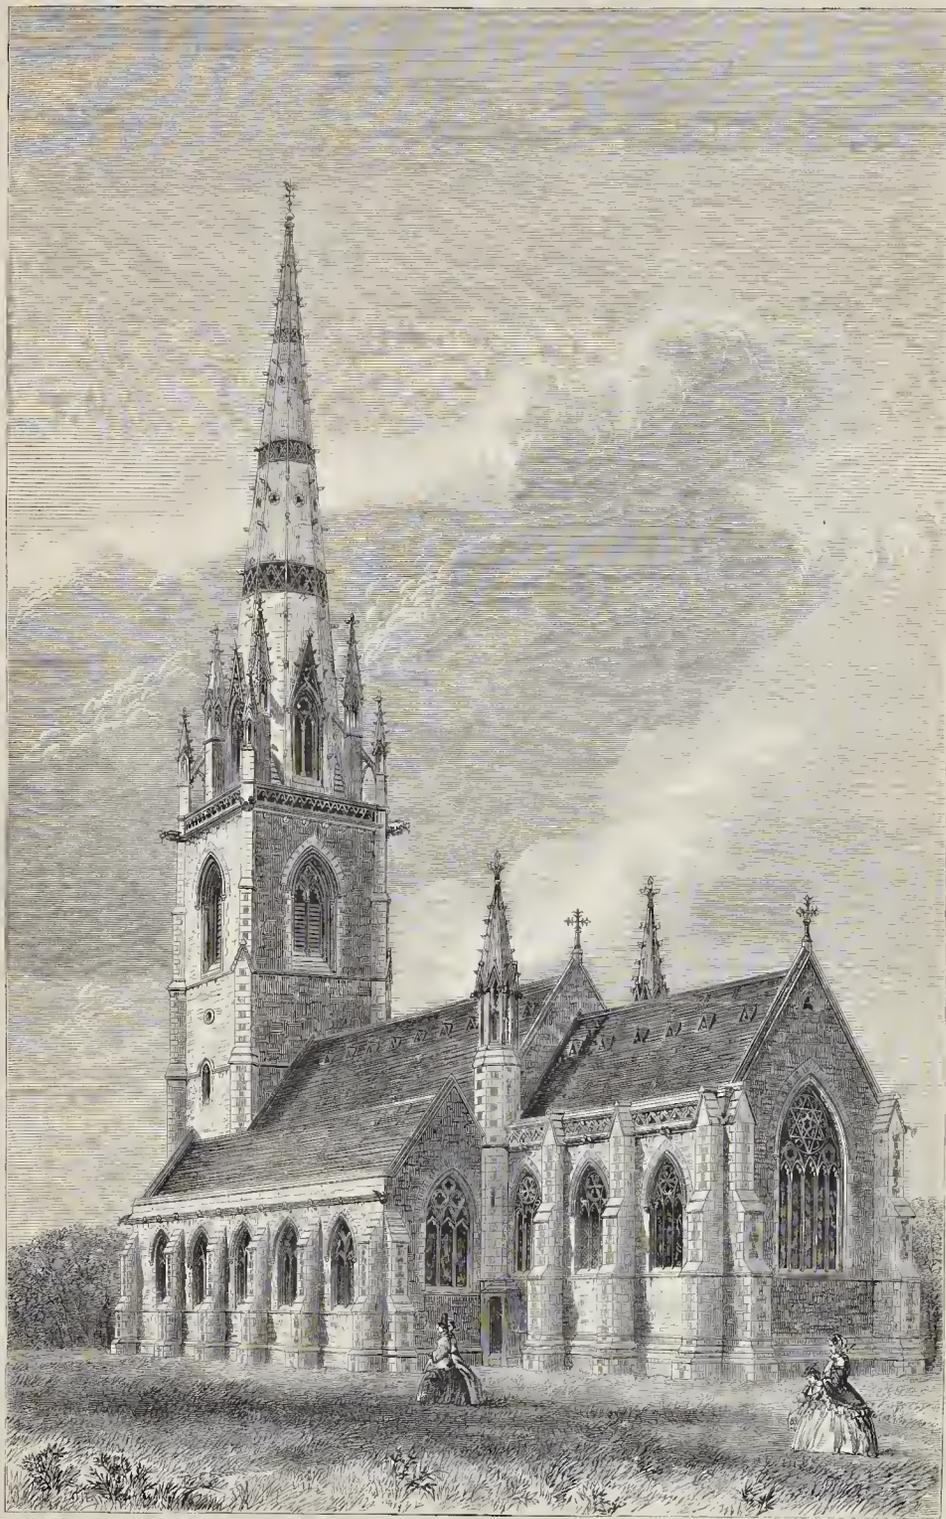

and south windows of the tower or entrance, representing—one, Kentigen, the first bishop of St. Asaph; and the other, St. Margaret. In the east window of the south aisle are the arms of St. Asaph and other bearings. The vestry is covered with a leaded roof concealed behind its parapet; and it is lighted by cusped spherical-triangular windows in the upper part of the walls.

The pavement of the church was supplied by Mr. Field. In the nave and aisles there are borders of Irish black and rouge-royal marble polished, bands of rouge-royal and dots of Irish black marble polished, and squares of Portland stone rubbed. In the chancel, communion, and vestry floors the same arrangement is adopted, but the squares are Sicilian marble. In the tower and its recesses the bordering is of Irish black marble polished; the bands are of slate, the squares of Portland stone, and the dots of red tile; whilst in the tower-entrance, Portland stone, and Irish black polished dots, are used. The steps of the communion, chancel, vestry, and private entrance to the chancel, are of polished Sicilian marble. The western doorway, which is skillfully planned to get extra effect from depth beyond that from thickness of the wall, has shafts of polished Aberdeen granite. The screen of the tower archway has the shafts of polished Anglesea marble.

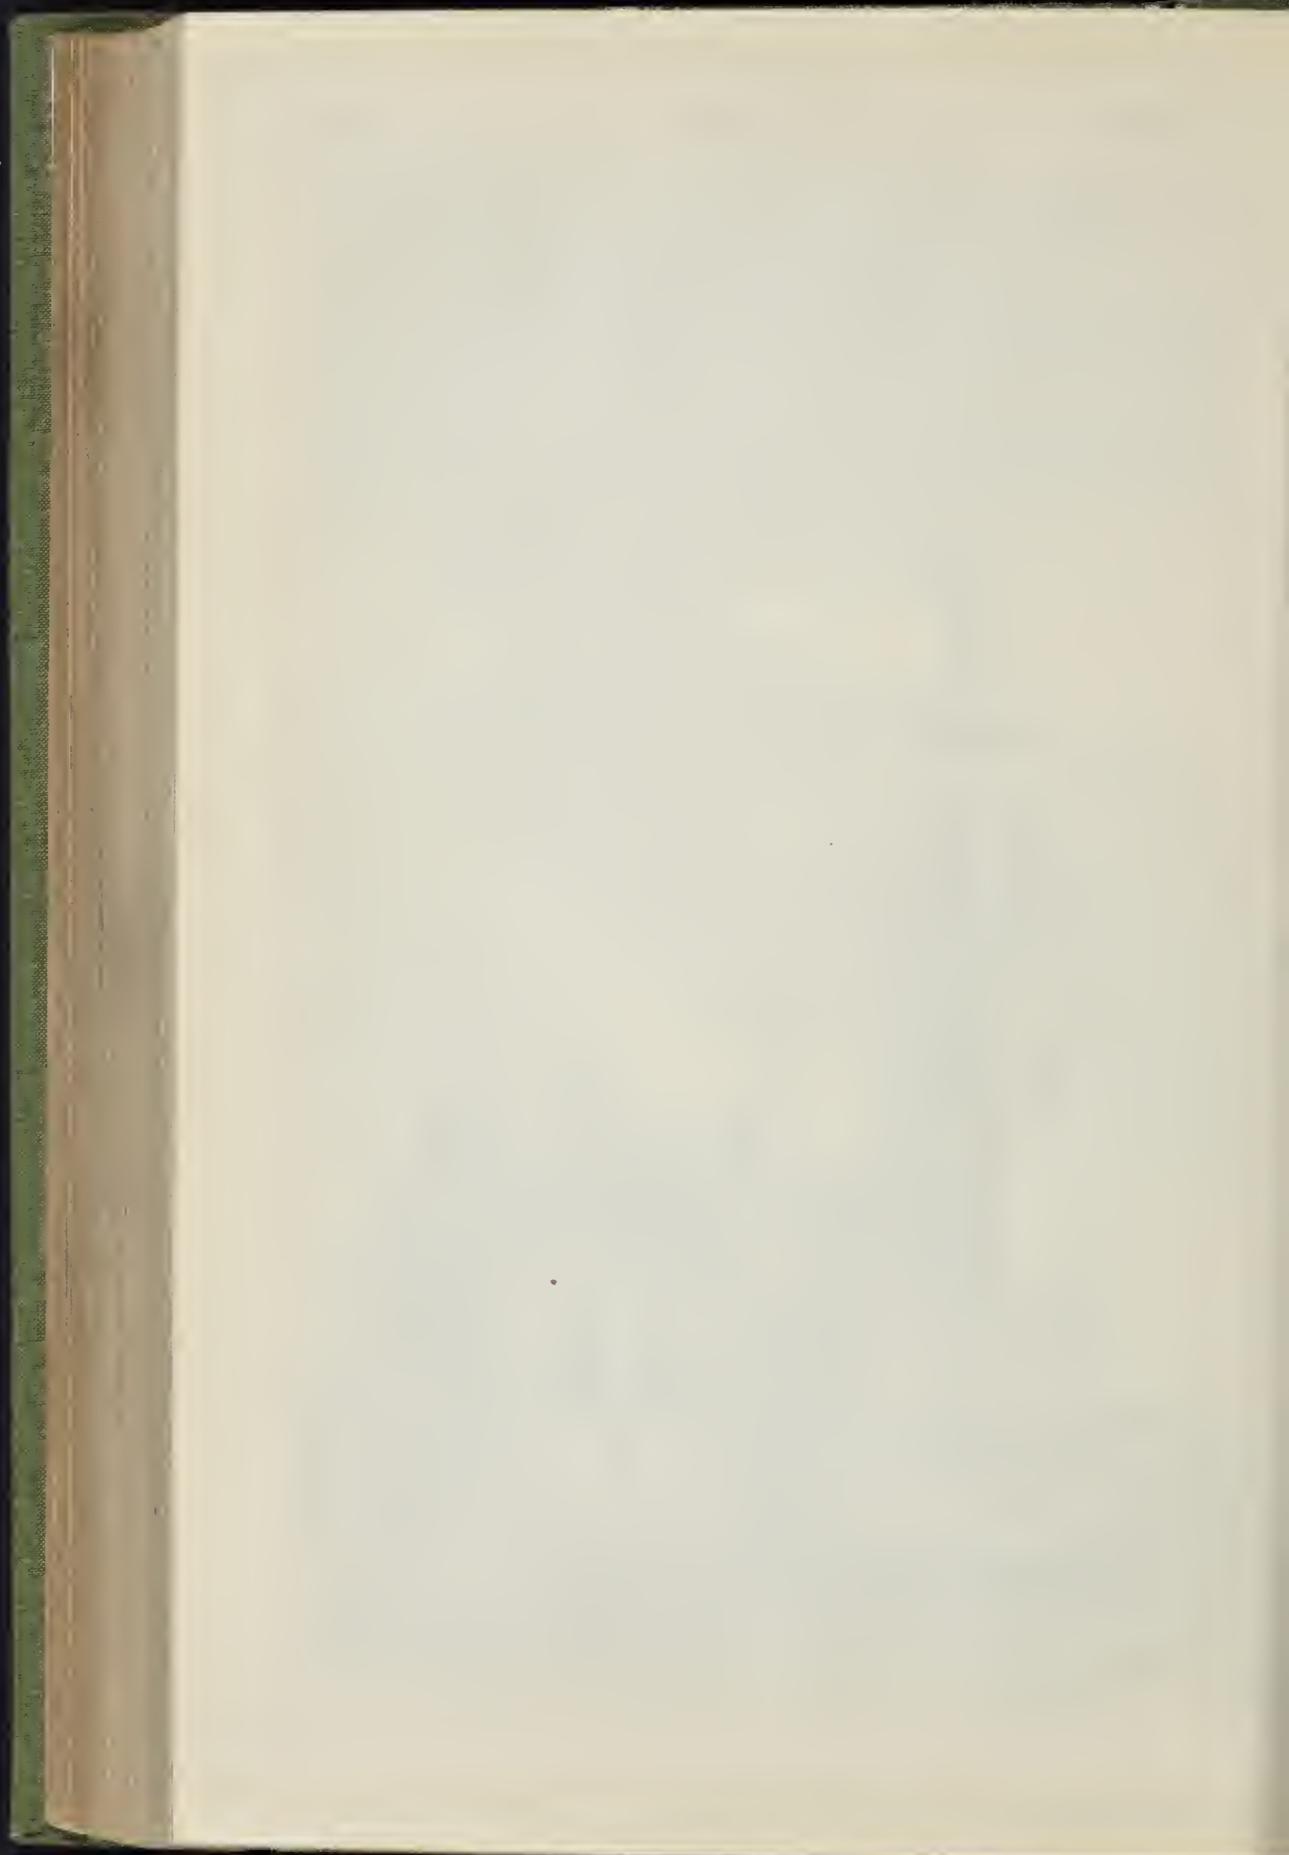

The tower measures 24 feet square on the outside, exclusive of buttresses: the height to the base of spire is 82 feet 6 inches; and the whole height from the ground is about 202 feet. The view and small plans together will show much of what has been aimed at through details. The actual effect of the pierced work of the spire and of the shafts of pinnacles, and of the peculiar crockets, is, we believe, good. Some attention has been given to modifications from the original perpendicular or other right lines of the buttresses and spire, in a manner analogous to the optical corrections in the Greek temples. The buttresses are all built with a batter on the face: the pinnacles of the tower and lucarne lights of the spire incline towards the centre, the horizontal lines being kept horizontal; and the spire has an entasis of about 6 inches on each side, or an addition of 1 foot to the total breadth in the middle.

The structural part of the design seems to have been carefully attended to: the masonry throughout is well jointed and put together, especially where the open work occurs in the spire in a thickness of material diminishing from 9 to 6 inches. The gutters of the roofs are protected from an accumulation of snow, by an arrangement of short lengths of battens, fixed transversely to longitudinal pieces, and laid, on blocks, like a ladder, along the gutter. The spaces between the battens will be not more than  $\frac{1}{2}$  of an inch wide after the shrinkage; so that snow will not pass through, and there is a clear depth for water to flow in the gutter beneath.

Many contractors have been engaged on the mason's work of the building: some of the number have been already named. Mr. John Thomas (not the sculptor) constructed the carcass of the building, or greater portion of it; and Messrs. Holme & Nicol, of Liverpool, built the spire. Mr. John Gibson, of Westminster, was the architect.

BODELWYDDAN CHURCH, NEAR ST. ASAPH.—MR. JOHN GIBSON, ARCHITECT.

ILLUSTRATIONS OF FRANCE IN THE BODLEIAN LIBRARY.

SOME months ago the archaeological section of Historical Works (Paris) ordered several of its members to study a question which for some long time past, has occupied the attention of the scientific world, viz., the importance and origin of a collection of drawings known under the name of the "Collection de Gaignières," now in the Bodleian Library at Oxford. The report, presented by M. Dauban, in the name of the commission, to the Minister of Public Instruction, &c., has signalled the great value of this collection, and has shown what interest the Imperial Library ought to take in completing, by a reproduction of the Oxford drawings, the rich collection which it already possesses from the same source.

The collections of M. de Gaignières, tutor of the sons of the Grand Dauphin, were presented in 1711 by the *savant* to Louis XIV. They consisted of a considerable number of books, manuscripts, prints, drawings, &c., containing most precious information as to the history and ancient customs of France, and were placed in the King's Library, now the Bibliothèque Impériale. This establishment has preserved the greater portion, and their being so frequently consulted proves their utility to the scientific world. A number, however, of drawings, consisting of twenty-five portfolios full of designs of monuments, especially tombs, escaped from the French possession during the period 1785 to 1801, according to various documents. In comparing the list of drawings at Oxford with the detailed catalogue of the Gaignières collection, drawn up in 1815 by Clairambault, there is every reason to believe that the sixteen folio volumes, hatched in 1809 by Richard Plough to the Bodleian Library, belong to this collection. A commission has been appointed to consult upon the best means of reproducing the above, and M. Jules Frappaz, an experienced artist, has been charged by the Minister with the mission of executing, first experimentally and then definitively, the drawings of the Oxford collection, containing about 3,000 subjects. M. Frappaz speaks in the handsomest terms of his reception by the conservators of the Bodleian Library.

THE LATE MR. EBENEZER LANDELLS, ENGRAVER ON WOOD.

We hear with regret of the death of this clever artist, who has in his time done good work. Mr. Landells was a native of Newcastle-on-Tyne, where he was born in 1808, and was descended from a family reared on the banks of the Tweed, but who removed to Newcastle, and carried forward a successful business as drapers. He received an excellent education at Mr. Bruce's academy in Newcastle,—the same good school wherein Robert Stephenson, the engineer, laid the foundation of his knowledge. When about fourteen years of age Landells was apprenticed to Mr. Isaac Nicholson, a wood-engraver, who, however, like the Bewicks, executed general work—engraving on brass, copper, and silver. At that time Thomas Bewick and his brother were showing the capabilities of engraving on wood; but generally the work done was still of a very coarse description. During the days of Mr. Landells's apprenticeship schools of art were not thought of; but in Mr. Nicholson's establishment the boys had an opportunity of learning to sketch and draw: they had also the means of gaining a more general knowledge of art than is obtained by many wood-engravers at present. Having finished his apprenticeship, Mr. Landells came to London, where he found plenty of demand for his work: he was, however, induced to undertake the management of an eminent printer and publisher; and this office he held for a considerable period. By this means Mr. Landells was thrown amongst many artistic and literary celebrities, and eventually he was enabled to commence business on his own account, and give employment to a number of engravers and draughtsmen. From that time Mr. Landells has been eminently connected with the illustrated periodical literature of the metropolis. Many of our readers will remember the commencement, in 1841, of the now venerable but still healthy and vigorous *Punch*. Mr. Landells was one of the original three who started the publication. At that time the market was polluted with several journals, which pretended to wit, but had an injurious tendency. It was thought, and wisely, that the wit and satirist, assisted by the draughtsman and engraver, might play a useful part without indulging in calumny or profanity. *Punch* was accordingly launched,

Mr. Landells being the chief proprietor, and supplying the engravings. Mr. Mayhew, and, if we remember rightly, Mr. Mark Lemon, the first and present editor, were the other two originators. A late member for Pontefract assisted Landells with cash, and was to undertake the printing in order to repay himself. The sight of a journal, in a coffee-house, printed by Bradbury & Evans, led him to call upon them for a tender, and resulted in a very short time in their purchasing the copyright of what has been to them a fortune, and to the public a boon.

After this Mr. Landells, together with the late Mr. Douglas Jerrold, projected "The Illustrated Magazine," which, under the editorship of Jerrold, was continued for two years. Some of the drawings by Kenney Meadows, engraved by Landells, have much merit. After the decline of this, Mr. Landells, advised, we believe, by Mr. Henry Mayhew, started the *Lady's Newspaper*, which, for many years, was under the management of Landells. The *Express*, a weekly journal illustrative of the Great Exhibition of 1851, and other works, which have had a varied amount of success, were also planned by him. About the time that he originated *Punch* he was employed upon the *Illustrated News*, and was deputed to follow the Queen in her visit to Scotland, referred to in our notice of the late Mr. Ingram, in our last, and to sketch and engrave the incidents of the journey. This was the first attempt of the kind, and Mr. Landells executed it so successfully that he was afterwards deputed to follow Her Majesty in various other progresses for the same purpose.

More lately Mr. Landells, assisted, by one of his daughters (Alice), produced several artistic works for children (the boys' and girls' toy-makers). These ingenious contrivances enable the young to prepare models of houses, locomotives, and other objects, and so to create things for their amusement, instead of, in the common fashion, destroying the toys which are put into their hands ready made. The last years of Mr. Landells's life have been clouded by difficulties, in a measure resulting from a want of that adherence to matters well planned and commenced, and of those business habits, which, when united with talent, lead to fortune. Many will long remember Mr. Landells for his genial and friendly disposition, and join in the regret experienced by his family at his loss.

THE RECORD OF MATTERS AFFECTING OUR PURSUIT.

AMONG the papers read at the Social Science Congress at Glasgow, was one of some interest to the order of architects. It was by

Mr. Arthur Symonds, recommending the systematic formation of libraries adapted to every calling, from the Sovereign or Minister of State to each class of man of business. He traces to the want of systematic method in recording matters as they arise, many drawbacks to our social progress, and to the development of the knowledge appropriate to each class of public and private service. To obviate this evil he proposes that, instead of the haphazard formation of libraries, they should be prepared for by an apt, logical, practical arrangement of receptacles, after the manner of books, which would afford a proper place for whatever arises. In exemplification, he produced plans of the arrangement of a state register, and other subsidiary registers, exhibited in due order in cases capable of receiving papers of the folio size, the contents of which are indicated on the backs of the cases. The plan showed various methods of distinguishing by signs and by colours the classes of the books, as well as of relieving the monotony which a long range of books of the same sort would occasion.

Though thus embodied in convenient form, the plan is not formal, but logical. It is framed so as to comprehend every class of matter in due subordination to the general plan, which comprehends the entire field of public service, each out into the minutest detail, according to the peculiar position and exigencies of the person by whom the plan is used, while, if all Associations would each according to the scope of their own purposes adopt it, the community at large would find in its possession, somewhere, the whole range of science and art provided for.

The author stated that he had originally been led to adopt the plan for official and legislative purposes; but in doing so had discovered its applicability to all other purposes; and that, in the measure of its general adoption, would be the facility of applying it in any instance.

He had read, at the three former meetings of the Association, papers declaratory of the prin-

ciples and general methods; and it was now his purpose to give, according to a promise, some illustration of the details.

The subject was recommended to the Council of the Association for investigation, as to its applicability to the purpose of reducing, into some scientific shape, the multitudinous topics and communications which it has under consideration.

Every one of us must feel, and every public office and associated body must know, how advantageous it would be if every suggestion, memoir, or record that had been brought forward, bearing on their special objects, were so put away that it could be at any time referred to without trahle.

ARTICLED PUPILS AND THEIR MASTERS.

A CORRESPONDENT writes as follows:—

"Sir,—May I ask you a question? First, is it legal, and, secondly, is it gentlemanly, in a case where an architect is engaged in public competition, for his articulated pupils, without his knowledge, to send their private designs to the same competition? A short notice in your next number would greatly oblige a reader, and one who values your journal and his profession. ARCHITECT."

Although we do not know the terms of the "articles," we say at once it is neither legal nor gentlemanly, and we do not envy either master or pupils between whom such a feeling exists as should permit the occurrence. There ought to be between artist-master and pupils deference, confidence, anxiety to aid and instruct, gratitude for aid given, mutual affection; and, these existing, no one of them would think of inquiring whether such a dirty act as that mentioned be "legal" or not.

Years ago, in the early travel of hoy-days, we enjoyed for a short time the society of the venerable Dr. Müller, of Darmstadt. In his office there were two pupils, or disciples as they would have been called in earlier days. The earnestness with which one of them said, in the course of a conversation as to his master, "If Dr. Müller were to tell me to polish his boots, I should do it, satisfied he was right in asking it, and only too glad to show my thankfulness for the advantage I derive simply from being near him," recurs to us as illustrating a relationship between master and pupil one would desire to find more often than we do.

BIRMINGHAM ARCHITECTURAL SOCIETY.

THE first meeting for the present session of the Birmingham Architectural Society was held on Thursday evening, the 4th. It was announced that during the recess a correspondence had been carried on with the Royal Institute of British Architects, relative to the establishment of a voluntary professional examination; a scheme having been proposed by the council of the Institute which, in all its main features, met with the thorough approval of the Birmingham Society. The following gentlemen were put in nomination as honorary members of the society: Sir Francis E. Scott, Bart., Mr. J. T. Bunce, Mr. S. Timmins, Mr. A. Davidson. The president of the society, Mr. J. G. Bland, then proceeded, after a few prefatory remarks, to read a paper "On the Disposition and Construction of Farm Buildings." Mr. Bland sketched the rise and progress of that class of improved farm buildings which is now becoming every day more and more common. He pointed out the great necessity for economising labour as much as possible, and showed that by judicious arrangements with regard to the position of buildings, a great portion of labour that is ordinarily wasted might easily be saved. The questions of site, of aspect, of the concentration of the buildings, of the uses of water and steam-power, and a variety of other topics, were successively brought forward. After the conclusion of the paper, a conversation followed, and various matters of detail were debated by the members.

HERBERT INGRAM'S PARLIAMENTARY SUCCESSOR.—We last week gave a review of the life of the late Member for Boston, and are led to add to it, that he seems likely to be succeeded by another self-made man, connected with those trades, undertakings, and works, in which our readers are more particularly interested.—Mr. S. C. Kitley (a native of the town), who has just returned from America, where he has been many years engaged in the construction of railways, docks, and public works. In his address to the Electors he declares himself to be in favour of various improvements calculated to benefit Boston; and having a large fortune to spend, he will not be stopped for lack of means. There is a want of such men in the House of Commons.

## THE LIFE-BOAT STATION BAROMETERS.

To the subject of life-boats and their arrangements, and the importance of the barometer, we have ere now given attention; and we are glad to learn that the life-boat stations on our coasts will soon be supplied, as some forty of them already are, with barometers such as that in our engraving. A good barometer will not infrequently indicate a coming storm two or three days before it actually takes place or reaches the locality where it has been indicated. If such barometers were placed in every harbour, with instructions given to capable residents appointed as storm-warners, an immense saving of life and property would speedily be the consequence. Practical instructions, just such as are wanted, have been drawn up by a nautical man of experience and intelligence, namely, Rear-admiral Fitzroy, F.R.S., and it was he who, as chief of the Meteorological Department of the Government, obtained, some time since, the sanction of the Board of Trade to supply about forty of our poorer fishing villages with barometers, some of which have already proved their value by the services they have rendered. The subject has now been taken up by the National Life Boat Institution, of which the Admiral is a committee-man, and who propose to fix such instruments as the engraving represents wherever useful and practicable at the Society's stations, and in charge of their permanent coxswains as storm-warners. The manufacturers of the instruments will probably be Messrs. Negretti & Zambra, who supplied the forty already fixed, and the cost will be under 6*l.* each. A gentleman has already subscribed 50*l.*, and it is anticipated that the public will readily make up what more may be requisite.

Some curious and interesting information on "signs of weather" are given in the admiral's "Instructions."

"Whether clear or cloudy, a rosy sky at sun-set, presages fine weather; a red sky in the morning bad weather or much wind, perhaps rain; a gray sky in the morning, fine weather; a high dawn, wind; a low dawn, fair weather." Light, delicate, quiet tints or colours, with soft, unde-

\* A high dawn is the break of day seen above clouds, instead of the horizon.

fined forms of clouds, indicate or accompany fine weather, but gandy or unusual hues, with hard definitely-outlined clouds, foretell rain, and probably strong wind.

Remarkable clearness of atmosphere near the horizon at distant objects, such as hills, usually visible; or raised (by refraction), and what is called "a good hearing day," may be mentioned among signs of wind, if not wet, to be expected.

More than usual twinkling of the stars, indistinctness or apparent multiplication of the moon's horns, halos, "wind dogs" (fragments or pieces of rainbows, sometimes called "wind galls"), seen on detached clouds, and the rainbow, are more or less significant of increasing wind, if not approaching rain, with or without wind.\*

Whether we are indebted to the Admiral for the rhythmical form in which the following "wise saws" are put we know not; but the form is at all events a useful one, and well adapted for record in the sailor's brain, among his longer and tougher but less valuable rope-yarns and other odds and ends:—

"When the wind shifts against the sun,  
Trust it not, for back it will run.

First rise after very low  
Indicates a stronger blow.

Long foretold, long last;  
Short notice, soon past."

Perhaps this is the first "poetry," as well as one of the first specimens of weather-wisdom, ever issued on the authority of an official member of a grave Government department. The lines remind us, by the way, of a very old rhythmical weather axiom prevalent in Scotland, and which is in perfect accordance with the Admiral's first prose axiom:—

"The evening red and the morning grey,  
That's the sign of a bonnie day."

## BREAKWATERS AND HARBOURS.

A SELECT COMMITTEE was appointed by the House of Lords to inquire how far it may be practicable to afford better shelter to shipping upon our coasts than is at present afforded, by the adoption of some plan for the construction of breakwaters and harbours less costly and better adapted for certain localities than the system of solid masonry harbours in use. This committee has just published a report, of which the following is the principal point:—

"The committee feel the importance of seeking every means by which harbours and breakwaters of a less costly construction than those at present in use, or formation could be placed on various parts of the coast.

They have taken much evince on this subject, and have had their attention especially called to floating breakwaters, of which several plans have been submitted to them. Upon the advantages to be derived from these constructions the evidence is conflicting.

The committee are not prepared to recommend that the Government should undertake the task of constructing breakwaters on these principles; but, looking to the vast cost of harbours constructed upon the systems hitherto in use, they are of opinion that a moderate sum might be advantageously expended by Government in testing any plan which may offer a probability of important results in great future saving of money, and in giving protection to life and property in various localities. To carry this object into effect, the committee recommend that a sum, not exceeding 10,000*l.*, be placed at the disposal of the Admiralty."

## LIVERPOOL ARCHITECTURAL SOCIETY.

## THE BANKRUPTCY CASE.

The first meeting of the thirteenth session of this society was held on Wednesday evening, the 3rd, at the Royal Institution. Mr. James Hay, the president, occupied the chair. The president presented to Mr. Raphael C. Isaac a copy of "Brandon's Parish Churches," the prize offered by the society, for the best design for a villa, during the session of 1859-60.

The president announced that a special meeting of the society had been held that day upon professional matters, and called upon the secretary to read the report of that meeting, which was as follows:—"At a meeting of the professional members of the Architectural Society, held for the purpose of receiving an explanation from two members of the society in reference to certain paragraphs which have appeared in the press reports of a bankruptcy case,—It was resolved, 'That, as these members have volunteered a full and detailed statement of the transaction, the meeting desire to record their deliberate opinion;—1st. That it is very much to be regretted that these gentlemen should have been betrayed by any provocation into the adoption of a proceeding so extremely irregular and open to abuse;—2nd. That from the evidence there is no foundation for the imputation of any fraud on the part of these gentlemen;—3rd. That the sum obtained is a very inadequate remuneration for the services rendered in the preparation of the drawings and specifications referred to."

The president drew attention to a report of

\* Full particulars are given in the journal of the Association, *The Life-boat*.

the sub-committee of the five literary and scientific societies of Liverpool, appointed to take into consideration the offer of Mr. William Brown to set apart a portion of the new Free Public Library for the purpose of exhibiting scientific and mechanical appliances. The committee reported that the result of their labours would be the realisation of Mr. Brown's wishes, and that a valuable addition would be made to the scientific institutions of the town, not contemplated when the library was commenced. Mr. Huggins exhibited and explained a chart of the various styles of architecture in the form of a stream, with various branches and ramifications, showing the way in which the styles flow out one from the other. The president then read his inaugural address, which was warmly applauded; and Mr. J. Audsley read the paper of the evening, "History of the Art of Illumination, and its Revival and Application in the Nineteenth Century."

## A BIG PIPE.

A NEW iron main of great size is being formed near New York, for the Croton Water-works. The sheets prepared for this pipe are 6 feet wide by 8 feet long, and half an inch thick. The iron used is required to stand a strain of 40,000 lbs. per square inch. The pipe is 1,350 feet long, and 7½ feet in diameter. It will be made in sections of 12 feet, requiring 675 sheets, each of which contains 48 square feet, and weighs 960 lbs., or 20 lbs. to the square foot.

Each sheet is punched near the edges with 200 holes. The sheets are then put under a drilling-machine, and each hole is countersunk so that the rivets may be driven flush, leaving the pipe perfectly smooth on the inside. Next the sheets are sent to the rolling-machine, and rolled to the required curve or radius, three sheets hatted together forming the pipe. In each 12 feet section there are just 1,200 rivets. The weight of the plates is 618,000 lbs.; of the straps, 145,125 lbs.; of the rivets 50,000 lbs.—making in all a total of about 810,000 lbs. The contract of Abbot & Son, for furnishing the plates and straps, was for 28,859 dol. 81 c. Sweden & Rowland do the remainder of the work, and supply the other materials, for 29 dol. 31 c. per linear foot, amounting to 43,260 dol. 50 c. Total, 78,120 dol. 31 c.

The pipe will rest on about 170 cast-iron standards, or saddles, which are placed 8 feet apart, and weigh about 1,000 lbs. each. It will be protected inwardly and outwardly by coatings of Prince's metallic paint.

The estimated difference in the length of the pipe in summer and winter is 4 inches; and to provide for this expansion and contraction there will be a slip joint at either end, which will be made of cast-iron, with slipping surfaces lined with brass, to prevent their becoming fixed by oxidation. The pipe is mounted on rollers. In regard to the strength of this pipe, it is said that, if supported at its extremities, with 1,350 feet intervening between the supports, it will sustain itself when filled with water.

## METROPOLITAN BOARD OF WORKS.

## THE PROGRESS OF THE MAIN DRAINAGE WORKS.

At the usual meeting of the Metropolitan Board of Works, held on the 5th instant, Mr. J. Thwaites in the chair, Mr. Bazalgette presented the following report of the progress and cost of works executed on the several lines constructing for main drainage purposes:—

"I beg to report that the progress of main drainage works during the past summer has not been so satisfactory as could have been wished, owing mainly to the unusually wet season we have had, and other unforeseen difficulties which have occurred.

On the North Side of the Thames.—The Northern High Level Sewer would, with ordinary fine weather, have been completed ere this, but the old Hackney-brook remains to be filled in, and several branch connections and divisions of local drainage will have to be made under this contract. The value of the work executed up to the present time is about 157,760*l.*

The Middle Level Sewer Works have also been delayed by some difficulties with the contractor; it is hoped these will now be satisfactorily settled, and that the works will proceed more rapidly. About 1,300 feet of sewer, 9 feet 6 inches in diameter, has been constructed at Old Ford, and about 2,000 at Paddington. The value of the work executed under the contract is about 16,400*l.*

The Ranelagh storm overflow across Hyde-park is being well executed, about 660 feet of sewer, 8 feet 6 inches in diameter, having been completed, and works to the amount of about 2,200*l.* executed, besides 630*l.* for the underpinning of the Ranelagh Sewer in connection with these works.

On the South Side of the Thames.—The Southern High Level Sewer works were delayed considerably by the inability of the former contractor to proceed with them, but they are now being more satisfactorily performed by their successors, and about 960 feet of double sewer, from about 10 feet 6 inches in diameter, have been constructed at Pinner, about 1,650 feet of 10-foot sewer at Brixton,

and about 2,000 feet of smaller sewers, besides 3,000 feet of the Effra branch, 9 feet 3 inches in diameter, and another 900 feet, 7 feet in diameter. The works executed under this contract are valued at about 35,000.

"Southern Low Level Sewer"—The portion of this work under the Surrey Consumers' Gas yard, recently let, has not been commenced, owing, first, to some delay in getting the late contractor's plant off the ground, and then to the necessity of sinking further cylinders for the pumping-engines, and the time required to provide suitable engines prior to the commencement of this work. The contract with Mr. Aird for the completion of the work done is still in the course of settlement. The Deptford pumping engines are rapidly progressing, and will be ready for delivery before the engine-house foundations are ready for their reception."

The report was received, and ordered to be printed and circulated.

#### THE THAMES' EMBANKMENT.

Mr. Le Breton rose to move the resolution of which he had given notice:—

"That it be referred to the Main Drainage Committee to consider and report as to what measures it is expedient to take as to the proposal of carrying out the Thames Embankment in connection with the Northern Low-level Sewer; the throwing open, toll-free, of Waterloo and Southwark bridges; and the making of a viaduct across the Holborn valleys, with power to confer with the Government and other parties as to the provision of the necessary funds for all or such of the above works as the Board may resolve upon undertaking."

But, adopting Mr. Deputy Harrison's suggestion, he altered his resolution as follows:—

"That it be referred to the Main Drainage Committee to consider and report as to what measures it is expedient to take as to the recommendations in the report of the Committee of the House of Commons on the Thames Embankment and other improvements connected therewith, and to report to the Board."

The resolution was put and carried unanimously.

#### ELECTRO-TELEGRAPHIC PROGRESS.

The contracts for laying down the wires (under Allen's new patent) of the United Kingdom Electric Telegraph Company, to Manchester, Liverpool, and Birmingham, have been signed. It is stated that the works will be completed and messages transmitted by Christmas. It is estimated that the entire cost of completing the line (including all necessary offices for 32 stations, instruments, &c.), from London to Liverpool, will be 35,000*l.* The annual expenditure is estimated at 13,500*l.*, and the returns at 41,181*l.*, leaving a profit of upwards of 27,000*l.*, or about 50 per cent. on the capital!

News has arrived of the laying of four submarine cables in the Mediterranean, by Sir Charles Bright, between Valencia and the islands of Ivica, Majorca, and Minorca, and thence to Barcelona.

The Asiatic telegraph has now been carried down to Jezrah, on the Tigris, a hundred miles north of Mosul; and it is expected that, by the end of this month, messages will be transmissible from Constantinople to Nineveh.

New kinds of deep sea telegraphs are now the order of the day; but we are still of opinion that all such schemes should have been preceded by a formal and authoritative investigation, which has not yet taken place.

One of these new telegraphic cables is thus spoken of:—The Algiers and Toulon cable, says the *Birmingham Journal*, is made on an entirely new principle, being composed of hemp and steel wire, and is the invention and the patent of Messrs. John & E. Wright, of the Universe Works, in this town. The wire used is manufactured by the new process of which the firm of Webster & Horsefall are the patentees. Some idea of the extraordinary lightness of this cable may be gathered from the fact that it weighs a ton to the mile. The cable is laid down at the expense of the French Government.

Another new cable, said to be suitable for the Atlantic, is thus described by another contemporary:—We have had the opportunity of examining the entire details and process of manufacture, from the covering of the copper wire to the completion of the cable, upon a system introduced by Messrs. Hall & Wells. The copper wire is first covered with cotton, over which are wound two or more spiral layers of pure India-rubber, each spiral running in the reverse direction, the whole being covered with a cord of well-tarred hemp: this forms the core, which in turn is protected by longitudinal strands of hemp and wire, kept in position by a closely-plaited hempen covering.

The specific gravity of the finished cable is little greater than that of water [and may it not be too light for safe laying? One extreme may be as bad as the other: the safe mean is just one of those important points which still require to be investigated], and the tensile strength is considerably above that of an ordinary electric cable of equal bulk. The machinery by which the core-covering is made, we should mention, is

simply the application, on an enlarged scale, of the ordinary plating machine, with the addition of a series of independent hollow tubes for laying the longitudinal strands, so that the practicality of manufacturing any length cannot be questioned."

#### GAS.

UNDER the operation of the Metropolitan Gas Act, the directors of the South Metropolitan Gas Company have reduced the price of gas 4*d.* per 1,000 feet. The Phoenix Company has reduced the price 3*d.* per 1,000 feet. It is anticipated that a similar reduction will shortly be made by the Imperial Company.

The Surrey Consumers' Gas Company have declared their usual dividend of 8 per cent. per annum for the half-year last past. The net profit amounted to 6,609*l.*, odd, out of which a balance of 1,227*l.* was carried over to the account of unappropriated profits after payment of the 8 per cent.

The Manchester gas committee report that the sale of gas continues steadily to increase, the rental for the past year having amounted to 154,655*l.* 4*s.* 2*d.*, being an increase of 9,403*l.* 6*s.* 2*d.* upon the rental of the previous year, notwithstanding the reduced price which, during the last six months, has been charged to private consumers within the city. The gross profit amounts to 64,779*l.* 1*s.* 10*d.* as against 58,789*l.* 13*s.* 4*d.* the previous year, leaving,—after deducting for interest, 16,255*l.* 12*s.* 4*d.*, and on Sinking Fund account 13,306*l.* 5*s.* 6*d.*,—a surplus of 35,217*l.* 17*s.*, divisible between the improvement and water-works departments. From the pressure, apparently, made by the Local Gas Consumers Association, who are bent on having their gas at 3*s.* 9*d.*, and object to city improvements out of gas profits, the gas committee and the council have resolved on further reductions in price according to quantity consumed, the lowest to be 3*s.* 8*d.* for 1,500,000 feet and upwards per quarterly consumption, and the highest 4*s.* for quantities under 200,000 cubic feet. Beyond the city the prices are to range from 4*s.* 2*d.* to 4*s.* 6*d.*

The Sheffield gas company directors report their dividend for the half-year to be the maximum of 10 per cent. on old, and 8 per cent. on new stock, leaving a surplus of 2,269*l.*, which will raise the reserve fund to its conditional maximum, being now 6,908*l.*; so that the directors contemplate a further reduction in price. They therefore propose at once to reduce the charge for their gas to 3*s.* 9*d.* to the general consumer, and they anticipate a greatly increased consumption when they shall have reduced it to 3*s.* 6*d.*

About eighteen months ago a company was formed for lighting St. Petersburg with gas. The works have now been successfully started: upwards of fifty miles of main pipes are laid, the greater portion being the larger sizes, from 12 to 36 inches diameter.

#### PROPOSED UTILIZATION OF SEWAGE.

*Croydon*.—A prospectus of the Croydon Sewage Irrigation Company (Limited) has been issued. This company proposes to apply the sewage of Croydon to irrigate the land contiguous to that town, on a plan devised by the company's engineer, which is said to have received the approbation of high agricultural authorities. It is mentioned that by the plan proposed the sewage manure can be supplied over a large area to estates and farms, at a rate remunerative to all parties. It is to be pumped into a reservoir situated on an elevation about two miles from the town, whence it is to flow to each farm and field by gravitation. The company has obtained privileges for a term of 100 years. The capital is fixed at 30,000*l.*, in shares of 10*l.* each, with a deposit of 2*l.* 10*s.*

*Birmingham*.—The residents along the banks of the River Tame, says the local *Gazette*, "have frequently complained that the sewage of this town has polluted their river, killed the fish, and half-poisoned the people. In some instances, legal proceedings have been taken against the corporation, and no slight degree of anxiety or small amount of expense has resulted. The works carried on for some time past at the outlets of the sewers have, we believe, done a great deal towards removing the former causes of complaint; and it is now in contemplation to go a step further, and ascertain whether the sewage matter, having ceased to be a nuisance to the neighbouring farmers, cannot be converted into a positive benefit to them, and at the same time be made a source of revenue to the town. The subject will

receive ample discussion; and we believe it will not be the fault of the mayor and corporation if some plan cannot be devised to carry into effect an object in every way so greatly to be desired." A meeting with this view has already been held. It was convened as a conference, by Mr. Lloyd (the mayor), and attended by a number of land-owners, farmers, and others. The meeting has appointed a committee to consider the best method of bringing the corporation and the farmers into close contact in this matter.

#### PROVINCIAL NEWS.

*Belper*.—The waterworks directors have accepted the following tenders, viz., the Butterley Company's for the supply of cast-iron pipes, &c., and the tender of Messrs. Tomlinson & Harper, of Derby, for the construction of the reservoirs and pipe laying. Operations will be commenced forthwith, to ensure the works being ready by the spring of next year. The plans were furnished by Mr. R. Bayliss, of Derby.

*Newcastle-upon-Tyne*.—The new Mechanics' Institute and Baths and Wash-houses at Low Walker, built by Mr. Charles Mitchell, of the firm of C. Mitchell & Co., for the workpeople of his firm and the inhabitants of that village, have been inaugurated. The building is situate in the principal street of the village. Mr. Mitchell acted as his own architect. There are apartments on the ground-floor for the keeper of the institute. Above these are the reading-room and library, 52 feet in length and 27 feet in breadth.

#### STAINED GLASS.

AMONGST those glass-painters who are at any rate trying to raise the character of their productions, by the employment, amongst other means, of able artists when terms or opportunity permit it, we may name Messrs. Lavers & Barrand. This firm have recently produced a small light, after a cartoon by Mr. E. B. Jones, artist, of the school known as "P. R.," which deserves mention. The subject is the Annunciation. The Virgin is kneeling amidst flowers, holding in her hand the dove. Gabriel,—

— "The angel who came down to earth  
With tidings of the peace so many years  
Went for in vain, that op'd the heavenly gates  
From their long interdict,"—

stands behind. The Annunciation places before us, as Mrs. Jameson says, "the two most graceful forms which the hand of man was ever called on to delineate,—the winged spirit fresh from Paradise; the woman not less pure, and even more highly blessed—the chosen vessel of redemption, and the personification of all female loveliness, all female excellence, all wisdom, and all purity." It is small blame to say that the cartoon falls short of this; but Mr. Jones has given the Virgin a singularly sweet and touching face. This has been transferred to some extent to the glass; and the whole, although confused and wanting in white light, presents an agreeable mosaic of colours, and a pleasing sentiment for those who rightly look for something more than sparkle.

*St. Thomas's, Oxford*.—A new window of some importance has just been placed in this church at the east end of the new aisle. The subject is intended to be an embodiment of the idea of Christian worship as seen by St. John in his Apocalyptic vision. The centre of the three lights contains a figure of the Lamb standing on the heavenly altar, His blood streaming into a chalice. Two angels are represented in the two small lights above as holding candles. Below is seen a Priest celebrating the Holy Communion at an altar in correspondence with the altar in Heaven. In the two side lights are angels "harping with their harps," and saints, with palms in their hands, casting their crowns before the throne. The lowest of these alone appear to be historical figures—most conspicuously those who may be supposed to be connected with the locality—St. Thomas the Martyr, St. Frideswide, and St. Margaret, and with them others well known in the history of the English church. On each side is the tree bearing "twelve manner of fruits." The window, based on a suggestion by Mr. Street, is the work of Messrs. Clayton & Bell, of London.

*Axminster*.—An east window has just been placed in the church of Axminster. The character of it is said to be in keeping with the style of the sacristy, which is Early Decorated,—about A.D. 1315. The ground is a diaper of blue and crimson, bearing medallions, representing in their ecclesiastical order the Circumcision, the Epiphany, the Baptism, the Agony, the Crucifixion, the Entombment, the Resurrection, and the Ascension. In the highest

quatrefoil is "The Descent of the Holy Ghost." The works were executed by Messrs. Powell, of Whitefriars.

**Liverpool.**—A stained-glass window has just been completed and placed over the sacristy door of St. Augustine's (R. C.) Church, Liverpool. It consists of three lights in the centre, one the figure of Christ as the Good Shepherd, having a lamb in His arms, and in the side lights figures of St. Charles Borromeo and St. Francis de Sales. These figures are placed under canopies formed of cusped equilateral arches, ornamented with the ball flower, and springing from the foliated caps of slender banded columns, of a character united to the geometrical style of the window. The spaces above the canopies are filled with ornamentation composed of the vine, &c., upon the alternate ruby and blue grounds, and surrounded by borders of the strawberry and lily. The spaces underneath the figures, and the openings in the geometrical head of the window, are filled with foliated tracery. The window has been executed by the St. Helen's Crown Glass Company.

**Halifax.**—The two windows in the north wall of the Rokeby chapel, at the parish church of Halifax, have been filled with stained glass. Mr. Warrington was the artist. Each of the windows consists of three lights, with Perpendicular tracery in the heading. By elevating the centre subject, a pyramidal arrangement has been effected. The window nearest the east is devoted to the life of Abraham. In the centre light the Father of the Faithful is depicted in the act of offering up his son Isaac on Mount Moriah. In the sinister light is the Blessing of Abraham by Melchisedek, king of Salem. The dexter light presents the Meeting of Abraham's Servant with Rebekah at the Well, near the city of Nahor. The other window is devoted to incidents in the life of Moses, viz. the Offerings of the People towards the making of the Tabernacle, the Uplifting of the Brazen Serpent, and the Anointing of Aaron. The Uplifting of the Brazen Serpent occupies the centre light. The head-lights in each window are filled in with angels playing instruments of music; as in the west window of this chapel, which was filled by the same artist about a year ago. For these three additions to the church the parishioners are indebted to the Waterhouse family.

**Newcastle-upon-Tyne.**—The Ions memorial window, at St. Nicholas' Church, in this town, has been inaugurated. It will be remembered that, about this time last year, the local churchwardens determined to place a new east window in the church, with a view of filling it with stained glass to the memory of the late Dr. Ions, the organist of the church. A design for the architectural portion of the work was supplied by Mr. A. M. Dunn, architect, and Mr. Wailles supplied the glass. The window contains seven lights, the stonework of which was executed by Messrs. Patterson & Barstall. The top of the window is enriched by tracery, and the first figure in stained glass, represents the Lamb and Banner; the two immediately below representing St. George and the Dragon and St. Michael. On either side of these are two large ones of angels, conveying emblems of the passions, surrounded by points of foliage, beneath which are the monograms I. H. S. Further down are double rows of figures, of the sixteen prophets, eight forming a row. To the right and left are figures of cherubim, and the side openings are allotted to the four evangelists. The five central divisions are occupied by incidents connected with the crucifixion of Our Lord. The base of the window is devoted to a representation of the Lord's Supper. The sum raised for the memorial was between 400l. and 500l.

#### ROMAN CATHOLIC CHURCH-BUILDING.

**Hoveford.**—The new Church and Monastery of the Benedictines, at Belmont, near Hereford, have been formally opened. The church, the first stone of which was laid six years ago by Mr. Wegg-Prosser, and which has just been consecrated, is cruciform in plan, and comprises chancel, lateral chapels, central tower, transepts, nave, aisles, and south porch. The extreme length is 150 feet by 60 across the transepts. The whole of the interior is worked in Caen, Painswick, and Bath stone. Exteriously it is built in Sargardine coursed stone, with tracery and dressings in stone from the forest of Dean. The roofs are covered with ornamental Bressley tiles with crests in metal and earthenware. The ceiling of chancel is sub-divided into compartments by wrought oak principals resting on curved hammer-beams, which are further supported by cusped brackets

which rest on angel corbels. The ceilings of the side chapels and transepts are also paneled, but in a manner less elaborate. The clerestory of the chancel is partly formed by gables jutting out of the main roof, forming a line of tracery, terminating in crosses carved in stone. The ceiling of the tower is groined in Caen stone, with carved bosses at the intersection: the same is supported on Devonshire marble columns, which jut out in emblem of the four Evangelists. The east end of the chancel has a window of five lights, which is filled with stained glass, by Messrs. Hardman & Co., of Birmingham. It contains five figures, representing our Saviour surrounded by angels; St. Michael, St. Raphael, and St. Gabriel, with choirs of angels surrounding the archangels. The roof of the nave and aisles are open, and are constructed with arch-principals, strengthened with ring posts and collar beams. The west end is filled with a large rose window, the tracery of which forms a cross composed of roses. The internal decorations are not yet commenced, except the high altar, which is executed in alabaster and marble. The church was commenced long anterior to a monastery being thought of, and it is undergoing several alterations. The monastery is entered from the church by a ground cloister, in which recesses are formed for resting. At present only one wing of the monastery is completed: this measures over 200 feet, and contains upwards of 40 cells, with rooms in proportion. The refectory is 60 feet long by 20 feet wide, above which is the library. Of the cloister only one side is at present completed, in local stone, with Bath stone dressing. The whole of the buildings were designed by Mr. Pugin.

**Garstang.**—The foundation-stone of a new Roman Catholic church has been laid at the village of Scorton, near Garstang. It is intended to be in the Early Decorated period of Gothic architecture. The architects are Messrs. J. Hanson & Son, of Clifton. The church will be seated to accommodate 300, and is expected to be completed in about nine months. The contractor for the joiner's work is Mr. J. Turner, of Preston; and for the masonry, Mr. W. Yates, of this town. The building is to cost about 2,500l.

**Brighton.**—A new Roman Catholic place of worship is about to be erected on a piece of ground now occupied as a timber-yard at the top of Hampton-place, Brighton. "Three tenders were at first sent in," says the local *Gazette*, "one from Messrs. G. Cheesman & Freeman, another from Mr. Fabian, and a third from a firm in London, and there was not 40l. difference between any of them. After Messrs. Cheesman & Co. had received a letter stating that theirs was the lowest tender, the next morning they received another letter to the effect that a subsequent tender had been sent in by the evening post, from Messrs. Patching & Son, precisely the same in amount. On Tuesday Messrs. Cheesman & Co. received information that their tender was accepted." The work will be forthwith commenced.

**Wexford.**—We are requested to state that the two churches at Wexford, described in the *Builder* on 29th September, were designed by the late Mr. R. Pierce, of Wexford, and were erected under his superintendance.

#### CHURCH-BUILDING NEWS.

**Sco-Ruston (Norfolk).**—The church of Sco-Ruston, situated about five miles from North Walsham, is having the chancel restored at the sole expense of the impropriator. The roof, which is of hammer-beam construction, will be taken off and re-framed, and new oak timbers inserted wherever required. The altar railing will be of open oak tracery, and the benching, running east and west, of the same material. New buttresses will be erected at the east end, with paneled stone fronts, and the gable finished with stone coping and cross. The paving will be Staffordshire tiles, laid in irregular devices. The interior of the walls will be stuccoed, and the east end diapered in fresco, with the commandments and texts on zinc, laid in flush with the plaster. The works will be carried out, under the superintendance of Mr. R. M. Phipson, by Mr. Mass, of Coltishall. The nave is in a terribly bad state of repair, the roofing covered with thatch in a most dilapidated condition. Plans for this part of the church have also been prepared by Mr. Phipson, and the rector, the Rev. H. White, has offered to guarantee the collection of three-fourths of the sum required for the properly restoring it; but the ratepayers, who consist solely of two farmers, have at present declined to accept this very liberal proposal.

**Ipswich.**—The church of St. Mary-at-Elms, Ipswich, is about to be hemed throughout, and new pulpit, reading desk, and altar railing erected, from designs by Mr. Phipson. The main body of the church, consisting of a nave and north aisle, is a common-place Late structure, but there is a good Norman doorway, with its original ironwork, of elaborate and excellent design, which will be carefully preserved. The tower is red brick, of Tudor date, relieved with black diamond work. The contractor for the works is Mr. Seager, of Ipswich.

**Wednesfield.**—The chief stone of the mortuary chapel, to be erected in the new parochial cemetery at Wednesfield, has been laid. The intended chapel will be erected opposite to the main entrance, the porch facing the gates. The material employed will be red brick, relieved by three bands of white brick, and white stone copings, window sills, and cross. To the left of the entrance porch there will be a small helvry tower, surmounted by a spire. The internal dimensions will be 35 feet in length by 15 feet 6 inches in breadth. Light will be communicated by two main windows, one at either end, and by six side lights. The entire cost of the building will be about 300l. Mr. Edward Banks, architect, supplied the design, and the work will be executed by Mr. Plant, builder, Wolverhampton.

**Bradpole (Dorset).**—St. Andrew's Church, Bradpole, near Bridport, has been opened. The edifice is intended as a Chapel of Ease to the parish church of Bradpole. The church is in the Early Decorated style of architecture. The interior comprises a nave and chancel, with a robing room on the south side, which also serves as an organ chamber. The edifice is capable of receiving more than 300 persons. The length of the nave is 84 feet, and its width 26 feet. The chancel—24 feet long by 18 feet wide—is separated from the nave by a moulded arch. All the seats are open: those in the nave are of stained deal; those in the chancel, of oak, carved. The pulpit and font are of Hambill stone, carved. The east window is of five stained glass, representing the Baptism, the Holy Supper, and the Crucifixion. The quatrefoil window, of stained glass, in the gable, represents the Ascension. Nearest the east window, on the north side, is an angel window, intended as a memorial to the father and mother of the vicar of the parish. There are two figures. Another stained glass window, by the side of the one just mentioned, has been raised by the laudable exertions of the organist and choir. On this are figures of the prophets Isaiah, Jeremiah, Ezekiel, and Daniel. The south window in the chancel is erected in memory of a brother of the vicar of the parish: it represents, in a style corresponding with that of the others, St. Peter and St. Andrew. The reveals of each of the side windows are ornamented with wreaths of passion flowers, executed, principally, by Mr. W. K. Brown, of Bridport. The end wall of the chancel is decorated with ornamental foliage, which, with most of the other decorations, are the work of Messrs. Harland and Fisher, of London. A wreath of grapes and corn ears runs along under the wall plate on each side of the chancel. This is the work of Mrs. Broadley (the wife of the vicar). The chancel is paved with ornamental and plain tiles. The five windows on each side of the nave, are respectively surmounted by a text in scroll. The eighteen corbels of the building are adorned with shields, each bearing a sacred emblem, executed by Mrs. Broadley. A border of passion flowers running the whole length of the nave, on each side, under the wall plate, was executed by Miss Ganning, daughter of Archdeacon Ganning. The roof is open, the rafters being filled in with plaster, coloured. The building will be fitted up for gas. The building site was the gift of Mr. Albert Wray, one of the landowners of the parish. The architect was Mr. Tallot Bury. Messrs. Chick & Son, of Beaminster, were the builders; and Mr. Gibbs, of Bradpole, the mason.

#### THE MIRACULOUS CABINET.

UNDER this title an extraordinary work of art, invented and produced by H. Nadolsky, was exhibited on Wednesday evening last, in the Dudley Gallery, Egyptian Hall. When we say that this cabinet, measuring only 5 feet high, 3 feet wide, and 18 inches deep, contains 150 pieces of furniture, of the same size as in ordinary use, some of our readers will ask for a list; and, as a curiosity, here it is:—A judge's large table, with ornaments, books, and six chairs; four large eard-tables, two Chinese tables, a smoking-table, a lady's work-table, two beautiful large Chinese toilet-tables, a large chess-table, four work-boxes, four flower-

pots with flowers, a what-not, a large candelabra, a full-sized bed with hangings, and a baby's swing cot; a round toilet table, an embroidery frame, a large flower-table, five small Chinese lamps, two large ditto, two Chinese toilet candlesticks, twelve fancy boxes, a footstool, a painter's easel, four music-stands, a dining-table with twenty-four covers laid complete; four large dishes, twenty-eight plates, thirty cups, saltcellars, &c.; a large chandelier containing twelve wax lights; nine garden chairs, four parlour candlesticks, a Chinese writing-desk, a fancy inlaid with wax tapers, rulers, and hells; a tea-tray, a drawing-room table, a throne, a throne-chair, four small flower-tables, a large table, inlaid with specimens of shells, glass top, &c., &c. It certainly is a most ingenious work of mechanical skill. When the various articles are put together and spread over the apartment, the notion of putting them all back again into the snug little cabinet seems scarcely less than absurd. We have seen many a good packing-case, but never such a wonderful case of packing.

#### SANITARY STATE OF ST. GILES'S.

A REPORT by the medical officer of the district, Dr. Buchanan, to the Local Board of Works, has been printed, in which the sanitary state of St. Giles's in 1859 is treated of, together with the means taken for its further improvement. From this report it appears that the unhealthiness of this once notorious district is steadily diminishing.

The district south of Great Queen-street, as about Great Wild-street, is the worst part of St. Giles's; and in this part there has been an increase of mortality, although formerly other portions were more unhealthy. This may probably have in some measure arisen from sanitary attention having naturally been first given to the unhealthiest part of the district, and this would only show more clearly the power of sanitary efforts to save life and improve health. At the old rate of mortality, 292 lives have been saved in St. Giles's during the last two years.

Russell-square must be still a remarkably healthy spot: the mortality there is only 13·6 per 1,000, although 17 per 1,000 has been regarded as the inevitable death-rate of a town population; this axiom, therefore, demands correction.

It is a notable circumstance that the births of females were last year the most numerous in St. Giles's. This is of very rare occurrence anywhere, one should think, although more females live than males, the surplus of the latter, and somewhat more, dying off, till the females exceed the males; but there are generally more males born than females. Last year, in St. Giles's, however, 887 females and 842 males were born: 687 females and 727 males died: 602 children died under five years of age.

The truthfulness of the illustrated delineation of a nuisance in Drury-lane, in shape of a cow-house, given in the *Builder*, is testified by the medical officer, who remarks that an interior view would have proved worse than the exterior one, and adds that some improvements have been effected in this class of unmitigated nuisances.

The reports of the local medical and other officers of health in the metropolitan districts are very valuable, and will be of still greater interest in future years. There ought to be some central repository, in which every one of these reports should be carefully kept, so as to be available to the public when required; otherwise it will soon become difficult to obtain them. Would not the office of the Metropolitan Board of Works be a very proper site for a public sanitary library, in which these records could be stored? The new Society of Officers of Health should see to this.

#### THE COLOSSAL RIVETTED STATUE OF ST. CHARLES BORROMEO.

In my professional peregrinations I have recently come across the curious colossal statue of St. Charles Borromeo, placed on a hill near Arona, overlooking the Lago Maggiore.

This statue, which is upwards of 70 feet in height and mounted on a pedestal which rises 30 feet above the top of the hill, was placed in its present position in the year 1624.

The pedestal is of stone, but the statue itself is entirely formed of plates of bronze and of copper riveted together in patches of every form and description something after the manner, but without the regularity, of the Britannia tubular bridge over the Menai Straits. The work is very strong—stands the war of the elements in its exposed

situation in a very remarkable and instructive manner—and is a monumental attestation to the truth of the proverb, that "there is nothing new under the sun."

It is even more wonderful than our wrought metal bridges and boats, inasmuch as its exterior represents in an almost life-like manner all the beauties of sculptured humanity. The expression of the features, the attitude of the body, I might almost say the vigour of the intellect, are here admirably portrayed; and, down to the minutest details, although on so large a scale, the whole is in excellent keeping. The folds of the drapery are exhibited in the most natural manner imaginable. It is altogether a most interesting work of art, executed with great talent, while it is also a curious specimen of engineering and constructive skill. It cost nearly 40,000*l.* in those days when labour was cheap, and money had not the value it has now: probably, in our days, the cost of such an undertaking could not be afforded. It is, therefore, precious on every account.

In French measure, the face is 7 feet 2 inches wide, and 7 feet 6 inches long. The length of the nose is 2 feet 7 inches. The eyes are 1 foot 6 inches long; the mouth is 2 feet 4 inches. The length of the arm is 28 feet; the length of the thumb is 4 feet; and the circumference of the robe 51 feet.

I went up the statue to examine its structure, but shall not do so again in a hurry; nor would I have done so then merely for the sake of saying I had been inside the nose, and walked about in the head. Had it not been that I wished to make a personal inspection of the work, I should have employed a chimney-sweeper to examine it for me, and bring me back his report in the event of his getting down safely, as the operation I had to perform was (as far as I can judge, seeing that I never did ascend a chimney), much more akin to the performances of his profession than mine—*mais revenons à nos moutons*.

A ladder, about 40 feet long, borne by some three or four men, was brought up to the top of the hill, and placed against the cornice of the pedestal. This was kept in position by a kind of scaffolding of poles, so as to prevent it swaying in the wind, or oscillating with the weight of my body while performing the climbing operation of raising my feet and hands from one rung to the other, which are about a foot apart.

When I got upon the pedestal, which is very narrow, and altogether too small for the mass of metal placed upon it, a circumstance which gives the whole monument a somewhat top-heavy appearance, I began to examine the plates of metal of which the statue is composed. During this time the men were affixing, by means of iron cramps, another ladder on the top of the first, by which I got up a further height of some 20 feet in addition, and then with no little difficulty had to squeeze myself into a small aperture between a fold in the robes and a *core*, if I may so say, of masonry, which is carried up inside the statue to about the top of its shoulders; and here the climbing becomes difficult or rather strange to such as myself, who have not been occupied very lately in such peculiar gymnastic exercises. This chimney is very wide, and has bars built into the masonry of it on either side: thus it becomes necessary to extend the legs and arms very widely apart, and feel on either side with hands and feet for the frail supports to which, *volens volens*, after having got so far, it is incumbent to cling. I do not remember having made such a peculiar ascent anywhere before, and it put me in mind of the mountebanks sometimes seen in Italian cities, raising themselves to an altitude between two columns, so as to enjoy an elevated position from whence they may baroque the crowd congregated to witness their saltimbanics.

Having then, by dint of exercising every muscle in my body, during which time it would not have been wholesome to have been attacked with the least symptom of cramp, seeing that any relaxing of my hold would have precipitated me immediately to the bottom, without meeting anything on the way even to break my fall, I arrived on the top of the masonry, and my head was about on a level with the lower jaw of the figure. No sooner had I arrived, than I was invited to look down on the other side at the book held under the left arm of the statue, which is open at the top, and presented all the appearance of a brewer's vat.

The interior of the head would make a comfortable little sitting-room, as you can well understand when I tell you that it measures some 20 feet round. I looked out from a little chink between the plates, just above the right eye, and which to the less initiated below probably repre-

sents the eyebrow. From this the view is magnificent. The tranquil waters of the "Langen-see," as the Germans call it, lay stretched before me, and the blue hills of Lombardy were scattered and piled up capriciously and fantastically beyond the ripple of its waters; then the wide plains of Lombardy lay farther off in the distance, and lured the eye towards the far horizon. The plates are not half an inch thick, and are connected together by an immense number of small-headed copper rivets. The whole mass must have been adapted to some mould before being put up, otherwise it would have been altogether impossible to get the external shape so accurately.

The eyes are evidently cast, as the pupils are well defined, inside as well as out. The ears stand out remarkably, as the figure is represented with very short hair. All the details are well managed, and even two or three days' growth of beard upon the chin is cleverly imitated, and, from the great size of the figure, may be remarked even from the foot of the pedestal below. Sculptors and artists who visit Italy should not fail to see it, while engineers, if they could not take a leaf out of its big book, may find plenty to learn from it, and perhaps something to copy.

WILLIAM H. VILLIERS SANKEY.

#### THE FUTURE FOR ARCHITECTS.

LONDON AND PARIS.

In his annual notification that the architectural courses at the University College, London, will commence on Tuesday, the 23rd instant (of which, by the way, we hope many will avail themselves), Professor Donaldson makes the following observations, which may be usefully made permanent in our pages:—

In the *Moniteur*, of the 25th August last, there appeared a very striking review of the works executed at Paris by the Emperor Louis Napoleon, since his accession to the throne of France in 1852. This enumeration embraces the operations of the Imperial Government and of the Municipality of Paris: it records lines of streets and boulevards pierced through the centre of the city, the doubling of its superficial area by the addition of a suburban zone; the completion of the stupendous palace of the Louvre; the erection of churches, schools, district courts of justice, six barracks, market-places, fountains, theatres, squares, hospitals, eight bridges, making, together, two which span the Seine; while we have at most eight for all London, with its immense population and colossal commerce, improving also the public health,—the result of a determined concentrated will for the public good.

This presents a humiliating picture to us when we compare this statement with the torpid operations of our Government and our Municipal Corporation, even although we call to mind that many of the works above enumerated are in this country carried out by individual or associated private enterprise. Our Administration requires offices for the Indian Department, and takes refuge in part of an hotel, built as a speculation by a company. And insuperable appear to be the obstructions and difficulties which attend the realization of our public works, however imperative that the absolute need of War and Foreign Offices, for the due administration of the business connected with those departments, urgent as it may be, is made to yield to personal interests and to a battle of parties and styles; and years may intervene before the work is supplied. Even our City Corporation, important as the works have been which they have carried out, can, with unaccountable shortsightedness, cover with a huge warren a vacant plot which afforded the finest view of our metropolitan cathedral and facilitated direct communication with various parts of the City where most required.

Still London, although far behind in the Government activity to promote improvements and to direct, as in Paris, the public taste for monumental splendour and magnificence, has advanced, through private enterprise, in the style of its commercial and domestic buildings more than any other metropolis. We see clubs, banks, insurance offices, and lake institutions, offer erections honourable to the present school of art, and evidencing great progress in professional skill and taste.

There is a noble future for the rising generation of architects. The development of the British empire has been incalculable: the population has doubled within a short period: its commerce knows no limit. England, and even London, of 1859, compared with England and London of 1860, are as giants to pygmies. A like extension of Government establishments, to insure a ready and economic administration of the public business, must take place; and necessarily will compel our Government to satisfy these requirements, which foreign administrations would seize with eagerness, to adorn a sovereign's reign or reflect honour on a ministry that would misuse and them. Our Ministers and Parliament cannot continue to hesitate, when our great commercial cities and provincial towns show what energy and taste for architecture may effect.

It is then for the young architects and builders to fit themselves for coming opportunities. The war of styles may still continue: our usages and tastes may become modified. There will be required fresh combinations and appliances. Science must progress as well as Art; and construction must advance with like energy. There is a wide field open, and who shall be equal to the struggle on the occasion, for reputation, if success? Those only who acquire beforehand the elements of sound professional knowledge,—who make themselves acquainted with the great productions of the ablest and most refined minds of past ages,—who devote a zealous earnestness to the study of the subject,—who are determined to excel and to rank among the great architects and builders and who have endowed their country with noble works,—who take place with our Hugo Jones, our Wren and his master-mason Strong, our Vanbrugh, our Chambers, of the past; with our Barry and Cubitt of recent times.

## STEPNEY UNION COMPETITION.

Sir,—I truly hope, for the honour of the profession, that not a single architect will apply for the "particulars" relative to the above competition. I fear, however, that the usual "unimproved applications" will be made. If so, it would be very desirable, if practicable, to obtain the names of such applicants, and publish them. We should then discover some of the "black sheep."

I have long entertained the opinion that the present disgraceful system is fostered by those architects who enter indiscriminately into all competitions (as a wheel of fortune from which a prize may possibly be drawn), without considering the respect due to themselves or the profession of which they are members.

N. E. STEVENS.

## LEICESTER CHAPEL COMPETITION.

Sir,—As one of the competitors for the Leicester New Connection Methodist Chapel, I ask for the admittance of this protest in your journal. As this result was made known through the *Builder*, I think the injustice of the committee should also be made known through the same medium. I was informed that on no account would the stipulated sum of 1,500*l.* be allowed to be increased by the architect. It turns out, however, that the successful competitor had ornamented his design so as to considerably exceed the stipulated sum,—to the amount of six or seven hundred *l.* more. Of course this amount enabled the architect to please the eyes of the committee far better than would a design which was limited to the stipulated sum. This is a piece of great injustice to the other competitors.

OSK OF THE COVERING.

\*. The tenders will be found in our present number.

## ST. PATRICK'S CATHEDRAL, DUBLIN.

Sir,—If any justification of the statements in my letter of the 22nd of September were needed, such has been amply supplied by the writer of the paragraph in *Saunders's News-Letter* of September 29th.

I have to congratulate the authorities on the champion they have obtained, who has made the startling disclosure that for the last sixteen years they have wilfully and deliberately closed their eyes whilst the cathedral was undergoing a gradual process of "debasement." The had taste of the writer will be best shown by mentioning that these so-called "debasement" works were executed after the design, and, for the most part, under the immediate superintendence, of the late Mr. Carpenter. His ignorance may be guessed from his own admission, that he does not know what is meant by an "Early English wall," or how "a wall" could be designated as belonging to any "order." (2)

In point of fact, there are only two statements to which a denial has been given. As to the first, I have only to say, in reply to the writer's assertion that every care was taken to have an accurate restoration of the nave, that I have reason to believe that such accuracy has not been secured. As regards his denial that there has been any exclusion from viewing the works, I need not say that I did not make the assertion without having what I believed to be good authority for it; but I am glad to learn that I was mistaken; and I shall be happy to avail myself from time to time of the proffered permission to see the progress of the works.

The parties engaged in the present restoration cannot consistently claim immunity from criticism, seeing that they have themselves alluded to the unfortunate misapplication of the magnificent sums placed at the disposal of the dean and chapter of Armagh by his Grace the Lord Primate, for the restoration of that cathedral.

W. B. BALST.

## THE "BUILDER'S" LAW NOTES.

**Leases: Written Memorandum.**—A person agreed in writing to take the lease of a house for the residue of the lessor's term (being five years), and also to take a lease of stables "at the same rent and on the same conditions as the lessor held them." This was for an unexpired term of seven years; but, as the term for which the stables were held was not specified with certainty in the writing, it has been held that there was not a sufficient written memorandum to satisfy the law as laid down in the "Statute of Frauds."—*Fitzmaurice v. Boyley*.

**Railway Company: Compensation to Landholders.**—A landholder agreed to submit to arbitration his claims against a railway company for compensation for injury done to his land, and for the loss of the land taken by the company. He died before the final award was made; and when, after some enlargement of the time for the award, it was at length made, several objections were taken by the company. The whole case came, on appeal, before the House of Lords, and the following important points were decided. It was held that the submission to arbitration did not expire with the death of the landowner; that the time for making the award may be enlarged for the purpose of suiting the convenience of the parties, because the sections in the Lands Clauses Act, providing for the award in three months, was introduced for the benefit of the parties; that an arbitrator may employ any experienced person or scientific man to assist him; that he may award damages for injuries likely to occur; that he may include damages likely to be caused to the tenants of the landowner; and that under the Lands Clauses Act there is no compensation exists if the railway cause the injury, even though the lands affected may be distant from the line.—*Calcutt v. Railway Company v. Lockhart*.

**Charitable Legacy: the word "Poor."**—A lady left by her will certain sums of money to "twenty aged widows and spinsters," in a certain parish. As age did not necessarily imply poverty, it was argued that the legacy could not be supported as a charity, and it would thus lapse for uncertainty. It was decided, however, that, as the object was clearly charitable, the legacy was good, and it was ordered that the word "poor" should be added.—*Thompson v. Corby*.

**Railway Company: Repair of Highway.**—A railway company in Ireland carried its line over a bridge which spanned the highway; and, in order to afford head-room for traffic, the company lowered the highway and placed it in a substantial condition. The lowered part of the road afterwards became out of repair. The local justices ordered the company to repair the same; but this order was reversed on appeal to the Queen's Bench by the judgment of two judges out of three.—*The Waterford and Limerick Railway v. Kearney*.

## PATENTS IN CONNECTION WITH BUILDING.\*

**COMPRESSION OF BRICKS, TILES, &c.**—*L. J. Brethon*, Tours, France. Dated 22nd February, 1860.—This invention cannot be described without reference to the drawings.

**BRICKMAKING MACHINE.**—*G. Convery*, Strood, Kent. Dated 16th February, 1860.—The patentee claims the use of a triangular feeding shaft and endless band or chain of moulds or clay-holders, together with the movable projections on the centre rollers, in combination with the stampers or plungers described.

**BRICKS.**—*T. H. Morrell*, Leyland, Lancashire. Dated 17th February, 1860.—The patentee claims, firstly, the lining of machine moulds or dies for making solid or perforated bricks with raw untanned skin or hide, as described. Secondly, the use of one cross-bar, with two or more rows of perforators or studs attached thereto, for the moulding of perforated bricks, as described. Thirdly, with reference to the apparatus for pressing perforated bricks, the adaptation or use of two press-plates with panels and cores or studs attached. Fourthly, with reference to the apparatus for drying brick, tiles, and other articles made from plastic earths, the arrangement of racks or frames fixed to the roofs and walls of drying sheds, as described. Fifthly, the general construction and arrangement of hot air fires or ventilators in combination with a central shaft, sleds, and hot air chamber, as described, and also the use of such or similar fires or ventilators in combination with a chimney-shaft and sheds only for such or similar purposes.

## Miscellaneous.

**PROPOSED NEW LAW COURTS.**—The inhabitants of Holywell-street, Strand, and places adjoining, have received the following circular:—"Sir: It having been determined to seek powers from Parliament in the ensuing session to concentrate the law courts and offices on the locality on which your house stands, and I having been authorized to prepare the necessary survey and reference, venture to beg the favour that you will permit the surveyors engaged on the work to have access to your premises to take the necessary plans, and that you will further oblige by affording them all the information in your power relative to ownership.—*H. R. ABRAMSON*, Surveyor."

**THE "CONTINENTAL DIORAMA" AT EGYPTIAN HALL.**—This exhibition consists of a hotel-potch of views which have been exhibited already in London under different titles, some of them more than once. Several of the pictures are very well painted; but, holding it to be dishonest to lure the public to what professes to be a new exhibition, but which many of course discover, after they have paid their money, they have seen before, we have no words for it but those of reproach. Mr. Leicester Backingham, who supplies the descriptive lecture, can scarcely be aware of the fact.

**PATENTS.—LOCKS FOR DOORS.**—In your impression of 29th September last, p. 630, is an account of a lock "formed to admit the key at opposite sides," &c., for which a patent has been obtained. Probably the inventor is not aware that a lock of the same kind, upwards of 300 years old, exists upon a door in King's College Chapel, Cambridge. The lock was taken off and carefully repaired last year, at an expense of 1*l.* 6*s.* 6*d.*, and is now in good working order.

CANTAD.

\* Selected from the *Engineer's* lists.

**GREAT LENGTH OF RAILWAY RAILS.**—The Messrs. Barningham, of the Darlington Iron Works, are at present engaged in rolling a large quantity of rails of unusual dimensions. They are 27 feet in length, and their weight is 82 lbs. to the yard.

**COST OF LEEDS TOWNHALL.**—A printed document, produced at the town council the other day, showed that the total cost of the building was 113,239*l.* 19*s.* 7*d.* Mr. Titley said that statement did not include the expenses attending the Queen's visit, nor the cost of the expensive lamps outside the hall, nor was there any allowance for interest. If those three items were taken into consideration, the cost of the building was from 125,000*l.* to 130,000*l.*

**SINKING OF MAGAZINE, WOOLWICH.**—A spacious flat-roofed magazine, under construction in Woolwich marsh, and now nearly complete, was last week discovered to have suffered from the yielding of the base to such an extent that a considerable portion of the building will, probably, have to be removed and rebuilt. The disaster is attributed to the late rains having carried away some of the subjacent marshy stratum insufficiently prepared with concrete and other heavy substances in forming the foundation.

**THE LAND OF SONG AND DANCE.**—According to the "*Travatore*" Italian journal the number of singers of both sexes in Italy amounts at present to 1,730. Among these are enumerated 410 *prima donne*, 330 tenors, 250 baritones, 160 bass singers, 50 comic. Italy produces 1,670 *dansesurs* and *dansettes*, viz., 150 of the first rank of the latter class, called *di rango Francese*; 320 first *dansesurs*, *di rango Italiano*; 110 first dancers, 970 of both sexes, *mezzo carattere*, and 40 ballet-masters.

**NEW INVENTION IN PRINTING.**—At Vienna a printing machine has been brought out, dispensing with the use of all other assistance save that of mechanical apparatus. No persons are required to feed it with paper, or to remove the printed sheets, both processes being accomplished through the instrumentality of the machine itself. The paper for this purpose is supplied in rolls many hundred yards in length. The machine first cuts a sheet off the requisite size, then prints, and finally throws it off—a newspaper ready for the reader. All that manual labour is required to do is to bring forward fresh rolls, and to take away the printed sheets.

**NEW APPLICATION OF PEAT.**—Some improvements in manufactures from peat have been patented by Mr. H. Hodgson, of Ballyreine and Merlin Park, and Mr. P. M. Crane, of the Irish Peat-works, Athy. The invention consists in preparing from peat, in its natural state, blocks, slabs, or pieces of any size, form, or thickness, which blocks, slabs, or pieces are said, when so prepared, to be useful and economical in the construction of parts of buildings, and for various other useful purposes. They place these blocks between cloths of woven or textile fabric, or other suitable material, and the peat is placed between shelves, and submitted to hydraulic or other pressure. The water is entirely forced out and the peat solidified, and drying is effected either by exposure to the atmosphere or in a room heated artificially, or by any other process. They are then put again between the plates of a hydraulic or other press, and extreme pressure put on them. If the product of their invention be required for use for inside work in building, such as partitions, linings, inside roofing, or for other work, as a non-conducting substance, they do not require any further preparation than shipping, provided they are not to be exposed to wet. But the slabs or pieces need for roofing (instead of slates, tiles, or other things of that nature) they prepare to resist the wet, or action of the atmosphere by steeping them in, or saturating or coating them with, some fitting material to resist wet, such, we presume, as pitch.

**THE LATE A. E. CHALON, R.A.**—Mr. Alfred E. Chalou, R.A., portrait painter to Her Majesty, has just passed away from among us, having died a few days since, at his villa on Campden-hill, Kensington, at the ripe age of fourscore years. He was of Swiss extraction, and brother of the late Mr. John James Chalou, R.A. He drew entirely with the pencil and in water colours, and he attained celebrity as a painter of ladies of rank and fashion, more especially in their court dresses and trains. He continued to exhibit at the Royal Academy down to the last. A few months since he offered to bestow his collection of paintings and sketches upon the parish of Hampstead, on condition that the parishioners should subscribe money sufficient to build a place for them, and pay a small stipend to a curator; but the offer was not accepted.

# The Builder.

VOL. XVIII.—No. 924.

Mr. Hodges' Account of the Great Victoria Bridge, Canada.

**R**AILWAY ENGINEERS and railway contractors usually carry things with a high hand, not allowing "I would" to wait upon "I dare not," and here we have a striking example of the fact,—not alone in the remarkable bridge which now spans the river St. Lawrence,—but also in the book that describes it.\* This volume, containing, as we have already told our readers, 21 illustrative plates and 40 engineering plates, giving all the details of construction, and on which book about 4,000 have been spent, was produced in seven weeks. Looking at one of the Columbian folio copies, with its gold borders to the text, its chromolithographs, and sumptuous binding, it would be difficult to believe in this despatch, had we not the assertion of Mr. Weale himself. Within that space the drawings were made, the book produced, and six hundred copies forwarded to arrive in time for presentation on the day the Prince of Wales laid the last stone and drove the last rivet.

The Grand Trunk Railway of Canada, as most of our readers know, traverses British North America from the shores of the Atlantic to the rich country of the Far West. By one unbroken line of railway, through upwards of 1,200 miles of cultivated country, it carries the products of the distant western states of America to the sea-board. It opens up for the inhabitants of the valley through which it passes the means of inter-communication throughout the whole of the year; and, moreover, connects and associates together the British dependencies in North America, and, by means of the Great Bridge over the St. Lawrence, it brings them all into direct communication with the United States and the best ports of the Atlantic. For six months of the year the St. Lawrence was sealed up by frost. For six months of the year, therefore, Quebec and the other ports and harbours of the river were unavailable, and trade was virtually suspended.

Following the course of the St. Lawrence, and uniting all the principal towns, the Grand Trunk Railway of Canada brings the whole country to the best ports on the sea-board by the nearest route, and affords the greatest facilities for communication with Europe by a passage 600 miles shorter than any other that can be made between the continents.

We have on various occasions given particulars of the Victoria Bridge, which forms the connecting link in the line between British North America and the United States, but it may be interesting, now that the work is finished, and with Mr. Hodges' book before us, to jot down a few of the leading points in its history. It was in 1852, at the request of the Provincial Government of Canada, that the firm of Peto, Brassey, and Betts made an examination of the country with a view to assisting in the development of a complete system of railways for the colony; and Mr. W.

Jackson, M.P., afterwards associated in the undertaking, accompanied by Mr. A. M. Ross, C.E., proceeded thither for that purpose.

As early as 1846, the Hon. John Young, of Montreal, suggested the practicability of a bridge across the St. Lawrence, and succeeded in obtaining reports upon the subject from several engineers, with which, and the information he obtained on the spot, Mr. Ross on his return to England designed the structure upon the principle on which it is carried out, and, as engineer-in-chief of the Grand Trunk Railway, afterwards resided in Canada until the works were completed. Upon the inauguration of the company, Mr. Stephenson was consulted; and he, after examining the information and designs laid before him by Mr. Ross, signified his approval of them, and undertook jointly with him the responsibility of engineer to the bridge. In 1853, Mr. Stephenson visited Canada personally; and, with the additional information procured during the previous winter, then decided conjointly with Mr. Ross upon the structure as it at present exists. This is the account of Mr. Stephenson's connection with the undertaking as given by Mr. Hodges.

The site of the bridge is at the lower end of a small lake, called La Prairie Basin, which is situated about one mile above the entrance to the Lachine Canal, at the west end of Montreal Harbour. At this point the River St. Lawrence is, from shore to shore, 8,600 feet, or a mile and three-quarters, wide. The lake, however, which is full of boulders, is extremely shallow; so much so, that excepting in the main channels it is only navigable for vessels drawing from 1 foot 6 inches to 2 feet of water. And even these have difficulty in approaching the shore, there being no landing-place above the site of the bridge except at La Prairie village.

The most serious difficulty to be guarded against, both in the design and in the execution of the Victoria-bridge, was that operation of nature which occurs twice in the year, and which is known in North America as the "shoving" of the ice: of this forcible illustrations are given.

The surface ice, arrested in its progress, packs into all sorts of imaginable shapes: a crust is soon formed, and the river becomes frozen over till many square miles of surface packed ice is formed. As the water rises, the jamb against which this field rests, if not of sufficient strength to hold it in place, gives way; when the whole river, after it is thus frozen into one immense sheet, moves *en masse* down stream, causing the "shovings" so much dreaded by the people of Montreal.

To avoid the dangers consequent on these and other operations of nature, it was determined to build the Victoria-bridge with stone piers, placed at wide intervals, each pier having a large wedge-shaped cut-water of stone-work inclined against the current, and presenting an angle to the ice sufficient to separate and

fracture it as it rose against the piers. Mr. Hodges describes the movement of the ice which took place on the 4th January, 1855, as presenting a sight never to be forgotten—"The whole of the river and La Prairie Basin were one mass of packed ice, which, being held up by the jamb below, had been accumulating and rising for four days. At last some slight symptoms of motion were visible. The universal stillness which prevailed was interrupted by an occasional creaking, and every one breathlessly awaited the result, straining every nerve to ascertain if the movement was general. The uncertainty lasted but a short period; for, in a few minutes, the uproar arising from the rushing waters, the cracking, grinding, and shoving of the fields of ice, burst on our ears. The sight of twenty square miles (over 124,000,000 tons) of packed ice (which but a few minutes before seemed as a lake of solid rock) all in motion, presented a scene grand beyond description."

The engineer may well have "felt relieved" when he found that the solitary pier, No. 1, which had been hantling alone amid this chaos, had not been disturbed.

Stone quarries, on a scale commensurate with the magnitude of the undertaking, were opened at Point Claire, some sixteen miles west of Montreal. But, before this could be done, the Indians had to be arranged with. We may scarcely stop to say how disappointed the author was when, expecting to meet chiefs ornamented after the manner of those in Cooper's novels, with paint and feathers, and prepared, before they proceeded to council, to offer him the "calumet of peace," he was introduced to a body of miserably dirty-looking old men, with lank hair, smoking short clay pipes!

The St. Lawrence, where it is crossed by the Victoria-bridge, was, by the soundings taken previously to the commencement of the work, shown to be of a depth varying from 5 feet to 15 feet at summer water level, and to have a bed of limestone rock, with large boulders upon its surface. This led to the contriving of floating dams or caissons, which might be built during the winter season, and immediately upon the opening of the navigation floated into position and scuttled, so as at once to form a nucleus from which the dam could be constructed.

The construction of these dams will be better understood upon reference to Fig. 1 (page 672). They consisted of a framework of timber, forming a large caisson of proper shape and dimensions to encircle a pier, with sufficient space for piling, puddle chamber, and for the workmen engaged in the construction of the masonry. These caissons were 188 feet in length, and 90 feet in width over all. The front part, or bows, were made wedge-shape to stem the current, and the stem, or hinder part, was made so that it could be removed when the masonry was completed, thus enabling the floating dam to be taken to winter-quarters.

The frame-work, or caissons forming the sides of the dams, were 20 feet broad, and 12 feet to 16 feet deep, the width being increased near the bows to give additional strength where the sides unite, and likewise to give more space for workshops and dormitories. The bottom and lower part of the sides were carefully calked, and when launched they drew some 18 inches of water only.

The floating dams were commenced in the winter of 1853, and two of them were completed and launched in May.

The first working season was a period of disaster, difficulty, and trouble, what with inexperience of the climate and of the country; secondly, numerous strikes of the workmen; and, above all, the ravages of the cholera.

The amount of work in progress at this period was so great, and the demand for labour in consequence so pressing, that it was no uncommon thing for an agent from some other works to come amongst the workmen, and, by an offer of almost fabulous wages, induce perhaps more than half

The Emigrants' Monument.

\* "Construction of the Great Victoria Bridge in Canada." By James Hodges, engineer to Messrs. Peto, Brassey, & Betts, contractors. London: Weale, High Holborn. 1859.

of them to leave. The workmen brought from England were also exceedingly troublesome in that year. In one instance, a number of mechanics, taken out at a cost of upwards of 3,000*l.*, became so unmanageable, that in a fortnight from the time they got to work they were all disorganized, and struck.

It appears to be almost a custom in Canada for mechanics and labourers to strike twice a year, let the rate of wages be what it may. The first period of general strike is in the spring, when increased activity in every business is occasioned by the arrival of the spring fleet. The second is at the commencement of harvest, when there is abundant demand for labour. Nevertheless the writer has occasion to speak strongly of the devotion and energy of large numbers of his workmen. Once brought into proper discipline, they worked as British workmen alone can work; and he records an anecdote which we cannot resist alluding to. The miserable accommodation afforded in vessels that were sometimes used for the emigrant traffic between Great Britain and America killed hundreds of the passengers. Those who survived the voyage and were put on shore at Quebec or Montreal, with the seeds of pestilence implanted in them in the shape of a ship fever, were sent to sheds built away from the city for their accommodation.

During the years 1846 and 1847, perhaps the most fatal that Montreal ever experienced, some 6,000 poor emigrants died in these emigrant sheds, and were interred in a large pit or grave common to the whole, in much the same manner as those are described to have been buried who died of the plague which devastated London in early times.

Towards the close of the work, when the workmen were thinking of leaving Canada, the remains of their poor countrymen were not forgotten, and they determined to erect a monument upon the spot. A large granite boulder, shown by the engraving on the previous page, weighing some thirty tons, was selected, which was placed upon a pedestal some 6 feet high, and which, it may be hoped, will to future generations preserve the remains of the dead from desecration.

On the 1st of December, 1859, the Rev. Canon Leach, in the presence of the Bishop of Montreal, the Rev. Mr. Elligood, and the assembled workmen, set the stone in its place. It bears this inscription:—

TO PRESERVE FROM DESECRATION  
THE REMAINS OF 6,000 EMIGRANTS WHO DIED OF  
SHIP FEVER IN 1846 AND 1847,  
THIS STONE IS ERECTED  
BY THE WORKMEN OF MESSRS. PETO, BRASSEY, & BETTS,  
ENGAGED IN THE ERECTION OF THE  
VICTORIA BRIDGE,  
1859.

Mention is made, too, of the skill shown by many of the men when thrown upon their own resources. Here is one instance. Before leaving England, Mr. Hodges prepared a sketch and description of a "steamer traveller." One of the most eminent firms in England was consulted and employed to accomplish what he required; and, after some two years of experiment and an expenditure of some thousands of pounds, a machine was sent out which could never be made to do very much more than move itself about; and which, after various fruitless attempts to make it available, was thrown on one side and never used afterwards. In the meantime, the same drawings and description were shown to Mr. Chafey, one of the sub-contractors, himself an Englishman, but who had been in Canada a sufficient length of time to free his genius from the shackles riveted to him in early life, and during the winter of 1854 and 1855, the rough, ugly, but invaluable machine, which handled the whole of the work on the south side of the river, was constructed, and in the spring was put to work. This is only one illustration which could be given of acquired skill and ready application, out of many exhibited by members of the staff, men who, when they left home, gave little evidence of being above the ordinary rank, but who, in Canada, proved themselves full of enterprise and resource.

This traveller was 60 feet in span, moving upon gawntrees 1,300 feet in length and 20 feet in height. Between these the stone was sorted and stacked ready for work. The engine and hoisting apparatus formed one machine, moving transversely upon the traveller, which was likewise moved longitudinally with the greatest facility by the steam power. The machine unloaded the waggons, and stacked the largest blocks of stone, some of which weighed ten tons, with the greatest ease. Over 70,000 tons of stone were moved twice by this machine.

The occurrence of boulders such as we have

mentioned constantly interposed difficulties. For example, in sinking the framework to carry the inner row of piles, a large one, fig. 2, was discovered occupying the whole breadth of the puddle-chamber. The removal of it caused a loss of time equal to six days. Several attempts were made to split it by blasting, which failed; but it was eventually removed *en masse* on the 7th of July. It weighed more than twenty tons.

The brevity of the Canadian season made these occurrences the more vexatious. That season is, at the outside, six months. The earlier portion of it was taken up in preparing for the setting of the masonry; and about *sixteen weeks* constituted the whole of the working season for the pier masonry.

This shortness of the season for setting masonry induced a consideration of the advisability of using felt during the winter to bed the ashlar in, as at St. Ann's Bridge, over the river Ottawa, where several of the piers were so constructed, and made good sound work. Strips of asphalted felt, about 3 inches in width, were laid along the whole of the front edge of the masonry, at such a distance in, that the work might be effectually pointed. On each of the cross joints similar strips were laid, as likewise at the back of the ashlar. As soon as one course of ashlar was laid, it was dressed perfectly fair on the bed to a straight edge for the reception of another course, which was laid on in a similar manner, the backing being laid dry and packed as closely as possible. Open spaces or flues were left, about 1 foot square, throughout the whole height of the pier. The work was completed in this manner during the winter; and, as soon as the weather permitted, and the frost was fairly out of the stone, the piers were carefully pointed, and the whole of the interior well grouted from the flues. The work, it is said, thus became one solid mass.

During the extreme cold, or when the thermometer was more than 20° below zero, Fahrenheit, if there was any wind at all, the men could not work, as at such times the smallest portion of the body left exposed was frozen instantly. The greatest care was, therefore, requisite. The men had to work in thick gloves, and with heavy coats on. Fur caps covered their ears, and heavy handkerchiefs were worn over the greater part of their faces, so that only a very small portion was visible. Even with all this care they were occasionally frost-bitten.

It should be remembered that the whole of the iron work for the tubes was prepared at the Canada Works, Birkenhead. At these works every plate and other part was finished ready for putting in place. With what accuracy this was done will be seen when it is said that in the centre tube, consisting of 10,309 pieces, in which were punched nearly half a million of holes, not one piece required alteration, neither was there a hole punched wrong! Therefore, to Mr. George Harrison, the manager of the Birkenhead works, and to his assistants, Messrs. Alexander and Heap, is due a good share of credit.

We must hasten on. The roofing of the bridge was put on. This roofing (Fig. 3 shows its aspect) was of wood covered with tin, which was so laid as to allow the snow and water to run off from it. Upon the top of the ridge was a footway for workmen, two feet broad. Immediately over the sides of the tubes, rails were laid upon longitudinal rods of oak, bracketed up to allow for the passage of water under them. The rails were designed to carry a "traveller" hestriding the tube, to be used for painting. Fig. 4 shows the bridge with travellers upon it; and Fig. 5 is a view down the tube.

The tubes are lighted from the sides, in which holes are cut at every 60 feet. The interior is so light, that on a clear day every rivet-head inside of the tube is distinctly visible.

In closing his account, Mr. Hodges justly says,—"Looking back at all the various difficulties, practical and financial, by which this work was from time to time embarrassed, it scarcely admits of doubt that, in the hands of other and less energetic and persevering contractors than Messrs. Peto, Brassey, and Betts, it would not have seen the successful issue to which it has been brought. Amid every discouragement they stood stonily to the task; and, when the hearts of all around them seemed about to fail, their encouragement, enterprise, and assuring confidence kept everything going."

We should have been glad if we had found a little more said of the designers,—of those who were responsible for the success of the work.

We have left ourselves space for little more than a few dimensions and statistics. The beams of the bridge are 16 feet wide: they are 18 feet

6 inches high at the abutments, increased to 22 feet in the centre, and are constructed of iron plates on the tubular principle, the same as those at the Britannia Bridge over the Menai Straits, except that there are no cells either at top or bottom. The spans are 25 in number, viz., 24 of 242 to 247 feet, while the centre span for the navigation is 330 feet.

In building the tubes, the greatest increase of camber which occurred in one day, consequent upon the difference of temperature between the bottom and top of tubes, was  $\frac{1}{4}$  inch.

The greatest expansion of a single tube from the centre of the resting pier to the extremity of the roller end, say 258 feet, with a variation of temperature of  $-27^{\circ}$  to  $+128^{\circ}$ , or equal to  $155^{\circ}$  Fahrenheit, was  $\frac{3}{8}$  inches. This was ascertained by an index, locked up for twelve months.

The first part of the north abutment coffer-dam was towed into place on the 21th of May, 1854. The first stone of the bridge was laid 20th July, 1854, and the first train passed over the bridge on the 17th of December, 1859. The total length of the tubes is 6,592 feet. The total length of bridge, 9,143 feet. The height of the tube above surface of water is 60 feet. The weight of iron in tubes is 9,044 tons. The number of rivets, 1,540,000. The tube was painted four times; and, as the area is thirty-two acres, there are, of course, 128 acres of painting. Number of piers, twenty-four. The quantity of masonry in piers and abutments is 2,713,095 cubic feet. The quantity of timber in temporary works, is 2,530,000 cubic feet.

The following are the inscriptions at the entrance of the bridge:—

(On the outer limit.)  
ERECTED A.D. MDCCCLIX.  
ROBERT STEPHENSON AND ALEX. M. ROSS,  
ENGINEERS.

(On the interior limit.)

BUILT  
BY  
JAMES HODGES,  
FOR  
SIR S. MORTON PETO, BART., THOMAS BRASSEY,  
AND  
EDWARD LADD BETTS,  
CONTRACTORS.

That this remarkable work, of great social and international importance, may long stand to fulfil its special purposes and to attest the skill, science, pluck, perseverance, and power of Englishmen, is our sincere and fervent hope.

We append the names of the contractors' staff: all who were concerned in the construction doubtless desiring to have their names connected with it.

*Engineering Department.*—John Duncan, engineer in charge of works; Charles Legge, assistant ditto on south side; W. Oliver Gooding, assistant engineer; Frederick Cullib, ditto; William Graft, ditto; H. H. Elling, assistant engineer and draughtsman; J. W. Woodford, mechanical engineer; James Dunbar, mechanical draughtsman.

*Office Department.*—W. C. Spiller, secretary and chief accountant; David Aikman, assistant accountant and storekeeper; Thomas Cole, cash clerk.

*Steam Boat and Berth Department.*—D. Ross Kerr, superintendent; Slater, Davis, J. Ryan, Thomas Dutton, and Robert Duncan, masters; W. C. Dutton, clerk.

*Sub-Contractors.*—Benjamin Chaffey, for south abutment and for nine piers; John O. Hodges, for four piers; Messrs. Brown & Watson, for two piers; William Newcombe, quarrying and cutting stone at Ponte Claire; William Bisant, setting masonry; Hillman, setting masonry; Jacques Normand, crib work; J. W. Wilestad, crib work and staking; Walter Wardle, staking; James Hodgkinson, erection of tubes; Martineau, fitting of roof; Thomas, painting.

*Superintendents, Inspectors, Foremen, &c.*—A. G. Fowler and Milton Sessions, general superintendents; L. Kirkup, Jun., W. R. Bell, Simon Foote, and Goulder, inspectors of riveting; Alex. Sutherland, J. Harrison, J. Akenhead, J. Hill, and John Thompson, inspectors of masonry; G. Pyke, inspector of painting; John Melville, foreman of shops; John McNeil, S. Bonnevile, Joseph Kirkbride, William Kirkbride, Duncan McDonald, and Ed. Williams, foremen of carpenters; D. Wilson, and J. Turner, foremen of masons; Samuel Batchelor and Edward Coulton, foremen of riveters; George Perkins, foreman of sailors; Robert Wilbar and John Bailey, foremen of labourers; Barney Seery, superintendent of divers and boatmen.

#### THE IMPORTANCE OF SANITARY KNOWLEDGE.

PUBLIC HEALTH DEPARTMENT, GLASGOW.

On the closing day of the recent congress of the Social Science Association Mr. Edwin Chadwick, as we have already mentioned, delivered an address as president of that department. He referred especially at the commencement to the injury resulting to the community from the want of sanitary knowledge, and the loss which is taking place in the effective strength of our productive populations. He thus proceeded:—"Great Britain, having regard to her acknowledged position and destinies, and the qualities of labour and service required to fulfil them, is at this time actually getting more and more underpeopled, even at her present rate

of increasing population. Industrial demands of external as well as of internal enterprise are now checked for want of available labouring hands of the quality of those by which, under competent directing heads, her present industrial position has been achieved. The primary qualities of those hands whom we are accustomed to call Anglo-Saxon without any very exact knowledge of what they were, but which include the Lowland Scotch as well as English, are, as I have elsewhere stated, great bodily strength, applied under the command of a steady, persevering will, mental self-containedness, and impassibility to external irrelevant impressions, or to distractive pleasurable excitement, that carries them through the continued repetition of toilsome labour—'steady as time.' To the British workman work is a serious thing; and it is a serious and great thing. Negatively in what it excludes, as well as positively in what it insures, it is a great virtue. In every-day life it ensures truthfulness, getting work done in time and according to order; it excludes lying excuses, cheating, and the necessity for excessive labour of superintendence; it excludes evasion of obligations, and frauds, to obtain without labour the produce of other people's labour, to obtain pleasure and subsistence at other people's expense; it excludes shams. Persistent labour, impassibility to pleasurable excitement, excludes vagabondage. I have been in a position to obtain the impartial testimony of foreign employers to the superior efficiency of the British labourer,—that two British labourers do as much work as three modern Norwegians, or three modern Danes. Our sanitary engineer, Mr. Rawlinson, who directed works in the Crimea, avers that it would have been economical to have exported British labourers at 5s. a-day to have performed the work done by the Eastern workers at less than one-fifth the rate of daily wages. And British engineers who have conducted works in other parts of the world give similar testimony. The quality which singly, willingly, silently, and steadily takes the lead of other labourers in mining and tunnelling takes the lead in penetrating forests and clearances for colonization. Volney and other French witnesses acknowledge the superiority of the Anglo-Saxon in this respect. The foremost labour of every kind and degree, mental as well as manual, which has supplied the waste of life and energy in our towns, has been sustained by superior physical stamina derived from those comparatively good sanitary conditions enjoyed for generations in rural districts which we wish to give to towns,—pure air, pure water, and abundant food. Now the drain upon this description of labour has been and is such as to weaken our defences more seriously than we have been disposed to admit: at this time when the improvements in the implements of war require an improved quality of hands to wield them, though the condition of the sailor in the royal navy has undergone great improvement, as denoted among other things by the death-rate, which, the deaths from violence included, is little more than one-third that of the mercantile marine; yet it has been a complaint of many of the commanders that the hands they now obtain, and those with difficulty, are often the refuse of the ports. The hill districts which formerly 'grew Guardsmen,' where the sons of small farmers who had no capital preferred enlistment to the wages of a shilling a day as agricultural labourers, are now reported to be almost fruitless as enlisting grounds; but the royal com-missioners appear to be uninformed of the fact that the same men have now the indentments of wages of several shillings a day as navvies, and that there is an army of a hundred thousand men of the quality which supplied the Guards, chiefly got from these now almost barren enlistment fields, engaged in the works of new construction abroad as well as at home; and there is another army of upwards of a hundred and twenty thousand men engaged in working the new modes of conveyance.

After alluding to various drains on the working population, he said,—In the manufacturing districts certainly, and I believe the mining districts, extensions of establishments, and entirely new establishments, are standing still for want of hands of the right quality, and the increasing demand for the labour of children is everywhere felt as a most grievous barrier to what is commonly deemed a requisite education. These are large facts, on which it behoves us to ponder for the future of the country. Wide examination will sustain the large premiss which I assert, that Great Britain is at this time underpopled in respect to the demands of a suitable quality of labour and service,—an assertion of importance not to imperial interests alone, but to the progress of civilization,—

and, notwithstanding the increase of the population, is getting, relatively to the future demand for labour of the right quality, more and more underpopled. The important conclusion from the premiss is, that it behoves all civic communities to take measures to arrest the insanitary conditions which annually slaughter full two hundred thousand persons by preventible disease, and which more and more deteriorate, in spite of all manufacturing and commercial and general prosperity, the physical, and thence the mental and moral, condition of the population who survive. It is not because wages are augmenting, or with the view to countenance any notion that the increase of wages should be checked, that I present these considerations for saving and thereby increasing the population. On the contrary, I think it well for the advance of machinery and the arts, as also for the good of the people themselves, that wages should be advanced. I have elsewhere shown that there are conditions inherent to an advance of the arts of production and improvements in machinery exemplified in Glasgow itself, which require advanced rates of wages independently of the ordinary economical principles of supply and demand. With an immense increase of population and machinery in Lancashire, wages have more than doubled since the beginning of the century. And this increase of wages with the advance of the productive arts will, I hope, occasion labour to be better economised, and life to be better cared for. The death-rate in Great Britain may be stated in round numbers altogether at half a million annually. On an analysis of the causes of sanitary science, it is declared that one-half may be prevented; and that, too, by tried and well-ascertained means. In old dwellings the death-rate has been reduced from fluctuations of from 30 to 40 per 1,000, to fluctuations of from 13 to 20 and of from 13 to 15 per 1,000; from 23 per 1,000 to 16, from 26 to 17. In particular districts, by one measure alone, by an improved supply of water carried into houses, and by improved drainage within the houses, abolishing the middenstead and substituting a water-closet apparatus, the death-rate has been reduced by one-third; that is to say, it has been made as if each third year there were a jubilee, and no deaths and no sickness. I have an instance where, in an agricultural district, and with labourers alone, by care, the death-rate has been reduced to less than one-half within twelve in a thousand. From common lodging-houses, by the enforcement, through the police, of sanitary regulations, typhus and diarrhoea, as epidemics (whilst prevalent amongst the houses of the labouring classes), are banished. In our well-regulated district institutions for pauper children those epidemic visitations which ravage the children of the families of working men are almost unknown, and the death-rate is reduced to one-third that prevailing amongst their children.

So certain will the chief data be found to be when competently examined, as to enable a contractor to contract for the attainment of given sanitary results; and he ought, with the requisite powers, to contract for the attainment of given ends; and he ought to contract for the reduction of the sickness and death-rate of such a city as Glasgow, by at least one-third, at an expense of about 1d. a week per head of the entire population, a charge less than the insurance charge for the alleviation of the present excess of sickness and mortality. The course most urgently required by the present demands for labour and service, improved in quality, as well as increased in amount, is first to arrest the great infantile slaughter from preventible causes in towns, and next to improve the physical, and thence the moral, training of the children of all classes, especially the children of the labouring classes. The treatment of children, a real public concern for their welfare, is in itself a high test of the moral and social condition of a city, of a nation, of an age, and commonly of a family. An infantile death-rate, that is to say of children within the year of their birth, I have always held to be the best single test of the sanitary condition of a place or of a population, as that test is the least affected by occupation, or by immigration, or irrigation, as children are the most sensitive to aerial impurities. One pernicious effect of the present uncertainty of infantile life consequent on the insanitary condition of the dwellings of the labouring classes,—and, indeed, of the lower middle classes too, and of the excessive miseries and anxieties encountered in rearing children, and the uncertainty of the means of rearing them, and the uncertainties of the parents' own lives,—is

to render the marriage of the most prudent and competent to become heads of families improvident.

MR. SHERIFF BELL ON ARCHITECTURE.  
THE GLASGOW ARCHITECTURAL SOCIETY.

THE first meeting for the session was held on the 15th inst.; Mr. Charles Wilson in the chair. A report from the Committee having been read, and other business transacted, Mr. Sheriff Bell addressed the meeting. He said—'I felt honoured when your Committee requested that I would make a few observations on this opening night of your session. These observations will be very brief, and I am afraid very desultory, but I have all my life felt the power of architecture, been thoroughly cognizant of its importance, and I trust, therefore, that while I speak with that feeling of respect which architecture deserves, you will, at the same time, pardon my shortcomings in point of skill and practical knowledge. Architecture, in the largest sense of the word, may be defined as artistic feeling in stone. The architect is a person who possesses the power of giving artistic beauty to building in stone; and the design in architecture, when it reaches the highest flights, has been assimilated by many enthusiastic minds to poetry in stone. Madame de Staël spoke of Milan Cathedral as frozen music. I think that perhaps the public mind generally is not sufficiently impressed with the amount of intelligence, information, and intellect that is required to make up a great architect. We have produced in Great Britain some very illustrious architects, who are entitled to take rank with the most eminent men in any department of literature or of art. It is impossible to read of the achievements of such men as Inigo Jones, Sir Christopher Wren, and Sir William Chambers, without feeling that we have to do with minds of the highest order. Sir Christopher Wren, in the course of his life, not only gave this country two of the most splendid buildings which the world possesses—I mean Greenwich Hospital and St. Paul's Cathedral,—but he covered the country with many other noble specimens—at least twenty-five beautiful churches. We know that we are indebted for Whitehall to Jones, and for Somerset House to Chambers. But we need not go quite so far back to find the intellectual power of a great architect. I venture to say that, if we look at any intellectual effort in any department of intellect or of art that has been achieved within the last twenty-five years, there is none entitled to take pre-eminence over the creation of Sir Charles Barry in the British Houses of Parliament. They have been twenty years in building, but they remain a monument of Barry's genius, which will descend, no doubt, to long ages, and excite the admiration of our children's children. Poor Barry was often during his lifetime, when he found it necessary to make additional demands upon the exchequer, when he had to contend with necessary causes of delay and many inconveniences that started up to oppose him—he was often, I say, I may almost call it badgered in the House of Commons by his employers for alleged delays and occasional alleged defects; but I am satisfied that time will show that those were narrow-minded criticisms, and that Barry, going on quietly, determinedly, and with consummate skill in his own noble and beautiful art, has produced a building which reflects honour upon this nation, and which would be an ornament in any quarter of Europe. Now, just let us consider, in some of the kindred departments of intellect, what has been done within the last twenty-five years, in order that we may form some sort of notion of this great work of Barry's: shall we compare it with any of the poetry of the last twenty-five years? I do not know any single poem that has been produced within that period that appears to me a finer and more poetical creation than that building of Barry's. Take the "Idylls of the King," if you like—that great and beautiful poem of our great poet Tennyson. I do not think the "Idylls of the King" puts Tennyson intellectually on higher ground than the Houses of Parliament put Barry. Take any popular work of fiction of the present day, and I believe Barry is far above them. We shall never say that the successful and clever author of "Adam Bede" or of "Nicholas Nickleby," has produced in these works anything so intellectual or so great as that noble and beautiful building. Take successful pictures—and no one admires the beautiful art of painting more than I do. We have some very eminent artists now living in this country; but, taking their individual works, I am prepared to challenge comparison with any one of them—at least, as a great effort—an effort

likely to command the respect and admiration of thousands, I may say millions, of our posterity, with the Palace of Westminster. A sort of comparison of this kind enables us to come to some more distinct understanding of the real platform upon which a great architect is entitled to stand. It appears to me that Barry's Palace puts him upon the same platform as his "Ivanhoe" did Sir Walter Scott, or the "Excursion" put Wordsworth. I do not know that within the last twenty-five years, taking it for all in all, taking the beautiful exterior, and the still more exquisite interior, so complete, so harmonious, so perfect in all its parts—there is any one more entitled to the respect of his countrymen for having produced a grand creation. Sir Charles Barry, you all well remember, was not simply a Gothic architect, although he selected that rich and beautiful style of architecture for the Houses of Parliament. He has adorned London with hardly less beautiful buildings in a totally different description of architecture—the Italian or Palladian. Witness his Travellers' Club and his Reform Club. Palladian or Italian architecture may be said to have dated its origin from about the beginning of the sixteenth century. At that time commercial enterprise and popular freedom were making considerable strides, and feudalism and ecclesiasticism were giving way a little before them, and with these the Gothic architecture receded considerably from the high position which it had taken; and for commercial purposes and the purposes of a great nation rising into wealth and prosperity, it was found that in many instances the Palladian, or Italian style, was more suitable and more appropriate. Hence, we find that during the whole of the sixteenth, and a large portion of the seventeenth century, that style was in very general acceptance and use. Various modifications, both of the Gothic and of the pure Roman or Italian have ensued; and we perhaps may now say, generally, talking of the various styles—which has been a great subject of discussion recently in the architectural world—that it seems to be pretty well admitted that for ecclesiastical or baronial buildings, Gothic, upon the whole, is the best; for civil or municipal buildings, the Italian or Palladian; and for family mansions, the Tudor. You are aware that in the competition for the Houses of Parliament, the competitors were restricted to two styles—the Gothic and the Elizabethan. Barry wisely, I think, chose the Gothic, because there can be no doubt that it is a more forcible and a grander style of architecture than the Elizabethan. However, the second prize in the competition was given for a very beautiful Elizabethan design. In the recent competition for the new Government Offices in London, which has excited so much attention, there has been no restriction of style—all styles have been thrown open to the competitors; but we are aware that there seems to be a division in the Cabinet on the subject, some of its members being clear that the style ought to be the horizontal—either Italian or Grecian; others being equally clear, for the sake of uniformity with the Houses of Parliament, and upon the ground of the merit of the style itself, that it ought to be Gothic. In the meantime, I understand, it is a Gothic design that has obtained the first prize. But whether that design is to be ultimately executed remains at this moment, I believe, a little doubtful. Now, whilst architecture, viewed in this way, is the main instrument by which populous cities are reared beautiful and grand, and striking to the eye, and delightful to live in, and delightful to gaze at, we must not forget that architecture has also no less important, though, perhaps, not such conspicuous, duties to perform. Architecture has to make cities also, and the dwelling-places of man comfortable, healthy, salubrious, and safe. Architecture and all sanitary requisites go hand in hand. It was well said by Mr. Chadwick, at the recent meeting of the Social Science Association here, that the physician now, instead of sending his recipe to the apothecary, might with greater propriety send it to the architect. For if the architect, at least, is left to his own way—if he is not trammelled by his employer, and tied down to do certain things which he would far rather not do—if he is allowed the freedom which every independent architect ought to endeavour to obtain, I say that he, in many circumstances, becomes responsible not only for the beauty and the grandeur, but the comfort and the health of cities. Therefore, whether we look at those great prizes in the intellectual world of architecture, which occur only occasionally, but to which a man of genius will ever look as affording the means for handing down his name and doing the greatest and the highest things that can be done in the art,—

whether we look to that or to the simpler and daily avocations of ordinary architecture, we cannot but feel that the profession of architecture is at once a most noble and a most useful one; and happy, say I, is it for any city in which an intelligent body of men, such as I now see before me, take a deep and daily interest in such a subject. The duties of the architect are not confined simply to the building—to the mere use and superintendence of the mode of the use of the stone and the lime. There are a number of subsidiary matters, all of which go to the comfort or the beauty of a building, and in all of which the architect is entitled to have a voice, nay, a predominant voice. I heard to-night, with great pleasure, from the report of your proceedings of last session, that you have looked with no small interest upon the decoration of our beautiful old cathedral, and that you, as you were not only entitled, but as you were bound to do, have watched anxiously what has been doing there in the matter of painted glass. I think, in the first place, that the public of Glasgow are greatly indebted to those public-minded citizens who originated the idea of restoring the old glories of painted glass to that fine old building, because there can be no doubt that, especially in a fine ecclesiastical building, the interior very finely coloured produces a richness, a beauty, a grandeur of light and shadow, a solemnity, a religious awe and effect which almost no other adjunct will give. I regret that a difference of opinion has arisen as to the mode in which the windows were to be executed and obtained. I think that, as usual, where a difference of opinion gets up, and where, perhaps, some little anxiety and heat has been shown on both sides, there has, perhaps, been a little exaggeration on both sides. On the one side it has been maintained that it was impossible to get proper windows for our cathedral from the exertions of native artists, and that the only safe place to go to for those windows was Munich, a city of the arts, and a city in which the art of painting glass has been much cultivated; and the committee, having finally resolved to go there, have also adopted the opinion that it is necessary to be uniform in the cathedral; and to preserve, therefore, uniformity, they seem now to think that they can go, or should go, nowhere else. It is also maintained, upon that side of the question, that the two windows which have been obtained from Munich, are so infinitely superior to anything that could have been got in this country, that they prove the propriety of their resolution to go there. Upon the other side of the question it has been stated, and certainly well stated, by many intelligent men, that we have sufficient art within the confines of our own country to have justified our committee in appealing to it; and that there are both glass-stainers, as artisans and manipulators in glass, who can well transfer those designs on to the proper material, and that there are artists as high as any that Munich possesses, capable of giving suitable and appropriate designs to those windows. And this party, who so think, are inclined to say that the Munich style of painted windows is not the best—that it is conventional, that it is of a peculiar character, that it is not so rich or strong in colour or in tone as other styles, and that the truth of this is proved by the two specimens which have been already put up in the cathedral. Now, it is not for me to pronounce any decision between these two contending parties. It would be the height of arrogance in me to attempt to do so. I believe that Munich is capable of sending out some most excellent specimens of painted glass; I believe that Munich is entitled to the honour of being permitted to send windows to our cathedral, and that those windows, whether they entirely come up to all that could be wished of them, whether they may not be to a certain extent feeble in tone and in colour, yet possess great artistic excellencies and beauty. But, whilst I believe this, I also believe that Munich is not the only place in the world where painted glass can be got, and the most thoroughly believe that it is not, upon the whole, judging by the specimens which we have already seen in this city, the very best school of painted glass at this moment. If any one take the trouble of going into our crypt, where we have windows from Munich, from Brussels, from Dresden, I think no one accustomed to the effect of colour, looking at the richness and purity of tone or colour, and looking at the effect which this rich and deep tone produces within an interior, but will acknowledge that, in the crypt at least, the Dresden windows are decidedly superior to those from Munich. But I go further, and I have no hesitation whatsoever in stating my belief that we have artists in this

country capable of producing at least as fine windows as those which we have got. I do not object to that intelligent committee having given certain orders to the artists in Munich, but I doubt that they are altogether right in holding that it is absolutely necessary that because they have got two or three, and are going to get one or two more from Munich, the whole windows in the cathedral should come from Munich. I know that they stand up for what they call uniformity of style, and the probable introduction of discord if they put in windows which cannot be considered to be precisely in the same style as that which has been adopted in Munich. Now, I differ with great diffidence, in the feeling as to that. I do not think that a monotony of style in a great building like our cathedral is at all necessary, or desirable. I do not think there will be any discord, any disagreeable harshness, in having, in certain of those windows, fine rich glass from Dresden; nor do I think there would be anything discreditible, but something very creditable to this country, if we had two or three beautiful windows by our native artists, such windows as we can see in Gloucester Cathedral, such a window as I know is to be put up in St. Paul's, commissioned from native artists alone. Whilst, therefore, I think we are much indebted to that most intelligent Committee for what they have done, and whilst, if their arrangements are complete, I do not think that it would perhaps be safe or right to attempt at this stage to interfere with them, still that is not to prevent intelligent men who think upon the subject—it is not to prevent artists who visit Glasgow, of the highest fame, with some of whom I have visited the cathedral—it is not to prevent professors from London, men of accredited reputation, from making their observations and their fair criticisms upon the Munich glass. We are not to be tied down to the implicit faith that Munich, and Munich alone, can produce painted glass for the Glasgow Cathedral. I hold that dogma to be a fallacy, whilst I give all due credit to the talent and power of some of the Munich artists who do spend their lives in producing windows. This is one of the subsidiary subjects deeply connected with architecture. There are many others, such as the decoration of the interior of the buildings, and other matters not immediately connected with building, such as our drains and sewers, all of which are subjects interesting to architects, and with which they peculiarly are bound to be familiar.

The Rev. Mr. Batchelor, Mr. R. Somers, Mr. John Honeyman, jun., and others addressed the meeting.

#### EXHIBITION BUILDING OF THE BOARD OF ARTS AND MANUFACTURES OF LOWER CANADA.

The brief accounts of this structure, as the Crystal Palace, which have appeared in some of the English papers, and our own reference to it, have not satisfied some who are concerned in its erection, and we have in consequence received a few additional particulars from Montreal. In form the building is that of a cross, the main body consisting of a nave and aisles, 184 feet in length by a total width of 80 feet, and a height from the street level to the underside of the circular roof of 80 feet, or equal to that of the transepts of the '51 Exhibition. The transepts, with their aisles, (one bay only of which is at present completed on each side), are 60 feet wide, with a present length across the entire building of 124 feet.

The two principal fronts have columns, girders, and outer circles and ornaments of the large fanlights, of iron: the windows, ventilators, blinds, &c., are of ornamental woodwork. The side walls above the stone base course are built of red brick, with white pressed brick dressings to the windows, panels, and piers. There is a stone basement, 9 feet high, under the entire building.

In the interior are two tiers of galleries, each 20 feet wide, running round the building over the aisles, the lowest one being at a level of 20 feet above the ground-floor. The internal columns and girders, with their mode of junction, &c., are somewhat similar to those in the Sydenham Palace. The roofs are of wood, covered for the present with patent felt and composition; but they will eventually have an outer covering of tin. This description of roof was determined on in preference to one of glass, in consequence of the great changes in the climate from Midsummer's heat to winter's intense cold, rendering it very difficult,—in fact, in a building of this magnitude quite impossible,—to keep it sufficiently cool in summer and warm in winter, were it otherwise constructed.

As a proof of the energy with which this building was carried on, we may mention that, from the time that the first pile was driven (upwards of one-half of the entire foundation had to be piled in consequence of the soft state of the ground on a portion of the site), until its inauguration by H. R. H. the Prince of Wales, a period of only sixteen weeks elapsed. The style of the building as to its construction, and the description of the iron work, both in the castings and the fitting together, being entirely new to the contractors engaged upon the several portions of the building, render this, even under favourable circumstances, a very short period to erect so large an edifice in a new country. Mr. J. W. Hopkins is the architect, and Mr. D. McNevin the builder.

#### PROGRESS.

We really live in marvelous times when science, with giant strides, is surprising the most sanguine. Amongst the new wonders, we have accounts from Austria of the invention of a printing-machine of extraordinary quality, dispensing, it is said, with the use of all assistance, save that of mechanical apparatus. No persons are required to feed it with paper, or to remove the printed sheets, both processes being accomplished through the instrumentality of the machine itself. The paper for this purpose is supplied in rolls or webs, many hundred yards in length. The machine first cuts a sheet of the requisite size, then prints, and finally throws it off—a newspaper ready for the reader, and in Austria, too! All that manual labour in this case is required to do is to bring forward fresh webs of paper, and to take away the printed sheets. Thus, in the Vienna State Printing-office ten presses are attended by one man only. The same office is said to have started a capital invention for the manufacture of paper itself from straw.

The electric telegraph is progressing in usefulness, is ever developing new power, and will, ere long, be an important element in the management of business, and also be a means of carrying out other objects.

Professor Wheatstone's instruments (as is generally known), consist of two kinds. The one is described as the Automatic Telegraph, and the other as the Universal Telegraph. The latter is the most useful for distances of from one to three miles. It is so easy of manipulation that any one who can spell can dispense intelligence. On a

small circular dial are the letters of the alphabet and the numerals, one to nine, with a cypher. As these letters and figures are touched, in the same manner as the keys of a pianoforte, the same letters or figures are indicated at the place to which the communication is to be made. Another dial, with a pointer, which points to letters and figures exactly the same as the other dial, is fixed close by for communication. It is thus plain that any one, even of the most ordinary intellect, and without practice, can hold communication with another by this simple means; and so portable are these instruments, that as one man carries them another can push the truck which contains the reel of wire. By their means communications were made throughout the French army at the battle of Solferino. There seems to be nothing to prevent the application of this principle, at a moderate cost, to dwellings, to the same extent as gas and water are now laid on (this we have before hinted at), and by proper arrangements at the different stations of the Metropolitan Telegraph, which stations may soon be as numerous as the post-offices now are. When Mr. Jones, or Mr. Brown, has had the electric telegraph laid on, he will be placed in communication, at a lightning rate, with the whole of the metropolis, and, for an extra payment, with the chief part of Europe. It may, however, be that in course of time facilities will be thus afforded for the conveyance of messages throughout the entire empire. It is curious to speculate on the changes which may be made by this means in the usages of society. For instance, if the weather is unfavourable or other circumstances occur, ladies of fashion may sit in their bonnet, and perform all the necessary small gossip of a morning call with friends, despatching fifty polite messages and receiving the answers from places at a considerable distance within an hour, their maids delivering the same by touching that marvelous dial which in days of yore would have been considered a supernatural agency, and then awaiting the reply. In fact, the telegraph may be made to write its own messages and replies, and thus save further trouble. We can fancy in those days to come, in the houses of our merchants, artists, and others, in London and elsewhere, the

electric signal being given, little children spelling the letters indicated by the distinct but rapid pointing on the dial which brings news from all directions, and hastening to inform their parents or guardians that Aunt So-and-so, or Mrs. Blank, or it may be their brother Tom at Oxford, or Uncle Jack at Aberdeen, is talking to them.

The swiftest of the express locomotive trains, or all the means of Mr. Rowland Hill, are as nothing in comparison with the speed at which thoughts can thus be exchanged.

From the Houses of Parliament a line of the description alluded to already communicates with the Queen's Printers in Fleet-street, by which Members, without the intervention of a third person, can readily send any messages.

To ministers of state, to those engaged in departments of great companies, or connected with the press, this species of telegraphy will ere long be as familiar as the morning newspaper; and that, too, may then be cut without hands from the Vienna paper-web, printed off also without human intervention, and wrapped up and addressed by the American newspaper-addressing machine, of which we some time since gave an account.

An instance is mentioned in *Chambers's Journal* of a nobleman who resides five miles from Dundee now habitually sending orders to his tradesmen in the town by domestic telegraph.

What a wonderful power the special telegraphic system must give to the police, and how useful it must be to the fire-brigades of the metropolis. The Americans already have something of the kind. In coal and other mines, in the carrying forward of military operations, in the management of large manufactories, and in a hundred other ways, its operation will be most valuable.

At Chatham, twenty-five fuses were fired by telegraphic influence at two miles' distance. How suggestive this circumstance is of many applications, such as the blasting-works of coal pits and quarries, already in partial use. With management it might be made the means of simultaneously lighting all the gas-lamps in a town, as long ago suggested. This, however, may not be for long needed, for who can say how soon the electric lights may as effectually supersede gas as that invention did the oil lamps of Queen Anne and George III.'s days? As it is, the gas-jets in an assembly-room in Edinburgh have been lit simultaneously by electricity.

It seems but the other day that we saw the first beginning of photography. We remember the speculative observations which were made respecting it, while the great mass of the people were incredulous. Year after year this art-science has progressed. From time to time the public have been astonished by fresh developments. Portraits of a power and excellence which rival, nay, far excel, the best efforts of the most distinguished miniature painters are produced by means of photography. Tinted in oils or water-colours by artists of ability, coins, shells, and other objects of natural history, &c., can be most perfectly copied by this means; and it appears that by the sun's rays, chemical appliances, and scientific arrangements combined, photography will soon be made useful for book and other illustrations, for the last news respecting photography is, as we only the other day first informed the British public, that a method has been found of multiplying complete and beautiful photographs with a speed vastly greater than that by which engravings can be printed even by the steam press.

We have already noticed a process by which artistic subjects, already engraved and printed, as well as letter-press can be reproduced in any number from the printed surface. Of the expansion or enlargement, and contraction or diminution of prints and letter-press we also lately gave an account.

The sewing machine is getting into extensive use in the making of clothes, boots and shoes, and other things,—in America, more so than in England. Some idea of the appropriations of this instrument may be gathered from the following particulars from a recent article in the *Times*. It seems that a discussion has taken place in the United States as to the right of Mr. Howe, the inventor of the sewing-machine, to a renewal of his patent. A renewed term of seven years has been granted. In the argument before the States' Commissioners of Patents it was shown that the value of the sewing done in the United States which is capable of being done by the sewing-machine is at least 58,000,000 dols. per annum, and that Howe's machine even if applied to the work in the exact form in which he first introduced it, would save to the public 34,000,000 dols. per annum. Look-

ing at the exact results achieved, it was pointed out that the sewing-machine had already entered into and revolutionized more than thirty-seven distinct departments of manufactures, besides enlarging many, and also creating new ones.

In the city of New York it is asserted that the annual saving is 1,500,000 dols. on men and boys' clothing, 92,000 dols. in hats and caps, and 170,000 dols. in shirt-fronts; while, in Massachusetts, in the manufacture of boots and shoes the labour value of its performance is 1,500,000 dols.

When we turn to the condition of agriculture,—its steam ploughs, steam thrashing-machines, and improved methods of management, we find that there is only a comparatively small beginning made and much still to do. It is shown that by proper management and well-directed labour even without any special or new appliances, the ground in the neighbourhood of the metropolis might be made to produce five times the present average quantity of produce. It is evident, therefore, that a great deal has yet to be done in this direction. In spite of the chemical knowledge which has been brought to bear on this subject, in parts of England, some not far distant from London, the same methods are in use as were employed two centuries ago. Nevertheless, steam is making considerable progress, too, in agricultural manufactures, here and there throughout the country.

In the improvement of varieties of crops much has been done, but still more remains to be done. There seems to be here a boundless field for culture. The grains and roots, as well as the sheep and cattle, of recent years are, many of them, enormous in size compared with those of past years, and there really would appear to be scarcely any limits in this as well as other directions connected with agriculture. We do believe that vegetable and animal life can be either enlarged or diminished almost to any extent by patient and long-continued culture and selection,—that sheep could be enlarged to the size of cattle on the one hand, or dwindled to the size of lapdogs on the other, by breeding and selection. How can the "old oaks and pines" of the Chinese and Japanese, dwindled to a few inches in height, have been produced but by long-continued selection of the smallest trees and the smallest seeds, reiterated over and over, till the dwindling process was accomplished? And so with the enlargement of vegetable and animal produce: how have the enormous swine and other animals of the modern farm been produced but by some such system of breeding and selection? Here, we say, there is a vast field for improvement, even independent altogether of steam, though that will soon be making rapid and extensive strides in agriculture as in other manufactures, and in commerce and social intercourse.

#### LIVERPOOL FREE PUBLIC LIBRARY AND MUSEUM.

THE new structure for a public library and museum, built and presented to Liverpool by an individual citizen, was opened on Thursday last. We have on various occasions spoken of the building during its progress, but the following connected particulars, from the local *Journal* and elsewhere, will be interesting at this moment. The first stone, let us say, was laid in April, 1857. The building is on the north side of Shaw's brow, very near to St. George's Hall: it extends in front about 222 feet, and in extreme depth about 161 feet, and occupies an area entirely covered, of about 3,770 square yards. The front and the returns, to the extent of about 45 feet at each end, are executed in stone, chiefly from quarries near Wretham, and in part, where that stone could not be obtained of sufficient dimensions, or where not of sufficient hardness, from the Darley Dale quarries or from Yorkshire, the remainder of the sides or ends, and the back part, or north front, being faced with straw-coloured bricks from near Tamworth, with stone dressings.

The south façade is broken up into five parts, baving in the centre a hexastyle portico of the Corinthian order, with four columns in the rear, and the centre part deeply recessed. The recessed parts of the front contain each five windows, over which are sunk panels with large carved wreaths on raised blocks. The two wings have on the face four pilasters of like order with the portico, the two centre ones projecting before the line of the angle ones about 2 feet, and between the centre pilasters are niches, with pediment caps and carved trusses, and above are sunk panels and carved wreaths. The flanks to the extent of the stonework contain the windows which, at the east end, light the students' reading-room, and at the west end the corresponding room in

the Museum. The columns are 33 feet high: the basement is 9 feet high; and the entire height, from the surface of the ground to the top of the entablature, is about 51 feet, exclusive of an attic or parapet round the building, 7 feet 6 inches high, for the purpose of screening the roofs, which would be otherwise overlooked from the higher level of London-road. There is also a lofty attic above the portico, returned on each side for the purpose of screening the roof of the central hall, otherwise overlooked from the higher ground.

The portico is approached at each end by steps, enclosed in screen walls, with iron gates, and the remainder of the front is enclosed from the street by a stone balustrade having iron gates to the side entrances.

The general entrance to the building is from the portico, into an entrance-hall, 31 feet by 23 feet, having a flat panelled ceiling. Turning to the right is the entrance to the reading-room and library, and to the left a similar entrance to the museum-rooms. Each of the entrances and the central hall are approached by four steps, the general level of the principal floor of the building being 2 feet above the level of the entrance-hall, and 2 feet 6 inches above the level of the portico floor.

Facing the entrance, and beyond the entrance-hall, from which it is separated by a screen, consisting of two Doric columns, flanked by two pilasters, is the central hall. This apartment is 90 feet long, 53 feet wide, and 46 feet high. It is surrounded by a gallery, supported upon an arcade, the gallery being 10 feet wide. Above this gallery the roof is supported by Yorkshire stone columns of the Ionic order, twenty in number, the shaft of each column being in one stone. Between the columns the gallery is protected by a stone balustrade, and from these columns, surmounted by their proper entablature, spring the groined arches which support the ceiling, the centre portion of which is divided into compartments by enriched bands opposite each column, three of those compartments having horizontal lights, and the others being filled in with enriched panelling and flowers. In addition to the horizontal lights before mentioned, the hall is lighted on each side by seven circular-headed windows, and by windows in the external walls at the ends of the hall, which are seen partially through the semicircular arches over the entablature surmounting the end columns.

Looking through the end of the arcade and a screen of two Doric columns, with their flanking pilasters, is the principal staircase, which is 31½ feet by 30 feet. This staircase consists of a central flight of steps, with a continuous landing extending the full width of the staircase, and two return flights of steps. These steps and landings are from the Craig Leith quarries, near Edinburgh. The staircase is protected by Yorkshire stone dado, having moulded plinths, cappings, and pedestals; and the walls round the landings and the sides of the upper flights of steps are cased with Yorkshire stone, with moulded plinth and capping.

The upper part of the staircase is surrounded with pilasters and pedestals to correspond with those in the central hall, and the ceiling is divided by enriched bands into nine compartments, two of which admit the light from skylights, and the remainder are panelled.

The room at the south end of the upper part of the hall on the level of the gallery is finished in like manner with the upper part of the staircase; and the upper part of this room and the staircase being each only separated from the central hall by two columns, the vista is complete from the front to the back wall of the building, about 152 feet.

The central hall is intended for the reception of works of art, such as sculpture, on the lower or ground-floor; the walls of the gallery, the upper part of staircase, and the upper room at the south end, being intended for the reception of pictures, &c. Generally, the portion of the building eastward of the central hall contains the Free Public Library, and that to the westward of the central hall is appropriated to museum purposes.

Descending again to the entrance-hall, and standing at the entrance doorway, the entrance to the reading-room is on the right hand through a small vestibule, whence the reader also obtains access to the lavatories, &c. The reading-room is 110 feet long and 50 feet wide. The south end, forming part of the main building, is separated from the remainder by a screen of two Doric columns, with their attic. This portion is lighted by the five windows in the eastern recess of the south front. The remainder of the room is lighted by two skylights, and by windows in an attic, raised upon segment and panelled arches across

and on each side of this portion of the room. These arcades spring from four piers, intended to enclose shafts to be used in the warming and ventilating of the building. To these shafts, and to corresponding shafts in the angles of the room, are attached Doric pilasters, the whole surmounted by a Doric entablature. Adjoining the large reading room, and in the south-east angle of the building, is the students' reading-room, 40 feet 6 inches by 28 feet; and on the east side of the reading-room is the reference library, 75 feet by 27 feet, which is now being fitted up with bookcases, and having also a gallery round it for bookcases. The cases in this room, and those intended to be fixed round the students' reading-room, will contain, say 30,000 volumes, being about the present extent of the library. Northward of the reading-room, and divided from it by a staircase and passage, is the committee-room, and also three class-rooms, the staircase being intended for access to the upper rooms of the library and to the lecture-room, hereafter described.

Upon the upper story of the building, on the library side, are three rooms intended to be used when required for library purposes. Their dimensions are as follows:—One 50 feet by 27 feet, one 40 feet 6 inches by 28 feet, and one 75 feet by 27 feet. These are all lighted from the roofs, and will, when filled, afford, with the lower rooms, space for about 100,000 volumes. They communicate at one end with the staircase just mentioned, and at the other, by means of a small ante-room, with the upper room at the south end of the central hall.

Over the committee-room is a lecture-room, 28 feet by 25 feet; and over the class-room a theatre for lectures, seated with circular seats, capable of affording accommodation for upwards of 340 persons. This theatre is approached from the north-east angle of the gallery in the central hall, and from the staircase in the north-east wing; so that, by means of the latter, it may be used in the evenings without necessitating the lighting of the hall when not required for other purposes.

The basement of this eastern portion of the building is in part to be used in connection with the working of the library. The portion under the reference library is intended as rooms for the reception of books purchased, and for the binding and classification of them. The parts under the committee-room and class-rooms, though not at present completed, or intended so to be, can at any time, if required, be, at a slight expense, rendered serviceable. A portion under the south end of the reading-room is intended for water-closets and lavatories for the use of the readers. Like conveniences will be found on either side of the principal staircase, entering from the central hall.

Having completed the circuit of the portion appropriated to library purposes, we proceed to the museum, and, again descending to the entrance-hall, on the left hand from the outer doorway looking northwards, is the entrance to the museum-rooms, on the principal story of which there are five, two of them each 50 feet by 27 feet; two of them each 40 feet 6 inches by 28 feet; and one 70 feet by 27 feet. Upon the left hand side of the vestibule to these rooms is a small room for the reception of cloaks, umbrellas, and for the parcels of excursionists, &c. Leaving these rooms, and entering by the north-west corner into the central hall, the principal staircase will take the visitor to the upper museum-rooms, also five in number, and of like dimensions with the lower ones, all lighted from the roof.

The entire cost of the erection of the building, the lighting, warming, and ventilating, is borne by Mr. Brown, and also the cost of the fittings; and the total expense, including the extension, will not be far short of 40,000.

When the building was first designed, it was intended to place it upon the incline of the then Shaw's Brow; but serious objections to such a course having arisen, the council determined to raise it up to its present level, and for that purpose authorized the construction of the present raised platform or terraced approach, by which means the building has been lifted up about 12 feet, and the portico floor is now on the level of the northern entrances to St. George's Hall. This necessitated the construction of a platform or foundation to the same extent for the building, the cost of which has been also borne by the corporation. The site of the building having been purchased in part out of the surplus funds of the corporation, and in part out of money raised on the security of the museum-rates, the total cost incurred by the corporation and by the Museum Committee for the site, and for the necessary works for raising the building to its present level, will be about 25,000. The designs for the build-

ing have been furnished by the surveyor of the corporation, and the works have been and are being carried out under his directions, Messrs. Holme & Nicol being the contractors, and Mr. Jacob Crieie, the clerk of the works; the sub-contractors being, for the masons' work, Mr. Hugh Yates; for the plasterers' and slaters' work, Mr. John Bromley; for the plumbers' and painters' work, Mr. Thomas Holt; for the glazing, Messrs. Moss & Co.; and for the iron work, Messrs. Weber & Co.

#### DOMESTIC ARCHITECTURE OF SOMERSET IN THE MIDDLE AGES.

SOMERSETSHIRE ARCHÆOLOGICAL SOCIETY.

At the congress of this Society, held at the end of last month, Mr. J. H. Parker, being called on, said Somerset was the richest county in England in specimens of the Domestic architecture of the Middle Ages. He was not aware that there was any house in the county of the twelfth century, though there were a few in some parts of England; but of the thirteenth century there was the finest house in England, or perhaps in Europe—the Bishop's Palace at Wells, which was built by Bishop Jocelyn in the early part of that century. In the fourteenth century it was found not sufficiently large to suit the occasion of the bishops of those days, and another palace, he might almost say, was built by the side of the entrance to the courtyard. The building of the fourteenth century was in ruins. It seemed to have been merely occupied by state apartments, not used as a regular dwelling; and the house that still remained always had been, as at present, the dwelling of the bishops. It should be taken into consideration also, that it was part of a batch of buildings, and that the palace, the cathedral and chapter-house, and the close, formed one magnificent conception, which gave an idea of the noble architecture of the Middle Ages, such as was seldom seen anywhere else; indeed, he knew of no place equal to Wells in this particular. Mr. Dickinson had informed him that the houses of the canons were not in the close. He thought that must have been a subsequent arrangement arising from the requirement of increased accommodation. There were many houses in the county of the fourteenth century,—one at Meare, which was visited last year, and a very interesting and beautiful specimen it was. It was a very common practice in the Middle Ages to have the lower story stone floored, so that the collars and store-rooms were fireproof, and the adjoining parts were used as cloisters. That was the case with castles, abbeys, and monasteries. There was a house of the fourteenth century at Martock, in which the arrangements were somewhat singular. It was situated near the church. In that immediate neighbourhood there was Clevedon Court, a house of the time of Edward III., and he was proud to say, in a nearly perfect state; for, though it had been altered, and that to a great extent, the original house still existed. It was built in the shape of the letter H, the hall forming the connecting portion, and various buildings the two other parts. The offices were external. It was a common practice of the period, and appeared a very sensible practice, to have the kitchen out of doors, communicating with the house, but detached from it. There was thus less of the smell of dinner, which was very inconvenient in some houses. The servants had their hall, in which there were three doors—one leading to the pantry, another to the lutey, and the third to the kitchen. In many houses the great hall was upstairs, and the kitchen on the ground-floor; the lord's apartments were at one end of the hall, and those of the servants at the other. The lower rooms were called the cellar or parlours. It seemed strange to confound these two names; but in the Middle Ages a cellar did not always mean a place of deposit; it was a sort of lower chamber, above which there was an upper one, occupied by the lord and his family, and affording a look-out on the lawn. At Clevedon this situation was, however, from the "lady's bower." There were two doors, over each of which was a portullis, and below the roof were windlasses to raise the portullis. The house was slightly fortified. There was a round tower and embattled wall, but from its situation it could not be intended as a place of any great strength. The fortifications were most probably intended to keep out the highwaymen who infested the country. Of the fifteenth century there were a great number of houses in the county, of which it was needless for him to give any description. He was sorry to say that some of them were being destroyed. At Kingston Seymour there was a

very nice house of this date that had been destroyed. The houses of the sixteenth century were innumerable. These houses were all well worth preserving and examining, for no two of them were alike: the arrangements varied according to the caprice or wants of the inhabitants. While some had been destroyed, he had great pleasure in observing that many were extremely well kept up, and others were being built with as great spirit and liberality as were displayed by our ancestors. At Butleigh there was an example where the expenditure had been as liberal as in the middle ages. Our architects were not quite up to the mark in houses. They had made immense strides in regard to churches, which were as well built now as in the Middle Ages; and there was one in the neighbourhood of that town which was as perfect as if it had been built in the thirteenth century. But the architects do not understand the mode of building a Medieval house. A Medieval house might be made as comfortable as any other, and need not cost more; but, generally speaking, those that were built now were not so convenient or so good-looking as those of an older date. However, there was an improvement; and he hoped that as much progress would be made in the next ten years as there had been in churches in the last ten.

#### HARVESTING IN WET SEASONS.

THIS season of 1860 has been throughout a time of severe trial for farmers; yet many of them may still be found so obstinately wedded to the old school routine of farming, that they refuse to adopt any novel preservative and remedial processes, although these may have been fully tested by more practical men, belonging to what may be termed the new school. The ripening of corn by the sun's rays may be the better process and bestow a superior flavour; but experience has shown us the ripening of much of the fruit grown in this country after being plucked, and of probably the greater proportion of that exported to England, as for example oranges, grapes, &c., the oranges being actually packed for exportation while in a green state. An author of some note in all relating to agricultural matters, many years back stated that when corn, &c., had attained its full development of *earing*, and its further growth was evidently at an end, no time should be lost in garnering in the precious produce, the staple necessary of life to millions of our population. In Russia wet harvests are frequent, and the agriculturist gathers in his crop before the weather wet or dry. There they employ a very rude process of drying it, first piling huge bundles together in masses similar to our haystacks; in these are placed dried clay pipes, of about a foot in diameter, in such a uniform disposition as to enable them to convey hot air through them, produced by the combustion of wood or other suitable material: this proceeds from a stove placed at a sufficient distance to ensure safety, and demands care to avoid destruction by fire. Even this rude method might be used with advantage, especially by small farmers whose resources and means are limited. But for farmers of the higher class, owning their hundreds or thousands of acres, a *modus operandi* of a superior type and consistent with the magnitude of operations would be desirable if not necessary.

To this end it is now suggested that buildings should be erected having the special object in view of being used in wet seasons for drying the corn. Such erections might be constructed so as to serve the purposes of the ordinary barn-house before and after the time of harvest, and when required for drying the grain or any other produce; indeed, the firm buildings already standing might be readily adapted and altered for the purpose. In these, stoves conveying hot air or water should be carried throughout the buildings; the heating apparatus being fixed upon the ground-floor and the electric produced rising through the floor above it, which must be perforated with numerous holes for the purpose if it be a wooden one, but it would probably be far better to construct such flooring of an open wire-work or grating. The wet corn or other produce, &c., littered over it would only require to be frequently turned. A quicker system of drying has been proposed by artificial currents of air, but we believe that the hot air process now suggested would ripen the produce better, and give to it a more natural flavour than if it were subjected to the cold blast. The valuable properties of the *chloride of calcium* were pointed out by a scientific journal in 1857, but without receiving that attention it probably merited. That mineral is a very rapid absorbent of moisture: by its

employment corn and other matters might be dried by a process free from any objection on the possible ground of danger from fire. The only point for consideration is that of cost; and this it is believed may soon be disposed of: hitherto, this ebolicum has been little used, but a reliable authority has stated that it could be manufactured on a large scale at a moderate price, and there is reason to believe it might eventually become a valuable auxiliary with agriculturists.

Due provision should be made for the contingency of a wet harvest time. To this end, it would simply repay the expense of outlay were farmers to erect on their farmsteads buildings expressly for the purpose of drying all kinds of agricultural produce as they in turn become full-grown and ready for an artificial ripening. Mr. W. W. Wynne, Mr. Wakley, and others have recently borne testimony to the possibility of evaporating the water from corn or any other produce by the employment of hot air, and by the means of comparatively simple mechanical arrangements; a correspondent of our own, shows a very early use made by him of hot air for the purpose; but the system proposed in this paper being of a simple and inexpensive character, and having none of those difficulties to which machinery is ever liable, such as getting out of repair and breaking down (often at a critical moment),—as also requiring great care, intelligence, and steady persistence on the part of farm servants,—is, perhaps, better calculated for general use by agriculturists.

#### INFORMATION FROM ABROAD.

THE municipal administration of Paris, on the 21st ult. deposited in the 12th, 13th, 14th, 15th, 16th, 17th, 18th, 19th, and 20th arrondissements, a project for enlarging and regulating the Rue Militaire. This, which acts as means of communication between the new *barrières* of Paris, must now replace the *Chemin de Ronde*, formerly connecting the old *barrières*, and the circular boulevard necessary for so active a traffic. So, the Council have resolved to transform the above thoroughfare into a large avenue, planted with trees, that it may unite together all the existing thoroughfares radiating from Paris towards the new *enceinte*, and may serve as a healthful promenade to the inhabitants of the new circle.

The Minister of Public Works is authorized, in the name of the state, to allow a subvention of 600,000 francs for the execution of a railway from Strasbourg to Barr, to Metz and to Wasselonne, by Molsheim; and subvention of 240,000 francs for the execution of a railway from Haguenau to Neiderbronn, with a branch to the Reischoffen factory.

An agricultural Institute has been just founded on the largest scale, by the Belgian Government. This establishment, situated at Gembloux, in proximity with Brussels and Namur, in the midst of the best cultivated lands of Belgium, combines theory with practice. It includes—two farms, gardens, and land cultivated for the special purpose of instruction; a sugar factory, and a distillery; stables, with proper means of utilizing the manure; access to the "Haras" of Government (horse-breeding stables), which are close by. The pupils are internal, but a certain number of externals may be authorized. They must be sixteen years of age at least, and must pass an examination to prove that they are possessed with sufficient information to profit by the course they are to undergo. Application to be made to the Minister of the Interior, Brussels, before the 15th October, 1860. Charge for in-door students, 700 francs, all included; out-door, 300 francs. Opening of classes, November, 1860.

The works undertaken in the Bois du Vésinet proceeded actively. The area of this wood, which is in a fair way of becoming a delightful promenade, like the Bois de Boulogne and the Bois de Vincennes, is no less than 450 hectares (1,101 acres British), of which 100 hectares (247 acres) have been reserved for roadways, lakes, and rivers. Up to the present, three lakes and 4 kilometres of river add to the embellishment of this new park, which receives its supply of water from the Seine, opposite Port-Marly, by two steam-engines, of 60-horse power each. When completed, this spot of ground for the recreation of Paris folk will contain five lakes (the largest being 4,000 square metres), and 7 kilometres of rivers. Moreover, small animals have been carried on, for a total length of 50 kilometres, so as to afford abundant supply of water for the rising colony. A handsome church is to be erected in the square of the town, around which a considerable number of

elegant villas have sprung up. The works received the benediction of the Bishop of Versailles with great ceremony, attended by the Minister of State and the "Maison" of the Emperor.

The transformation of the Champs Elysées is not confined to the widening out of the beside spaces and throwing them open, so as to render it an unrivalled promenade. More is projected to be done, and an inquiry has been opened at the *Mairie* of the eighth arrondissement for opening a new thoroughfare, 36 metres wide, between the "Rond-point des Champs Elysées" and the Rue du Faubourg Saint Honoré, in line with the prolongation of the Avenue d'Antin.

The works of the square before the Conservatoire des Arts et Métiers, between the Rue Saint Martin and the Boulevard de Sebastopol, are carried out, as usual, most rapidly.

#### DRINKING-FOUNTAIN MOVEMENT.

A FOUNTAIN in the Early English style has been erected in Sheffield, opposite to the Midland Station, at the junction of Spital-hill and Saville-street, at the cost of Mr. J. H. Sales. The base is a square structure, built of rubbed Darley Dale stone, ornamented with mouldings and a carved band, and upon it stand four pillars of polished granite, finished with capitals and bases cast in bronze. These have been modelled by Mr. Green, of Sheffield, and have been cast by Messrs. Yates, Haywood, & Co., Rotherham. Above the pillars is a superstructure, consisting of a canopy, arched on the four sides, groined, and with lead mouldings and carved foliage. Its height is upwards of 12 feet, and the breadth of its base 5 feet. The cost will be 200l. Mr. John Frith, of Sheffield, is the architect, and the work has been executed by Mr. Ald. Mycock.

#### WANT OF A MUSEUM AND LIBRARY FOR THE EASTERN PART OF LONDON.

An effort is being made by a number of gentlemen who sympathise with the working classes of the east of London, to provide a public museum, combining a library, reading, and lecture rooms, for the eastern districts of the metropolis. The working men of the neighbourhood bearing of this, and understanding that a select committee of the house of Commons had recommended the formation of branch museums in the crowded districts of the metropolis, have formed a society, called "The East London Museum and Library Working Men's Association," and have forwarded a petition to Parliament, signed by 10,500 working men, praying them to grant their assistance towards establishing a museum for the east of London. The secretaries, addressing us on the subject, say:—"We invite your attention to the actual condition of our rolling artisans, weavers, mechanics, labourers, &c., of the east of London. We long for improvement; but, alas! what have we after our daily toil? Little else than the public-house, the cheap theatre, low concert-rooms, or to stroll the public streets. Thousands of our young people (the hope of our country) are being ruined by these means, and poverty and vice habits fostered, which must degrade and impoverish those who are thus led. A committee of working men are now actively employed in endeavouring to establish a museum, library, reading-rooms, lecture hall (on a large scale), to be opened from ten till four o'clock as an ordinary museum, and from six till ten o'clock (free) for reading, lectures, classes, and study. We have sent a petition to Parliament signed, in sixteen evenings, by 10,630 *bona fide* working men. We hope to raise from the working classes themselves 5,000l. towards this object, and, by public meetings, advertisements, &c., to secure the cordial assistance of those who obtain their wealth by the toil of the working man."

Looking to the interests of the thousands of Whitechapel, Spitalfields, Bethnal-green, Shore-ditch, Limehouse, Poplar, Shadwell, and their suburbs, we entreat assistance for them. Here is a good practical work that wants doing and surely aid will not be wanting. There is no reason why the east should be left unprovided with intellectual resources any more than the west. The officers of the South Kensington Museum are understood to be perfectly willing to co-operate in the provision of a museum for the district in question. Objects would be lent and given if a proper building were provided. The means of healthful and instructive enjoyment should be widely afforded. Let us add that Mr. Smither, of 1, Well-street, St. George's-in-the-East, who acts as treasurer, would receive any communication on the subject that might be addressed to him.

PROPOSED TERRACE IN HARROW, MIDDLESEX.—MR. T. HARRIS, ARCHITECT.

J. HARRIS

*[The text on this page is extremely faint and illegible. It appears to be a book review or a list of references, but the specific content cannot be transcribed.]*

DESIGN FOR A TERRACE OF HOUSES IN HARROW, MIDDLESEX.

"VICTORIAN ARCHITECTURE."

The difficulty experienced in obtaining residences at Harrow-on-the-Hill, with its foundation school and other attractions, has led to the formation of a Tontine Association; and we learn that,—

"The intention is to lay out and plant ornamental grounds, and to build twenty-three substantial houses, of attractive architecture elevation and design, and with all modern improvements calculated to promote health, comfort, and convenience. For this purpose the association is in 1,000 shares (or nominations), of 50l. each, by which to raise 50,000, as the capital."

A terrace of houses to be erected by the Association has been designed by Mr. Thomas Harris, architect; and we give a representation of this, not because of any special interest in the undertaking, but as serving to illustrate the author's views as set forth in a pamphlet recently published.

The terrace comprises ten dwelling-houses, the centre portion being devoted to lecture and reading rooms, and observatory. The building is five stories high, and each house is to contain on the basement a spacious kitchen, 10 feet high, with necessary offices and service-rooms attached; on the ground-floor, which is 11 feet high, a dining-room (22 feet by 16), a study, principal and servants' staircases, &c.; also terraces formed at the rear over the servants' offices, with steps leading to the garden; on the one pair, which is 12 feet high, a spacious drawing-room and a lady's boudoir; on the two pair, two bedrooms and dressing-rooms; on the third pair, a bed, dressing, and bath room; and two attics in the roof.

All the houses are provided with the same accommodation, but the plan of each is varied to meet different tastes. Throughout, internally and externally, it is intended, as far as possible, to exhibit the details of construction ornamentally.

It is designed to preserve the natural character of all the internal woodwork by varnish or polish, and no paint will be permitted.

The author claims to have aimed at uniformity of principle instead of uniformity of parts. There is throughout an entire absence of cornices or similar projections, effect being sought by recessed and coloured brick combined with stone.

We will let Mr. Harris state in his own words some of his principles, and our readers who wish to see further may consult the pamphlet:—

"In applying stone, the main horizontal joints should be parallel, in courses of irregular widths, the vertical joints occasionally assuming the direction of a natural fracture. In domestic architecture, the largest stones are used to span the openings, in one or more stones, which, for the most part, should be square-headed, or at slightly arched. Random work should only be used as a filling-in in the upper part of the structure, or where strength is not wished to be conveyed. Mouldings should be sparingly introduced, and when employed with carving, admit of deep undercutting; but relief angles must be avoided as much as possible. In representing every variety of natural foliage (in reference to animals) should be freely introduced, but must be kept, for the most part, in bold and effective masses, affording scope for the carver to show his power, not frittered away over the composition, as frequently is the case. A word of manufacture and an honest public character. The effect may also be heightened in such works by the introduction of varied-tinted stones as bands and relieving arches; and, where expense is not spared, marble may be used for small columns, or inserted in panels, slightly recessed from the general surface for their protection, but always sparingly used, and set in as gems. No case should any artificial materials, such as ornamental tiles or cements, be employed in a pure stone building; but the composition should be kept sharp, bold, and impressive, and not laboured. All the ornamentation ought to be cut from the solid, and kept within the surface, and unnecessary projections avoided as much as possible. The effect of a stone building will be greatly enhanced by the association of wrought metals and the more durable Brickwork, from the variety of good coloured bricks available, presents a larger scope for originality of design than any other material; and, from its general use, account of its strength and durability, must necessarily occupy a prominent place in a new style. In applying

The programme issued says,—"A few words in explanation of the plan are given. Suppose each of the nominators subscribes 50l. on his own, or on such life as he elects; this raises a capital of 5,000l., and capital contributed is expended in building five houses; the profits of rents of these houses being divided amongst the whole 100 lives at the commencement. As each life pays, the capital of 50l. on that life survives to the rest, rather the advantage of it, as the whole income derives from the five houses divided amongst the survivors, so on till all die but five. When that period arrives, each of the five survivors becomes owner of a house, and the Tontine is closed; or, in other words, the 50l. may be used to purchase an increasing annuity for the life of the nominee, and the absolute ownership of a house by each of the five survivors superadded."

National Architecture. A few words to show that the National Architecture of the nineteenth century is attainable." London: Bell & Co. 1860.

brick, the various colours should be treated constructionally, not that of repeated and meaningless scoring and banding of the surface, or those unconstructive and fantastic patchworks of device, but an expressive, harmonious, and constructive application of the materials and colours. For instance, red, implying strength, should be used at the base, for constructive bands and relieving arches, and in every position where solidity or strength is desired to be conveyed; but in no case where light is required to be rendered, as, for instance, the reverse of windows, white bricks being most consistent with that object. Yellow bricks or common stocks (in inexpensive works) being a quiet medium, should be used to form the groundwork, bands of tiles being introduced where great strength is required. Blue or black bricks should be sparingly used, and require great discretion when employed, being apt to give the work a heavy, unnatural appearance. Cut-splays and notchings sharply executed will be found most appropriate to the character of the material, but rounded edges and simple mouldings may be sparingly introduced, but with caution.

"Woodwork—in all cases the natural face of the wood should be exposed wherever practicable, so as to exhibit its constructive character. When used by the carpenter for bonds, or in any position implying particular strength, it should have plain wrought faces with notchings, chamfers, beads, &c., wrought on the edges. Mouldings should be very sparingly used, care being taken to preserve the character and office of the material. But when used by the joiner, a large field for design is presented, every variety of mouldings may be introduced wrought with planes, or in more expensive works, by hand. Perforated wood, and carving in endless variety is admissible, except in hard woods, very little undercutting being practicable in exposed positions, from the aptitude to fracture. In all cases woodwork must show careful execution, and the character and office of the material must be strictly preserved, and never in internal works destroyed by painting; but in the commoner kinds, stained a tint to harmonize with the intended decorations, and be varnished or polished as their texture require. Most woods exposed to the weather require to be protected by paint; but in that case the character must be preserved by appropriate colours or grainings.

Plaster and Cement work should be mostly of uniform surface, with mouldings of simple form, and enrichments consisting of conventionalized natural forms and geometric patterns in low relief, not stuck on or projecting, but incised, so as to give a distinctive character, and not to clash with carving or iron works. Circular facings and roundings are very appropriate features. Cement externally is only admissible as a remedial work, to protect old works past retaining in their original material, in which case the most suitable ornament is encaustic tiles, or materials of a like nature, set in flush with the surface. Plastic materials should not be jointed, or made in any way to represent stone, in internal works, where expense is not a consideration, the surface of plaster-work may be polished."

RAMBLING; WINCHELSEA AND RYE, SUSSEX.

PERCHED on two bold eminences in the southeast corner of Sussex, and distant about three miles the one from the other, stand the picturesque towns of Winchelsea and Rye.

Placed as sentinels to keep guard over the smiling bay that once glittered at their feet, but perchance too proudly trusting in the natural and artificial strength of their position, they, in times long past, allowed themselves to be surprised by their enemies, ravaged, burned, and destroyed, and now we see them, shrunk away from their former grandeur into almost utter insignificance; even the very sea, their once friend and servant, has deserted them, and—retreating from their borders—has left behind only flat, marshy wastes, where once his bright waves brought plenty and luxury to their very doors.

Winchelsea was invaded and burned by the French in 1360, and by the Spaniards in 1389; Rye suffered the like fate from the French in the years 1377 and 1447.

Samuel Jeake, long an inhabitant, and supposed to have been a native of Rye, in his posthumous history of that town—which is still the great authority in all matters connected with it—derives the name from the old British word "Rhy," signifying a "ford;" and strength is given to the supposition by the fact, that "on the opposite side of the river Rother to the east, lies Gullford, formerly called Guldoford, which name implies that a ford existed near that spot in old times. Samuel Jeake died about 1650, before his book was printed, which was not till 1723.

In the conflagration of 1377 Rye Church perished, and was shortly afterwards rebuilt; but the destruction could not have been total; for much of the original edifice still exists. The fine north door, with its round arch and billet-mouldings; the Norman arching on the west walls of the transepts, and arch to the north aisle; with many other little bits scattered about, point to a much earlier date of construction than the reign of Richard II.

The rebuilding was conducted on a large scale. The church has a spacious chancel, with large chapel north and south. The northernmost one is used as a repository for lumber, amongst which a pillory, in perfect preservation, stands a silent, yet suggestive, memorial of the past.

The windows on the north wall of this chapel are lofty and elegant lancets in couples, with-

out a connecting hood-moulding; they are all bricked up. On the opposite wall, spacious Early English arches, now also closed up, formerly gave communication with the chancel; in which, in the thickness of the pier of the chancel arch, the hollowed space for the staircase to the roof-loft is still visible; but whitewash and devastation have done their utmost to obliterate the past. The bays carved oak screen, closed up and whitewashed, is made to serve as an end to the deserted north chapel; the south is used as the National school-room.

The chancel has a handsome Perpendicular east window, repaired; and on the floor a late brass, seventeenth century, attests that "Here lyeth the bodie of Thomas Hamon." The altar table is a handsome carved mahogany sideboard-looking thing, totally inappropriate, but of fine workmanship, and said to be the gift of Queen Elizabeth, and to have been taken from the Spanish Armada. The Tudor rose, intermingled with well-executed scroll-work, foliage, and ears of corn, to say nothing of its apparent date, contradicts the Armada origin. The font is copied from one of the Norman period at Newenden, in Kent, and has only three sides carved; the exemplar was, perhaps, fixed against a wall, but here the copy stands free. The nave of the church has five large bays, the arches decorated with a beautiful dog-tooth moulding, but, unfortunately, in many places damaged; the chancel has three bays, and a low tower stands at the crux. This tower had at one time a lofty spire, for in a petition to the king, in 1701, to have their church repaired, the inhabitants of Rye say, "The steeple of the said church was heretofore used as a famous seamark." The tower contains eight bells, "one of which," says Horsfield, "is curiously charged with figures, and on the top an inscription thus:—'O mater Dei, memento mei,' and at the bottom, 'Petrus Chineus me fecit, 1566;'" but it is to be feared they have been, or at any rate some of them, recast, for the sexton, an intelligent man, says they bear the date 1776, and the name of Mears. The stairs leading to the bell-tower have been repaired with portions of the chancel screen; one step has a beautiful little bit of carved oak tracery running under it to cover a bole, and a whitewashed "poppy-head" stands in an angle, to serve as a baluster.

On the outside the church is still more deplorably disfigured. A finely ornamented raking moulding, that must have formed an acute arch over the south door; a pretty little turret, with a lancet-shaped niche in the angle; and a magnificent flying buttress—one of a pair—pierced with fabicated openings, to let the blue sky smile through; such are the relics that tell of the bygone beauty of Rye church.

Close by stands Ypres Castle, now the gaol. It was built in the twelfth century by William de Ypre, Earl of Kent. It is a square building, with four round towers at the angles; below it is the battery.

One of the original three gates of Rye, one only remains, the Land-gate, called by the townspeople "the Tower-gate." This also has round towers, and very perfect machicolations. In going to it, a small ornamented Gothic building enclosed in a wall is passed. The present names of the streets are very suggestive: Watchbell-street, Mermaid-street, Gun-garden, and Conduit-bill; while those of the shopholders tell of their foreign origin: Bonn, Gason (oddly enough, on contiguous houses, and reading much like "Bon garçon"), and Dumb; to which may be added that of Fatima, a dark-eyed girl who kindly constituted herself guide to the weary travellers when, in the murky evening and the dimly-lighted streets, they feared to miss their way.

In 1572, Rye afforded an asylum to the persecuted Huguenots, and ten years later it contained 1,534 French Protestants; so that the poor town which the French had so repeatedly endeavoured to destroy, made them a noble return in their extremity.

Near the river Rother, in a field not far from Rye, a Danish ship was discovered in 1822. Many relics of its ancient navigators were found within: a half-finished sundial, still containing the "last;" a pomard; several glazed tiles; some fire-bricks; two earthen jars, a stone mug, and a curious board, perforated with holes, supposed to have been used as a sort of calendar. This ship is thought to be one of an expedition mentioned in the Saxon Chronicle of 893, as having landed in Kent, "at the end of the vast wood that we call 'Andred.'"

A short railway-ride, of about five minutes' duration, takes the traveller to the station of Winchelsea, which is popped down in the marshes just nowhere. There are no conveyances of any

sort, but as there are ordinarily no passengers, their absence is not of much consequence.

The adventurous few who would see Winchelsea must walk up to it; and on a sunny day that is not much hardship. The road winding like a long bright-coloured serpent across the marshy level, its track marked out by stunted pollards, has a singular effect; so quiet the plain around, so silent the town-crowned hill in front, approaching it seems like walking in a dream, or like entering the charmed city of which one reads in fairy tales. Suddenly rising from the surrounding level is seen the rock on which Winchelsea is built; the present Winchelsea: the old town lies below, near Camber Castle, and was finally submerged in the year 1287. In 1250, thirty-seven years previously, the devastation had commenced, and the inhabitants then petitioned the King, Edward I., to grant them a fresh site on which to erect a new town, the present Winchelsea. Its Latin name is said to have been *Frigimarevici*, which in Saxon reads *Wind—ehils—sea*; "and well," says Jaako, "might the old town deserve that name, standing in a low plain open both to the winds and sea." Like its neighbour Rye, it has suffered much, as has been said, from the incursions of the French and Spaniards; the last attack by the French was in 1449. Formerly, the principal trade of the town was in French wines, and, consequently, nearly all the houses have spacious cellars beneath them in which to store them; but all this has long since passed away. John Evelyn, writing in 1652, says—"The sea, which formerly rendered it a rich and commodious port, has now forsaken it." Strange to say, the corporate seal of the town bears a monkish distich, which at this time reads like a prophecy; after calling upon the inhabitants to do honour to their patron saints, Giles and Thomas, it continues—"lest, occupying like birds a lofty position, you should be abandoned by the river, the source of your wealth."

Proceeding to Winchelsea by rail, the road leads up the steep side of the hill, and is embowered in trees. The first object of interest that attracts attention, is the old Land-gate, rebuilt in 1404 or 1405, and bearing the inscription, in Old English characters, of the (supposed) mayor's name, J. Hald, and, above, a shield with a squirrel's *esjant*. Passing through this gateway, and turning to the right, a marvellous picture presents itself. Two exquisite arches, shown of their tracery, but filled in with azure other, in lieu of glass: two symmetrical gables, and a third crowned with an execrable clock-tower, which beneficent Nature is fast screening from sight.—the low sun giving depth of colour to the myriad-leaved ivy that literally covers the building; and the full blue Italian-looking sky above and around,—form it: and those who have thus first beheld Winchelsea Church will surely never forget it.

The present edifice, though but the chance of the original building, is very spacious, and of grand proportions. It was commenced about 1288, and dedicated to St. Thomas the Martyr. The style is Early Decorated. There are lofty clustered columns, with small intermediary shafts and connecting bands of Sussex marble: and large window arches, filled in with tracery, somewhat Continental in its character, and having a traceried panel on each side, which give them increased richness. The hood-mould of the inner, or escotillon arch, extends past the small marble column at the edge of the window jamb, and is terminated with another small column, so as to include a space of the wall on each side of the window, and form a panel, at the top of which a traceried head is introduced. These windows; magnificent sedilia, formed of acute arches, wrought into lacelike tracery with finials above, and foliated and cusped below, the wall at the back covered with hold, rich diapering; the piscina, with its carved basin and shelf; and the superb monuments in the north and south aisle, crowd together such wealth of beauty as to be positively oppressive.

The south aisle, appropriated by Mr. Durrant Cooper to the Alard Chantry, forms a side chapel, with piscina. The monuments it is useless to attempt to describe in a short notice like the present. They are magnificent, and must be seen to be appreciated. One of them has been cast in plaster for the Crystal Palace. They are said to have been all bricked up for many years, which would account for the comparatively small amount of mutilation they have suffered; nevertheless, the figures from the niches, the cusplings of the foliations, and many other crowning touches, are missing. The back of the principal monuments is diapered like the sedilia, and the whole work is so exactly similar in feeling and execution, that it must have been completed about the same time. The hold ense in the

flowing lines of the carved foliage is very admirable. The figures, life size, are of Purbeck marble. Mr. Durrant Cooper says the Alard Chantry "was founded in 1312, by Stephen Alard, son of Nicholas Alard and Isabel his wife, and, in 1321, captain and admiral of the Cinque Ports, and of the king's western fleet." The wall of the vestry is built up just in the centre of one of the monuments, and conceals half of the figure, a female, from sight. Another monument is enclosed in the vestry, and can only be seen by standing on a chair and peering over the wooden partition, or by walking across the graves outside and looking in through the window. The effect of the grand old tomb shut up alone, so silent and solitary, with the calm light of the setting sun sleeping on its carved stonework, is very impressive.

The present font is a modern abomination; the old one is stowed away with other rubbish; but from what little could be seen and felt of it, it appears to have been adorned with a delicate tracery of interlaced Gothic arches.

On the floor of the principal chancel is a large stoupe slab, containing the matrix of what must have been a most elegant brass, a foliated cross with a small figure in the centre. The inscription bordering the slab is in Norman French,—"*Reynaud Alard, Qi mouret le 15 d'April l'an M.CCC.III. gist ici. Dieu de s'ame et merci. Qi por sa alme priera, L jours de pardon avera.*" The stone was moved to its present position in 1809, probably when the font was fixed, and when taken up there were found beneath it a common glass bottle and the bones.

Within the last nine or ten years some judicious alterations have been made in the interior of the church, under the care of the Messrs. Smith, of Rye. The flat plaster ceiling has been removed, and the open wooden roof displayed; the whitewash scraped from the monuments, the walls, and from some of the Purbeck columns, which last have been repolished. The floor of what is now the chancel has been relaid with glazed tiles by Minton, imitated from some few found in the church; and the altar-table enclosed with a low, semi-octagon screen, of pierced stone, in quatre-fols, surmounted by a narrow slab of polished Sussex marble: the gates are of the same materials, but are hung so true upon their hinges that,—although of course exceedingly heavy—they swing with as much ease as if made of wood. All the stone carving of the restorations is attributed to James Holt, son of the carver, who has worked with a most loving spirit, contenting himself with strictly imitating what he saw left behind by the master-workers who had preceded him. Even to a fraction of a leaf he has religiously preserved it, matching on his modern portion with all the skill of which he was capable; and though he has not always been able to attain to the same feeling of beautiful repose which pervades the old work, nor to such exact delicacy of execution, still great praise is due to him for the evident endeavour.

On the green sward outside, the walls of the old transepts can easily be traced. The nave is said to have extended to the wall of the present churchyard, and the ash-tree standing there was planted on the extreme site of its west end. Under this tree John Wesley preached his last sermon in the open air, October, 1799. He died early in the following year. The bell-tower of the church was standing in 1790; it was then pulled down, the foundations of the aisles were dug up, and all the stones sold to repair Rye harbour.

The exterior of the chancel is almost entirely clothed with ivy; but the noble transept windows, the slight, elegant buttresses of the chancel, and portions of its delicate, lace-like parapet, are still visible, and prove it to have been worthy of the beautiful interior we have been contemplating.

Enclosed in private grounds that adjoin the churchyard stand the ruins of the Grey Friars' Church; but they can be viewed only on a Monday.

The Court-house has some interesting little niches on what is now the outer wall; and in the wall of the house opposite, where the key of the church is kept, several carved stones have been built in; but no information could be obtained respecting them, and the person who had lived there twenty-two years had never even seen them till they were thus pointed out. From between the paving-stones laid down in front of the indoor, roots of grass spring thickly up, in spite of the endeavours of a youth with a large elapso-knife to eradicate them. *Sic transit!*

Passing out of Winchelsea through the Strand-gate,—still in pretty good preservation, and having the slide through which its portcullis was

raised almost perfect,—the pedestrian who would see Camber Castle must turn off to the right from the Rye-road and strike across the grass, following a very narrow, indistinct foot-track. The massive tower looks very solemn and impressive standing quite alone on the vast marshy desert, especially when seen at sunset, the slowly advancing gloaming creeping steadily on, enveloping all the distance in its mysterious shroud,—Winchelsea's pointed gables sharply cutting the reddish western sky,—in front, nought but the wide spreading flat, stretching right away to the foot of the steep hill on which Rye stands, her lights brightly twinkling afar off, and massive Camber Castle in the middle distance.

The castle was built by Henry VIII. in 1539, and 1540, as a defence to the coast against the threatened invasion of the Roman Catholic potentates. It is of brick cased with stone, and is thought to be erected on the site and with the materials of a more ancient fortification. It consists of a large circular centre tower or keep, with smaller towers, also circular, at the four angles of the surrounding wall. Covered passages, now underground, form a communication all round the keep, and, apparently, with the outer towers. The whole building is said to have been inclosed by a low battery, pierced with openings for firing through, but nothing of that is now to be seen above the sward.

Queen Elizabeth visited Winchelsea in 1573. In 1584 an order of council directed the repair of the castles and forts on the sea-coast, and in it "Cambre" Castle is mentioned as requiring £141. 13s. 4d.

Among the papers in the Town Hall of Rye are several letters from the Queen, directed to the Mayor of Winchelsea and Rye, and her Captain of Camber Castle.

#### CHURCH-BUILDING NEWS.

**Lincoln.**—The important work of restoring and cleansing the grand west front of Lincoln Cathedral has been brought to a close for the present season. It is anticipated, according to the local *Chronicle*, that five years will elapse before the task will be finished. A large portion of the lead roofing of the nave has been removed, and is being replaced with new.

**Yarmouth.**—St. Andrew's (Wherryman's) Church, Yarmouth, has been consecrated. The edifice is in the Early English style. It will accommodate 400 adults, besides children. The organ, which, for its size, is of a fine tone, was the gift of Miss Burdett Coutts. The stone pulpit, carved, is the gift of another lady, as also is the lectern. The architect was Mr. C. E. Giles, of London; and Mr. Stanley, of Yarmouth, contracted for the building at 1,050*l.* There are additional buildings yet to be erected, schools, &c., and more ground is required, to meet the cost of which 1,000*l.* more will be necessary.

**Bowdon (Cheshire).**—The parish church has been restored. Speaking generally, the characteristics of the old church have been preserved. The new building is of the Perpendicular style of the fifteenth century. North and south transepts, each 13 feet 9 inches by 20 feet, are added, as is also a north porch: an additional length of 21 feet is also given to the chancel. The tower has been rebuilt, and the total height is 95 feet apart from the pinnacles. The length of the church, from the inner line of the tower to the chancel window, is 130 feet: the nave is 20 feet 1 inch wide; the arched walls marking the side aisles, 2 feet 6 inches thick; the north aisle 19 feet wide, and the south, 17 feet 10 inches. The height of nave and aisles has been increased several feet. The nave had an old tie-beam roof: the timbers from it have been converted into those for a hammer-beam arched principal roof, with tracery filling the spandrels, and also with pendants, stone corbels, &c. The ceiling is panelled, with bosses at the intersections, and closely boarded. The chancel roof has arched principals, with king-posts, &c. The north aisle roof, which was restored some forty years ago, has been retained. The total number of sittings is 1,164, of which 100 are set apart for children. The exterior is constructed of Runcorn red sandstone; the interior work of stone from Lymm. Instead of pews, open seats have been substituted. The church is lighted with gasaliers. The whole of the windows are ornamented with stained glass; and in the chancel there is a memorial stained-glass window, representing the Crucifixion, erected by Alderman Neild to the memory of his deceased wife. This and the other stained-glass windows are by Mr. Chatterluck, of London. A

stained-glass window in the south of the chancel is also a memorial erection by Mr. Nicholls, of Altrincham. Two large windows in the transepts are to be thus decorated. The tower window is the memorial gift of Mr. Clegg. The ordinary windows have diapered quarries and stained ornamental margins, and were manufactured by Messrs. Edmundson & Son, of Manchester. The restoration has been carried out from the designs of Mr. W. H. Brakspear, of London, architect; and the general contract has been executed by Mr. Samuel Delves, of Altrincham. The entire restoration is said to have cost £2,000.

**Swanwick (Derbyshire).**—The church of Swanwick has been consecrated. The edifice is situated on half an acre of ground at the angle of the roads leading from Derby to Alfreton and from Swanwick to Greenhill-lane. It is of the Decorated Gothic style, and consists of nave, 61 feet long by 24 feet wide; a chancel, 99 feet long and 19 feet wide, with north and south aisles, of about the same length as the nave, and 13 feet wide. The nave is divided into four bays, on each side supported by octagonal columns with equilateral pointed arches. The chancel arch is 40 feet in height. At the east end of the chancel, and occupying nearly the whole of the wall, is a three-light window, and on the north and south sides are two-light windows. At the west end and over the chancel arch is a triangular window filled with tracery. The sides of the church are lighted by four windows on each side of the aisles, and one four-light window over the principal entrance at the west end, all of varied design and tracery. The whole of the roofs are of stained deal open framing, with ironwork shown in relief with light line and gill. Upon the outside, above the west window, is a small Decorated stone turret, with the cornice preventing the erection of a tower or spire. The sittings are open, made of pitch pine, stained and varnished, and will accommodate about 450 persons, about 100 being set apart for the school children. The floor, together with the aisles, is boarded. The church will be lighted by gas-pendants, descending from the centre of the principals, and terminating in gilt stars, the shafts being of a bright blue. The acoustic properties of the building are said to be satisfactory. The church is built of stone from Amber-lane quarries, above, and the works have been executed by Mr. Josh. Evans, builder, at a cost, including the fence walls, of 2,300*l.*, from the designs, selected from four invited competitors, of Mr. Benjamin Wilson, architect, Derby; and the whole of the works have been executed under that gentleman's superintendence. By the great fall of the ground from west to east, a large room was secured underneath the chancel, having boarded floor and three large windows filled with tracery. The church is dedicated to St. Andrew.

**Knowle (Warwickshire).**—The parish church of Knowle, which had been closed since Easter for the purpose of restoring the interior, has been reopened. The old high-backed pews are replaced by open seats with stall ends, in Riga oak, many of them carved from designs by Mr. Nevill, of Coventry. The walls have been scraped and cleaned, and the carved screen repaired. The floor has been paved with Milton tiles, and other improvements have also been effected. By the new arrangement, 180 sittings for the poor are obtained. The cost of the alteration is about 1,000*l.*

**Hulme.**—St. Philip's new church has been opened. It is built of Peol stone, in the Geometric style, from designs by Messrs. Sheppard & Brown, architects, Manchester. It consists of a nave with side aisles, and a chancel with a north side aisle. On the south side of the chancel are the organ chamber and vestry. The tower, with a spire, stands at the corner, and fronts both Chester and Newcastle-street, and by its breadth the north aisle of the nave is shorter than that of the south side. A porch entrance gives ingress from Newcastle-street; while, from Chester-street, the entrance is through the lower part of the tower. The chancel aisle is also entered from Chester-street. The total length of the chancel, laterally, is 117 feet 10 inches; the width, 10 feet 2 inches. From the floor to the ridge of the roof of the nave the height is 54 feet. The tower, with its spire, is 155 feet 3 inches high. The whole of the seats are open in a double sense, to sit all, and unumbered with doors; while space in the nave are partitioned off like arm-chairs, to prevent crowding. There is accommodation for 670 adults. The principal front of the church is that in Chester-street. It is divided into five bays, with a three-light pointed tracery window in each, while five similar windows, rather

smaller, are placed in the clerestory above. The chancel aisle is in two bays, each of which contains a four-light pointed tracery window. There is a four-light pointed tracery window in the end of the nave, next to Newcastle-street; and over the altar, in the chancel, a pointed tracery five-light window. The tracery of the windows is varied. The tower is a conspicuous object, being built in four stages, the two upper ones areaded and pinnacled, with pointed belfry windows; and each angle is finished by enriched pinnacles. The spire is in three heights of incarnes. The tower contains a peal of eight bells, cast by Messrs. Taylor & Son, of Loughborough. The stained-glass windows are the production of Messrs. R. B. Edmundson & Son, of Manchester. The aisles are separated from the nave by six pointed arches on the south side and five on the north side. The chancel has an arcade of two pointed arches on the south side, separating it from the aisle, and one on the north side for the organ chamber. The chancel, nave, and aisles are paved with Messrs. Maw & Co.'s red and black ornamental tiles. The roof is open timbered, stained and varnished, to correspond with the seats. The roof is covered with Westmoreland slates. An illuminated clock is placed in the tower. The organ, constructed by Messrs. Eccleston & Bowes, of Manchester, is nearly finished. The cost of the church is about 8,000*l.*, exclusive of the land. Messrs. Ellis & Hinchliff executed the brick and masons' work; Messrs. Bowden, Edwards, & Forster, the joiners' work; and Messrs. Thompson & Co., of Birmingham, put up the gas fittings, which are of Gothic design. The church is heated by hot air, on the plan of Messrs. Haden, of Trowbridge. A parsonage-house is being built on the south side of the chancel, fronting Newcastle-street. It is in the Elizabethan style. The cost of the parsonage will be about 1,700*l.* The schools cost about 3,000*l.*

**Blackburn.**—The first stone of a new church at Bottom gate has been laid. The design, furnished by Mr. Paley, of Lancaster, contemplates sittings for 766 persons on the ground-floor, including children, and the estimated cost of erection is 3,000*l.* A suite of schools also is contemplated.

**Charnock Richard (Lancashire).**—A church has recently been erected at Charnock Richard, mainly through the instrumentality of Mr. James Darlington, and on 21st September it was consecrated. The church is capable of accommodating about 450, and is situated a little off the high road from Wigan to Preston, and about four miles from Chorley, the nearest market-town. It is built of freestone. The architecture is Pointed Gothic. Mr. Darlington has provided for the whole cost of its erection and endowment, excepting a grant of 200*l.* from the Manchester Diocesan Society, and 150*l.* from the Incorporated Society.

**Shipley.**—The Congregationalists of the parish of Claverley have purchased a plot of land at the Hill End, Shipley, for the purpose of building a chapel thereon. The site is being prepared for the building, which will be 38 feet long, and 22 feet in width, and a vestry will be attached. It will likewise have a bell turret and bell. Accommodation will be provided in the chapel for about 160 persons, and the roof will be open timbered. Mr. G. Bidlake is the architect, and Mr. Burkitt the contractor. The latter has undertaken to execute the work at a cost of 310*l.*

**Barmby Dun.**—The *Doncaster Gazette* states that the chancel, tower, and nave of Barmby Dun Church will undergo a restoration. The cost of the chancel repairs will be sustained by Mr. Newsome, of Barmby Dun, the patron of the living. The arch is to be taken down to the foundation and rebuilt, and a new altar and rails will be introduced, and other minor additions, so as to render this part of the edifice in harmony with its sacred character. The church is to be entirely re-roofed; and the tower floor, which is slightly higher than the rest, will be lowered.

SCHOOL-BUILDING NEWS.

**Morton (Gloucestershire).**—The school, including master's house, in this village, has just been completed. The builder was Mr. Thomas Eyles, of Old Sodbury; and the architect, Mr. Philip Boyce.

**Disis (Norfolk).**—A mixed school is about to be erected at Disis Haywood, a hamlet of Disis, from the designs of Mr. R. M. Phipson, architect. The walls will be built of rubble, with stone windows and quoins. The style will be Early Decorated, partaking somewhat of the character of a small collegiate chapel, as one of the objects for which it will be built is to enable the Rev. C. R. Man-

ning, the rector, to hold service in it on Sunday evenings, as the inhabitants of this part of the parish are upwards of two miles from the church.

**Holbrook (Stafford).**—Through the efforts of the rector, the Rev. C. F. Child, and of the Rev. J. B. Wilkinson, who once held the living, two new schools have during the present year been erected in this village. One is a small mixed school, with class-room and porch, and is situated at the extreme end of the parish. It is so planned as to be convenient for service, which is conducted by one of the curates every Sunday evening. The exterior is red brick, the bond being Flemish, and every header a grey brick. The other school is being built in the centre of the parish, and consists of a boys', girls', and infants' school, with class-rooms attached to each, and a comfortable master's residence. Upwards of 200 children can with convenience be taught in this school. The style is Early Gothic, with bands of red, grey, and white brickwork, the vousoirs of the arches being relieved in the same manner. The schools have open trussed rafter roofs, and are covered with green and purple slates, in bands. The Rev. J. B. Wilkinson gave the site, including upwards of two acres of play-ground attached. The cost of the small school was 250*l.*, and the large one about 1,100*l.* Both were erected from the designs of Mr. R. W. Phipson, the builder of the former being Mr. Cornish, of Ipswich; and of the latter, Mr. Hunt, of Preston, Staffol.

STAINED GLASS.

**St. Paul's, Shipley.**—About two years ago more than one half of the east window of this church, a window of large dimensions, was filled with stained glass; and the original design has just been completed by the filling in of the remaining lights. The subject of the window is a series of full-length figures of the twelve apostles, with our Lord and St. Paul occupying the central lights, the whole number of principal lights being fourteen. Each apostle is represented as bearing his appropriate symbol. The whole of the figures are placed within enriched canopies, and are draped in diapered garments of varied colours. Beneath the upper division of the apostles is a series of medallions, representing scenes in our Lord's history;—the Angel appearing to Mary; the Birth of Christ; the Presentation in the Temple; the Flight into Egypt; Jesus in the midst of the Doctors; the Burial of Jesus. Above and below five of these medallions are legends, setting forth the donors, and the persons to whose memories they, along with the lights above, have been erected. The tracery in the head of the window is filled with the evangelistic symbols, the Resurrection, the Ascension, the Pelican with its Young, the Lamb and ribbons. The treatment of the glass is in the Perpendicular style. It is the work of Mr. F. Barnett, late of York, and now of Edinburgh. The entire cost is said to have been about 300*l.*

PROVINCIAL NEWS.

**Cambridge.**—The materials of the houses and other buildings, required to be taken down before the works for the new Townhall can be proceeded with, have been sold in lots, as follows:—

- 1. Mr. Lyon, chemist .....£181
- 2. Mr. Harvey, builder ..... 42
- 3. Mr. James Fletcher, bricklayer... 39
- 4. .... 39
- 5. Mr. Harvey ..... 37

Making a total of .....£285

The purchasers, according to the *Cambridge Chronicle*, have had notice to proceed to take the buildings down as speedily as possible.

**Liverpool and Birkenhead.**—The Liverpool Town Council has again postponed the consideration of the town improvement scheme, involving an outlay of 300,000*l.* At the last monthly meeting of the Council, one or two other matters of interest were discussed. A report was presented by a sub-committee with reference to the formation of street railways in the town. It was recommended that rails should be laid down on the plan of Mr. Newlands, the borough engineer, at the expense of the Council; that the use of the rails should be thrown open to the public; and that application should be made to Parliament for power to control the traffic on the proposed lines. The report was adopted. The foundation-stone of new iron works has been laid on the margin of the Great Flint, Birkenhead. The establishment, which is intended to be a very complete one, is to be called the Britannia Ironworks. At the usual weekly meeting of the Mersey Dock Board,

the proceedings of the works committee comprised the recommendation to erect staircases, with pipes and hydrants, at each end of the warehouses at Stanley Dock, at a cost of about 1,000*l.*; and to accept the tender of Messrs. Jones & Jump for roof and sliding doors to the Victoria Shed, Birkenhead, at a cost of 7,000*l.* The committee had ordered the engineer to survey the ground and prepare a plan for the erection of a shed near the Haskisson and Canada Docks, for the use of labourers employed at the timber yards. Mr. Brocklebank said it was impossible to put tanks on the tops of the warehouses; but the committee had under consideration the propriety of placing tanks over each staircase, and which tanks would hold 10,000 gallons of water each, and cost 450*l.* a piece. By putting a staircase at each end of the warehouse it would enable persons, in case of fire, to get to each floor, which was not the case before; so that, a fire taking place in any floor of the warehouse, persons would be at once able to communicate with the hydrants on the staircases.

**Manchester.**—It appears from official tables prepared by Mr. Francis, the city surveyor, that in the township of Manchester, during the year ending June 24, 1860, there were 2½ streets completed, their length being 1,554 yards, the surface paved and flagged being 11,697 yards, while 1,255 yards of main sewers, and 527 yards of cross sewers and eyes were put down; the cost of all these works (2,775*l.*) having been defrayed by the owners of property. Since 1830, there have been executed, at owners' cost, in 1,066 streets, measuring 60 miles 218 yards,—57 miles 153 yards of main, and 21 miles 1,589 yards of cross sewers; the total surface paved and flagged being 197 acres 4,350 yards. Courts and passages in the township to the number of 367 (45 during the past year) have had 9 miles 904 yards of main, and 6 miles 1,615 yards of cross sewers put down; the surface flagged and paved being 7 acres 233 yards. These works have, of course, been done at the expense of owners, as have also 13 miles 60 yards of private drains; the former being executed since 1830, the latter since 1849. The main sewers made at the cost of the township fund since 1830 are more than 22 miles long, and the cross sewers amount to 74 miles. 12,299 syphon traps have been laid in streets, courts, yards, and houses, the number last year being 971. Since 1830 the sewerage constructed measures 137½ miles (in the township alone), nearly 80 miles of that length being main, and 49 miles cross sewers and eyes. The total cost of paving and sewerage during the 30 years has been 311,623*l.*; the area of the work being 960,100 yards.

**Shotley Bridge.**—The contracts for the Town Hall have been let to Mr. Hessel, of South Shields, for the mason work, and Messrs. Muse & Co., of Shotley Bridge, for the remainder of the work, except the slating, which has been let to Mr. Robert Preston, of Sunderland. Messrs. Oliver & Lamb are the architects.

#### THE ELECTRIC LIGHT.

THE tall pyramidal scaffoldings erected at different points within Paris for the triangulation of this capital with its recent additions, having been found to oscillate to and fro from the constant traffic through the streets by day, it has been at length resolved to proceed with the triangulation at night, by means of the electric light; and experiments are to be made with the light itself, in order to discover some convenient means of applying it to the lighting of streets.—Professor Way, says the *Critic*, has discovered an electric light far superior to any yet known. It is produced by the action of a voltaic battery on a moving column of mercury. The mercury is contained in a crystal globe, of the size of an orange, and is sent from a very minute hole, under the form of a thin metallic thread; it is received in a small cup, whence it falls into a basin below, to be again conveyed to the globe above. No sooner are the wires of the battery in contact with the thread of mercury, than a vivid light is produced, which disappears as soon as the contact is interrupted. During this process no evaporation of the mercury is observable.—The old oil lights which have been in use so many years on the Portland lighthouses will shortly be discontinued, says the *Southern Times*, the electric light being its substitute, the Board of Trade considering the Portland lights of so much consequence to ships going down or coming up Channel, these having to pass in close proximity to that dangerous place the Portland Race. By referring to page 318 of the *Builder*, of May 19th, the reader will find a description of the electric light, from the pen of Dr. Faraday.—There will shortly be established at the Bill of Portland a

station for the purpose of telegraphing to ships, and *vice versa*, on their way up and down Channel. The electric wire will be laid from the station to join the Channel Islands Telegraph. The *Southern Times* says it will be a great boon to the owners of ships homeward bound, as they will receive intelligence of the arrival of their vessels much sooner than they have hitherto done?

#### THE RESTORATION OF MONUMENTS.

**Sir.**—Touching the remarks made at the Northampton Architectural Society's meeting on the 11th ult. by Sir Henry Dryden, on Restoration, he could not have weakened his objections more than by instancing the Elgin Marbles; as, firstly, their present isolated position precludes the necessity of restoring them; and secondly, if *in situ*, and restoration were required, I contend that the hardness of the material would, of itself, preclude, under ordinary hands, the possibility of converting these exquisite marbles "into little more than old lime." The same cry was raised in the case of the Templars, of Parbeck marble, but which I found in almost every instance far too hard a material to tamper with or re-surface; and in the numerous restorations of ancient statuary existing in the Italian museums, the additions are generally clearly marked, but upon which the most able sculptors were engaged. I contend that restorations of monuments (including the Royal Tombs, for which funds have been voted) in judicious hands are imperatively called for, notwithstanding the virulent tirades of such objectors as Sir Henry Dryden and others I could name.

EDWARD RICHARDSON.

#### RAILWAY EXTRAVAGANCE.

THE NORTH-WESTERN RAILWAY COMPANY.

**Sir.**—They are pulling to pieces the really pretty little [70 feet span, 30 feet wide] suspension bridge across the Paddington Canal and over the West London Railway Gallery under the Canal, at Wormwood Scrubs; and they seem to be making preparation for replacing it by one of their vilely ugly cast-iron beam-troughs; thus adding insult to injury. Can you not learn what pretext they have for this? Is it merely another freak of this ill-advised board? The only pretence that I can imagine for the change is, that the Canal Company is now so humbled that it submits to a headway of 8 or 9 feet instead of the 13 feet that the original engineer was compelled to give. But if it be even so, and they want to diminish the rise for the carriage-road from the level of the Scrubs, the roadway of the bridge might have been lowered by doing little more than lengthening the suspending rods, and thereby letting the floor down the difference. Pray ask the malfactors what they are about, and why. They have given a specimen of their beam-trough, or what they stupidly call "girder-bridge," in the means by which the West London Railway is for the future to pass up and down from the London and North-Western Railway north of the Canal and the Scrubs. It may be worth noticing, too, in the history of railways, that the inclination, or "grade," as the Yankees call it, of the new embankment to that trough bridge over the Canal cannot be much less steep than one in fifty or sixty at the utmost, whereas the late Stephenson's *circa* 1838, — formally reported to the board of the then Birmingham, Bristol, and Thames Junction — now the West London — that the gradient of 1 in 120 from road in the Uxbridge-road up to the crossing of the Great Western could never be worked by the locomotive engine! The suspension bridge and its conjuncts are shown in Weale's "Public Works of Great Britain, 1838," and there is in the George III. Museum at King's College a model of the group, by Salter, made at the time it was built, 1839.

SHAREHOLDER.

#### CONTROLLING CLOCKS BY GALVANIC CURRENTS.

"THE electric clock is now an old invention, but has not come into use." Such is the remark appended by you to a letter on the subject of electric clocks in your number of September the 22nd. Allow me to remark that working and regulating clocks by electricity is like most other inventions—progressive, and there have been abundant reasons for early attempts being failures, and for their having been abandoned. But there is now a method of controlling clocks by electricity which has been in use for four years, and which has not failed. The best description of it is in a

paper which was written by Mr. Hartnup, the astronomer, and director of the Liverpool Observatory, and was read at the Dublin meeting of the British Association.

I may add that the system has been extended in Liverpool; other public clocks there are regulated, and a time-ball is dropped, by its means. It is in use in the Royal Observatory, Greenwich; that of the Cape of Good Hope, and in other places; but especially I would call attention to the clock on the roof of the Magnetic Telegraph Company's Offices, Threadneedle-street, and to a small clock in their public room, which are controlled upon the same principle. The officers of that establishment will be happy to show the clocks to any person really interested in the matter, and I can engage that any clock, old or new, large or small, shall be kept in time with any other clock within the smallest possible fraction of a second.

R. L. JONES.

\*\* The method which was devised by Mr. Jones himself is thus described in Mr. Hartnup's paper—

"The clock in its present state, with the improvements which have been made, differs in respect from an ordinary old turret clock, except that the pendulum-hub is a hollow electro-magnetic coil, which passes around permanent magnets at each oscillation. At each transmission of a current from our normal clock at the Observatory, the coil itself becomes a magnet, and the attraction, or repulsion, between it and the permanent magnets, prevents the pendulum from oscillating, except in strict conformity with the pendulum at the Observatory."

#### SUBWAYS FOR GAS AND WATER MAINS. REGENT STREET, &c.

In an article under this head inserted in the *Builder* of last week, it is stated that the loss of gas in the passage from the works to the various points of consumption was 22 per cent. on the entire manufacture. The authority for the statement is an admission made by the chairman of the Chartered Gas Company on the occasion of a conference with the St. James's Vestry on the 13th ult., and hence its accuracy is undoubted, so far at least as relates to that particular company's works, and probably near the truth as respects other manufactories.

Professor Spencer's report to the New River Water-works Company, on the corrosion of iron mains from the effects of gas leakage, reveals an important matter on this subject, and really serious as affecting the public. Basing his calculations on a gas waste of 20 per cent. (a standard somewhat below the fact, as seen by the above admission), after making a fair allowance for probable waste from other causes than that of leakage,—such, for instance, as defective meterage, condensation, &c.,—he estimates the actual amount of loss from leakage through the joints of the gas mains at 630,000,000 cubic feet per annum, all of which is absorbed into the earth, imparting to the subsoil of the streets the blackened appearance and odour so familiar to the in-dwellers of the metropolis.

As respects the more immediate object of his employment in this instance, viz., the cause of the premature decay of the iron mains that takes place in some of the denser parts of the metropolis, Professor Spencer—by careful observation, and a series of experiments conducted through a period of three years—arrives at the conclusion that such decay is caused by the gas that is always escaping from the joints of the gas mains, not directly by the action of the gas itself—for alone this is harmless in this way on the iron—but by an acid alkaline fluid, a sort of distillation, as it were, from the gas-charged earth, by means of moisture from the rain-fall; which fluid, coming in contact with the metal of the pipes, produces profuse corrosion, having the effect of converting the iron, in a shorter or longer period, into a sort of plumbo. Numerous specimens of decayed pipeage turned up during the progress of the inquiry, showing the action of this destructive agent, so rapid in certain spots where more than usual gas escape had been going on, as to effect that transition in the short space of from seven to ten years; the ordinary serviceable duration of iron similarly employed in earth in its natural state being about a century.

As respects the injuries sustained by the public from the chronic escape of gas, Professor Spencer affirms, first, that the gas-saturated earth, in combination with certain other chemical properties which the London street subsoil imbibes from other causes, gives out a sulphurous gaseous matter, which, inhaled, is highly prejudicial to health; and it is observed that, when it is taken

into account that each cubic foot of this enormous quantity of gas, which is continuously passing into the street ether, contains something like one-fifth of a grain of sulphur of carbon, and one-twentieth of a grain of ammonia, it becomes surprising that the effects, bad as they are, are not more sensibly felt. 2ndly. That the gas-mains and water-mains usually lying side by side, the escaped gas from the former will frequently enter the water-mains at their joints; and at times, when the water but partially fills the pipes, a large quantity of gas in this way gets admitted, and, mingling with the water, imparts to it that nauseous quality so frequently complained of. And hence, too, the cause of the not unfrequent occurrence of partial explosions by the ignition of gas from the presence of a lighted candle on the opening of the water-tap. 3rdly. That the mud banks, the sewage deposits on the tidal banks of the Thames within London, derive their peculiar fetid and blackened character from the action of gas leakage on the oxide of the corroded street mains, which finds its way by numerous channels into the sewers, and is thence carried to the river, where, retained in the sewage mud, it becomes the direct agent of the too well-known noxious odour the Thames water evolves in the summer months of June and July, when the temperature ranges above 70 degrees Fahrenheit.

The properly constructed accessible *sub-way*, for the "common" conveyance of the mains through at least the greater trunk lines of the metropolis, offers the medium of extensive mitigation of all these evils, since the facility for a system of daily inspection and immediate repair would admit of the maintenance of the mains gas-tight and water-tight, as in ordinary house fittings.

F. C.

ST. HELEN'S, LANCASHIRE.

THREE fountains are now erected in this town; two by Mr. Charles Bishop, flint-glass manufacturer; and one by Mr. John Ansdell, solicitor, both of St. Helen's. Very little taste has been exhibited in making the designs; one being an upright cast-iron plate, resembling a head-stone, relieved, but not improved, by a lion's head in the centre, vomiting the water people are to drink; another is a cast-iron basin, resting on a pedestal of the same material, with a jet *deux* in the centre; the third is partly composed of granite, partly surrounded by a brick wall, on which is placed a very heavy stone coping, which gives it a more expensive than elegant appearance.

St. Helen's is about to distinguish itself in another branch of sanitary reform, viz., by the construction of baths; Mr. G. A. Kurtz, manufacturing chemist, having taken the initiative in this very desirable undertaking, by the purchase of about 1,500 superficial yards of land close to the works. One swimming-bath, covering an area of about 180 superficial yards, with a suitable number of private baths, is to be proceeded with immediately; the remaining portion of the land to be similarly appropriated, as the demand for baths increases.

In few towns of the same population are baths so very much needed as in St. Helen's, three-fourths of the working population being engaged in works of a dusty nature, viz., chemical works, coal-mines, glass-works, copper-works, foundries, &c. Co-operative stores and shop, with residence for the superintendent of baths, are to be erected on the land fronting the baths.

The drawings have been prepared by Mr. Owen Duffy, the manager of Mr. Kurtz's works.

A Roman Catholic church is also in course of erection, on land given by the trustees of the late Mr. W. P. Cothran. The building will be Gothic: its length inside will be 104 feet; narrowest width, 60 feet; and will cost upwards of 10,000. The quoins, window-frames, and dressed work, are of red sandstone: the stone for walling is from Rainford, about four miles from St. Helen's. The architect is Mr. Scoles, of London; contractor, Mr. John Middlehurst, of St. Helen's. M. J.

GAS.—The *Wenchesbury Record* says:—"Mr. Hewitt, of Worcester, the architect of the works now in progress in this town for the 'Patent Inexpensive Hosiery Company,' has made an offer to the Gas Company to supply them with gas and deliver it into their mains at 3s. 6d. per 1,000 ft. Mr. Hewitt, we believe, is now engaged in the construction of gas works and in laying down mains for Malvern Link; he is, therefore, perfectly competent to fulfil his offer, which of course would not have been made had he been sure of realizing a fair profit by it."

RECENT PATENTS CONNECTED WITH BUILDING.

STOVES.—*W. Woodcock*, Beshorough-gardens, Pimlico. Dated 17th February, 1860.—The patentee claims the combination of an open fireplace with its open bright hearth, and having a descending flue and perforated back, with a close stove or pipe furnished with ribs, and enclosed in an air chamber, as described.

WINDOW SASHES, &c.—*J. Brown*, Norwich, Norfolk. Dated 20th March, 1860.—The beads or moulded stops connected with the sill and the top of the outer casing are bevelled, as also the lower rail of the bottom sash and the top rail of the upper sash. The bottom rail of the lower meeting rails and styles of the same, are all formed with a groove or grooves for the reception of a stuffing or packing of cloth or other suitable textile fabric or leather. The sashes should fit loosely except at the wedged portions of the bottom rail of the lower and top rail of the upper sash, so as to guard the packing from great friction. When, however, the two sashes are fastened by a screw, bolt, or other sash fastening, the packing surfaces are brought into contact with the respective parts opposed to them, and an air, dust, and water tight window sash is the result. For doors and French casements the patentee forms the related portions of the junks and inner heads on the same for hanging, with a water groove to the outer head. He forms a water bar and iron plate as projecting surfaces on the doors or casements, and he makes the grooves for the reception of the packing on the outer side of the bottom rails next to the water bar, as well as on the sides and head of the frame or jambs. The invention is applicable to old as well as to new sashes, frames, and doors, and the packing may be inserted in grooves made in the sashes, frames, and doors, or they may be inserted in beads or strips of wood which may be slidden in grooves formed for their reception in the sashes, frames, and doors.

WINDOW SASHES.—*W. E. Newton*, Chancery-lane, London. A communication. Dated 5th March, 1860.—This invention consists in arranging the sash on a slide or slides, which move up and down in suitable grooves in the frame, and to which slides the sash is attached by means of pivots, in such a manner that they can be turned clearly round, or nearly so, and that the outside of the sash can be conveniently reached. At the same time both sashes are allowed to be turned edgewise, whereby nearly the whole space of the frame is thrown open to admit of taking in and out such articles as cannot conveniently be brought up and down through the house, and also to admit fresh air, and cause a thorough ventilation.

MOWINGS FOR WINDOW BLINDS.—*J. M. and W. C. Bryden*, Edinburgh. Dated 29th February, 1860.—These improvements have reference to the details by which the lowering or descent is regulated by Venetian blinds, or of other blinds which lower by their own weight, or by the action of springs. The movement by which the pawl or ratchet catch holding the roller is released, is made to press a link or frictional appliance against the roller, and this regulates the descent. In one modification of the apparatus, the ratchet wheel is carried by one end of a lever, to the other end of which a cord is attached, the downward pull of this cord releasing the catch. The lever is formed with an inclined projection, which, on the lever being pulled down, presses a friction or brake-piece against the roller, or against the metal cap fixed upon its end.

Books Received.

*On the Eucæstic and Zopissa of the Ancients in general, and on its (sic) Application to Architecture and Shipbuilding in particular.*

UNDER this title a pamphlet has been recently published by Mr. Szerelmy, whose operations on some parts of the Houses of Parliament have been noticed by us. As Mr. Szerelmy possessed the confidence of the late Sir Charles Barry, and his method is alluded to favourably by Professor Faraday and Sir R. Murchison, we are bound to suppose that it is of some value; but we think we have a right to expect that one who claims our confidence in such a matter, and with such support, should not, when he addresses us, imitate the style and manner of a quack doctor, as seems to be the case in the pamphlet before us. Of fourteen pages forming the pamphlet, we find one half devoted to an account from which it appears

that neither the author nor any one else knows anything about eucæstic, and then he jumps at once to the conclusion that a composition to which the writer has given the name *Zopissa* (an unknown preparation of the ancients), is "the best preservative for buildings of every kind which are exposed to humidity whatever be the cause." From the rest of the pamphlet it is intended that we shall deduce that this same *Zopissa* is to supersede all paint, tar, red lead, tallow, oil, and copper sheeting, and be applied to every part of every construction inside and out, whether house, palace, or ship, bridge, railway, water-tank, or gas-pipe.

We shall be very glad to find, as regards stone, that the practice of Mr. Szerelmy, in preserving it from decay, is something better than the idea he entertains as to the causes of decay. With regard to the latter we are informed, that by exposure stone becomes less dense, and, being less dense, becomes more absorbent. We are also told that in London the atmosphere is saturated to excess with sulphuric acid, and the action of change of temperature is to increase the natural tendency of the particles of stone to separate or disintegrate by this alternate expansion and contraction.

We need scarcely refer to chemical authorities to expose the absurdities quoted above; but, when we find an experience of twenty-five years referred to, I think we have a right to ask for some proof. We find none whatever mentioned in the pamphlet beyond a statement that the preparation has been used on several public buildings, most of which are quite modern, while some are not yet completed.

Mr. Szerelmy has, we know, patented certain inventions for preserving stone and coating metals, but not only are these different from each other, but he has expressly declared that the method he adopts for the stonework of the Houses of Parliament is not patented. It is also certain that the methods adopted there have involved the necessity of frequent repetition; and, from recent observation, we are scarcely made certain that the desired object is accomplished.

The subject is one of great importance. It is clear that something must be done to preserve the decaying stone of many of our public buildings, and we ought by all means to try and obtain the best method, whatever that may be. But we should either be able to place reasonable confidence in the science of the inventor of a secret process, or we should demand proof of success. In the case before us the former is so manifestly doubtful, that we must look narrowly at the nature of the proof by actual experience.

If Mr. Szerelmy can convince us that he has for the last twenty-five years, or even half that time, been in possession of a method of preserving stone, and has actually applied it fairly in some place where it has stood the test of exposure to English weather for several winters, let him point to the specimen, and prove his case. We shall all be only too willing to listen to and employ him, and we will promise to say nothing about his chemistry. But if during all this time he has only been trying a series of experiments connected with some vague and fancied recovery of a preparation used by the ancients, the public money ought not to be fooled away in keeping up a system of deception supported by pretended erudition.

Miscellaneous.

MELTON MOWBRAY SURVEYORSHIP.—On Wednesday, the 10th, Mr. John Watson, M.L.B.A., was elected surveyor to the Local Board of Melton Mowbray.

ARCHITECTURE IN HIGH PLACES.—One of the young princes of the House of Orleans has entered his name as a pupil in the fine art course of lectures on Architecture, at University College, London. It would be well if he saw like earnestness to become acquainted with our art among our own scions of royalty and nobility. We might then hope for architecture as it ought to be.

SCAFFOLDING.—Mr. C. Thomas has put together a scaffold of some magnitude, to be used for decorations at Eastnor Castle, near Malvern, for Earl Somers. It is fastened together with bolts and screws, similar to bed-screws, and works on castors; its construction is so simple, that three men would lower the whole in one day. The standards drop into two wrought-iron sockets, and rest on a cast-iron bracket; they are then bolted together by a screw bolt and plate-nut, the material being so very light that the solidity of the scaffold, when put together, was more than he anticipated.

**ELECTRO-TELEGRAPHIC PROGRESS.**—Dr. L. Bradley, of New York, has invented a plan, says the *London American*, by which he can transmit 15,000 words per hour, using the signs constituting the Morse alphabet: this is at the rate of four words per second, the highest number reached by the ordinary method of operating being only thirty-three words per minute. He has discovered a relay magnet capable of acting at the rate of 10,000 words per hour.

**FARMS.**—The farm occupied by Mr. Proctor, at Walls-court, near Bristol, has become well known to the agricultural public in consequence of the high degree of fertility to which it has been raised by the present occupant; and the readers of the *Builder* will probably remember the plans and views which have already been given in our pages. We regret to hear that the illness of Mr. Proctor renders it compulsory that he should immediately give up the occupation of this estate, and that he will have to pass into other hands one of the most luxuriant grass farms in the West of England. The selection of a successor will devolve upon the agent of the Duke of Beaufort, who will doubtless look rather to character and merit than to other claims.

**CAUTION TO WORKMEN.**—James Jennings, Bernard Kelly, and David McDermott, riveters, recently in the employment of Messrs. Palmer, Brothers, of Jarrow, were brought before the South Shields magistrates, on Tuesday, having been apprehended at Hartlepool on a warrant, charged with leaving their employment without giving a week's notice. It seems that there had been a strike at Hartlepool, and the men had come across and found employment at Messrs. Palmer's. The strike, however, had been subsequently arranged, and, lest their places in the shop where they were originally employed should be filled up, they had gone off from Jarrow without giving the usual notice; indeed, without staying to receive the money they had worked for. They were sent fourteen days each to goal, and the money owing them was ordered to be applied to the expense of their apprehension and costs of the court.

**ROYAL ENGLISH OPERA, COVENT GARDEN.**—Mr. Wallace's "Lurline," as produced by Miss Pym and Mr. Harrison, has taken its place as one of the best works of the English school. The scenery has been strengthened since last season, and there is a change in the cast, not in all respects for the better. Mr. Wharton and Miss Leffler are, nevertheless, both promising accessions. Miss Leffler, who comes to us with the name of an old servant of the public, has been drilled both in the Academy and Mr. Leslie's choir: she must, nevertheless, consider that her musical and dramatic education are but beginning,—strive to feel what she sings and express what she feels,—and a good future is before her. Miss Pym is singing very finely. "Dinorah" was given on Thursday evening, and the "Frovatore" is on the bills; but if Mr. Harrison would hold his own against opposition he must try for something fresh, and doubtless will do so.

**METROPOLITAN TRAMWAYS: MARYLEBONE.**—The experiment at Westminster is to be seconded by one in Marylebone, the vestry having agreed with their committee's recommendation to allow Mr. Train to lay his tramways down on a route indicated, on his undertaking to remove them and relay the street should the vestry require him to do so. Since this permission has been granted a further proposal has been made by Mr. Train for laying down his tramways through or across a number of streets, including Edgware-road, Oxford-street, Regent-street, and many others. These new proposals have been referred by the vestry to the same committee who reported favourably on the preceding proposal. The General Omnibus Company attempted to obtain a delay of a fortnight before the first proposal was agreed to, but failed; and, considering the monopolizing disposition and the past history of this company, such a result is not to be regretted. The tramways to be laid down will be too broad for general use by ordinary omnibuses, cabs, or waggon, but, except to this extent, the lay down will have no monopoly of their use, so that the General Omnibus Company or any other may build omnibuses wide enough for the tramways and run them upon the lines laid down. Moreover, should the system prove a nuisance in crowded streets, the whole can and will be cleared away in a very short time, and it remains to be seen, however, whether such tramways will not diminish instead of increase the nuisance of street-crowding and obstruction. One large omnibus where two smaller ones now run is likely, one would think, to be less of a nuisance than the two which it will replace.

**MAGAZINE, WOOLWICH.**—Mr. W. Higgs denies that a magazine under construction in Woolwich Marsh has settled. Our informant repeats his statement, and sends us the *Wolverhampton Chronicle* of October 3rd, containing a paragraph to the same effect. We are quite willing, however, to take Mr. Higgs's assurance.

**SHAKESPEARE MEMORIAL IN MELBOURNE.**—The Shakspeare Memorial Committee have resolved to place the selection of the design for the memorial proposed to be erected in Melbourne in the hands of a committee of taste, composed of Messrs. Thomas Carlyle and John Ruskin, and Sir Charles Eastlake, and through them to invite six of the most eminent English sculptors to send in designs. All artists in Victoria will receive a similar invitation. With the committee of taste a business committee will be associated.—*Melbourne Argus.*

TENDERS

For additions to warehouse, Cannon-street, for Messrs. Morgan. Mr. T. C. Clarke, architect:—  
Foster ..... £1,430 0 0  
Putnam & Fisherburgam ..... 1,240 0 0  
Lawrence & Sons ..... 1,180 0 0

For the East London Catholic Cemetery, Low Leyton, Essex. Messrs. Bulson & Nicholls, architects:—  
Smith ..... £5,155 10 0  
Bird ..... 5,145 0 0  
Rivett ..... 4,905 0 0  
Coxell ..... 4,735 0 0  
Hill (accepted) ..... 4,608 0 0

For a parsonage-house, at Agar town, King's-cross; Mr. S. S. Tendon, architect. Quantities supplied by Mr. Giffen:

Brown & Robinson ..... £2,150 0 0  
Myers ..... 2,150 0 0  
Mansfield & Son ..... 2,100 0 0  
Ferry ..... 1,675 0 0  
Child, Son, & Martin ..... 1,025 0 0

For the erection of a villa residence, in the Bath-road, Reading, for Mr. G. Harris, Messrs. Cooper & Goulding, architects, Reading. Quantities supplied by the architects:—

Jackson ..... £2,400 0 0  
Woodroffe ..... 2,400 0 0  
Ogden & Child ..... 2,100 0 0  
Matthews ..... 2,027 0 0  
Wells ..... 1,980 0 0

For works required to be done on the estate of "The Northampton Town and County Freehold Land Society," Kingsthorpe-road, Northampton; Mr. A. Milne, architect:—

**Roadmaking, Culterberg, &c.**  
Ireson ..... £890 0 0  
Cosford (accepted) ..... 890 0 0

**York Paving, &c.**  
Cosford ..... £880 0 0  
Ireson (accepted) ..... 875 0 0

**Dwarf Walls, Coping, &c.**  
Birchall & Son ..... £568 6 0  
Ireson ..... 472 0 0  
Cosford (accepted) ..... 464 0 0

**Stoneasons' Work.**  
Slaymaker ..... £1,460 18 11  
Birchall & Son ..... 1,240 0 0  
Ireson ..... 1,050 0 0  
Cosford (accepted) ..... 945 0 0

For the completion of three pairs of villas, at Dovercourt, near Harwich, the property of Messrs. Henry Lee & Son; Mr. W. Moxon, London, surveyor to the estate:—  
Hun ..... £2,521 0 0  
Newton ..... 2,458 0 0  
Newrick & Morley ..... 2,340 0 0  
Wilding ..... 2,303 0 0  
Orpitt ..... 2,255 0 0  
Ladd ..... 2,167 0 0  
Ply & Kerrot ..... 1,955 0 0

For works at Kettering Cemetery; Mr. R. W. Johnson, architect:—  
**For Chapels, Tower and Spire, and Entrance Lodge.**  
Boddington ..... £2,375 0 0  
Henson ..... 1,610 0 0

**For Fence Wall, Iron Pulteney, Entrance Gates, &c.**  
Boddington ..... £495 0 0  
Henson ..... 477 0 0

**For Draining Works, Making Roads, &c.**  
Sharon ..... £630 0 0  
Beate ..... 525 13 0  
Freeman ..... 422 10 0  
Strickston ..... 410 10 0  
Boddington ..... 365 0 0

For alterations and additions to two houses, Sydenham, for Mr. J. Curtis; Mr. C. H. Badger, architect:—  
Little ..... £240 0 0  
Amer ..... 169 0 0  
Adams ..... 155 0 0  
Barnet ..... 149 0 0  
Pearson ..... 135 0 0  
Pawsey ..... 135 0 0  
Hooker (accepted) ..... 114 0 0

For rebuilding house and shop, No. 29, Bishopsgate-street Without, for Mr. William Mann; Mr. William Ellis, architect. Quantities supplied:—  
Wilson ..... £2,475 0 0  
Piper & Son ..... 2,454 0 0  
Hack & Son ..... 2,421 0 0  
Ashby & Son ..... 2,413 0 0  
Jeffrey ..... 2,359 0 0  
Watts ..... 2,330 0 0  
Wood ..... 2,300 0 0  
Brass ..... 2,279 0 0

For enlarging Brook-street Chapel, Tottenham; Mr. D. Campbell, architect:—  
Lawrence ..... £76 10 0  
Humphreys ..... £300 0 0  
Clarke (accepted) ..... 250 0 0  
Williams (not properly filled in).

For building a Baptist Chapel and School, &c., at Lower Edmonton; Mr. D. Campbell, architect:—  
Chapel. Fences. Schools and Vestries.  
Harridge ..... £755 0 0 ..... £47 10 0  
Lawrence ..... 755 10 0 ..... 45 0 0  
Williams (accepted) 749 0 0 ..... 13 0 0 ..... £238 0 0

TO CORRESPONDENTS.

P. B.—D. & W.—R. C.—J. M.—"Get Fortuna Domus."—W. W. T.—A. M. & S. W. Inquire (the proper allowance must of course be made for the deviation of the compass).—Nonsensical queries (apply to the Public Architectural Works, or Skinner & Co. Stockton-on-Tees).—J. A. C. P. can be published with his name; not without.—T. D. D.—A. Bunker (Broadstairs, &c. styled, in Street; Harriet Keyne).—W. T. G.—W. D. Manley (*vous ne pouvez pas satisfaire votre correspondance*).—Volunteer Clerk of Works (we are sorry to decline supplying to such inquiries. Answer, however, would depend on circumstances not stated).—J. H. (although you have many years before the public both here and abroad).—J. M. H.—W. E. (yes).—F. G.—Mr. H.—A.—W.—R.

**NOTICE.**—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent-garden. All other Communications should be addressed to the "Editor," and not to the "Publisher." Post-office Orders and Remittances should be made payable to Mr. Morris T. Coleman.

ADVERTISEMENTS.

**MR. WILLIAM ELLISON,** CONSULTING SURVEYOR, late of STAINES ROAD, Has taken Office at 13, FENCHURCH LANE, LONDON, EC4, near the Old Bailey, and at 10, BISHOPSGATE STREET, E.C. Where he continues to advise BUILDERS on ERRANDS OF CONTRACT, DISPUTED ACCOUNTS, &c.

**ARCHITECTURAL ASSISTANCE.**—A Every description of Architectural Drawings, Plans, Elevations, and Sections prepared, and Perspectives Outlined, Etched, or Coloured, by Mr. T. T. MARLTON, Junr., also, Duplication of Treatises of Engineering and Drawing, Survey, &c.—Address, No. 1, MARK LANE, Great James-street, Bedford-row, W.C. Office hours, Ten to Four.

**TO ARCHITECTS AND OTHERS.**—Consultation, Working, and Detail DRAWINGS, Speculative SKETCHES, PERSPECTIVES in Outline, Colour, or Etching, from plans or sketches, SHEDS, LEVINGS, LANS, &c. OUT ESTATES, and all descriptions of Professional Assistance RENDERED.—Apply to R. BASSITT KEEBLING, 3, Upper-terrace, Edington, N.—City Office, 25, Old-street, Lincoln's Inn-church.

**CARPENTERS WANTED.**—Several experienced MEN, Only those who are acquainted with short turn work will be considered.—Apply to Messrs. HARRISON, CLARKS PATENT REVOLVING SHUTTER WORKS, 1, Old-street, Lincoln's Inn-church.

**MODELLE WANTED,** for Classical and Gothic Work. None need apply unless thoroughly acquainted with all kinds of modelling, and where last employed, to PHOENIX IRON WORKS, Doncaster.

**PRESS TOOL MAKER WANTED,** one who thoroughly understands the making of all kinds of patterns, where last employed, and how long, to PHOENIX IRON WORKS, Doncaster.

**REQUIRED, a CLERK OF WORKS.**—By Salary, 3l. per week; by letter only, addressed to Mr. A. J. Jernyn, near London, to arrive FRIDAY, the 21st inst. stating age, references, and qualifications.

**SUSSEX LUNATIC ASYLUM, Hayward's Road.**—WANTED, a WORKING ENGINEER, to take charge of the water and gas supply, and of the erecting of the ASYLUM. Previous experience in a county asylum preferred. Wages, 50s. a week, with free house, coal, gas, and water.—Apply to Mr. EDWARD SON, at the Asylum, enclosing copies of testimonials, and stating age, condition, and previous experience. Also a HOUSE PORTER WANTED—a single man and a non-communicated officer preferred. Wages 30s. and 15s.

**WANTED, in a Builder's Yard, in Fenny Stratford, Town, a good LATH CLEARER,** to make laths, keep annual accounts, and make himself useful in the business of the yard. With a satisfactory character, if approved of, the man may then have constant employment.—Send particulars to A. B. Mr. Berry, Printer and Stationer, 26, St. James's-street, Brighton.

**TO WHITESMITHS.** WANTED, a FIREMAN and FITTER, accustomed to General Jobbing House Work, Constant employment.—Apply by letter to NUNN & SON, Hertford.

**WANTED, a GENTLEMAN,** having the command of from 1,000 to 2,000, and some knowledge of drawing and book-keeping, to conduct the London Trade of an established high class Pottery Business. The amount advanced will be secured.—Address, T. C. care of Messrs. Robertson & White, Accountants, 4, Prince-street, Bank, E.C.

**WANTED, an experienced GAS-FITTER and BRASS-FINISHER.** None need apply who cannot give satisfactory references.—Apply by letter to ALBERTSON & SHEWSEBURY, Hastings.

**TO TOWN SURVEYORS.** WANTED, immediately, a good TOWN SURVEYOR. He must be expert in the field, and a good plotter and draughtsman, and capable of using the theodolite.—Applicants, enclosing copies of testimonials, stating experience and salary required, to be made to X. Y. Z. Posters Hotel, London.

**WANTED, a SITUATION in a Builder's Office,** by a Young Man, aged 31, who understands copying and making original drawings, taking out quantities, and making estimates, and has had a long and successful career. He has passed the Government School of Art examination; has also had good practice in joinery, and would have no objection, when his business was short, to work at the 24th years of the trade.—Address, D. C. Flying Post Office, Rochester.

# The Builder.

VOL. XVIII.—No. 925.

Renovations and Spoliations in Hexham Abbey Church.

NE of the monks of Hexham Abbey, writing the Saxon history of the church, said there was nothing to compare to it on this side of the Alps. It was the fifth church that was built of stone in England, and was curiously and cunningly contrived throughout its foundations, with subterranean chapels and winding galleries. The statement of the incomparable excellence of the building might be ascribed to monkish exaggeration, but for the description of the peculiarities of the foundations proving to be correct. To this day the Saxon crypt, as built by the founder, Wilfred, in the seventh century, is one of the marvels of the county.

It differs from Norman and later crypts, inasmuch as it consists of several oratories and small chapels, branching out from one of large dimensions, in which there are the marks of an altar at the east end, a stone bracket, and three niches in the walls. Three winding passages in different directions form approaches to these lonely and dark cells. Another piece of corroborative evidence has been fortunately preserved in the Saxon Frid-stool, or seat of Sanctuary, from which to pluck a fugitive was to incur excommunication; and the presence of riches and honours in Saxon times was brought even more vividly to conviction, when the sexton, in 1853, dug up a large bronze vessel full of some thousands of Saxon Stycas, bearing dates of the eighth and ninth centuries.

The Saxon founder of Hexham Abbey, Wilfred, was created bishop, but was not permitted by the monarchs of those days to perform the duties of his office in peace. When his power was at its height, when he was served from vessels of gold, when the sons of princes and nobles were honoured by his notice and instructions, an attempt was made to wrest part of his episcopal privileges from him. Finding all appeal useless, he proceeded to Rome to lay his case before the pontifical chair. The pope decided in his favour; as he did a second time, a few years afterwards, when Wilfred again journeyed to Rome for redress. It was probably his familiarity with the arts in vogue beyond the Alps, that led to the splendour that was exhibited in the adornment of Hexham Church; a surmise borne out by the old chroniclers, who affirm that the artists employed upon the structure came from Rome.

After the lapse of a century and a half, the bishopric was merged, with that of Lindisfarne, into the see of Durham. Thus denuded of some part of its importance, it fell a prey to the rapacity of the Danes, who were, in the Saxon times, the scourge that the Scots were to the northern ecclesiastical edifices in the Middle Ages—they destroyed both church and monastery. Scornful of the memory of the Venerable Bede, who was first ordained deacon, and afterwards invested with the full order of priesthood within these walls,—unmindful of the memory of Aeca, the second bishop, to whom one of the extant epistles of Bede is addressed, and who enriched the monastery with a noble library, and with relics of the Apostles and Martyrs, collected at great cost, and who was, besides, "a heavenly singer," and one of the earliest encouragers of church

music,—regardless of the sanctity of St. Cuthbert, who was, some time, bishop of Hexham,—careless of the many miracles that were reported to be performed at the different shrines, the structure was razed to the ground.

For two centuries the site remained a heap of ruins piled upon the subterranean chambers that thus escaped destruction. Then, when the Early English style was just beginning to prevail in its purest severity, the present building was erected, with all excellence of workmanship, in the form of a true cross; nave and choir being both 100 feet long, measuring from the point of intersection with the transepts. The tower, up to the parapets, was 100 feet high; and a hundred lancet windows lighted the edifice. The transepts measure 157 feet, and are 66 feet high. The details present the same consummate elegance, lightness, and variety, the same arcadings of lancets alternating with panels, enriched with clustered columns, the same ornamental carvings in the spandrels, as are found at the nine altars in Durham Cathedral, and in the priory churches of Brinkburn, Lanercost, and Tynemouth. The triforium is surmounted by an unusually rich and imposing clerestory of arcades resting upon arcades of clustered columns, through which runs a continuous passage round the choir and transepts. Eight bells still hang in the tower, attuned to the nicest harmony, bearing dates and legends.

The second destruction of Hexham was effected by the Scots, who, in their ravaging marches between Carlisle and Newcastle, always found Hexham Abbey a well-stored halting-place midway. In 1296, they pillaged the monastery and set fire to the church, which last proceeding resulted in the utter annihilation of the nave—a loss that has never been restored. From that time the church has consisted of the choir and transepts only. The Scots, under King David, again visited Hexham, a few days before the battle of Neville's Cross. They failed not to leave a trail of desolation behind them as on every previous occasion. The battle of Hexham, between the White and Red Roses, which proved so fatal to the Lancastrian cause; and the romantic episode of Queen Margaret's flight with her youthful son, and guidance through the forests, and seclusion in caves by a loyal robber, are also circumstances which have invested Hexham with more than common interest.

In the period when the Perpendicular style prevailed a re-arrangement of the church was effected,—not a restoration; for, instead of rebuilding the burnt nave, a large Lady Chapel was thrown out from the east end. Between two of the arches of the choir a shrine to the memory of a member of the great Northumbrian family of Ogle—Robert Ogle—was erected, and a stone oratory was subsequently placed between corresponding arches on the opposite side, as a shrine for Prior Richard. A rood-screen, richly panelled, carved, and decorated with "the Dance of Death," and oak stalls, were among the minor features of these improvements. Throughout all these changes the Saxon stone Frid-stool, or Frithstool, was punctiliously kept near the altar, and, although in later times it has been occasionally shifted, still it has never been removed from the choir, until the alterations that have just been made; not even when, by a mutual arrangement, the inhabitants agreed to abandon the parish church, which was in great decay, and to maintain the abbey church in its place. Despite the usual rough usage consequent upon the introduction of large galleries, sash windows, and high pews, the features of the choir were not so much disturbed and spoliated by this parochial arrangement as they have been recently.

The restoration has been in contemplation for some years, and has now been carried out. The re-opening ceremony took place on the 10th instant, when the newly installed Bishop of Durham was the preacher. The first step towards its execution consisted in the purchase of several old houses that were built against the Lady chapel, and in their demolition. This proceeding disclosed the fact that the walls of this Perpendicular part of the building had been so cut into by the erection of these houses that it was considered advisable to take down

and erase all existence of this chapel. The scheme of restoration then resolved itself into the rebuilding of the east end. A plan at first, however, was prepared by a London architect, and approved, and contracts entered into, which converted the splendid ancient choir into a neat modern parish church, and has unfortunately resulted in the loss of the two shrines that occupied two such important places before. So little provision was made for their preservation that the beautiful Perpendicular wood screen-work of the Ogle shrine is broken up and scattered, and the altar picture is now in the possession of the joiner, being claimed by him as part of the *old materials* he was entitled to *per contract*. It is a choice specimen of fifteenth century painting upon panel, and represents, on a surface about 8 feet by 4 feet, in three compartments, the Virgin and Child, surrounded by a glory; our Saviour rising from the tomb, surrounded by clouds and stars; and St. John, also surrounded by a glory; the nimbi and ornaments being curiously raised in wax from the surface.

The stone shrine, reputed to be that of Prior Richard de Hexham, the historian of the abbey, has also been removed and re-set up, awkwardly, in the north transept; and at length, the Saxon stone Frid-stool, for so many centuries jealously kept near the altar, is removed to an unconsidered and unprotected place in the same transept. The ancient oak stalls have been plucked from their places by the rood-loft, and set up without their book-boards against the walls of the aisles; all to admit of the crowding of the new plain benches round the communion-table.

We are informed that a Newcastle architect is responsible for the new east end. We much regret that instead of taking as the theme for his composition the matchless design and details of the choir, or the very beautiful arrangement of the two rows of triple lancets, with panels between each lancet, existing in the north transept, as the basis for this restoration, he has inserted six unnecessarily wide lancets, with a profusion of clustered columns between each, unlike any thing in the church, composed from remains at Whitby with carvings from Stone Church, in Kent, and elsewhere.

The absence of proper historic and archaeological feeling in the working committee is apparent from the fact, among others, that no competent person has been placed, locally, in charge of the restoration. This absence of supervision has enabled the contractors to use considerable license. On the day we visited the church they were forming a large warm-air drain, 6 feet wide and 6 feet deep, and 120 feet long, through the length of the north transept; that is to say, making a cutting through layers upon layers of coffins and skeletons,—the burials of generations,—the fragments of which were being wheeled out openly to the church-yard; and to form a cover for this drain the contractors were using up fragments of Norman coffin-lids with zig-zag ornaments, and entire gravestones of more modern date, because the *scrtion thought the churchyard too full of them and wanted them put out of his way*. Many sculptured stones were lying about the churchyard, of a very interesting description from their early character and comprehensiveness, of which it would be a great pity to lose sight. For the sake of future reference, and to enable the public to keep an eye upon them, we here catalogue two large stone coffin-lids, with early floriated crosses, complete; six large stone coffin-lids, complete, with the simple legends—here Latin and there English—deeply incised in large Early English capitals, respectively thus:—

- \* JOHANNIS MALHERBE JACET HIC. \*
- \* HENRICUS DE WALTONA. \*
- \* ROBERT DE GISBURNE. \*
- \* ROBERTUS DE BEUDEDLDT. \*
- \* ROBERT DE KIRKBRIDE. \*
- \* HIC JACET RAD DE TALKAN CANOIC. \*
- \* JONES DE DALTONA. \*
- \* HIC JACET MATILDA UXOR LIFFI MENCENARN. \*

It is to be regretted that a person of antiquarian information, who, if we may judge from the carefully-written "Guide to the

Church," is not wanting, has not been deputed to watch proceedings of so much importance to historians and archaeologists. The lord of the manor and lay rector has given liberal aid to the extent of 5,000*l.* or more, towards the removal of the parasitical buildings and the renovation of the Abbey Church, which, we must repeat, might have been treated with more reverence for its historic antecedents.

There is a proposal to divide the diocese of Durham and form a bishopric of Northumberland, to which, it is said, the Ecclesiastical Commissioners are favourably inclined. Hexham having already been an episcopal seat, might properly take precedence of Newcastle, Alnwick, Morpeth, or other competing towns, and claim restitution of its privileges as a see. Consider, then, the magnitude of the opportunity that has been lost. If the money just expended upon unfitting the edifice for this probability had been employed upon seating the large area under the tower and transepts, the Abbey Church would have presented every condition requisite for the various solemnities and ordinances connected with episcopal duties. As it is, this space remains a vacant vestibule to the crowded choir. If it had been taken into consideration we should not have to deplore the transformation of the venerable choir into a closely-packed parish church, and the removal of historic memorials,—the Saxon Frid-stool, the Ogle and Prior Richard's shrines, and the canons' oaken stalls.

#### ON THE PROGRESS AND PRESENT ASPECT OF THE MOVEMENT FOR IMPROVING THE DWELLINGS OF THE LABOURING CLASSES.

The paper on this subject, briefly alluded to in our report of the Glasgow meeting for the Promotion of Social Science (October 6th), was drawn up for the Association by Mr. Henry Roberts, F.S.A., at the special request of the Standing Committee of the Social Economy Section. From the desire of serving a cause which is so much our own, we shall notice this paper more at length.

Forming a continuation of another paper, which was read by Mr. Roberts at the Liverpool meeting of the National Association, and which is given *in extenso* in the Transactions for 1858, this report, in connection with it, presents an historical sketch of the rise and progress of the movement to the present time; it notices all the legislative enactments bearing on the subject; the efforts of public bodies or associations, and of many individuals, as well as the extension of the movement in other countries. Regarded as a simple record, it will be useful for future reference; whilst, on one important point, that of financial returns, which were dwelt on at considerable length, the figures given will tend to remove misapprehensions, and to aid the cause by indicating the class of buildings, which experience has proved to be most remunerative. Moreover, in his introductory remarks, the writer said, that "as a faithful discharge of the duty which devolved on him would require, in some instances, the notice of discouraging circumstances, his aim would be to gather from them such practical lessons as may hereafter be of service in the management of other similar undertakings."

The only direct legislative measures to be recorded since 1858 have reference to Scotland and Ireland. The former is intended to facilitate the building of cottages on entailed estates, by enabling the proprietors to charge on the estate three-fourths the amount expended on such substantially built cottages. The measures relating to Ireland are also to facilitate the building of cottages; and under certain conditions, money granted by Government for the improvement of landed property may be so applied. Some amendment Acts with reference to England were pointed out, as granting powers which may possibly facilitate the compulsory improvement of low-classed dwellings; and it was remarked that, excepting within the City of London, and in the case of common lodging-houses, no power as yet has been granted which will effectually check that worst of all unwholesome influences—the evil of over-crowding.

Mr. Roberts stated that an effort had been made by the council of the National Association to secure, in connection with the Bill for taking the census, a return of reliable statistics as to the number of dwellings of various classes throughout the kingdom; of such information as led in 1851 to the fact being ascertained that in Ireland

there were then 135,589 *single-roomed* mud cabins, of which the proportions were given in each county. But notwithstanding that the unobjectionable character of the inquiry, and the ease with which it could be made, were fully admitted to a deputation which waited on the authorities at the Home Office, the application proved fruitless.

It was remarked that the bringing before the public such facts as that of the large number of single-roomed mud-cabins in Ireland, and the leaving them open to such searching comments as those of the Registrar-General, must arouse the attention of proprietors, and from a sense of shame and self-interest, if not from more worthy motives, lead many to improve the cottages on their estates. The hills relating to cottages in Ireland are evidence of this result; whilst the necessity for the desired general investigation may be proved by numerous confessions on the part of great proprietors, some of which, by his Grace the Duke of Buccleugh, were given, and summed up thus: "He had found on his own property in England cottages quite as bad as those in Scotland."

The vote in the last session of Parliament, of 30,000*l.* for providing suitable accommodation for married soldiers, recognizes the necessity for this much-required amelioration in barrack life.

After alluding to the benefits likely to result from the affording facilities for the adoption of well-arranged and economically-designed plans for labourers' dwellings, which may be useful, not only to landed proprietors, but also to the members of benefit building societies, reference was made to the importance of imparting, in connection with mechanics' institutions, sound views on the essentials of a healthy and convenient dwelling, as well as a knowledge of the modern domestic appliances conducive thereto. Reference was also made to the field occupied by the Ladies' Association for the Diffusion of Sanitary Knowledge, in the circulating information and the exercise of influence, by means of publications suited to various classes of society.

The great importance of the financial returns, and of strict accuracy in the accounts kept by societies engaged in providing improved dwellings for the working classes had led, at the late meeting of the International Statistical Congress, to a resolution recommending the general adoption of such a uniform system of accounts as will facilitate their examination, and the comparing, in this respect, the results obtained by different societies.

Various societies engaged in improving the dwellings of the labouring classes were then referred to, commencing with the Metropolis, in reference to which the writer said that the two leading and earliest-formed associations have not, since 1858, increased the number of their tenants nor their expenditure to any considerable extent; but as their financial results for some time have, during the past three or four years, had a discouraging effect on the movement, it may be of service to examine the cause. Numerous figures were given to render these financial results perfectly clear and unquestionable; but an abridgment is all we think necessary to show what the facts are.

The Metropolitan Association for Improving the Dwellings of the Industrious Classes has done nothing recently besides rebuilding eighteen of their old cottages, which accommodate thirty-three families. The arrangement adopted in fifteen of them is similar to some in the first range of model buildings at Bagnigge Wells, built by the Labourers' Friend Society, which provide for two families in each house, with entrances for the occupants of the first floor distinct from those of the ground floor. In the society's annual report for 1859, it is remarked, in reference to those dwellings, "although the cost of buildings of this description is less per room than the lofty blocks, where the dwellings are arranged in flats, this advantage is very materially lessened, if not altogether lost in the metropolis, on account of the high value of land, and the consequent high ground-rents which must be charged on the cottage buildings."

This Association within the fifteen years nearly expired since its buildings were commenced, has expended 89,613*l.* 14*s.* 10*d.* on ten district ranges of dwellings, which accommodate 114 families and 326 single men. The net returns for the last year from their *new* houses, occupied by families, is about 3*l.* per cent., and an expenditure of about 3,000*l.* on *old* dwellings, occupied by nineteen families, has yielded only 2*l.* per cent.

From two lodging-houses for single men, one a *new* building for 254 inmates, which cost 13,772*l.* 7*s.* 3*d.*, the net return was only

161*l.* 14*s.* 6*d.* The other, an *old* leasehold building with accommodation for 128, and on which 1,422*l.* 7*s.* 7*d.* was expended, there has been a clear loss of 139*l.* 19*s.* 7*d.*, besides interest on the outlay.

Owing to these last-named unfavourable results, the net return on the total outlay of the Association has been reduced to 3*l.* per cent., from which the office expenses of general management, and interest on preliminary expenses have to be deducted before the payment of a dividend to the shareholders. It is, however, satisfactory to notice an increase in the net returns for the last two, as compared with the previous years.

The Society for Improving the Condition of the Labouring Classes, or Labourers' Friend Society, after being actively engaged in the work from 1844, had, at the close of 1852, expended 35,187*l.* 13*s.* 3*d.* in the establishment of models for the improvement of labourers' dwellings, which in four distinct piles of *new* buildings, accommodate ninety-seven families in separate tenements, provide ninety-four rooms for single women, and lodging for 104 single men, as well as a public wash-house and baths. Besides which, lodgings for 158 single men are supplied in three distinct houses, formed out of renovated *old* buildings.

The average net return from these establishments, after deducting all current expenses and repairs, was, in 1852, 4 per cent. on the outlay, whilst some of them yielded a much higher rate. The houses for fifty-four families, in Streatham-street, yielded 5 per cent., and the renovated men's lodging-house in Charles-street, as much as 15 per cent., whilst the Thanksgiving-buildings in Portpool-lane, a very mixed and avowedly experimental establishment, returned not more than 2*l.* per cent. on the outlay.

The last annual Report of this Society, shows a considerable diminution in the average net return on the cost of the buildings possessed by the society at the close of 1859, being then only 2*l.* per cent. on the outlay.

The obvious tendency of such a retrograde movement, in regard to financial results, is to discourage similar efforts; it may, therefore, be useful to point out that this unsatisfactory issue has not arisen from any falling off in the occupation, or in the gross receipts at the houses; but in some degree from an increase in the current expenses, as well as the sale of one range of dwellings, and mainly from the small return on the outlay of 7,226*l.* 1*s.* 4*d.* in renovating three old courts, where, notwithstanding that the gross receipts for the year 1859, amounted to 1,619*l.* 9*s.* 3*d.*, the deductions for rent, taxes, current expenses, and repairs, were 1,574*l.* 9*s.* 1*d.*; leaving a net return of only 92*l.* 0*s.* 2*d.*, or 1*l.* per cent. on the outlay.

Mr. Roberts noticed that in the society's report for 1858, the following *allusion* was made to what had been done at the three old courts in question: "This work has been as economically as it has been thoroughly effected, and they wish their subscribers to know that they have adopted a plan wholly foreign to, and in fact the very converse of, the system formerly pursued by the society." "They have employed their own work-people, and purchased all their own materials." The change of system, he remarked, was made during his absence on the Continent, from 1853. That pursued prior thereto, when he acted as honorary architect to the society, was invariably to contract by competition.

The financial results of this experiment were dwelt upon chiefly on account of the hearing they have on the practicability of effecting, without further legislative enactment, any thing like a reformation in the domestic condition of tens of thousands of our population, who dwell, as was once said by the Earl of Shaftesbury, where "there is no such thing as a home, and the man who has a wife and children is not the head of a family, but the chief pig in a pig-stye."

After alluding to discussions in the public journals some years since on the question of building new houses, or renovating old ones, the writer said that in a letter to the *Times* he had then stated the result of his experience, and pointed out the difficulties in the metropolis arising out of the high price asked for old houses when they are *inquired after*, and referred to the opinion which he gave nearly eight years since on an examination of one of the three old courts in question.

\* The advantage of a fireproof construction was recently shown by the occurrence of a fire in one of the rooms of this building, occupied by an aged man, which was entirely confined to the woodwork about it, and easily extinguished.

Of the other societies in the metropolis, it would be satisfactory if he could report the same pecuniary results which have enabled the Strand Building Company to pay for the past half-year a dividend at the rate of 44 per cent. to their shareholders. The want of it has apparently prevented any increase in their numbers or any extension in their operations, although the growing necessity for them must be obvious from the constant increase in the population, as well as the want of any obligatory provision for those who are unhouse-d in consequence of the clearance of old dwellings in effecting public and other improvements. Whether the facilities for obtaining healthy dwellings out of town, by the introduction of railways to the very centre of the metropolis, will be such as to counterbalance the greatly-increased disadvantages under which they must labour in consequence of the further extensive destruction of low-classed property, is very problematical. As yet they have not thus been much used.

The operations of private individuals in the metropolis have, in regard to pecuniary results, proved more satisfactory and encouraging than those of associations. Reference was made particularly to those of Mr. Hilliard, a barrister, of Gray's-inn, in rebuilding near the Sadwell station, on the Blackwall Railway, an entire street of houses on the general plan of H.R.H. the Prince Consort's Exhibition houses, which provides for 112 families in blocks of four tenements each, and cost 487. per block, the total outlay being about 12,614. On the authority of the owner, it was stated that "they pay upwards of six, in fact nearly seven, per cent. as a net return on the investment, and are almost constantly let, and appreciated by the tenants." Each family has three rooms, and a wash-house or scullery.

A tabular statement was given to show the cost and rental, as well as the number of families provided for, and the current expenses, at each of the five piles of improved houses constructed by Mr. Newson, the builder, of Grosvenor-mews. Two of these blocks of houses are situated in Grosvenor-mews, parish of St. George, Hanover-square; one in Bull Head-court, King-street, Snow-hill; another is the Bull Inn Chambers, Holborn; and the fifth a small house in Grosvenor-market. The whole accommodate 125 families, and the total outlay, including builders' profit, was 12,200. The gross receipts were stated at 1,560., and the total outgoings, including ground-rent, repairs, and collecting, amounted to 829l. 11s. 3d., leaving a net return of about 5½ per cent. on the outlay, exclusive of any deduction for the redemption of leases. All of these buildings are arranged with open galleries, resembling in that respect the Streatham-street model houses, which renders them exempt from house-duties. Whilst in some details, it was remarked, that the arrangement of the houses might be improved, they present a very striking contrast to the dwellings mostly occupied by the working classes in London. Indeed, a greater boon could scarcely be conferred on large masses of the lower orders than a transformation in their dwellings similar to that effected by Mr. Newson in Bull Head-court, Smithfield, which in its former state must have been an embodiment of filth and wretchedness. Surely the construction of such houses as these ought to be encouraged by parochial authorities, as one of the surest means of diminishing the charges on a parish which ordinarily arise out of the sickness of the poor.

Messrs. Pickford & Co., the well-known carriers, established in 1854, at Camden Town, a lodging-house for the unmarried men in their employ, which accommodates sixty inmates. It was built originally for a public house, and on the refusal of a license was taken by them and fitted up at a total outlay of 452l. 8s. 2d. The return from a charge of 2s. 6d. per week, defrays all expenses and repairs as well as the interest on outlay, whilst the establishment of the house is stated by Messrs. Pickford to have led to a great improvement in the men as regards orderly conduct, cleanliness, &c.

Of the societies, about twenty in number, which have been established in various parts of England, besides those in the metropolis, Mr. Roberts said that the Windsor Royal Society has now 9,000. invested in newly-built cottages and two lodging-houses, the net return from which yield a dividend of 4 per cent. The Society at Ramsgate has divided 4 per cent. for the present year, which is an improvement on the last. That at Brighton is also improving financially, and its success as an independent enterprise was announced by the directors in June last with a dividend of 15s. per share. Its paid-up capital is about 6,000. The Red Hill and Reigate Cottage Improvement

Society has added twelve more to the nineteen cottages with which its operations commenced, having been encouraged to do so by the eagerness with which the first were occupied. The contract for those of the second series was at the rate of 120l. 7s. 1d. per cottage. A dividend of 5 per cent. has been paid to the shareholders, and 65l. 16s. 3d. added to the reserve fund. The Hastings Cottage Improvement Society, the capital of which now amounts to 10,400., has purchased and put into good condition fourteen ranges of old houses, in which there are dwellings for ninety-five families, and two lodging-houses. A dividend of 6 per cent. has been paid, and the reserve fund nearly reaches 200l. The only society established within the two past years, mentioned as having come to his knowledge, is that at Hertford, "for building and improving the dwellings of the working classes;" from which, it was remarked, much benefit may be anticipated to the neighbourhood, if the sound views enunciated by some of the managers be carried into practical operation.

As an instance of the recognition by those who have working people in their regular and exclusive employ, of an obligation to see that they are properly housed, the building by the Great Northern Railway Company of 160 cottages at their station called New England, near Peterborough, was mentioned, although this had avowedly been done from necessity. The average cost per house had been about 140l., and the return is about 6 per cent., from which the amount of repairs and depreciation have to be deducted. Without entirely approving the internal arrangement of some of these cottages, it may be said that the directors have rightly judged that the comfort and respectability of their men is of more importance to the company than the exact per-centage return.

Another field of action was alluded to, as greatly tending to the domiciliary improvement of the very poorest class in the metropolis. It is the Female Domestic Mission, which within the two past years has so extended its operations as now to count 130 agents, who are employed in a combined effort to promote the physical, the moral, and the spiritual well-being of the very lowest and most wretched of the population. As Bible collectors, they carry with them, and urge the adoption of, those sacred truths which are alike profitable to the body and to the soul; the further duty of each of these women, acting under the direction of a lady superintendent, is to inculcate, and by various ways to aid in the adoption of, those habits which, with the vast majority, are diametrically opposed to their prevalent customs and practices.

In connection with this work, the writer alluded to three recent publications, as giving many instructive illustrations of the domiciliary condition of the poor in the metropolis. Two of them are by ladies, "Ragged Homes, and how to Mend them," and "The Missing Link;" the other, known to our readers, "Town Swamps and Social Bridges."

In reference to the progress of this movement on the Continent, it was maintained that, however disproportionate the number of improved, or so-called model houses, are in London to the existing necessity, the disparaging comparison, in this respect, between our own metropolis and that of France, which had been made in a late number of the *Quarterly Review*, is not borne out by the facts, although in that country a large Government subvention had been granted. The *Cité Ouvrière*, at Mulhouse, was named as the most complete undertaking of the kind in France, where 480 houses have now been built by an association of manufacturers, and two-thirds of them sold to the occupants, whilst 90 more are in the course of construction; there being space for 800 in the whole.

The Berlin General Building Society, at its last meeting, presided over by his Royal Highness the Prince Frederick William, reported a paid-up capital equal to 34,655. sterling, and that it had dwellings for 219 families, with 31 workshops. The shareholders receive a dividend of 4 per cent., and the available addition to the reserve fund last year was about 3,195. sterling; one-half of which was, however, repaid to the tenants. A smaller society, called the "Alexandra Stiftung," by desire of one of its donors, the late Emperor of Russia, has a capital of about 21,338. sterling, arising from donations, and from loans at 4 per cent.

The most zealous promoter of a society lately formed at Frankfurt, Dr. Varrantrapp, has recently sought, through a personal examination, to profit by the experience gained in England, where this movement originated, adding thus another to

many previous instances in which the practical results arrived at with us have been studied for the benefit of other countries; and showing that, whether they be successful or discouraging, those results may have an influence far beyond the particular undertaking wherein they occur.

*Examples of Efforts in Scotland to provide Improved Dwellings for the Working Classes.*

A supplementary paper under the above title, which was read by Mr. Roberts, gave a general view of what has been done in Edinburgh, dwelling particularly on the first constructed range of model houses. It noticed also the model lodging-houses established in Dundee and Aberdeen, but assumed that local contributors would supply full information with regard to what has been done in Glasgow, and in the rural districts of Scotland. In reference to the latter field for exertion, it was remarked, that the society in Edinburgh for "Promoting Improvement in the Dwellings and Domestic Condition of Agricultural Labourers in Scotland," appears to merit more extensive support than it has hitherto received.

The "Miring Model Buildings, near Leith Walk, the first range of improved family houses for the working classes in Edinburgh, were commenced in 1850, by an association of gentlemen, amongst whom may be named the late Professor Alison, David Muir, esq. (late Lord Advocate), Robert Chambers, esq., and F. Brown Dongles, esq. (now Lord Provost). They consist of forty-four dwellings, in three blocks, two stories high, with double fronts or access on both sides, the tenements on the upper floor being approached from the opposite side to that on which the ground-floor tenements are entered. Two of the blocks are parallel, and the third flanks one end of the other two, ample space being left between them. A foot-path runs along each row of houses on both sides; every tenement has a front door of its own, and is self-contained. Each house has a small garden, or drying plot, opposite to its own entrance door. The number of apartments varies. No house has fewer than two; some have three, and the size of the rooms varies. Each house has, moreover, a scullery or washing-closet, and also (what is very rare in workmen's houses in Scotland), a water-closet. The houses are fitted up with gas as well as water, and they have permanent grates. The greatest economy consistent with fitness and durability, was maintained in the construction, so that the total cost of the forty-four houses, including drains, &c., was only 4,052l. 15s. 9d., being on an average about 92. per house, with scarcely any extras, greatly to the credit of the architect, Mr. Patrick Wilson. The annual rent of the whole is 303l. 19s., varying from 5l. 5s. per house, up to 9l. 15s., one half of them not exceeding 6l. 6s. per house. Higher rents might have been charged had not the committee desired to benefit a class of persons who could not afford to pay more. After deducting all expenses, fee duty, 22l. 11s. 10½d.; insurance, 5l. 12s. 6d.; rates and taxes, 13l. 11s. 2½d.; repairs, 13l. 1s. 7d. (the tenants being bound to keep their houses in good repair); management, 21l. 6s. 3d., and paying a dividend of 5 per cent. less income-tax, amounting to 196l. 16s. 6d., a balance of 30l. 13s. 1d. was last year added to the sinking fund, from which sundry expenses, such as painting and papering, are defrayed. This fund now amounts to about 150l.

The results of this scheme have been most encouraging. In general the demand for the houses has been at least six times equal to the supply. The rents are paid with great regularity, and the total sum lost through defaulters from the commencement, is under 5l. The Rev. W. G. Blaikie, one of the committee of management, bears a high testimony to the character of the occupants, whilst he contrasts his own sensations when visiting, as a clergyman, in places where it is a calamity to have the "smell of smell."

After combating the charge that "the most necessitous of the working classes are not benefited by such efforts as that described," and showing that it is the want of an adequate supply of such houses, which, in most of our thickly populated towns, forces so many working people into those miserable dwellings where they gradually sink in the scale of physical and moral position,—the writer remarked that his recent sojourn for a few days in the capital of Scotland, a city unrivalled for picturesque beauty, and remarkable for the classic elegance of so many of its modern buildings, had revealed to him what he had not seen in former visits, a degree and extent of wretchedness which has endeared more painful feelings than all that he had witnessed of a similar character during a long residence on the Continent. Even amidst the

misery and degradation which may be seen in the back slums of Paris, Genoa, Rome, and Naples, the vice of drunkenness rarely obtrudes itself, and is certainly, but in a very slight degree, as it is with us to a very considerable extent, both a cause and a consequence of the miserable state of the deus which so many human beings call their homes. Such a state of things is a reproach to our country, and to our Protestant Christianity, whilst it proves that those who have had the power to effect the needed change in regard to the dwellings of the working population have long forgotten their responsibility to Him who has said, "Thou shalt love thy neighbour as thyself," as well as ignored the lower motives which are dictated by self-interest and patriotism.

An act of Parliament was then noticed applicable only to Scotland, which was passed in 1855, whereby duly constituted improvement associations are empowered to obtain possession of buildings "faulty in their original construction, or fallen into a state of dilapidation, or being in a condition which may cause disease to the inhabitants, or the neighbourhood;" and it was added that the results of inquiries lead to the belief that the existence of such a power is not generally known.

The example given at the Pilrig buildings was repeated under the same architect, and on a plan similar, as to its leading features, in a range of thirty houses called Chalmers-buildings, belonging to Mr. Matheson; and in addition to these two ranges of improved family dwellings for working people the writer mentioned having seen in Edinburgh and its suburbs, eight other distinct blocks of houses for families either completed and occupied, or now in progress; three belonging to associations, and five to individuals, one of whom is a lady of property.

The first constructed of these are the Ashley-buildings, to the north of the Canongate, near to John Knox's house. There are thirty-nine tenements, approached by three staircases, and mostly let at a rent of 8*l.* per annum. In Blair-street a large building, formerly the office of the Queen's printers, has been subdivided into thirty-three tenements and fitted up with suitable conveniences at a cost of about 1,700*l.* The houses are all let, the loss from bad tenants does not exceed 5 per cent, and on the whole there is a fair return. To the south of the railway and east of the North-bridge, whence it appears to advantage, is a neat pile of brick houses recently built by Mr. Milne, a brass founder. They accommodate twenty-one families, whose apartments, consisting of two rooms each, with suitable fittings, are approached by an open staircase and an external gallery. In some of its features this pile of building resembles the Prince Consort's Exhibition model houses.

In a south-western suburb, at Rosebank, a range of thirty-six houses has been built by Mr. James Gowan, a railway contractor. They are disposed in three rows, with gardens and distinct access to the upper floor tenements; in that respect resembling the Pilrig buildings, but with projecting external stone staircases, which are no improvement. These houses are two highly rented to be within the means of ordinary working people. Close to them an association has very recently constructed an extensive range of ninety-six houses, called Rosemont Buildings. They are disposed on three stories, with open galleries towards an internal quadrangle, which they surround. In each corner is a stone fire-proof staircase, with a wash-house, &c. The quadrangle is arranged for a drying ground, subdivided into four compartments, and having a fountain in the centre. The rents vary from 6*l.* 10*s.* to 10*l.* 10*s.* per annum, according to the extent of accommodation, which mostly consist of three rooms with closets, &c. The total outlay is expected to be about 11,000*l.*

In Hamilton-place, Stockbridge, a range of houses, called Patriot Hall, is near completion. It will accommodate forty-two families, and is being built at the expense of Mr. Chyne, of Lisnore, in Argyleshire. These, as well as the last-named houses, are of red brick with white dressings. They are three stories in height, including the ground floor, and towards the front form the three sides of a quadrangle. There are three enclosed projecting stone staircases; one in the centre is the approach to two open galleries, extending on each side and giving access to twenty of the first and second floor tenements, all of which have an entrance lobby, a large living-room, with spacious recess for a bed; two bedrooms in the back (one of them full small), and a well-arranged water-closet, but no scullery; and a sink in the living-room, ample closet and separate washing accommodation are to be provided.

All the rooms are 9 feet high. The cost of the whole range of houses will be about 4,500*l.*, and the rents are to be about 10*l.* per annum. The general arrangement of these buildings, and their substantial yet economical construction, recommend them to notice; but, unquestionably, the impure stream which runs at their back should, for the health of the tenants, be either permanently cleansed or covered over.

Near to Holyrood Palace, at Abbey-hill, an extensive range of work-people's houses, designated Dr. Bigg's Buildings, has been constructed by Mr. Robert Cranston. They are five stories high, and, with an addition now in progress, will accommodate sixty families. There are three internal staircases, from which four sets of apartments open on each floor. They consist of two rooms only, are defective in some important conveniences, and the passages are very narrow. The rents are from 7*l.* to 7*l.* 10*s.* with extras. Near the end of Arthur-street, south of Holyrood Palace, a range of neat stone dwellings, called Dumbiedike House, is now in the course of construction by Mr. Hume, formerly a plumber. Three internal stone staircases give access to thirteen sets of work-people's houses. There are four rooms, including a scullery and a distinct water-closet to each tenement. In all essentials the accommodation is ample and well worthy of notice.

The fearfully wretched condition of the low-classed lodging-houses in Edinburgh long since led to the establishment of an association for their improvement. The first of their houses was opened at the West Port in 1844; that in Cowgate in 1847, and the Merchant-street house in 1849; the two former being for men, and the latter for married people with their young children, and for single women. The average accommodation in each of these establishments, which are known as the Victoria Lodging-houses, is for about seventy persons. The first-named yielded for twelve years an annual surplus of 327*l.* 2*s.*, after deducting interest on the outlay in fitting up, and the current expenses, taxes, &c. The second yielded for nine years an annual surplus of 83*l.*; and at the last-named there was, for seven years, an annual deficiency of 21*l.* 7*s.* Mr. Roberts said that he could with pleasure testify to the cleanliness and order exhibited in these houses at the present time, particularly in the Merchant-street house, which, in this respect, is quite a pattern for imitation. In the Grass Market another house has been fitted up for three classes of lodgers, by Dr. R. Foulis, a member of the same association.

The model lodging-houses at Dundee, which were referred to in a letter from Lord Kinnaird, quoted by Mr. Roberts in his paper of 1858, he now reported on, particularly as to their financial results. The Victoria Lodging-house for men, during the last year, supplied 28,251 nights' lodgings, and its financial prosperity is clearly shown by the balance of 224*l.* 14*s.* 3*d.*, shown in January, 1858, in favour of the house, after the first outlay had been paid; and the profits for the last two years have together exceeded 100*l.* It having been found desirable at different periods since the general enforcement of the Lodging-house Regulation Act to close two of the lodging-houses belonging to the association, the debt which had accrued on their account is nearly met by the profits of the Victoria House. In the large establishment for women in King-street, which accommodates nearly 300, the inmates at one time numbered 245, but, owing to the commercial crisis, there had been a temporary reduction to 180; and last year the number was only 191. Notwithstanding this, the receipts exceeded the expenditure by 14*l.* 8*s.* 2*d.*, and the cost of fitting and furnishing the house, which was 729*l.* 13*s.* 4*d.*, had, in January last, been reduced to 629*l.* 16*s.* 8*d.*, by the excess of receipts beyond the expenditure.

The model lodging-house opened by an association at Aberdeen, in 1849, was formed out of two old adjoining buildings, altered and fitted up for seventy-five inmates, at a cost of about 2500*l.* One of the houses is appropriated to married persons, and to unmarried females; the other to males, including sailors occasionally. The amount received annually for the last five years has averaged 193*l.* 10*s.*, and the expenses, including rent and repairs, have been about 173*l.* The profit in hand is now about 1000*l.*

The financial results which have enabled these associations either to repay out of profit the whole of their outlay, or to reduce it considerably, after paying interest on the capital, is a proof of good management, and may afford to some other societies an instructive lesson.

The writer, in conclusion, argued from the

testimony so universally borne to the very great improvement in ordinary lodging-houses since the establishment of model houses, and more especially since the enforcement of the Act for regulating common lodging-houses, that however difficult it may be, and requiring much consideration, the Legislature ought to enforce on the owners of all houses in towns, let to families in tenements at low rents their being in a healthy condition, and that there is no other means by which the much-needed improvement of the lowest class of such dwellings can be effected on a scale at all commensurate to the existing circumstances. He added that this is not an opinion hastily expressed, but the deliberate conviction resulting from more than fifteen years' observation and experience in the endeavour to advance that object.

#### HOSPITAL CONSTRUCTION.

The following is Dr. Combe's reply:—

Having read with much interest, attention, and, let me hope, profit, the remarks and criticisms in your leading article on Hospital Construction (*ante*, p. 649), there are two points on which it seems to me incumbent on me to ask the favour of being permitted to say a word or two; on one, because it involves a question of fact,—on the other, because you impute to me something very like ignorance on a subject with which I ought, at least, to be well acquainted.

Incidentally to the question of cost per bed, I had intimated the very latest projected hospital, and had remarked that the ground being comparatively worthless for building purposes, owing to the nature of the subsoil, the sum paid for the site of the intended hospital near Shooter's-hill can have made no great inroad on the total vote for it. As the sum paid is 3,700*l.* for more than eleven acres within eight miles of London and close to Blackheath, where house rent is so high, my remark seems to be justified. But you have been assured that the site "has not a clay sub-soil, but is geologically known as the Woolwich Pebble Bed, a mixture of shingle and loam resting on clay." Now, without entering into a description of the geological formation of the neighbourhood, or of the exact disposition of the so-called Woolwich Pebble Bed, the real fact of the matter, as affecting the one spot—Kidbrooke-common,—is that, last winter, it was treated at several points by professional borers, who found no thickness of loam and shingle greater than 3 feet, and then clay, all clay, and nothing but clay, to a depth of 50 feet, which was as far as they went. The hospital will, therefore, stand on a great bed of clay. But you say that, "to obviate any risk even of subsoil damp, the floors will be isolated by a basement above the level of the ground." Doubtless this will be done; but that is not the point. Why, if a clay soil causes a damp local climate, as we are taught to believe, and as the commonest observation shows to be the case, the hospital will be surrounded with a damp local climate. On the left of Kidbrooke-common is the slope which reaches from the Eltham-road to Severndroog Castle. In that direction there is nothing but clay till you reach the crown of Shooter's-hill. On the right there is clay, extending, in the direction of Blackheath, to the "Arnold's Farm Brick-field," and beyond it; in front there is the clay country which dips towards Footscray and Chislehurst; immediately in front there is a vast grate-way, the soil of which is all clay; in the rear there is clay until about the middle of Woolwich-common. I am only concerned, at present, with my own defence,—not with the question of the suitability of this site; otherwise there might be a good deal to say.

Let us pass to the other matter. You say that "Dr. Combe appears scarcely to have apprehended the idea of a general hospital," and that "there are general hospitals at this moment with fewer sick under one roof than Dr. Combe proposes to put in his." With respect to this latter paragraph, my allusion was pointedly made to Miss Nightingale's proposal to establish general hospitals, under the influence of a totally new "idea," whenever "larger numbers of troops than one regiment are collected."—(Report, "Army Sanitary Commission," ans. 10,041, p. 384.) The "idea" of a general hospital is such a very simple one, that I venture to profess that I do apprehend it. I think that I know what was meant by Pringle's general hospitals at Peckenheim and Newid, by the general hospital at Lisbon, by Mr. Guthrie's hospital at Toulouse, even by the hospital at Fort Pitt. But there is one "idea" which I am not ashamed to confess that I do not understand, which, having tried to do so for

more than two years, I am altogether at a loss to understand. That is the sort of general hospital proposed in the evidence referred to, and of which it is plain that you are speaking. I read that evidence with ever-increasing wonder, that such a blot should occur in a body of statements and opinions which indicate such extraordinary powers of observation, and such extraordinary good sense. I would be beyond measure surprised that the objections to such a scheme should have escaped so penetrating an eye, if I did not find these very objections most admirably stated in another part of the same evidence. You are mistaken in supposing that the new regulations provide for such a state of completion. The symmetry of that admirably arranged and most methodical code is not marred by such an attempt. I do believe that if the author of the proposal had to arrange for its being carried out, even her great powers of organization would fill her. A well-built and well-furnished hospital is a good thing, but there are some things that are better even than that,—order and method intelligently defined, a clearly established incidence of responsibility, unity of authority. There is a principle which is attacked by the proposal, and which it is incumbent on all practitioners of medicine,—I say nothing of those who profess but do not practise the art,—to defend,—the principle of absolute freedom from external professional interference in particulars. It can need but little acquaintance with certain elementary principles to be able to foresee the exact point at which the system, if ever attempted, will break down, and the manner in which it will break down.

When you state such excellent objections to a hall with a glass roof, I bow at once to your professional opinion. In the same way you must give some little weight to my professional opinion when I say that, if you wish to moderate the light for the exclusive use of an eye case, you must either put your patient into a small ward, or put a screen round his head, which is the smallest and worst sort of small ward. Mark, I say *if*. In point of fact, it is very rarely that such a step is required. But, thank Heaven, doctors differ, and we must provide for their differences of opinion.

For the rest, I am confident enough to be willing to leave my plan for a cheap but efficient regimental hospital, side by side with your objection to it. I believe that the system of parallel blocks does not admit of a sufficiency of what the old writers call "currency of air." I believe that before long that difficulty will be perceived, and that it will be overcome. I would be sorry to say that I have done so, because I do not think that I have done so, but I have tried. When the difficulty is recognized and surmounted, and when the *Builder* adopts the improvement, as you will do some day, I shall write to remind you of this poor project of mine, which you have been so good as to publish.

M. COMBE.

We are quite as anxious as Dr. Combe can be that the site chosen for the new hospital should be the best possible, and give him credit for his anxiety in that respect, the more so as he early pointed out in our pages other sites.

In his previous paper he described the site as clay. We believe it to be pebbles and loam, resting on a clay. The sanitary difference is that a clay surface is soft and sloppy in wet weather, while the Kidbrooke-common surface is porous and firm.

Dr. Combe's objection to general hospitals, if at all valid, would lead to a recurrence of all the calamities of the Scutari hospitals. A certain number of general hospitals are to be established to train officers for general hospital service during war, and Woolwich will probably be one of them. The necessity is paramount. And for Dr. Combe to cite any medical inconvenience against such necessity is simply to incur the risk of calamity for a mere professional pettefoglio. The heads of Dr. Combe's own department differ entirely from him on this very point.

The answer to the objection that arrangement in parallel blocks does not admit of sufficient circulation of air is met by the simple fact that, wherever this principle has been properly applied, the external ventilation has been quite sufficient.

Dr. Combe will understand that we regard him as an ally, not an opponent; and in that relationship talk the matter over with him.

STAIRCASES SUPPRESSED.—The hotel about to be constructed by Percire, opposite the new Opera House, Paris, it is said, will be the largest in existence. The staircase is to be entirely suppressed, and the inmates, goods, and luggage are to be raised and lowered by machinery.

MURRAY'S "BERKS, BUCKS, AND OXFORDSHIRE."

MR. MURRAY'S last hand-book for home travellers,\* is especially good in its first section, which relates to Berkshire. To the county of Buckingham, much less space has been given; but in that, many particulars will be found of places interesting to the architect, and not always accessible, as Eton and Stowe. The bulk of the third section is devoted to Oxford and Blenheim, of which the accounts are ably and succinctly given. The notice of the former place would have been more serviceable, accompanied by a better plan: that given is incomplete, and, indeed, in most respects inaccurate. In the first section, the plan of Windsor Castle might, with slight trouble, have been much improved. In the map of the three counties, the principal antiquities and battle-fields, with great advantage, are indicated: but the name of the Thames, we observe, is given to the branch of the stream, properly called the Isis. There is no plan of Eton College in the book, and none of St. George's Chapel, in detail. The deficiency in this respect, greater than in some of the Continental hand-books, however, being duly noted by us,—and simply because, as we have urged on previous occasions, geological and statistical maps, as well as plans of important buildings, would be of chief service to the objects of a hand-book,—we are glad to be able to say that the present volume has been put together in such a manner that it is entertaining and instructive for fireside reading, as it is indispensable to tourists. The historic and anecdotal features of interest in the several places have been thoroughly well worked.

Each section has prefixed to the Routes, in a small compass, much necessary information on points such as those of the boundaries and divisions of the county; the rivers and canals; the climate, agriculture, and manufactures; the antiquities; and the country-seats. The objects on both sides of the Thames, from Goring to Maidenhead, are included under Berkshire.

Berkshire, "the royal county," has not been so well described before the publication of this volume. Amongst the objects of interest at Windsor that are not generally shown, may be mentioned Canaletto's views of Venice and Rome (admirable works they are); the pictures by Zuccarelli, in which some of the chief buildings in London are introduced; three volumes of drawings, by Leonardo da Vinci; drawings by Michelangelo, Raffaele, and others; and the two volumes with portraits by Holbein. Coleshill House, by Inigo Jones; a summer-house at Beckett, by the same architect, and the house at Ashdown Park, by his nephew Webb, are in the same county. The route from Newbury to Lambourn is "exceedingly interesting to the architect." But the objects are too numerous in every direction, for us to do much more than refer the reader to the volume.

At Eton College, in Buckinghamshire, many curious paintings were discovered in restoring the chapel, some of which were erased, and the others covered with the new whitewashing, contrary to the recommendation of the Prince Consort. At Stowe,—

"A work to wonder at . . ."

the objects of interest to architects in the gardens, if not in the interior of the mansion, are still numerous. In Buckinghamshire is Olney, the home of the poet Cowper.

In the account of Oxford due attention is given to the important fact of the prevalence of Gothic details at the University, even down to the time of James II. This character of art obtains in the "Schools," of which Thomas Holt, who died in the early part of the seventeenth century, was the architect. The beautiful staircase, with fan-groining, of Christ Church Hall, is as late as 1640. A play was acted at Christ Church, before Charles I., in 1635, which was remarkable for its scenes and stage machinery; and these, the writer in the Handbook says, "were the earliest of the kind made in England, and are mentioned by Antony Wood, 'in order that posterity might know that what is now seen in the play-houses is due to the invention of Oxford scholars.'" This statement, however, is erroneous. Saying nothing of what the ancients had in the way of movable scenery, and the "properties" used in the "Mysteries" of the Middle Ages, we have shown

\* "A Handbook for Travellers in Berks, Bucks, and Oxfordshire; including a particular Description of the University and City of Oxford, and the Descent of the Thames to Maidenhead and Windsor: with a Travelling Map and Plans." 12mo, pp. vi. 211. London: John Murray, 1860.

in our "Sketch of the History of Scene Painting" that Baltazar Peruzzi, who died in 1536, practised scene-painting, leaving, as we know, beautiful specimens behind him, and that Inigo Jones in 1604-5, produced scenes and stage-machinery before King James I. and his queen, and in the autumn of that year, in this very hall of Christ Church, Inigo being paid 50*l.* for his pains. The statement in the notice of All Souls', that Wren's designs for St. Paul's thereat, are 300 in number, those who read our recent notice of them will be aware is not strictly accurate. And an erroneous impression may be produced from repetition of such a statement as that the Sheldonian Theatre is a happy imitation of the theatre of Marcellus at Rome, that is without mention of the fact that the sort of imitation in question is really very different from what the ordinary reader understands by "imitation." The new museum does not get entire praise from the writer in the Handbook.

Relative to the works at Blenheim, commenced June 18th, 1705, and the "malicious thwarting" of the architect, who was "even refused admittance to see his own work by an order from the hand of Atossa herself," it is said:—

"In 1710 the duchess stopped the works, and desired the workmen to pay no attention to the architect's orders."

To what extent the duchess herself thus spoiled Blenheim "in her own way," as Vanbrugh said she would with the money left her by the duke, cannot be decided; but the circumstances should be remembered in any estimate of the skill of the architect, who, moreover, was defrauded in money. In 1704, quoting from the Handbook, the duchess had written on a bill for 100*l.*—"Is not that 7*½*d. per bushel a very high price when they had the advantage of making it in the park? Besides, in many things of that nature, false measure has been proved." So that she watched matters closely.

We are well disposed to endorse the assertion that the collection of paintings at Blenheim, "both in extent and selectness, is one of the finest in Britain." The works by Rubens are marvellous; and the views of the building and park, as that from Rosamond's Well, with the noble bridge in the foreground, every architect should go to see. Wangen has said:—"If nothing were to be seen in England but Blenheim, with its park and treasures of art, there would be no reason to repent the journey to this country." Starting early from London, it is quite possible to get time for the walk from the Maidenhead Station, and arrive by eleven o'clock, at which hour, on any day but Saturday or Sunday, the palace is shown for a small fee; and afterwards the traveller can be refreshed at the Bear at Woodstock, where he will find, besides an obliging landlady, an early drawing (a view of the said hotel), signed "T. Allason," and some other curiosities, and a general contrast to the inns at Oxford, of which last the compiler of this excellent Handbook correctly says—"All bad, dirty, comfortable, and very high in charges."

DESIGN IN GLASS WINDOWS.

A RECENT number of the *Builder* contains a notice of a memorial window to the memory of the late Dr. Ions, the organist of St. Nicholas's Church, Newcastle-on-Tyne. In the account of this window it is stated that the top is enriched with tracery, and the first figure in stained glass represents the Lamb and Banner, the two immediately below representing St. George and the Dragon, and St. Michael. There are also angels carrying emblems of the passions, foliage, &c. There are sixteen prophets, the evangelists, incidents connected with the crucifixion of our Saviour, a representation of the Last Supper, &c. No mention is, however, made of matters which would seem to connect the design of the window with the profession of the talented musician in whose memory and honour this monument is placed. Doubtless in the position in which this window is fixed, the emblems, figures, and pictures are very fit; but in a monument intended to preserve the memory of an individual, surely the general design should in some way bear upon the circumstances and peculiarities of the person whose fame it is intended to preserve.

In the crypt of St. Paul's Cathedral, near the grave of Sir Christopher Wren, there is a monument in white marble, which has considerable artistic merit. This is to the memory of the daughter of Sir Christopher Wren, who was herself a skilful architect, but was more famous for

ber musical ability. In bas relief on a large portion of this is a figure of St. Cecilia, seated at the organ. In the background and in other parts are groups of angels. This introduction is appropriate, and also devotional.

In a monumental window to the memory of a distinguished musician placed in a cathedral or church, passages might be taken from the life of King David, or illustrations of the glorious heavenly choir which are referred to in several portions of the Scriptures.

A fitting subject for such a purpose as this might be chosen, if well and artistically treated, from the following passage—"By the rivers of Babylon there we sat down, yea, we wept, when we remembered Zion. We hanged our harps upon the willows in the midst thereof," &c.

In memory of a person who during life had been distinguished for charitable or worthy actions, the story of the Good Samaritan might be pictorially given with good and proper effect, and passages from the history of Moses might be given in this way in connection with an eminent statesman. We have looked at many examples, and find in various cases, that even where the colouring is brilliant, there is a sad want of point and sentiment.

In a memorial window to a young female child, we have noticed a blaze of colour, figures of the prophets Ezekiel and Daniel, the figures of several saints, heraldic emblemmations, and flowers and plants simply placed for show. How much better it would have been to have given prominence to a figure of Christ blessing little children, or as the Good Shepherd, with a lamb in his arms. Lilies, white roses, primroses, and other tender flowers, should be made the foundation of the ornamentation.

In such a case this general colour should be pale and pure, the sky of a delicate ethereal tint, and the trees as they bud in the early spring time. Generally, as it seems to us, there is want of variety in the broad arrangement of the colour of the designs made for this important portion of church decoration; nor is sufficient care taken in arranging the colour and effect in a manner suitable to the position in which the glass has to be placed. The best examples of old Flemish stained glass are well worthy of study in this respect. The clear pearly tints, light and silvery, which foil the deep and richer colours, are pleasant to the eye when it has been fatigued by the masses of crimson, dark-blue, purple, and other heavy colours, which are so much used by the English glass painters of these days. In the Flemish glass there are portions left entirely or very nearly colourless, and a quantity of straw colour, gray, and black, which produce a delicate harmony.

Admiring much the colour of some of the best examples of coloured glass which have been left in this country (in York Cathedral, for instance), it must, nevertheless, be said that, in many of the details, there is not shown the skill in drawing which is necessary to give satisfaction in our times. We look at the grotesque and unnatural figures in illuminated manuscripts, and the coarse woodcuts in books of more modern days, with the intention, but the want of power of hand to give expression to their meaning. We see figures with the heads and limbs curiously distorted, and contortions of the most singular description. In the best of the modern book illustrations the contrast is great, and the improvement satisfactory. With the advance of skill in pictorial art it does not seem to have been in all cases applied to glass painting, and we have lately seen examples exhibiting the stiffness and imperfection of the old work, which were only so executed formerly in consequence of the artists not being able to do better.

When we notice the beautiful outlines by Flaxman, some of the elegant compositions of Stoddart, and many of the works of more recent execution, it seems clear that a great deal more is required in the application of power and high-class design to glass painting. Since the Mediaeval days in which this work so much flourished, there have lived Michelangelo, Raffaele, Rubens, and other great masters; the science of perspective has become generally understood; and the principles of composition, light and shade, and colouring, have been reduced to a more perfect system; so that we would not now like to have our eyes offended by figures outrageously wrong in drawing and proportion, with unmeaning expression, and in other ways faulty. Why, then, should we continue in painted glass that which would not be in other branches tolerated?

Admitting that it is necessary to adapt the design of the stained glass to the forms of the Gothic tracery, and that to a certain extent a

conventional style is demanded—that the subjects delineated on the apertures of buildings should not convey a similar feeling to those hung on walls or painted in panels,—there is nothing to prevent the successful application of the best and most artistic arrangements, the most correct and pure outline, and that expression of countenance which will have its effect on the spectator. It is, unfortunately, in some quarters, still thought that not only the windows, but also the paintings used for the purposes of decoration, and the sculpture, in Gothic churches, should, as a matter of course, be rude in form and execution. This is a wrong idea. Some of the sculpture of the Middle Ages has much excellence, but generally, particularly in the figures, there are the same imperfections as are to be found in the delineations above referred to: the old workers of the best order, in cutting foliage, were careful students of nature, adapting it with marvellous freedom to geometrical arrangements. In order to make church decoration what it ought to be, we want a Flaxman to design the heads and statues; a religious, poetic, and artistic mind to suggest the designs of windows and other pictorial matters. The services of the most eminent artists should be called to this work: we should not—Chinese-wise—imitate visible defects, but use the means which are dictated by the advanced improvement and intelligence of our age. In conclusion, it may be remarked that the faces painted and drawn on the glass are often faulty, and show the need of the employment of more skilled artists in this department.

AN ARTIST.

#### STAINED GLASS.

A WINDOW is wanted as a memorial of Dr. Sharpe in the new church at Doncaster, for which purpose nearly 1,100*l.* have been subscribed. The committee are not agreed as to the best mode of obtaining what they want—a fine work;—and when we last heard of the matter had arrived at no resolution beyond requesting the architect of the church to name a subject for the memorial window. We fully appreciate their difficulty.

A glass-painter acknowledging our endeavours to make known what is doing on the subject, writes:—"We have no excuse now for the omission of good glass in our works, the manufacture of the material having improved immensely; but, really, it is most difficult to decide the best style of drawing. A. says one thing, B. another, C. something else, and all set themselves up as critics and judges. You will indeed do good service to the art, if through the medium of the *Builder* this point can be fairly and properly discussed and settled."

*Earl Somers on Glass-painting.*—Lord Somers, himself an artist, has written a letter on the painted window recently put up in the east end of Worcester Cathedral, in the course of which he says,—"I have seen your new window in the cathedral, and have examined it with a great deal of pleasure. The brown unfinished panes below detract from the intended effect, and are very injurious to it; nevertheless the work is on the whole a very satisfactory one, and should leave little ground for unfavourable criticism. The general treatment appears to me to be correct, avoiding a too natural representation, by the means of figures in relief, and yet not running into the opposite extreme of being too formal or archaic in style. At the first glance the eye is struck by the predominance of blue, but I cannot say that on further consideration this continues to be felt as a defect. After looking at it for some time in a changing light I felt satisfied with the tone, and think the colours well varied, rich, and harmonious. In the ancient glass the figure of the Saviour after the Resurrection is invariably represented as robed in white; the robe, in this instance crimson, is conventionally incorrect. There is also too much of the prevailing blue in the ground of this picture. If the colours in the quatrefoil above the chief compartment were repeated in this one, they would make the balance of colour more complete. These seem to me to be errors; but I would repeat that I consider you are most fortunate in now possessing in your church a beautiful decoration, in which, after two careful examinations, no more striking errors could be pointed out. It is my impression that this predominance of ultramarine blue is most usually found in the windows of French cathedrals, which are contemporaneous with the Early English Lancet style. Does this accord with your experience?" The cost of the six lights already filled in, together with wire guard, is stated at 724*l.* 16*s.*

#### LIVERPOOL ARCHITECTURAL SOCIETY. DIPLOMA QUESTION.

THE second meeting of the session was held on the 17th inst., Mr. James M. Hay, the president of the society, in the chair. A drawing of the front elevation of the new Free Library, executed by Mr. Heffer, was on view. The chairman said that two designs from student members would be taken into consideration at the next meeting. The principal business was the discussion of several propositions, contained in a circular received from the secretary of the Royal Institute of British Architects, in which it was stated that it has now become an established rule, both with the Government authorities and with the heads of the learned professions, that candidates entering into any branch of the public service should undergo an examination to test their capabilities, and recommending that architects in future should undergo a voluntary examination in mathematics, land surveying, mensuration, geology, ordinary construction and materials, styles of architecture, history of architecture, jurisprudence, the Building Act, sanitary requirements, the theory of the beautiful, languages, &c. That two guineas be paid for the elementary examination, and three guineas for the higher examination. Mr. Boulton, in the course of a lengthy speech, said he was sorry that the Liverpool Architectural Society was rather behindhand in this matter, as it ought to have been the first to set an example; but they had let Newcastle and other places step before them. He had no objection to a voluntary examination, and should be most happy to award all the honours due to those who gained them; but the tug of war would be when the examination, instead of being voluntary, became compulsory. He was of opinion that architects should go through some ordeal before they were allowed to practise; and, ultimately, he hoped that, before an architect could commence in his profession, he would have to receive a diploma of his fitness, the same as the doctor or the lawyer. The speaker dwelt on the annoyance that architects were subjected to at the hands of local boards of health on account of the enactments of building regulations; and in consequence it was important that architects should study among other things the by-laws of the different local boards, for he knew of one house that was in four jurisdictions. Mr. Weightman, in the course of some remarks, referred to the fact that the different Building Acts now in force rendered it extremely awkward for the architect who removed from one place to another. He thought that one Act ought to regulate all places, so that the annoyance of being plagued with a lot of petty regulations might be avoided. Mr. F. Howard objected to architects being fettered with such an examination, and Mr. Iniggins was of a similar opinion. After a long discussion, in which Mr. Andeley, Mr. Callaghan, and Mr. Goodall also took part, it was eventually agreed that the whole of the propositions should be considered and discussed at the next ordinary meeting of the society.

#### THE GAS LIGHTING OF THE BRITISH MUSEUM.

IN looking round with the memory of a number of years, observing persons cannot but notice how many of those with whom they have been acquainted, have died between the ages of forty and fifty years, many at about forty-four or forty-five years of age,—a period when they ought to have been in the prime and strength of manhood and intellect, ground to death in the unnatural mill of modern business. We could readily mention the names of many persons who have passed away at about this age, worn out by the continued over-exertion which is now enforced. It is satisfactory to see that arrangements are being made, so that shopkeepers' assistants will not be obliged to remain behind the counter from seven o'clock in the morning until nine, ten, and even eleven at night. It is, however, a matter of very great moment that, as spare time is given to our young men, we should afford opportunities for them profitably to dispose of it. For this purpose we want places of recreation and amusement, which are accessible, in a central position in the metropolis. Undoubtedly, one of the most convenient places for this purpose is the British Museum, a place which, in the winter evenings, might be made attractive and useful to many thousands. The reports show that in the present arrangements, notwithstanding the increase of the population, the annual number of visitors to the British Museum is declining. This may be partly accounted for by the circumstance that, during the hours at which the Museum is open,

the great masses of the male part of the fixed population of the metropolis is too busily engaged in their various avocations to visit this or any other similar place. To a working man the first cost is, say 6s. 6d. for his day's work; and, if he take his family from a distance, he must be very careful to make half a sovereign pay the expenses. This is a sum which people of much greater affluence would consider extravagant. The bulk of those who are there to be found on ordinary occasions are persons from the provinces, and foreigners. There are a number of women with children, who seemingly belong to the more respectable of the working classes; there are also many belonging to the middle and upper classes of society. The great masses of the working part of this vast community are but very little represented.

The building of the Museum, the various collections, the staff of officials, is an enormous cost; and it has been calculated that the interest of the sum invested in this national educational establishment, and the other expenses, amount to several shillings for each visitor. At holiday-times the British Museum becomes crowded with persons who are evidently engaged in employments at other times (shopkeepers, mechanics, and others). The great numbers who flock here on days of leisure show that the wonders of the Museum are extensively appreciated.

The only means of extending the usefulness of this collection is to take advantage of the evening leisure of the multitude, to whom the instruction of such an establishment is so necessary. This can readily be effected by the introduction of gas-lighting, as has been done with excellent effect at Brompton. That this can be accomplished without danger or damage has clearly been shown, and the matter only requires to be vigorously tackled with.

But without taking into thought this part of the question, it is worth while to inquire in what manner the number of daily visitors may be increased. The Museum is now open to the general public on Mondays, Wednesdays, and Fridays,—three working days of the week being ostensibly set apart for students; but if on these close days a person were to look in, he would find the place a comparative solitude. At the most there would be about a dozen students in the Gallery of Antiquities; and we have noticed quite as many working when the Museum has been open. In the other parts, amongst the Egyptian, Greek, Roman, and other ancient remains, attendants may be seen almost as still as the ancient statues. The footsteps echo curiously along the rooms; and the colossal fossils, the thousands of birds and beasts, and other objects, seem to be for half of the working days of the week comparatively useless.

It could not add to the expense to try what would be the effect of opening the Museum to the public every day; and also the result of those preparatory lectures on a large scale on natural history, which have been so much recommended by Professor Owen and other eminent authorities.

A. B.

#### THE EXHIBITION OF THE PAINTERS' COMPANY.

At the annual dinner held last week in their ancient Hall, repeated allusions were made to the recent efforts of the Painters' Company for the establishment of an annual exhibition of decorative painting. It appears that for many years a feeling has been gaining ground that this branch of every-day art is worthy of a place amongst those which are brought before the public of London in this way; and some months ago (as was fully recorded at the time in our pages), a collection of decorative work and imitations was brought together in the Hall of the Company, and exhibited to the public with great approbation. It is certainly due to such an endeavour that it should receive every encouragement.

Mr. Robert Kerr, as a guest, in responding to a toast, said he had heard with the very greatest satisfaction the allusions which had been made to the establishment by the Company of an exhibition of the branch of art from which they derived their name. Their art, although it might not compete in pretentiousness with the arts of painting, sculpture, and architecture, was a producer of those "things of beauty which are a joy for ever," to which none the less importance should be attached. Considered in the light of that simple beautifying of our domestic buildings which must render home more charming, the decorative arts were even perhaps of more importance to the general public than were those greater arts whose

productions were purchased at large cost, and shortly forgotten or neglected. Referring to the remarks of the worthy Master, as to the origination of such companies as that before him, he urged that although the motives which in the Middle Ages actuated their purpose had more or less passed away, yet the present age induced necessities of another kind, which in no inferior degree rendered the co-operative efforts of a Guild of the greatest service. The exhibition of decorative art which had been commenced in the past year was a thing to be welcomed and encouraged by every one who felt an interest in art at large. He hoped it would be energetically and perseveringly kept up. He considered the time had really come when such an exposition was an absolute necessity. Amongst so many other descriptions of artistic and similar endeavours, periodically brought before the public by illustration of this kind, their art ought no longer to be left unrepresented. As regarded their prospects of success, he would instance the case of the Architectural Exhibition. For generations the fine art of architecture had been annually presented to the public in the Royal Academy, by the setting apart of a small inferior room, in which, as scarcely anybody condescended to enter it, little else than nothing could be seen. The architectural profession had, therefore, established an exhibition of their own. And with what results? The most satisfactory, for it was already flourishing under active support and high patronage. The same would be the results of the laudable endeavour of the Painters' Company, if persevered in, as he hoped it would be. The architects, in their own exhibition to which he had referred, at present afforded what space they could for Decorative art; but, just as it had been desirable for the architects themselves to come forth from Trafalgar-square, so also would the decorators, by their present effort, find themselves equally able to stand alone.

The present Master of the Company is Mr. Henry Taylor, and the Wardens, Mr. David Laing and Mr. Morant.\*

#### WORKS IN FRANCE AND ALGIERS.

THE restoring and underpinning of the two pavilions of the Institute, whereof the foundations had sunk considerably, has been proceeded with most successfully and in a very interesting manner. Having freed the building from the weight of the enormous stone vases which surmounted it, the entablature was supported by a powerful framework of timbers; and, as soon as the staying was solidly effected, the two corner piers were removed immediately. The ground having been excavated to a good depth, a thick layer of concrete was placed, on which the new foundations rest. Every course is grouted with cement, so that it forms a compact mass. The corner piers being terminated, the intermediate ones will be subjected to the same process of renewal.

The deep excavations at present opened for the construction of a sewer in the recently formed portion of the Boulevard de Sebastopol, near the Luxembourg gardens, have led to the discovery of a great number of fragments of vases and other pottery apparently of a very remote date. Sauval informs us that when Jacques de Brosse, under the regency of Marie de Medicis, laid the foundations of the Luxembourg Palais, a bronze figure of Mercury was discovered, 5 or 6 inches in height. During the excavations of 1801, executed on that spot, many figures of divinities were brought to light, among which are a head of Cybele in bronze, instruments for sacrifices, &c. &c., also several objects which seemed to indicate that the present gardens of the Luxembourg were the site of a Roman camp.

When the Emperor and Empress of the French were at Algiers on the 18th September last, they laid the first stone of a magnificent boulevard, stretching along the sea coast, thus gifting the

\* Mr. Laing, writing as to the first exhibition, says, "If by possibility we can sustain the effort, I am sure it will be most beneficial to employers and employed; especially if we could concentrate, as it were, the whole trade, and bring it around one common focus: light must break forth. The savings of the men have been hitherto absorbed by the working machinery, and their Benefit Societies for sickness and burials been but very imperfectly administered. It is my hope that eventually all shall lodge their funds through our Guild, in the Bank of England, where they will be perfectly safe, and carefully distributed, and by this means a kindly feeling be brought about, such as will tend to the prevention of strikes, and a better feeling between master and man. The Hall has hitherto been only used, as our worthy Master stated, for one night in the year, until last year's exhibition. We are anxious to have it opened every night for drawing classes, except when the exhibition is on, or any extraordinary meeting of the profession has pre-occupied it."

city with a long wished-for promenade, likely to become an industrial artery of great importance. It is to be called *Le Boulevard de l'Impératrice*.

We have already in our pages mentioned the important works in course of execution on the left bank of the Seine, for the establishment of a large sewer, which is hereafter to be united with the great "collector" of Asnières, by means of a siphon under the river below the Pont de la Concorde. The conduit parallel to the river is completely finished from the latter place to the Quai Voltaire, and the circulation for vehicles re-established, it having been interrupted for some time past. Here the works will be suspended, to be resumed next season. In the Rue de Bac, the sewer in course of execution, starting from that of the quays, has arrived at the crossing of the Rue de l'Université.

The new square in front of the Conservatoire des Arts et Métiers, between the Rue Saint Martin and the Boulevard de Sebastopol, advances rapidly. Two basins are terminated, also the balustrade in Jura marble, which is to surmount it. Trees and shrubs are being planted, and there is every reason to suppose that this new promenade will be open to the public before the winter season. To the other squares and promenades in vogue in Paris may be added that of the Place Laborde, and several others, of which the plans are completed, so that every arrangement of new Paris will have a novel and delightful promenade.

Some modifications of detail have been deemed necessary to be applied to the Fontaine Saint Michel, of which we gave an engraving, page 609, on account of the severe ordeal of public criticism it has had to undergo. The pedestals on which the two griffins rest have been considerably raised, and the decorative effect on each side the inferior basin improved.

The restoring of the diocesan churches of Paris proceeds actively. One of the most curious monuments in this capital, the church of St. Etienne du Mont, the steeple and cross of which were renewed in 1856, from designs by Pérelle and Israel Sylvestre, is at present undergoing a series of important works of repair throughout. The rebuilding of this church, which at its origin in 1221 was only a chapel dedicated to St. Stephen (as Guillaume le Breton informs us) was executed under Francis I. in 1517.

As a substitute for the foot-bridge and the two swing bridges which were formerly on the canal at the Faubourg du Temple, a fine stone bridge is in construction resembling in section those recently erected at the Bois de Vincennes by the Eastern Railway Company of France. In order to lower the Roman cement from the place where it is worked up, to the masonry where it is to be set, a very ingenious system is economically adopted. As the slope down to the masonry is very rapid, two inclines have been laid of planks, on which the labourers descend and ascend by means of a cord attached to their waists, the heavier drawing up the lighter one round a gin, as in the case of tramways in slate and granite quarries, &c.

A most interesting ceremony took place at Chartres on the 17th inst., the 600th anniversary of the dedication of this admirable specimen of basilican architecture, in commemoration of the 17th October, 1260, when St. Louis, King of France, consecrated it. The restoring and re-opening of the crypts of the subterranean chapel have been completed, and the twelve new altars, closed up from divine service since 1789, were newly consecrated by twelve bishops.

#### IRELAND.

THE new church of St. Michael, Tipperary, is approaching completion, excepting the interior, which still remains unfinished. The building is Gothic, of an elaborate character, and has a tower and spire. The high and side altars are of Caen stone, with numerous sculptured figures, and were executed by Messrs. Hardman.

The church of Beltrulish, county Cavan, is to be enlarged, and various works executed at the churches of Kilglass, county Longford; Achill and Crossboyne, county Mayo; and St. Peter, Athlone, according to drawings by the architects to the Ecclesiastical Commissioners.

The War Department desire tenders for certain works in connection with the Military Cemetery, at Fermoy.

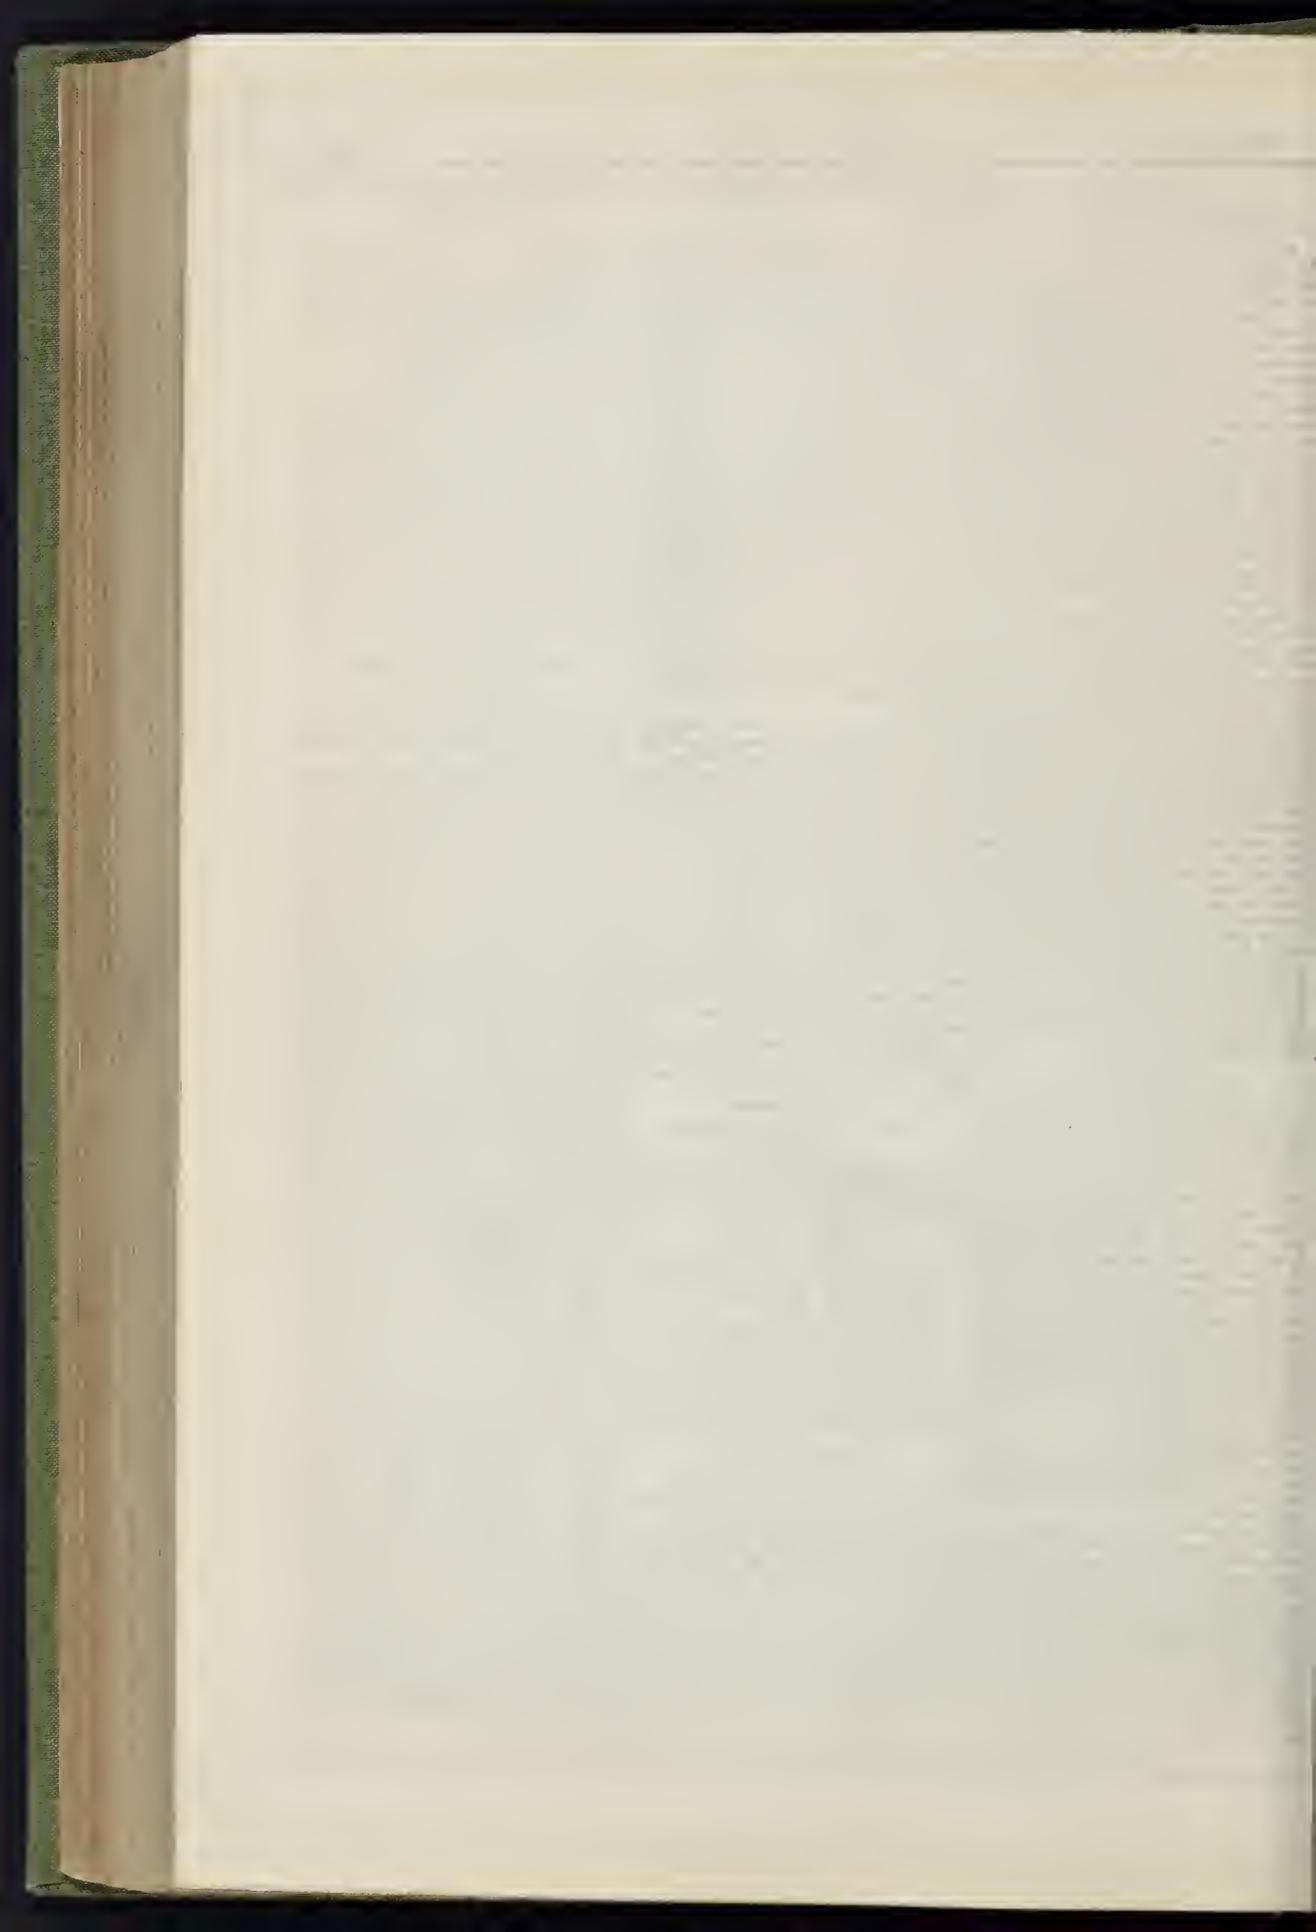

A new Protestant chapel is to be built at Richmond Lunatic Asylum, Dublin, Mr. Wilkinson, architect.

Kinsale bridge has been opened for traffic. The new Church of St. Mary, Guidore, has been con-

ST. STEPHEN'S CHURCH, SOUTH LAMBETH.—MR. JOHN BARNETT, ARCHITECT.

REIGATE.

A CORRESPONDENT who sends some descriptive notes on Reigate\* thus proceeds:—

Before many years every available spot will be taken up; for, though there is building land enough for hundreds of houses, and though "speculating builders" are not encouraged at Reigate, it is astonishing how fast the land is becoming occupied. It is much to be regretted that the workmanship is often questionable; but this is attributable to the spirit of meanness that seems to possess almost all classes of the building public of the present day, when everything is sacrificed to cheapness. The man who will undertake to execute the work for the smallest sum, though he may be as little troubled with capital as Adam, and as dishonest as Dick Turpin, is, in nine cases out of ten, entrusted with the work. It is not long since that a few respectable builders, noted for their integrity, were invited to tender for a Gothic villa, but unfortunately some unprincipled person, void of capital, was allowed to tender also. The consequence was that his tender was not more than half the amount of the lowest of the other builders, and he had scarcely laid the foundation ere he was gazetted.

These remarks are equally applicable to every other locality as well as that which I refer to; and I am strongly of opinion that some steps are necessary, for not only are architects dispensed with, but respectable builders ignored.

If the visitor to Reigate observe much to admire, he will find that it is no exception to the general rule, for it is not free from dark sides, though they are not so deep a dye as are to be found in many places. He will find that the humbler classes are not well looked after, as scores of the many building operatives employed in the place are compelled to walk miles to their homes, because cottages cannot be obtained for even enormous rents; and many of the cottages that are there are in a dilapidated condition. Moreover, they can fatten their pigs in their bedrooms if they choose, as they have no local board of health to fear. To the inhabitants the noted healthiness of the place, therefore, is not due.

I am gratified to learn that there is what is called a Mechanics' Institution, tolerably well frequented by those it is named after. It is much to be hoped that the committee will adopt such measures as will retain them; for it is a well-known fact that considerable reform is needed in the management of these institutions to make them attractive to that body of men.

EXCURSION RAILWAY TRIPS.

DAMP and unpleasant as the weather has been throughout the summer, great multitudes have used the cheap excursion trains; country people to visit the metropolis, and Londoners to pass at railway speed to pleasant and healthy places. For something between 25s. and 30s., the pent-up clerk, shopkeeper, or mechanic may travel to Glasgow, Edinburgh, and some other famous places far north: for that sum he may travel upwards of 800 miles, and have the opportunity of a week's pleasant ramble. For a less sum he may, weather permitting, roam for that time pleasantly along the Borders: he may view the stately abode of the Percys at Alnwick—the ruined picturesque castles along the coast. The antiquary may follow the Roman wall over heaths and moors to "merrie Carlisle": the disciple of Isaac Walton may enjoy fine scenery and throw his line in the Tweed or Coquet. On the Tyne, those inclined in that way may note marvellous scenes of industry—wonderful applications of mechanical powers. Twenty-five years ago, a journey outside the stage-coach from Newcastle-upon-Tyne to London, including fees to guards, coachmen, provisions on the road, &c., cost not much less than 5*l*.

For half-a-crown eight hours of enjoyment may be had at the sea-side at Brighton. For 4s. the seeker of health or pleasure may have the opportunity—conveyed in express train—of passing through Kent, that delightful garden of England, for this he may see the Sinkspear Cliff, the fane castle, and hold cliffs, of Dover; or he may stop and find amusement and instruction amongst the venerable walls at Canterbury, full of historical associations and fine pictures; or those inclined may stop at Ramsgate, or Margate, or other suitable spots: if he choose Tunbridge Wells, an agreeable walk or ride will bring him among the woods and groves of Penhurst, filled

with memories of the famous Sidneys, Rare Ben Jonson, Waller the poet, and other worthies of times gone by.

For 3s. 6d. one may have the opportunity of glancing at the wonders and beauties of Oxford; and, for a singularly small sum, he may have the opportunity of sailing round the Isle of Wight, and spending a few days amid the varied scenery of that delightful island. In other directions, there are facilities for transit which a few years ago would have scarcely been thought of; and, as we have hinted, those in the provinces are not without the opportunity of viewing the "lions" of London. It is a singular sight to see the monster trains arrive at the terminus,—to note the varied appearances of the travellers,—to hear, as the lundrels pass along, the variety of dialect: large, and steady-looking, are the men who come from the district of Birmingham. Still more sturdy and pushing are the men and women from Yorkshire; and loud the voice, and deep the guttural of those from broad Northumberland; and more mellifluous, but still characteristic, are the speeches of the "canny lads" from beyond the Tweed. From other parts the crowds pour in, who see the sights, and probably in many instances get useful hints for the improvement of their crafts, or at any rate acquire such knowledge as occasions many an agreeable thought, and affords the opportunity of interesting gossip at the winter fire-side. Vast are the advantages in several ways which result from these facilities of transit, and great the contrast with the means of travelling which preceded them.

Thirty or forty years ago, towns at twenty or thirty miles' distance were almost as much separated as London and Edinburgh now are. In those times, in consequence of the great expense of coach travelling, and before the use of steam-packets for the conveyance of passengers, the colliers and other trading vessels along the coast carried many persons to and from London. These voyages, notwithstanding the crowded and unwholesome condition of the cabins, were agreeable in fine weather, provided that time was not of consequence. It was not unusual for the voyage from the metropolis to the Tyne to take a fortnight or three weeks, in consequence of calm weather or contrary winds. Turner, the landscape painter, liked this manner of travelling; and it is probable that during these voyages he acquired some of that knowledge which enabled him to delineate the various peculiarities of the sea and sky.

It is possible now to travel across the broad Atlantic to the United States in a shorter time than it took to go between the Thames and the Tyne.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE opening meeting of the Royal Institute of British Architects will take place on Monday, November 5, when Mr. Sydney Smirke, R.A., will read a paper, entitled, "Recollections of Sicily."

THE ARCHITECTURAL ASSOCIATION.

THE *conversazione* and opening meeting will be held this Friday, 26th, in the galleries, Conduit-street.\*

A syllabus of papers and subjects for sketches for the ensuing session has been printed. The evenings of November 9th and 23rd will be devoted to "Consideration of the Subject of Architectural Examinations, and Report thereon." On December 7th a paper will be read by Mr. Blountfield, M.A., "On the Arrangement of Churches."

THE ARCHITECTURAL MUSEUM.

THE approaching lecture season at the Architectural Museum will include papers by Mr. J. H. Parker, on "The Architecture of the Eleventh Century;" Mr. Deputy Lott, on "The Architectural Antiquities of Guildhall;" Mr. S. C. Hall, on "The Art of Engraving and Printing Plates;" Mr. William White, on "Polychrome;" and Mr. John Bell, on "The Relationship of the Fine Arts."

Art-workmen should bear in mind that specimens intended for competition for the prizes for modelling, metal-work, wood-carving, coloured decoration, and cartoons for painted glass, should be sent to the Museum by the 1st of December next.

\* We are asked to state that—"Should any member of the Association not have received cards of invitation, they can be obtained by applying to the honorary secretary, Mr. Arthur Smith, at the meeting."

THE GREAT NORTHERN OUTFALL SEWER.

METROPOLITAN BOARD OF WORKS.

At the ordinary meeting of the Board of Works held last week, tenders were received for the execution of the great northern outfall sewer. The engineer's estimate was 635,000*l*., increased from his original estimate of 461,000*l*., in consequence of the great advance which has since taken place in the price of materials.

The tenders, when opened, were found to be as follows:—

Mr. G. Todd, Jan., Ranelagh Works, Chesham-walk, Chelsea .....	469,500
Mr. William Webster, Charlton-Wharf, Woolwich .....	690,000
Messrs. George Boulton & Co., Wakefield ..	666,666
Mr. Thomas Brassey, 4, Great George-street ..	661,215
Mr. Joseph Diggle, 1, Castle Terrace, Dover ..	650,600
Mr. Edward Thrust, John-street, Chelsea ..	650,000
Messrs. William Hill & Co., 203, Whitechapel-road .....	649,665
Mr. W. Dethick, 77, Great Cambridge-street, Hackney-road .....	645,000
Mr. W. Moxon, 25, Parliament-street .....	615,000
Mr. George Furness, 38, Great George-street .....	625,000

The tender of Mr. Furness was accepted, subject to the examination by the Main Drainage committee of the sufficiency of the surties, and the ability of Mr. Furness to carry out the work.

CHURCH SCHOOL AT REACH, CAMBRIDGESHIRE.

On Thursday, the 18th instant, a School Church was opened at Reach, a hamlet situated in the two parishes of Swaffham Prior and Burwell, Cambridgeshire.

This little place was of considerable importance before the Conquest, being situated at one end of that wonderful earthwork called the Devil's Dyke, which is continued hence several miles across the open of Newmarket-heath; but, though within sight almost of the University of Cambridge, and partly in the parish whence its chief revenues are derived, and though from it the grand lantern of Ely is distinctly visible, such has been the neglect with which this place has been treated, that no means of grace or education have been for centuries provided as far as the Established Church is concerned. A vast piece of ground, on which stands a ruined gable with some hints of tracery in its window jambs, shows that this was not always the case, and now, on this very waste spot,—given as a site by the vicar of Burwell (virtually by the University of Cambridge)—a fitting little edifice testifies to the reviving zeal of the Church, and the energy of the vicar of Swaffham Prior. This gable has been preserved as a monument, and forms a picturesque boundary at the eastern end. As the building has to serve the double purpose of a school on week days, and a church on Sundays, it required more care in the planning, and greater attention to the details than is usually given to a country school-house.

A parallel-gram, 50 feet by 20 feet, terminated by a central arch of wood tracery, and two small ones of clunch, with red brick vousoirs on isolated columns, beyond which is a small apse. In front of one of these small arches, is the desk; in the other the pulpit, which is also of clunch. Small transepts, 16 feet wide, contain respectively an infants' gallery, and the fixed desks, while a small vestry, and space for the harmonium, complete the arrangements.

At the west end are double doors, with an enclosed lobby for caps and bonnets. The fire-places are at the angles of the transepts, and, being four in number, are consequently small and unobtrusive. The windows are both single and in pairs, with pointed heads, except the west window, which is three-light under one arch, with a pierced cinquefoil over filled with stained glass. At the east end also, is a stained glass window, representing the Good Shepherd, by Messrs. Lavers & Barrad; but, except this, all the windows (by Rees & Baker) are in ornamental patterns of green and violet tinted glass. The walls are of clunch, a material peculiarly good in this neighbourhood, with red and white bricks in the vousoirs of arches, cornice weatherings of buttresses, &c. Casterton stone has been used for the columns, the east window, and part of bell-turret, which surmounts the west gable. This is prepared for a clock, so that in the end the whole building will be much more complete than the generality of village schools. Ventilation is provided for at the wall-plates, by several gratings inserted in the walls beneath the eaves,—opened or closed at pleasure from the inside,—while half the windows open as casements.

The total cost, including pulpit, bell, stoves, &c.,

\* Notices of Reigate will be found in previous volumes of the *Builder*, especially Vols. XIV. and XVI.

but exclusive of desks and benches, is under 600*l*. The architect is Mr. Charles Forster Hayward; and the builders are Messrs. Bell, of Cambridge.

It may be interesting to add that Swaffham Prior is commonly called Swaffham-two-churches, on account of there being two churches in the same churchyard. One of these is now a picturesque ruin, with the remains of a transitional Norman tower, commencing on a square base and becoming successively octagonal and polygonal, and formerly crowned with a low spire. The tower of the other church, which is the only portion of the old building remaining, is also a curious example of a Perpendicular octagonal belfry on a square base. All the churches in this neighbourhood, however, are worthy of a visit, and that at Burwell is particularly fine.

#### CHURCH-BUILDING NEWS.

**Stamford.**—The new reredos in St. Mary's Church, Stamford, says the *Lincolnshire Chronicle*, extends the whole width of the chancel, and consists of a series of Early English pointed trefoil-headed arches, springing from shafts of polished serpentine marble, on moulded abaster bases, standing upon a cill of Clapham stone, and representing an arcade of eight compartments. In the four centre compartments there are the Lord's Prayer, Ten Commandments, and Belief, illuminated in gold and colours; the whole is surmounted by a horizontal moulded cornice. The spandrels of the heads are filled with carvings, by Mr. R. Tinkler, jun., of natural foliage representing the vine, ivy, wheat, oak, maple, nut, and gernanium. The two ends contain carvings of butterflies. The capitals of the shafts are bell-shaped, having stems springing from the neck moulding, and finished with knobs of leaves and flowers. In the centre spandril there is the sacred monogram, "I. H. C." with a representation of the vine entwining each letter. The cornice, heads, capitals, tablets, and bases are worked out of alabaster procured from the quarries of Tuthury, Leicestershire. The space from the cill of the reredos to the floor is filled with Minton's chocolate-coloured encaustic tiles. The whole is the work of Mr. Tinkler. Further improvements in this church are required.

**Bassingham.**—The old church at Bassingham, which for years past has been falling into decay, has been reopened, after undergoing a restoration. The architect employed was Mr. J. H. Hakewill, architect to the Church-Building Society; and Mr. Huddleston, of Lincoln, builder, contracted for carrying out the work. The north arcade, which was partly Early English and partly Norman, has been taken down and reconstructed, the old Norman arch, which was in a good state of preservation, being again used. Two new arches have been placed at the side of the old one. The clerestory windows have been restored, and placed in the same position as they were before. The parapets on the nave and aisle have been taken down and restored, twelve new pinnacles being added to the nave, and placed on the old bases. A new chancel arch, with coping and cross on the apex, has been erected, and a new coping and cross have also been added to the chancel. The whole of the windows in the church have been taken out and restored, and glazed with cathedral glass. A new tower arch has been added. The oak roof of the nave, north and south aisles, and porch, have been taken off and restored. New oak doors have been added to the south and north entrances, and to the tower. The inside of the church has been fitted up with open benches. The whole of the fittings of the nave and aisles are of fir. The nave and aisles have been paved with 6-inch black and red Staffordshire bricks, and the chancel with Minton's 4-inch square brick. The building will be heated by one of Simpson & Co.'s apparatus. The total cost of the restoration is upwards of 1,200*l*.

**Farnsfield.**—The parish church of New St. Michael's, Farnsfield, has been consecrated by the Bishop of Lincoln. The edifice stands principally on the site of the old church, which was formerly of very limited dimensions, and has been entirely rebuilt, with the exception of the lower portion of the tower, and on a scale commensurate with the increased population of the parish. The new edifice is in the style of the fourteenth century, and consists of a nave, 60 feet by 21 feet; two aisles, with apsidal termination, 21 feet by 19 feet; and a porch and vestry. The tower, which now stands at the west end of the south aisle, is connected with the same by the opening of the arch. The upper, or belfry stage, has been raised; and in it are four traceried windows surmounted by gables,

from the intersection of which rises a plain slated spire to the height of 100 feet from the ground. The windows throughout the church are filled with tracery; and those in the clerestory are elevated by means of dormer gables, so as to appear externally over the ridge of the aisle roofs. These, with all the gables, are surmounted by crosses, of which, in stone and metal, there are upwards of twenty in number. The body of the church is filled with open benches; and in the chancel there is an organ recess, and seats and desks for the choir. The organ was provided by Messrs. Bevington, of London. The pulpit is of stone, and the prayer-desk and lectern of pierced and twisted ironwork. The architects of the building were Messrs. Hine & Evans, of Nottingham; and the builder, Mr. J. E. Hall, of Nottingham. Mr. Toft was clerk of the works.

**Ipswich.**—St. Clement's Church, Ipswich, has been reopened, after being enlarged and restored. The works were commenced in April, and include a new chancel and vestry; the site of the old vestry being now part of the church. These alterations, with a rearrangement of some of the old pews, give about 200 sittings. The roofs of the nave and aisles, which were much out of repair, some of the principal timbers being quite decayed, have been reconstructed and covered with slates instead of the old lead. The walls of the clerestory have been refaced with flintwork, and the old patterns of stone tracery over the surface restored; the stonework and glazing of the windows (twelve on each side) being new. The seats in the chancel are formed in open benches of oak, with tracery and poppy-heads; the altar-rail is oak, carved. The ceiling is boarded, and the roof constructed with solid arched principals of timber, resting on moulded corbels, the timber and boarding being stained and varnished. The east window, of five lights, is filled with stained glass, by Heaton & Butler; and below it is a new stone reredos. The work has been executed by Mr. H. B. Smith, builder, from the designs and under the superintendence of Mr. F. Barnes, architect, at the cost of about 1,400*l*.

#### ROMAN CATHOLIC CHURCH-BUILDING.

**Crawley.**—The chief stone of a new church has been laid here, in a meadow adjoining the village. The ground is given, and the building, costing upwards of 2,000*l*, is to be provided, by Mr. F. Blunt.

**Liverpool.**—The new church of Holy Cross, situated at the junction of Standish-street with Great Crosshall-street, has been opened for divine service. The edifice forms part of a pile of buildings erected from designs by Mr. Pugin, architect. They consist of a church capable of accommodating about 800 persons, and a presbytery, &c., affording accommodation for a numerous community of the priesthood. At present the only noticeable portion of the exterior of the church is the western front, which is in the Gothic style. The general design consists of a rose window set in revolve 5 feet deep, the sill terminating in a cornice, beneath which are four windows with lancet-headed lights, these being partly intersected by the double gables which cover the two principal entrances. These details are bounded by two buttresses, which rise to the height of 60 feet, and divide the front into three compartments, indicating the positions of the nave and aisles. The apex of the main western gable is surmounted by an open bell-turret of stone, about 45 feet in height. The ecclesiastical style of the church merges into the domestic architecture of the presbytery, though both are brought out in the same line. The interior of the church consists at present only of nave, north and south aisles, and small chancel, it is intended, we believe, to add either a chancel with the aisles or a chancel and transept, making the building cruciform. The confessionals are recessed into the thickness of the south aisle wall instead of protruding into the body of the church. The nave is 102 feet long, 70 feet high, about 30 feet wide, and is separated from the aisles by six Gothic arches on either side, resting upon columns of polished Drogheda marble, with foliated capitals, sculptured in Caen stone, each capital being of a different design. The church is lighted principally by the clerestory windows, of which there are six on each side; they are Gothic, of four lights, with cusped tracery. Aical corona of gaslights, supplied by Messrs. Hardman & Co., of Birmingham, are suspended from the apex of each of the nave arches. The church is fitted throughout with benches formed of ornamented standards of cast-iron, with polished pitch-pine seats and kneeling boards. The altars are but temporary

erections. The reredos is surmounted by a canopy and tabernacle work in Caen stone, polished red marble, and Derbyshire alabaster. This work was done by E. E. Gelfowski, a Pole, resident in Liverpool, by whom and under whose immediate superintendence the whole of the stone carving in the church has been executed. The presbytery entered from the church both at the eastern and western ends, and comprises a refectory, &c., or the basement, a library, parlour, and reception room on the first floor, and numerous bedrooms together with a cloister on each floor. The contract for the buildings, constructed externally of York stone hockers, with dressings of Runcorn stone, was taken for something over 5,000*l*, by Mr. Hugh Yates, of this town. The fittings, for which Mr. Baines was the contractor, are generally of polished pitch pine.

**Penrith.**—The Roman Catholic Church here dedicated to St. Catherine, has recently been enlarged. The dimensions of the church, as erected in 1850, were 18 feet by 40 feet. In 1860 the dimensions were more than doubled—the nave gaining an addition of 30 feet, with the apse, and the north and south transepts being 15 feet by 20 feet. The stylo of this latter addition is the Early English, besides the main altar enclosed by a screen within the apse. The south transept forms a "chapel of the Blessed Virgin;" and the north, a "chapel of St. Joseph." Above the main altar there is a triangular window fitted with Cherubim. The two windows have two lights each in the north and south side of the apse, containing monograms of the four Evangelists, and are filled up at their heads with emblems of the *Agnus Dei* and the Pelican. The two light windows above the "altar of the Blessed Virgin" in the south transept contain, one a figure of our Saviour, and the other that of Mary Magdalene. Between these lights is a figure of the Virgin, executed and painted by artists in Munich. The stained glass above the "altar of St. Joseph" is plain, bearing monograms of Joseph and our Lord. Between these lights is a figure of Joseph. The three light windows in the south transept contain seven passages of the history of our Lord. The stained glass of this window has been executed by Mr. Scott, of Carlisle, and the glass of the other windows by Mr. Barnett, of Edinburgh. Above the screen is a large crucifix, and figures of the Virgin and St. John. The forty panels of the ceiling are filled with emblematical figures and monograms and inscriptions of our Lord, the Virgin Mary, the Apostles, Mary Magdalene, and of St. Catherine, the patroness. These have been designed and executed by Mr. John Sead, the architect.

**Guernsey.**—The tower of St. Joseph's Church, Guernsey, has been provided with a bell, the gift of a generous person, who has presented a large sum to clear off a debt on the church. It is in contemplation to erect a spire.

#### PROVINCIAL NEWS.

**Moulsham.**—The first stone has been laid of new schools about to be erected in connection with St. John's Church, Moulsham, at a cost of 1,500*l*, from plans furnished by Mr. Chancellor. The building will stand immediately contiguous to Moulsham church, with an elevation towards Moulsham-street. It will include a boys' school, 39 feet 6 inches long by 18 feet wide; a girls' school, 33 feet 6 inches long by 18 feet wide; and an infant school 34 feet long by 17 feet wide, each room being 12 feet high to the plate. The entrance to the boys' school is by a porch, with hat-room attached on the south side; that to the girls' school, which has also porch and homest-room, being on the north side. The interiors of the school-rooms are to be faced throughout with white brick with bands and patterns in red brick. The roofs are open timbered and boarded, and in the centre of the boys' school rises a bell-turret, which also serves the purpose of ventilation. The boys' school is the principal elevation towards the street—two three-light pointed windows, with double gable over, and the bell-turret rising between, forming the chief feature. The exterior is to be faced with yellow bricks, with bands and ornamental patterns in red and black bricks, and the roofs will be slated with blue and red Bangor slates in alternate bands.

**Bridgwater.**—We understand, says the *Taunton Courier*, that an enterprising inhabitant of Bridgwater has made an offer to the town-clerk, with a view to its being laid before the corporation, of his readiness to build a town-hall, in accordance with plans which have been submitted to the council, on the site of the old assize halls. The cost of the proposed building would be about 1,600*l*, and the condition attached to the offer is,

that a lease of the land be granted by the council for 75 years, at a nominal rent;—free use of the hall to be given to the corporation for borough purposes at all times.

**Newport.**—The structures designed for the new offices of Lord Tredegar and the Messrs. Bailey's bank, on the site whereon the monument of the late Sir Charles Morgan and the bank formerly stood, are approaching completion exteriorly, according to the *Hereford Times*, the building being completed and the roof laid on. The edifice is from the designs of Messrs. Habershon, of London, who are the architects to Lord Tredegar. The contractor is Mr. John Griffiths, and the clerk of works Mr. Dixon.

**Birkenhead.**—The gigantic dock at Birkenhead is approaching completion, and it is expected that the water will be let into it in the course of a fortnight's time. The total water space of the Great Float is 110 acres, and the lineal space round it is upwards of four miles. During its formation the contractors, Messrs. Thompson & Co. and Messrs. M' Cormick & Co., removed 2,000,000 cubic yards of timber. The depth of water will be about 9 feet below the old dock sill at Liverpool—amply sufficient for the requirements of the largest vessels.

**Leith.**—The foundation stone of a corn-market and general exchange for the town and port of Leith has been laid by the Duke of Athole, Grand Master Mason of Scotland, with high Masonic honours. Messrs. Poddie & Kinnear are the architects. The edifice will be erected upon a site at the angle of Constitution street and Baltic street, and will have a plain Roman frontage. The chief feature in the design is, of course, the corn-hall or exchange, which is a spacious apartment, lighted from the roof. The contracts amount to about 4,000.

**Jersey.**—The foundation-stone of the new hospital at St. Helier's, according to the *Jersey Times*, has been laid; and, after the ceremony, the contractors, Messrs. Le Cras & Le Gros, gave a banquet to their workmen, ninety in number, in the large room of their carpentry, in Sand-street; Mr. Thomas Gallichan presiding.

**THE STRIKE IN BRISTOL AND BATLI.**

**Bristol.**—We regret to learn that the hopes of arriving at a settlement of the dispute between the masters and operative masons of this city have been dispelled.

At a meeting of the Master Builders' Association, it was resolved,—

"That if the operative masons now on strike are desirous of having the present dispute referred to arbitration, a communication to that effect, addressed to the secretary, will be accepted by this Association; and that the members elected to arbitrate should consist of six master masons, and six operative masons, with a chairman mutually agreed on."

To this the secretary of the operatives replied,— "I am instructed to state that a deputation of six operative masons are elected for that purpose, to attend any time or place agreeable to your Association. I am further instructed to state, in reference to a 'chairman mutually agreed on,' that there is no necessity to call in a separate party for any such purpose, well knowing that the dispute entirely belongs to master and operative masons. The masons are, therefore, willing that a chairman be appointed from the twelve parties who meet to discuss the question at issue."

On which, October 17th, the Master Builders' Association resolved, as follows:—

"That this Association having made a second offer of arbitration to operative masons now on strike, and on purpose to meet the objections last urged by them; and having exhausted all means to bring about a fair and equitable solution of the present differences, regret that no other course is open to them but to adjourn the present meeting until this day month."

It was also unanimously resolved,—

"That the thanks of this meeting be presented to all those employers and architects who have kindly allowed their work to remain suspended; and trust they will still continue their support to the master builders, in resisting the unjust demands of the operative masons."

Since then the operatives have issued an address, wherein, justifying their refusal to the proposed appointment of a chairman, they say:—

"They know the relative position with themselves and their employers, and freely admit that the employer is open to make his own terms with the workmen, and to obtain their labour as cheap as he can, while the men are perfectly free to obtain a fair and honest remuneration for their services. *No third party has any right to step in and say that the employers should do this, or that the employed should do that.* Any such interference would be both unjust and prove fatal to the interests of all."

And they append the following resolution, terminating with an unwise threat:—

"That the resolutions of the Master Builders' Association are calculated to mislead the public mind, and also to induce employers not belonging to the Association; we therefore agree to resume labour at 4s. 6d. per day till Nov. 13, 1860, and from that date to Feb. 6, 1861, at 4s. per day, and at the latter date advance to 4s. 6d. per day,

with two hours less labour per week; and will treat upon these terms with individual employers, if the Master Builders' Association as a body do not accept such terms, upon a written agreement. These terms to apply to those honourable employers who have already consented to our previous demands. If these terms are not accepted on or before Saturday, the 27th inst., a further suspension of labour will continue till 4s. 6d. per day be acceded to— even throughout the winter season."

At Bath an arrangement has been made, we learn (a deputation from the employers having met a deputation from the workmen), satisfactory to both parties. The employers agree to make an immediate advance of 1s. per week on the present rate of wages; to give another 1s. from the 1st of March next; and a third 1s. from September next. The men are to leave work on Saturdays at five o'clock from the 1st of March, and at four o'clock from September next. For work executed at three miles from Bath, they will be paid 4d. per day above their ordinary wages, and 6d. per day for work done at a distance of six miles. When at work in the country at a less distance than three miles, they are to proceed thither in their employers' time, and to return in their own time. We understand that at the interview of the deputation the employers expressed their readiness to render the men every assistance in establishing reading-rooms and libraries.

**PHOTOGRAPHIC PROGRESS.**

M. WOTHLÉY, of Aix-la-Chapelle, a member of the French Academy of Sciences, has sent them in specimens of a new process for enlarging photographs, taken on collodion, either by solar or electric light. M. Wohléy states that he arrives at these results by a series of manipulations, constituting almost a new art. By means of a heliostat he directs a broad pencil of parallel rays upon the negative impression. The light, in passing through, forms a wide cone of diverging rays, which casts the enlarged image on a sheet of prepared paper. The impression thus obtained may be of almost any dimensions: M. Wohléy has produced some eight feet by five. The exposure to the light lasts about twenty-five minutes. For washing and fixing the impression he employs various dexterous manipulations, rendered necessary by the large surface operated on.

Some time since it was suggested, in the *Builder*, that by the successive enlargements of daguerrotypes or photographs of the moon, and the use of good microscopes to the enlarged copies, our knowledge of the intimate nature of the lunar surface might be enlarged. Now seems to be the time for such an investigation; unless, indeed, something still remains to be done in the attainment of what we may call an infinitesimally true ground for the photographic or daguerrotypy representation. Collodion yields by no means a delicate ground when examined with the microscope. Portraits thus look as if they were rough masks of unvarnished paper-masb. The metallic surface of the daguerrotype forms a truer ground-surface; but that depends on the imperfect process of polishing. Could such a surface as that of liquid metal or glass itself be made available it might do. Would not sheets of prepared gelatine be a hopeful subject for experiment in this direction?

Apropos of photographic progress, the Naples correspondent of the *Daily Telegraph* saw an Englishman quietly engaged, on the 10th of September, in photographing a part of the scene of action between the Neapolitans and Garibaldians, the artist being himself at the moment under a heavy fire: on inquiry it was found that Major Stuart Wortley was the amateur photographer.

**CONSTRUCTION OF FLAT ROOFS.**

In reference to some remarks which recently appeared in the *Builder*, relative to flat roofs, I beg to send a description of one, some of which have been fixed under my superintendence, and for which I can speak as to durability, soundness, and being perfectly stanch. Many of the roofs of houses in Spain, Gibraltar, Malta, and other hot climates, are so constructed, affording a promenade, fresh air, and view of the surrounding scenery to the occupants, in the cool of the evenings and at sunset, which in these parts is very beautiful. In some places where ground is scarce and dear, the roofs are fitted up with drying-posts, and form a good place for a laundry.

It often occurs that for porches and other places a flat roof becomes more a matter of necessity than choice, and for such I would recommend the following:—

Joists laid as for a floor, 12 inches from centre to centre: they may be fixed with the required fall (the same as for lead), or with wedge-shaped

pieces nailed on. On the joists a course of tiles, 12 inches long, laid and jointed with mortar (bricks 12 inches long and 6 inches wide, 1 1/2 inch thick, were used in the cases I refer to); over the tiles a course of Dutchess or other slates, bedded and jointed in pozzolana mortar; and, lastly, one or two courses of tiles, Marseilles or others, closely jointed and bedded in pozzolana. One course of tiles will do; but, in cases where the roof is much used for walking, two courses should be laid, and let into the parapet 2 inches. Round the walls there may be a skirting of cement or glazed tiles. The cost is about 8s. per foot superficial, exclusive of joists, for this roof.

The work should, of course, be performed at a season of the year when it would not be affected by frost. I have not seen this description of roof used at home; but, from what I have seen abroad, I think it could be adopted in England, and would be found cheaper than lead, and seldom require repair. It may be used in buildings with or without a parapet: in the latter case it should pass over the walls, and project 3 inches.

Gibraltar.

G. D.

**PAINTING STONE.**

STR.—You will, no doubt, be surprised to learn that men are now busy painting these fine cloagraned, free-stone columns in front of the Glasgow Exchange! So much for taste, and science, and the skill of our architects, and the benefit derived from holding meetings and talking of what was said in olden times and what is done now; and at one of which meetings you have the address delivered by our worthy learned sheriff in your last journal. But to what effect has either that meeting or the large meeting of the Social Science Association been to develop or cultivate a taste for stone architecture, of which we were justly proud, and would be still, if it were not made to look like stucco, as is the case now? You kindly took notice of a former note from me regarding those fine single stone pillars (painted) in the interior of the Exchange. As the rage is decidedly for painting stone buildings, there is a dread of our cathedral meeting the same fate some day; and this induces me again to solicit your influence in staying the practice of effacing these fine buildings. What is to be done? One may suggest, but who can prevent? STONE, NOT BRICK.

**SPECULATIVE BUILDING IN THE SUBURBS.**

We willingly insert the following:—

Sir,—Let me entreat you to visit and caution the public against the vile speculative houses being run up for sale in parts of Islington. To form the roads all sorts of refuse have been shot, from which every bit or morsel of brick is picked out and used for party walls and foundations. Did I say foundations? Well, let me explain. Between two scaffold-boards they place some brick rubbish, and a little lime and gravel to bind it, on which they build the house. Mind you, no trench is dug and filled up with concrete, but in this way the foundation is higher than the surrounding soil. Although sand is on the estate, the mortar is mixed up of road drift: discharging arches are the exception, not the rule; in fact, the whole of the system pursued is of the vilest character (except in one respect, which is,—I believe each house has its own separate drainage). Again, why are the chimney-bars so often absent? Why dufling building still goes on without let or hindrance astonishes many besides myself. If by exposure we can only get one brick better bonded and laid we may do some good. The price asked and rent obtained for these structures command, in many cases, good sound materials and skilled labour. But why trouble you again, who year after year have so bravely written upon the subject? for proof, see Vol. XVII., No. 834; but pray visit Kingsland, and afterwards Holloway.

I have often thought if a printed form of warranty or questions could be published for the use of house-buyers, to be signed by the builder or seller, we might compel district surveyors to be vigilant, and we might stop the doings of

"THE DUFLING BUILDER."

Our correspondent is wrong in supposing there is necessarily any want of vigilance on the part of the district surveyor. In the very cases to which he alludes, we know personally that the district surveyor has proceeded by all available means to prevent the shortcomings alluded to, but has small power to compel. Take the question of concrete, for example. The Act says "the foundation shall rest upon solid ground, or upon concrete, or upon other solid substructure." The

answer to any summons for irregularity in the case alluded to would be "the house does rest on concrete," and no police magistrate would convict. Unfortunately, moreover, in other cases where the Act seems to give power, some of the magistrates think it right to exercise their ingenuity to discover grounds for not enforcing it. Witness some recent preposterous decisions in respect of warehouses containing more than 216,000 cubic feet, undivided by a party wall. As to chimneys, these are constantly taken out after the surveyor has seen them put in, by which means more harm is done to the work than if they had not been used.

#### DAMP ON WALLS: A QUERY.

SIR,—On my return home one evening, at 11 o'clock, I found the walls of my drawing-room saturated with damp, the wall paper blistered, and drops of discoloured water trickling down and spoiling the decoration. The singular part of the affair was this, that the dampness appeared only on that portion of the walls (all round the room) that was on a level with the lights in the gas chandelier. These basking lights are six in number, arranged in a circle in the centre of a room 12 feet high, 22 feet long, and 14 feet broad. The damp on the walls was about a foot in breadth: above and below this band the wall was quite dry. The looking-glasses also had a hand of wet of the same breadth, and on the same level. We have lighted fires, and continued them since, but of no avail, as the damp remains constantly in the same place. This effect cannot possibly be produced by any action on the external surface of the walls.

If any of your practical readers can explain the cause, and suggest a remedy, they will greatly oblige.

The house has been built and tenanted for ten years, but was newly papered twelve months since, the wall having been previously painted and fatted.

A SUBSCRIBER FOR SEVEN YEARS.

\* \* Continue the fires.

#### "TOUITING SURVEYORS."

SIR,—Your journal, some few weeks back, held up to obloquy the nefarious practices of this class of men, who in truth have no right to the name of surveyor. I hope, for the sake of the legitimate portion of the profession, you will always find a space to show us in quack. It becomes a well-known truth to the architect (as well as to the respectable surveyor) that these worthies more frequently than do the efforts of an architect who may unfortunately have allowed them to take off quantities from his drawings; for, as they don't understand the business sufficiently to bear investigation, they generally add "so much" to make up for any error. The poor architect has nothing but odium thrown upon his fine talent, and labour; and the job, more frequently than not, is abandoned, and the architect left to seek for redress by an expensive action at law.

The local Kensington and Chelsea paper of last week has the following bearing on this subject:—

"PAROCHIAL BUILDINGS, EBBWY WHARF.  
EXTRAORDINARY STATEMENT.

Mr. Rickman's letter (the Board's surveyor) states that he considered for this building that 4,600 ft. was an ample sum, Mr. Woodruff's contract (as made out by —, —, & —), was 5,497 ft."

Mr. Rickman stated, in addition to the revelation in his letter, that there were 5,400 feet of flooring too much; indeed, there was more than enough to cover over the wharf ground, as well as the inside, but this was a mere *prima facie* glance at the exorbitant amount of the tenders, which convinced him they were beyond all reason.

Mr. Westerton stated that the estimates from the quantities were swarming with the most gross errors. There was, in the brickwork alone to the chimney-stacks, 12 rods of brickwork too much, and other matters in like proportion. So you will please to make this known to the profession in general.

OBSERVER.

#### THE "BUILDER'S" LAW NOTES.

**Infringement of Patent.**—An inventor, in his specification respecting a patent for the application of centrifugal force to certain portions of a machine for "roving" cotton, put in a general claim for the invention of such application of centrifugal force. He afterwards entered a disclaimer of all applications of the principle of centrifugal force except by certain means described in the specification. It appeared that another person had used a similar machine, in which centrifugal force was used in another manner. It was held by the House of Lords that the disclaimer limited the general claim and left the patent good to the extent reserved, but only to that extent. Lord Wensleydale laid it down that the opinion of scientific witnesses, as to whether there has been an infringement, though often received, is, strictly speaking, inadmissible, and, if objected to, ought to be rejected. If the question turn on the construction of the specification, it is a question of law for the judges; but where the question turns on the extent to which one machine imitates another in that which is the alleged invention, it is a matter for the jury.

**Joint-Stock Company.**—A shareholder in a joint-stock company which had been ordered to be wound up was subsequently discharged under the Insolvent Debtors' Acts without noticing the company in his schedule. A call was made in respect of debts incurred before his discharge, but not proved till after that event. In settling the

list of contributors the name of such shareholder was held to be correctly retained.—*Ex parte Parbury.*

**Working Mines near a Railway.**—A railway company was empowered by its special Act to take land, the minerals to be reserved to the vendors; but the working of them not to be detrimental to the railway. By one clause the owners of the minerals, on working them up to within twenty yards of the company's buildings, might require the company to purchase the minerals; or, on their refusal, he might work them, provided he did no avoidable damage. Under these circumstances some land was taken by the company. Under this land there was a coal mine which had not been worked for a long time, and which had been forty years under water. The shaft was far from the land over which the railway passed, and this land was supported partly by some pillars left in the mine and partly by the hydrostatic pressure of the water in the shaft. The company built a bridge of great weight and length over the purchased land. Twenty years after the completion of the bridge the descendant of the former owner of the land threatened to draw off the water and to work the mine. The company sought to restrain him by injunctions, and it was held that, though he might lawfully work the mine, he would be liable for any damage resulting from the removal of the soil under the railway; but that he would not be liable for any damage caused by the withdrawal of the hydrostatic pressure, for that he had a right to drain the shaft.—*North-Eastern Railway Company v. Elliott.*

#### RECENT PATENTS CONNECTED WITH BUILDING.

**VENTILATION.**—*W. Williams, Merthyr Tydvil.* Dated 29th February, 1860.—This invention consists in constructing cast-iron cylinders or exhausters, having a piston in each somewhat similar to the ordinary blowing cylinders in common use. Each cylinder has at the top and bottom thereof a suitable chamber or chambers fitted with air-valves, either of leather, vulcanised india-rubber, or other suitable material. In the upstroke of the piston the air which is drawn into each cylinder is on the return stroke driven therefrom through the outlet valves.

**BLOCKS OR BRICKS FOR BUILDING PURPOSES.**—*M. Cranford, Kinson Clay Pottery, near Poole.* Dated 27th March, 1860.—The patentee proposes to form the pieces of which a building is composed of any superficial shape or area that may be required, but in a tubular form, the thickness of the sides being proportioned to the pressure to be sustained, whereby the amount of surface bearing would be obtained with a great saving of the material employed; and instead of trusting, as at present, to that and the use of mortar to prevent any slipping of one piece over another, he makes openings in the inner sides of these tubular pieces, into which other pieces of any convenient size or shape may be inserted and arranged, always so as to intersect the junction of two or more of the external pieces, so that it will be impossible to move one of these from the other without taking out or breaking the inner tie or ties.

**PLASTIC MOULDED MATERIALS FOR BUILDING PURPOSES.**—*C. F. Bielefeld, Gower-street, London.* Dated 19th March, 1860.—This invention consists in combining fibrous materials with water-glass (solution of silica in alkali), lime, and clay. In making or preparing plastic compounds of the materials above mentioned, some one or more of the other materials hereafter mentioned are generally used, according to the nature of the compound desired to be produced. These other materials are ground glass, ground lava, or pumice-stone, or ground marble or quartz, or carbonate and sulphate of lime, oxide of zinc and other metals, magnesia, ochres, and other earths containing like properties. The coarser ground matters above mentioned give mass, and the oxides of zinc and other metals, ochres and other carths, modify or give colour, as well as mass, to the compounds of the other matters.
